Locard recognized the great influence of Gross in his own writings. Most developments in Germany, Austria, and Central and Eastern Europe recognized the key influence of Gross who saw physical traces as rich indicators for strategic, operational, and tactical decisions by the magistrate. The dimensions of intelligence, investigative or probative value of physical traces, were already perceived. The phenomenological dimension – serial crime, intelligence – and the case solving (casuistic – inclusive of investigative and evidence dimensions of traces) combined to create this brand new discipline. Gross called in 1895 for the creation of this discipline as an academic discipline in Vienna, but he finally succeeded (2 years before his death) in

1913 with the creation of an institute at the University of Graz.

A. R. Reiss (1875–1929), a chemist and photographer, immediately saw the interest of anthropometry and crime scene documentation through his interaction with Bertillon. The interest went further in the treatment of databases and international exchanges of standardized data. An international meeting in Monaco in 1914 carried the seed of what would become Interpol after the Second World War (Roux 1926) and of the current Prüm Treaty in Europe, signed in 2005, which is institutionalizing database exchanges across signatory countries (DNA, fingerprints, car registration) (Dehousse and Sifflet 2006). Of German origin, Reiss saw the merit of being part of a judiciary (legal) process and followed up scientific developments from the Lyon School. He was able to create an institute at the University of Lausanne in 1909, linked administratively to the Law faculty and to the Science and Medicine faculties for research and education. This is the first academic program in forensic science, and it is still a major part of the Faculty of Law and Criminal Sciences nowadays. His contributions (Reiss 1911) included both phenomenological and casuistic dimensions that make up the various professions of forensic science nowadays (forensic intelligence, crime analysis, scientific investigation, and evaluator in the evidence process in court). It must be emphasized that history played an important role to have Gross and Reiss become scientific "enemies" each taking opposite sides in the Balkan wars in 1915 (Collectif 2009).

From Identification to Forensic Science, and Current Organizations

The absence of a uniform view, resistance by police organizations, together with controversial and political decisions led to the construction of forensic science as a discipline regrettably based on a patchwork of miscellaneous technical and scientific applications without real fundamental or conceptual developments as a discipline and without a unifying research agenda. Kirk, in 1963, called for fundamental work and academic research (Kirk 1963), but it is still currently an identified deficiency (National Academy of Sciences 2009). This also led to various structural decisions that still haunt the discipline today.

Although many developments occurred in the detection and analysis of various trace types, including biological traces and DNA (after 1985), the early developments discussed influenced most of the current structures, and difficulties, encountered today. Some viewed the development of forensic science as a law enforcement task, almost administrative, left for identification bureaus. These identification bureaus turned into police or crime laboratories depending on policies, management decisions, and whether or not science was considered a useful component of police activities. This developed with great variations across the world and across countries. They have become large organizations often accompanied by the development of identification databases. In many cases, management by police with little scientific inclination left forensic science within secondary and supporting structures with little or no influence on investigation and intelligence for that matter.

Other countries and organizations have decided to link expertise laboratories to the judiciary and belong, often, to departments of justice. This is indicating a certain independence from police services but also creating tensions as to who is responsible for scene of crime investigations and who is in charge of databases. Some countries, especially in Eastern Europe, have had dual laboratory services, police/crime laboratories, and justice department laboratories to this day. Ironically, Locard developed his expert activities within the Lyon tribunal, but his laboratory was reclaimed by the French National Police to become the headquarters of the French forensic science laboratories in Lyon, whereas the identification bureaus remain a distinct entity within the police. The first are manned by scientists and civilian, the second by police and are considered police province, but with some overlap.

Few of the academic programs that provided expertises both for law enforcement and courts survived the two World Wars (Lausanne and Berlin), and forensic medicine absorbed part of the forensic science activities within their laboratories (especially since the advent of DNA). Newer organizations or laboratories, whether part of the justice system or law enforcement agencies, have integrated forensic medicine within forensic science laboratories but with some administrative difficulties residing in their business models. Should forensic science laboratories be financially independent industries or are they part of the overall justice systems under government control? This is an opened entry that needs fundamental and policy decisions that may, in turn, overcome some of the barriers created by history.

Identification Issues in Life Course Criminology

Robert Brame and Michael G. Turner
Department of Criminal Justice and Criminology, University of North Carolina at Charlotte, Charlotte, NC, USA

Overview

In everyday language, the word “identify” refers to the presentation of proof or convincing evidence that something is what it appears to be. This is also what identification means in the social sciences and in life-course criminology. Life-course criminologists try to understand how crime develops, changes, and evolves over the life span. Their efforts usually fall into one or more of the following two categories: (1) describe stability and change in some criminologically interesting characteristic or behavior and (2) discern whether certain factors are causes or correlates of criminal behavior. Within each of these categories, a focus on identification leads to questions about what can be measured, what is being measured, and what are the main sources of uncertainty. This entry provides a brief discussion of the key identification issues in each category of life-course research.

General Terminology

The most comprehensive contemporary works in the identification area are those of Charles Manski (1995, 2003). In general, Manski's work revisits and then extends a much older literature (Koopmans 1949; Cochran et al. 1954). A key theme throughout all of this work is that identification is a matter of degree. So it is more useful to speak of stronger and weaker identification instead of speaking of an estimate as being identified or not identified Manski (2003, p. 2).

Manski further notes that the social sciences have typically overemphasized the importance of point identification. Point estimation occurs when a researcher is able to combine the data with a set of assumptions that are strong enough to yield an answer that can be transmitted with a single estimate. Point estimates can only be obtained when a parameter to be estimated is point-identified. And point identification is generally possible in the social sciences when certain (usually quite strong) "point-identifying assumptions" are met. The main problem is that well-informed researchers often disagree about the validity of the assumptions required for point identification. These disagreements end up creating ambiguity about the accuracy of the point estimate. Manski (2003, p. 1) describes this problem as "the law of decreasing credibility: the credibility of inference decreases with the strength of the assumptions maintained." With weaker assumptions, point identification may no longer be possible. But it will often still be possible to identify a set of values (a partial identification interval) that include the correct answer. Manski (2003, p. 2) refers to the practice of combining weaker assumptions with data to yield set-identified parameters as "partial identification." An important feature of this approach is that it will often be possible for well-informed scientists and policy makers to agree on the weaker identifying assumptions, thereby increasing the likelihood of achieving consensus about the validity of the set-identified estimate.

The level of uncertainty in estimates creates a tension in social science research. On the one hand, social scientists are generally trained to think about their analyses and the presentation of their results in terms of point estimates. Such estimates are often presented along with some measure of uncertainty due to sampling error (i.e., standard errors and confidence intervals). On the other hand, a careful "partial identification" analysis typically reveals much greater levels of uncertainty than what one would normally encounter with conventional point estimators (combined with estimates of sampling error). In fact, as Manski's work (and the work of others) has shown, analyses based on weaker identifying assumptions often lead to uncertainty that dwarfs what social scientists are accustomed to seeing (see, e.g., Manski and Nagin 1998). So, a partial identification analysis will typically transmit high levels of uncertainty in exchange for weaker assumptions – assumptions which will be plausible to a wide range of observers. An emphasis on point identification often transmits small degrees of uncertainty in exchange for assumptions that are much stronger – and often not credible to many observers.

Stability and Change

Life-course criminologists are concerned with questions about what stays the same and what varies over time. Sometimes efforts to answer these questions focus on cross-sectional data. A good example of a cross-sectional analysis with life-course implications comes from Tittle and Ward (1993). In this study, the authors used survey data collected at a single time point (1972) to study the relationship between age and criminal involvement covering ages 15–94 in three states (Iowa, New Jersey, and Oregon). The purpose of the study was to examine predictors and moderating influences on the venerable "age-crime curve" (Gottfredson and Hirschi 1990). Similarly, researchers have long used cross-sectional data from the Federal Bureau of Investigation's Uniform Crime Reporting (UCR) program to study arrest rates stratified by ageacross the population (Piquero et al. 2003) – with the goal of understanding how criminal involvement covaries with age.

Unfortunately there are ambiguities with each of these efforts. The Tittle and Ward (1993, p. 11) study states that "[i]nterviews were completed successfully with respondents from 57 % of the originally selected households (77 % of the screened subjects)." Despite Tittle and Ward's (1993, p. 11) claim that the resulting sample matched up closely to census demographic statistics in the surveyed areas, the high rate of missing data does create some ambiguities. And it is well known that a small – but not insignificant – number of law enforcement agencies decline to participate in the UCR program in any given year. After all, police departments can only arrest suspects in crimes that have been reported. Since many victims choose not to report their victimizations to the police, those cases are quite unlikely to lead to an arrest. More importantly if those reporting practices change in important ways over time, the biases in the data can change as well.

Over the past 40–50 years, criminologists have increasingly turned their focus to the analysis of longitudinal micro-data or "panel" datasets. Criminologists have relied on these studies to measure key features of what has come to be known as the "criminal career" (Piquero et al. 2003). They are distinguished from cross-sectional studies by their ability to measure how behaviors remain stable or change over time for the same individual persons. There are generally two methods by which longitudinal micro-data are collected: (1) retrospective studies of administrative records that yield a sequence of dates on which particular events occurred (Tracy et al. 1990; Piquero et al. 2007) and (2) prospective studies of the same individuals over a sustained period of time to measure a range of life events and experiences (Elliott et al. 1989; Piquero et al. 2007; Thornberry et al. 1991; Huizinga et al. 1991; Loeber et al. 1991). These two types of studies are not mutually exclusive. In some instances, the retrospective studies have been supplemented with interviews, and in some instances the prospective studies have included detailed reviews of administrative data. The difference between them is generally a difference in emphasis or focus. Both types of studies yield a stream of information for each individual about particular events, experiences, and perceptions.

These studies also have some measurement obstacles that may impact identification. Administrative records may be incomplete for some individuals, particularly if they move out of the area or become incapacitated. And, as in cross-sectional studies, administrative records only measure what is recorded by an agency. Survey data can be compromised when individuals who are targeted to be in a study cannot be located or do not provide consent for participation. This can be a problem at the time of initial contact (enrollment bias), or it can become a problem as the study progresses when individuals drop out (attrition bias). Still another concern is that survey participants learn over time that they can shorten the survey if they answer questions in particular ways (a testing effect) (Thornberry and Krohn 2000; Lauritsen 1998). Regardless of the source of the measurement obstacle, data that are measured incompletely affect the degree of identification.

A recent example of the ambiguity created by these sorts of issues comes from a study of the National Longitudinal Survey of Youth (1997 version; NLSY97) conducted by Brame et al. (2012). This study's main objective was to estimate the proportion of the US population that had been arrested or taken into custody at least one time for something other than a minor traffic offense by age 23. The NLSY97 was designed to be based on a nationally representative sample of households with youth between the ages of 12 and 16 years old on December 31, 1996. Two samples were surveyed – a self-weighting random sample and a minority oversample. Brame et al. (2012) focused their efforts on the 7,335 youths who were selected for inclusion in the random sample. Each person in the sample was asked an initial question about prior arrest experiences at the first interview (1997). Then, at each subsequent interview (through 2008), the respondents were asked about arrest experiences that had occurred since the last interview.

Aside from the obvious difficulties of asking individuals to self-report their own arrest experiences, the study encountered three additional problems. First, only 6,748 (91.9 %) of the originally selected 7,335 persons in the sample actually completed a first interview in 1997. Second, among those who did complete a first interview, many persons missed at least one interview by age 23. Third, even among those who were interviewed, some declined to answer questions about their arrest experiences. By age 23, Brame et al. (2012, p. 23) were able to identify 1,858 people who had been arrested at least once and 4,299 people who had not yet been arrested. For the remaining 1,178 (16.1 %) persons, the ever-arrested status could not be determined because of incomplete data.

Criminologists who study individual-level datasets like the NLSY97 often encounter these kinds of incomplete data problems. One way to address these problems is to assume that the missing cases are a simple random sample of the cases that were originally targeted for inclusion in the study (the missing at random assumption) (Manski 1995). With this assumption, Brame et al. (2012) study would yield an estimated arrest rate of 1,858/(1,858 + 4,299) = 30.2 %. The problem is that there is no way to test the validity of this assumption. It is quite possible the arrest experiences of the missing cases look quite different from those of the observed cases. Since the missing cases are missing, however, there is no way to verify this assumption.

An important insight offered by Manski (1995, 2003) provided the authors with a path forward, however. This way forward was based on the following question: what can the data alone reveal? The answer to this question is obtained by considering two extreme cases: (1) the arrest rate assuming that all of the missing cases were arrested ([1,858 + 1,178]/[1,858 + 4,299 + 1,178] = 41.4 %) and (2) the arrest rate assuming that none of the missing cases were arrested (1,858/[1,858 + 4,299 + 1,178] = 25.3 %). So, assuming individuals who participated accurately reported their experiences, the actual arrest rate must lie somewhere between 25.3 and 41.4 %. In the special case where the arrest rate is the same for both the observed and the missing cases, the arrest rate for the entire 7,335 cases originally targeted for the survey would be 30.2 %.

Some observers might look at the [25.3 % and 41.4 %] interval and find it to be excessively wide and therefore relatively useless to draw substantive conclusions. But a careful, scientific treatment of identification leads to a different set of insights. As Manski would point out: (1) the interval before looking at the data was [0 %,100 %] so the fact that the data allow us to reduce our uncertainty to [25.3 %,41.4 %] means that significant progress has been made; (2) without additional information about the missing cases, we cannot say with any empirical basis that one value in the interval is more probable than another value; (3) the ambiguity caused by not knowing the status of the missing cases leads to much greater amounts of uncertainty than what we normally encounter when we only consider sampling error; (4) studies often do not consider this kind of uncertainty, and if they did, the conclusions of social scientists would appear to be much more ambiguous and fragile than they are typically presented as being; and (5) the extreme bounds are a starting point for further analysis, not an ending point. Researchers can follow up on the extreme bounds analysis by examining how stronger assumptions may be invoked to tighten the bounds. The advantage of this approach is that it is clear how much of the identification is based on the data alone and how much is based on fundamentally untestable assumptions about what cannot be measured.

Toward this end, Brame et al. (2012) noted that if we are willing to assume that the missing cases are at least as likely to have been arrested as the observed cases, then the bounds shrink from the extreme case of [25.3 %, 41.4 %] to [30.2 %, 41.4 %]. There are some compelling criminological reasons to make this assumption. In fact, researchers using the NLSY97 have documented higher attrition rates at later survey waves for individuals self-reporting problem behaviors in the initial wave (McCurley 2006). These data suggest that individuals with a higher propensity of problem behaviors have a lower probability to remain within the sample of survey respondents, but if some researchers or policy analysts do not accept it, the bounds revert back to the extreme case. In this sense, the bounds take on a "no-free-lunch" quality. One starts by considering what can be learned with minimal assumptions (i.e., all respondents understand the question that is being asked, they are cognitively able to answer the question, and that the information they provide is accurate) combined with the data. If one is not willing to make further assumptions, then the extreme bounds will be as tight as possible. If one is willing to make further assumptions, then the argument for those assumptions can be made, and if the audience is convinced, the uncertainty will shrink. If the audience is not convinced, the extreme bounds will form what Manski calls the "domain of consensus" about how much the data are able to reduce uncertainty.

A first order of business in any developmental study of criminal behavior is to measure both stability and change in criminal involvement. Yet, criminological datasets used to measure these quantities are nearly always hampered by incomplete or missing data. Criminologists are accustomed to adopting easy and convenient fixes for these problems. But these fixes often do not come fully to terms with the uncertainty created by missing data. The advantage of a comprehensive identification analysis is that it shows the audience exactly what the data alone can reveal. Then, different sets of researchers and policy audiences can see how much a specific conclusion depends on the data and untestable assumptions about the data.

Distinguishing Between Correlation and Cause and Effect

Of course, criminologists are often interested in moving beyond descriptive analyses in order to measure the causal effect of interventions and life experiences on criminality. Early criminologists often thought of the causes of crime in terms of events, circumstances, and experiences that occurred at about the same time as criminal involvement. But contemporary criminologists take a more nuanced position on this issue arguing that some causes of crime are likely proximate to criminal involvement while others are rooted in the formative aspects of the life course – namely infancy, toddlerhood, and early childhood (Grasmick et al. 1993).

For example, Gottfredson and Hirschi's (1990; see also Hirschi and Gottfredson 1983) theory of self-control maintains that the failure of parents to adequately socialize children contributes to poor development of self-control which, in turn, leads to a greater risk of criminal involvement. From their perspective, while "socialization continues to occur throughout life" (Gottfredson and Hirschi 1990, p. 92), differences in self-control between individuals of the same age are destined to remain about the same throughout the life span (i.e., someone who ranks low in self-control at age 8 will also rank low in self-control at age 58). Their position gives voice to an important axiom of contemporary criminology: there is a rival hypothesis for any apparent effect of a post-childhood life experience or event on criminality. The implications are profound and can be illustrated with a few prominent examples.

Among the most well-replicated findings in life-course criminology are (1) the positive correlation between past and future criminal behavior (Nagin and Paternoster 2000) and (2) the negative correlation between the time since one's last offense and the likelihood or risk that one commits new offenses (Maltz 1984; Schmidt and Witte 1988; Kurlychek et al. 2012). There are clear causal interpretations of these results. Prior offending may reduce one's opportunity to live in stable housing, develop normal healthy relationships with family and friends, obtain an education, or secure employment, and these obstacles may, in turn, lead to increased criminality. Similarly, when an individual leaves prison, there may be a sustained effort to avoid criminality, and the actual experience of avoiding criminality each day causally and gradually reduces the risk of recidivism over time. But, of course, it is also possible that higher-risk individuals are more likely to offend at all times inducing a strong positive correlation between past and future offending behavior and a strong negative correlation between time since one's last offense and the risk of future offending. Hence, an important source of ambiguity in these results is whether the correlations are the result of causal effects or whether they are simply artifacts of failure to measure and properly control for the influence of stable tendencies (like low self-control). Econometricians have long understood that persistent between-individual differences are capable of producing these exact patterns (Heckman 1978). The question is as follows: when these patterns appear, are there reliable ways to discern their source?

This is a classic identification problem. If a researcher can measure the stable between-individual differences in factors like self-control, then it would be easy to identify individuals that are comparable in terms of these differences and look at the data to see whether the ones who have offended in the past are more likely to offend in the future or whether variation in time since the last offense is able to predict the limiting risk of future offending. The problem is that researchers will typically only be able to create partial measures of the relevant between-individual differences. Econometric models can help, but these models typically require strong assumptions related to the functional form of the model, the initial conditions preceding the sequence of over-time observations, the probability distribution of the error term, and the stability of measurement error over time. The ambiguity of partial measurement and questions about how much of the analysis depends on these strong and untestable assumptions can lead to intractable debates about whether causal inference is viable.

One way to make progress is for researchers to become more specific about the factors they believe will have important effects on criminality and then design studies to rigorously test for those effects. Toward this end, Daniel Nagin and his colleagues (see Nagin and Odgers 2010 for a useful discussion) have embarked on an increasingly comprehensive program of research to investigate causal effects for residential placement of juvenile offenders, gang membership, grade retention in school, imprisonment, and adolescent employment. A common theme of this work is that an explicit effort is made to ensure that comparisons between individuals are well posed so that the basis for identification of causal effects is transparent.

The first of these efforts – Manski and Nagin (1998) – considers the very difficult problem of estimating the effect of sanctions on recidivism for juvenile offenders. This study relied on a broad-ranging sample of 13,197 juveniles who were adjudicated delinquent in Utah juvenile courts at least 2 years before their 18th birthday. Each of these juveniles was characterized as receiving a residential placement (11 %) or a community placement (89 %). All of the juveniles were then followed up over a 2-year period, and the number who reappeared in the juvenile court within that period was counted for each group. This analysis revealed that 61 % of the juveniles returned to the court within the 2 years (77 % for the residential placement group and 59 % for the community group). The key question is what can be learned about the effects of residential versus community placement from these data. It turns out that with only minimal assumptions (i.e., no measurement bias, each person's outcome is independent of each other person's treatment), the sign of the sanction effect is not identified. If one is willing to make two assumptions, then it is possible to reduce uncertainty about the sanction effect: (1) sanctioning practices vary between Utah judicial districts, and (2) the average outcome after receiving a given sanction does not vary between Utah judicial districts. This pair of assumptions is called an exclusion restriction and has identifying power because there is no obvious reason to suppose that judicial district affects recidivism. Combining these assumptions with the additional assumption that the highest risk offenders are more likely to receive residential placement (what Manski and Nagin refer to as the "skimming model") leads to the conclusion that residential placement is criminogenic. On the other hand, combining these assumptions with the assumption that each individual receives the sanction that minimizes their risk of recidivism (what Manski and Nagin refer to as the "outcome optimization model") leads to the conclusion that residential placement reduces recidivism.

The identification analysis of Manski and Nagin is useful on three different levels. First, it tells us what the data alone (with minimal assumptions) can reveal about the sign and magnitude of sanction effects. Second, it tells us what assumptions are required to make progress. Third, it tells us where the priority needs to be placed for future research. In this case, researchers learn that a better understanding of juvenile judges' priorities in assigning dispositions is needed in order to better understand the sanction effects. It is noteworthy that efforts to simply condition the comparisons on a set of observed factors in the data would not have led to these insights.

Nagin's more recent efforts have emphasized the use of semi-parametric, group-based trajectory models to understand population variation in the development of criminal behavior over time. An important by-product of these models is a means to probabilistically classify individuals as belonging to groups or "latent classes" that are comprised of individuals with relatively similar developmental trajectories (Nagin and Odgers 2010) prior to some intervention or experience of interest. These models have been somewhat controversial among criminologists because of concerns about "group reification" (for discussion see Nagin and Tremblay 2005; Sampson and Laub 2005). But these concerns do not negate the fact that the method reliably identifies individuals with relatively similar developmental trajectories of criminality. The critical insight of Nagin and colleagues is that the trajectory groups can be used as the basis for creating reservoirs of comparable individuals prior to the occurrence of a treatment or experience that could affect future criminality. In practice, Nagin and colleagues have used trajectory groups in conjunction with so-called propensity scores (Rosenbaum and Rubin 1983) to identify persons that match each other on background characteristics but experience different treatments or interventions.

The identifying power of these comparisons is based on the idea that two or more people who match each other on an extensive set of pretreatment characteristics can be sufficiently comparable to have a reasonable discussion about causal inference. The advantage of the Nagin approach is that the discussion of identification does not devolve into debates about whether the modeling assumptions are correct. Instead the discussion is based on whether the set of characteristics on which one matches are reasonable and comprehensive. Such discussions can provide the field with an understanding of what a comparison of reasonably well-matched cases looks like and they can inform the priorities for variables that should be measured in subsequent research. An added benefit is that these analyses are easy to explain to nonscientific policy audiences.

A good illustration of these issues appears in Nieuwbeerta et al. (2009). In this study, Nieuwbeerta and colleagues used data from the Netherlands Criminal Career and Life-Course Study to investigate the effects of first-time imprisonment on recidivism. The first step of the analysis was to estimate a series of conviction trajectory models for varying durations beginning at age 12 (with a maximum of age 37). Next, within each trajectory group, a propensity score was estimated for each individual in that group. The propensity score for an individual measured the estimated probability that an individual receives a first term of imprisonment conditional on an extensive set of offense-related, demographic, and life circumstances characteristics that were measured before the sentence was imposed. The propensity score estimator is based on a theorem from Rosenbaum and Rubin (1983) which demonstrates that as the sample size grows infinitely large, matching or stratifying treatment and control cases on the estimated propensity score will tend to balance or "equalize" the factors used to estimate the propensity score between the treatment and the control groups. This is a powerful result and it is increasingly being used in criminology and the other social sciences to estimate treatment effects in ways that are more convincing than the standard regression-based estimators.

The third step of the analysis involved matching each imprisoned person to 1, 2, or 3 non-imprisoned individuals. The matching process guaranteed that matched individuals are similar in terms of their prior conviction histories and in terms of the pretreatment characteristics used to estimate the propensity score. The analysis showed that the recidivism rates of imprisoned individuals were significantly higher than those of non-imprisoned individuals after matching. While this is a compelling result, the analysis had some important limitations including (1) the inability to match some of the most serious imprisoned offenders in the study with a comparable person who did not receive a confinement-based sentence, (2) a wide-ranging but still finite set of covariates and background characteristics to match on, and (3) for the sake of inferential clarity, only first-time imprisonment experiences were studied. But even with these limitations, the Nieuwbeerta study provides a useful model for criminologists to consider as they think about causal inference and identification in life-course criminology.

Conclusions

Criminologists are increasingly devoting attention to issues of identification as they conduct life-course research. This trend is bringing a greater focus and scrutiny to issues such as missing data and estimation of treatment and intervention effects among individuals that are suitably comparable to each other on developmentally appropriate factors and characteristics. It is all too easy for researchers to simply drop cases with missing information from their analysis and proceed with a study of the residual sample of nonmissing cases while hoping that the biases are not large. It is all too easy for researchers to estimate a statistical model-based treatment effect while hoping that the functional form assumptions of that statistical model are consistent with the data. A focus on identification moves away from a criminology of excessive "certitude" (Manski 2011) and toward a criminology of sensitivity analysis, robustness testing, and verification.

When cases have missing data, a focus on identification leads to what-if questions about those cases. What if the missing cases are more likely than the observed cases to be involved in criminal behavior? If that is true, how would the analysis results change? What assumptions are criminologists willing to make to achieve identification? What assumptions will criminologists agree are reasonable? What do the data reveal about criminologically interesting quantities if researchers are only willing to make minimal assumptions? These are all questions that have not been asked much in life-course criminology. But they are starting to be asked more and the methods to make those questions answerable are becoming more widely available.

Methods for causal inference in observational life-course studies are also becoming more sophisticated and thoughtful. Here, a focus on identification leads to equally useful questions. For example, here is a question that should always be asked in a causation-focused study: what is the empirical basis for comparing these cases to each other? Is this comparison an apples-to-apples comparison? How are the groups being compared different from each other in terms of characteristics that are, at least in theory, measurable before an intervention (going to prison) or life experience (getting married or securing employment) occurs?

Criminologists are accustomed to thinking in theoretical terms about the causes of criminal involvement. But a focus on identification leads to broader questions like why some people go to prison while others do not. Why is it that some people get married or get a job and others do not? Does gang involvement lead to criminality? Or does criminality lead to gang involvement?

These are questions that criminologists have generally not considered as much as the questions addressed by traditional crime theories. But a focus on identification means these questions are every bit as important as the traditional theoretical terrain.

Ultimately, identification is about researchers coming to terms with what is known and that which remains unknown. If the data are missing, it is of little use to confine our analysis to the simplistic assumption that the data are missing purely at random. It is far more fruitful to present the analysis with reasonable attention to what happens to the analysis if the assumption is wrong. If the analysis relies on a comparison of one group of people to another group of people, then criminologists should make clear and convincing arguments about why those comparisons are sensible and what would happen to the analysis if the assumptions are wrong. In sum, the more the field thinks about identification, the farther the field will advance toward a more thoughtful and rigorous science of criminal behavior.

Overview

As citizens we are increasingly observed, traced, and documented in our routine and some of our not-so-routine activities. While it is common for citizens and scholarly commentators to question, and frequently criticize, invasive uses of emerging technologies, it is less common to focus attention on actual technical capacities and the use of "traces" as intelligence and evidence in criminal justice practice. This omission is curious, because there are long-standing problems with identification and proof in legal settings. This entry discusses the reliability, and therefore evidentiary (or probative) value, of techniques (and technologies) routinely used for surveillance and proof of criminal activities (including terror offenses). Recent work on surveillance and surveillance technologies has tended to focus on their potential to change or disrupt, particularly older, settlements (and values) around privacy and visibility. This entry endeavors to shift that focus by introducing some of the epistemic dimensions and institutional responses to surveillance technologies, and their role in identification, in order to understand their use as intelligence and evidence, in criminal investigations, plea bargains, and criminal prosecutions. Criminological literatures, particularly surveillance theory, have much to offer discussion of forensic science and forensic medicine, but recent challenges to the value of many technologies and derivative interpretations suggest that threats posed by "Big Brother" – that is, the state's ability to "watch" – might, in some regards, be more clumsy (and simultaneously complicated, attenuated, and remote) than is often assumed.

Thinking about the role and use of the artifacts (or products) of surveillance in investigative and prosecutorial contexts is revealing because it tends to expose, both directly and indirectly, the limits of the technologies as well as the limits of legal processes. Recent authoritative criticisms of many forensic sciences (e.g., Saks and Koehler 2005; National Research Council 2009) reinforce the importance of questioning claims made by

police, forensic scientists, lawyers, and judges. They might also lead us to doubt the value of legal institutions as appropriate regulators (or “gatekeepers”) of surveillance technologies and derivative evidence.

Substantially, our entry begins with a review of three technological assemblages ubiquitous in modern criminal investigations and prosecutions, namely, those associated with the analysis of latent fingerprints, DNA, and security and surveillance images. Reviews of these particular technologies and the transformation of traces into admissible evidence are rewarding because of their distinctive historical trajectories, divergent scientific foundations, and pervasive use across a range of intelligence, investigative, forensic, and administrative settings. Ubiquitous in forensics and surveillance literatures as well as the popular imagination, fingerprints, DNA, and images provide interesting insights and illuminating comparisons to aid our understanding of surveillance technologies and their *evidentiary* products.

Latent Fingerprints

The identification of individuals is, of course, a problem of long standing to which a variety of technological solutions have been proposed (e.g., Groebner 2007). Concerned with increasingly mobile populations, in the nineteenth century, state governments began to develop bureaucratic *systems* of identification that were attentive to the storage, deployment, and ability to retrieve information. One of these new systems, fingerprint identification, which was developed nearly simultaneously in colonial India for the control of native populations and Argentina for the control of “criminal classes” immigrating from Europe, was perhaps the first identification technology to develop, inadvertently it seems, a forensic application. While fingerprint identification was based on impressions of the “friction ridge skin” that covers the fingertips created deliberately using ink, it was noted that similar impressions are often deposited inadvertently when individuals touched objects with smooth services. Several different observers proposed that such impressions might provide evidence that a particular individual had touched an object that might, in some cases, prove useful in the investigation and prosecution of crimes. In early cases, the clerks who maintained identification bureaus were called upon to undertake the analysis of such “latent” impressions.

By the 1920s, fingerprint identification had become the world’s dominant system of identification for institutions, like prisons and police departments, charged with keeping track of “criminal” populations. These institutions began assembling large databases of inked fingerprints to prevent apprehended individuals escaping from their criminal pasts by adopting alternative identities (i.e., aliases). Latent fingerprint identification was becoming increasingly common as well. Methods for “dusting” (and photographing) objects in order to visualize latent impressions were developed, and the search for latent prints became a regular feature of police investigations, especially for more serious offenses. However, to be useful in identifying the perpetrator of a crime, latent print identification was dependent either on the selection of a suspect by other investigative means or a painstaking and resource-intensive “cold search” of a local or regional database – often a manual filing system. Nevertheless, fingerprint identification developed into the most trusted and iconic means of both forensic and administrative identification.

In court, the interpretation of latent prints was quickly deemed admissible following a modest degree of resistance by defendants. Courts based admissibility on: (1) a general assumption among informed observers that the evidence must be reliable; (2) the observation, though not systematically recorded or tested, that experts’ conclusions regarding latent prints were rarely refuted *post hoc* by external, epistemologically superior, facts; (3) an intuitive sense of the very high complexity and variability (or “selectivity,” Champod et al. 2004) of fiction ridge skin itself.

By the 1980s, automated fingerprint identification, which had been under development for decades, had become sufficiently mature to penetrate major law enforcement agencies. This development made database searches much less costly, greatly enhancing the utility of fingerprint databases and the potential value of recovered latent prints.

In the 1990s, influenced largely by the controversies over DNA typing (discussed below), many commentators began to question the legal assumption that the accuracy and discriminability of latent print association could be taken on trust. This rethinking, along with some high-profile errors, led to legal challenges to fingerprint evidence, especially in the United States (Cole 2001). For the most part, these challenges have not persuaded courts to substantially modify their practices, but they have generated renewed attention to fingerprint evidence, in the form of a number of high-profile official inquiries and reports (National Research Council 2009; Campbell 2011; Expert Working Group on Human Factors in Latent Print Analysis 2012), and arguably, they played a role in stimulating new efforts at basic research on the accuracy (Ulery et al. 2011; Tangen et al. 2011) and discriminability (e.g., Neumann et al. 2012) of latent print associations.

DNA Profiling

The development of a method for visualizing "hypervariable" regions of genotypes by Alec Jeffreys in the mid-1980s led to the proposal that genetic variations might be harnessed to provide another means of individual identification. Unlike fingerprinting, the forensic application was apparent – and, indeed, seemed the principal use of the new technique – from the outset. "DNA fingerprinting," as it was briefly called, could glean identity from genetic material, such as blood or semen. The method was applied to a serial rape-murder case in the vicinity of Jeffreys's institution, the University of Leicester, and it quickly became apparent that there were many crime scenes where biological material was present but fingerprints were absent.

"DNA profiling," as it was soon renamed, spread quickly, and the technology developed rapidly, with a series of new techniques replacing Jeffreys's original multi-locus probes. Of particular importance to forensics was the application of the polymerase chain reaction (PCR), developed by Kary Mullis. This allowed for the "amplification" of small amounts of genetic ("trace") material into volumes sufficient for analysis. Though the initial PCR techniques lacked discrimination, short tandem repeats (STRs) combined PCR with high discrimination. This technique remains the standard technology used today, although more powerful techniques are on the horizon.

As with fingerprints, state law enforcement agencies began assembling databases of genetic profiles. These databases were initially limited to serious sex crimes. Subsequently, they have expanded rapidly such that their eventual replacement of fingerprint databases seems probable. DNA databases have proved more controversial than fingerprint databases, largely based on the (in principle, questionable, Cole 2007) argument that DNA includes more "intimate" information than fingerprints (Krimsky and Simoncelli 2011).

Legal systems have differed sharply in reacting to this challenge. In the United States and the United Kingdom, the state's interest in public safety has generally trumped privacy concerns pertaining to genetic information. The European Court of Human Rights, however, recognized a fundamental privacy interest in both DNA and fingerprint information and this right, it ruled, demanded the exercise of moderation and proportionality in the state's retention of such information, a ruling which bound the United Kingdom as well (*S. and Marper v. United Kingdom* 2008). The European Court was particularly concerned by the potential practice of "familial searching," in which near correspondence in database searches would be used to generate investigative leads from the blood relatives of those in the database. American courts, in contrast, have generally approved of this practice.

In court, DNA evidence was challenged more forcefully than fingerprinting ever was, and this resulted in some adverse decisions. It is generally agreed that this small number of challenges and adverse rulings (e.g., *People v. Castro* 1989) stimulated improvement in the science. After a period of public controversy – often characterized as the "DNA wars" – the legal admissibility of routine DNA evidence became non-contentious. Issues remain, however, for cases involving complex mixtures of DNA from several individuals, more exotic techniques like mitochondrial and low copy number DNA profiling, and contamination and biased interpretation (Aronson 2007; Lynch et al. 2008; Kaye 2010).

Image Interpretation (e.g., of CCTV Recordings and Photographs)

Images have been used in and around legal proceedings and public inquiries (e.g., the Zapruder film at the Warren Commission) for more than a century – initially in the form of photographs, film, and video, and more recently in the guise of animation and "virtual" displays (Feigenson and Spiesel 2009). Photographic images, incorporated into many official documents (e.g. drivers' licenses, passports, and criminal records), provide important means of identification in administrative, commercial, and social settings. Accepting that images may have considerable potential as sources of information, here it is our intention to focus on their use in legal proceeding for purposes of identification.

In recent decades, especially with the advent of CCTV systems in public spaces, police, investigators, and prosecutors – and to a more limited extent criminal defendants – have begun to use images to piece together criminal activities and to identify the perpetrators of such acts (e.g., Goold 2004). In conjunction with the rapid expansion of security cameras in private spaces (e.g., houses, banks, bars, casinos, convenience stores) and/or quasi-public spaces (e.g., shopping malls, airports, and around ATMs), these systems have produced a very large number of images indexable to criminal activities – ranging from shoplifting to assault, armed robbery, and murder. The availability of images that, unlike DNA and fingerprint evidence, are susceptible to immediate interpretation by investigators (and others) has begun to change the way that criminal acts are investigated and presented to various publics whether as evidence in court or via various media in the public domain. By way of example, intelligence operatives, investigators, and general duty police officers – with limited, if any, specialist training – are often obliged to watch and interpret videos (and images) in order to advance investigations or assemble intelligence. Similarly, newspapers and television are used to enlist an expanded audience that might be capable of identifying individuals or providing investigative leads.

Ordinarily, images related to criminal offenses are admissible and the tribunal of fact is free to interpret the content, which may involve attempting to track events and/or identify those involved. The low quality of many crime-related images has meant that investigators and prosecutors often call upon others to provide supplementary interpretations and guidance. Courts, particularly in common law jurisdictions, have responded unevenly to the admission and use of opinion evidence to assist with identification. Approaches range from jurisdictions such as England – where police (including investigating officers) and a range of individuals, recognized as "face and body mapping" *experts* (with a background or training in intelligence, medical art, photography, information technology, anatomy or physical anthropology) or gait analysts (usually podiatrists), are permitted to express opinions about the content of images and positively identity persons of interest; to Australia – where police officers are generally prohibited from expressing opinions about identity, but "facial mappers" are allowed to describe similarities between a person of interest and the accused; to Canada – where police, prison and parole officers, possessing some familiarity with the accused, can positively identify them in incriminating images; to the United States – where investigators tend to rely upon quantitative (i.e., photogrammetric) approaches purporting to capture features such as the height or shoe size of offenders (Edmond et al. 2013).

The admission of images and incriminating interpretations of images appears to be an institutional attempt to accommodate the exponential proliferation of potentially probative evidence emerging in recent decades, in conjunction with a naive confidence in the abilities of lay people – whether lawyers, judges, or jurors – to manage image interpretation, and particularly identification, within the confines of the adversarial trial. Opinions about images are routinely admitted. Witnesses are sometimes limited to describing similarities rather than expressing positive opinions about identity. The value of such opinions is ordinarily left for the tribunal of fact – as a matter of weight.

This ready admission and reliance upon images in criminal investigations and prosecutions is revealing, particularly when contrasted to DNA profiles and latent fingerprints. For, there are no standardized or empirically validated approaches to the capture and storage, let alone interpretation, of images. Excepting some photogrammetric methods – with their origins outside of the forensic sciences – we have no indication of the validity or reliability of the variety of techniques and derivative opinions allowed in courts. To put this another way: we do not know how accurate the various "expert" witnesses are, or if they can consistently do what they claim.

Not insignificantly, experimental studies indicate that humans are error prone when asked to compare people in photographs or compare photographs and persons (i.e., typical courtroom scenarios) even when relying upon contemporaneous, high-quality, full-frontal images (Davis and Valentine 2008). Conspicuous exceptions are those with considerable familiarity (e.g., family members and close friends), especially where exposure covers significant periods of time and a variety of circumstances. On an average, when familiars are shown images and/or video and asked to express opinions about identity they tend to be reasonably accurate – even where the quality of images is low and the exposure short (Jenkins et al. 2011). Predictably, familiars are often reluctant to testify and incriminate. Such reticence helps to explain reliance on investigators, the legal recognition (or construction) of "expertise," and ready admission of opinions.

One factor, applicable to all identification technologies, though perhaps clearest in the forensic use of images, is the beguiling complexity of interpretation. The pervasiveness of photographs, films, and videos, along with the frequency or our exposure, encourages courts to admit images, frequently characterizing them as objective evidence of what transpired. Witnesses and juries are routinely asked or expected to approach images as mechanical reproductions of reality; their interpretation is implicitly straightforward – a relatively mundane or even intuitive activity. There are, however, serious complexities with image interpretation and with the kinds of intertextuality – e.g., the narration of images by prosecutors or expert witnesses during criminal proceedings – that may subtly (and sometimes unconsciously) shape or cue perception and interpretations. In contrast to electropherograms and latent fingerprints, the tribunal of fact is routinely encouraged to undertake its own interpretation of the primary data (i.e., the images), often in conjunction with "expert" opinion and the other evidence. Additional incriminating evidence may implicate the accused and be conveyed to those endeavoring to interpret images – whether analysts or juries – in ways that skew perception and attempts to convey difficulties with image interpretation. The interpretation of unfamiliar images, such as x-rays, fMRI scans, and aerial photographs, confirmed by numerous controversies in the long history of photography and film (e.g., Fenton's cannon balls and the detention of Rodney King), reinforces just how complex and controversial images and their interpretations can be (e.g., Morris 2011).

Key Issues

At this juncture, we turn to consider our three forensic technologies via a series of analytical frames and themes drawn from surveillance and other criminological and legal literatures.

Accommodation: Legal Responses Are Driven by Technological Advances and the Availability of Incriminating "Evidence"

Investigators, prosecutors, and judges tend to be rapid and uncritical adopters of identification technologies, typically embracing their outputs and opinions about their outputs as probative, and implicitly reliable, evidence. Admissibility standards and contests over the probative value of incriminating expert opinions have been ineffective – and at best inconsistent – at excluding unreliable opinions or exposing weaknesses in the interpretation and expression of opinions about fingerprints, DNA profiles, and images.

Courts in most jurisdictions – including those with reliability-based admissibility standards (e.g., in the United States and Canada following *Daubert v. Merrell Dow Pharmaceuticals, Inc.* 1993) – have been surprisingly uncritical and remarkably accommodating in their responses to opinion evidence derived from new technologies and older technologies subjected to new criticisms. Rather than require empirical support for interpretive techniques and expressions, courts express confidence in the efficacy of traditional legal processes and trial safeguards (see "The Limits of Legal Proceedings"). They have preferred to "grandfather" long-standing techniques (e.g., latent fingerprint comparison), accept witnesses with investigative experience (see "Reliability Discourses" and "Experience and the Reification (or Legal Construction) of Expertise") or broadly relevant qualifications – along with their self-serving claims – and they have relied primarily on the deconstructive abilities of poorly resourced defense lawyers to expose and convey limitations to lay jurors (and judges), rather than impose responsibility upon the state to demonstrate reliability (i.e., validity and reliability) through reference to empirical studies.

Moreover, once a technology or derivative interpretive technique is admitted in one jurisdiction, admission tends to follow in others. Conditions imposed on the initial admission are frequently elided in subsequent decisions, thereby facilitating technological creep (Risinger 2000).

Weapons of the Not So Weak: Resistance Is Not Always Useless

Following Scott (1985), a common theme in contemporary surveillance studies concerns the ability of various individuals and publics to resist or subvert surveillance, oversight, and identification. Concerned with visibility, traceability, and often privacy, a range of responses have emerged that, to varying degrees, enable individuals and groups to resist scrutiny or turn methods of surveillance and accountability back on to those who normally "watch" (e.g., sousveillance). The technologies we have selected are illuminating because they are more or less intrusive depending upon how information is captured and used, as well as their actual capabilities – both current and anticipated.

It is argued, for example, that DNA samples and profiles may be used to do more than determine a non-match or a match and a probability (or likelihood) of the accused being the source. DNA samples, which are often retained by government agencies, can theoretically be analyzed in ways that may facilitate discrimination – both positive and negative. Analysis might be used to identify a risk of a particular illness, such as susceptibility to breast cancer, and this might be used to prevent premature death or to discriminate through exclusion from insurance coverage. Many (negative) discriminatory uses are proscribed by constitutional rights or legislative enactments – always susceptible to the possibility that they might be reviewed, circumvented, or interpreted in ways that accommodate new technological capabilities, whether real or imagined.

Conversely, the current limits of interpretation mean that it is far from obvious that the availability of images will enable investigators, and even attentive publics and familiars, to definitively determine what took place and who was involved (e.g., the Vancouver and Tottenham riots). Depending on the cameras, systems, and sophistication of resistance, those capturing images, for whatever reason, may or may not be able to use the images as probative evidence. Techno-legal assemblages (see "Back to the Future: No Escape from Interpretation in

Complex Techno-legal Assemblages") have both technical and socio-legal constraints and limitations.

Anyone remotely conversant with criminal justice knows that some technologies can be resisted (or subverted) through relatively simple techniques such as wearing gloves (against fingerprint collection) or condoms (against DNA typing), or wearing bulky clothing, a hat or balaclava (for cameras) (e.g., Marx 2003). Such strategies of resistance, used by criminals and other citizens to disrupt comparison and identification, may or may not be effective. For, it is increasingly common for a variety of technologies (or artifacts) to be used collectively to assist with identification and proof. Where a DNA match is obtained, or similarity is observed between an image from a robbery and a suspect, an ATM transaction or mobile phone call may be used to place a person of interest in the vicinity of the offense. Moreover, certain forms of resistance (such as a particular disguise) might lead to propensity interpretations as criminal "signatures." Of course, where suspects offer a potentially innocent explanation or defense – such as consent in a sexual assault complaint – the value of identification technologies may rapidly depreciate along with the need for resistance or critique. Similarly, claims about what happened "off camera" might be useful to raise doubts around the cause of injury or culpability for serious injury resulting from a partially filmed (and therefore fragmentary) assault in a bar or street. This often shifts the hermeneutic exercise from the non-contentious issue of identity to questions about what actually transpired.

While there are means of resisting forensic and surveillance technologies, it is difficult to resist multiple identification technologies in court, especially when they are combined into a coherent narrative. Where a variety of different technological artifacts are aligned, especially if they are presented as independent and corroborative – it has become increasingly difficult to resist the cumulative results of skillfully integrated allegations.

Interestingly, not every criminal act is attended by resistance to the identification of its perpetrator. Many criminal acts are performed directly, some even deliberately, in front of cameras (and/or witnesses) or in ways that are seemingly indifferent to surveillance technologies and investigative possibilities.

Back to the Future: No Escape from Interpretation in Complex Techno-legal Assemblages

Drawing conspicuously on science and technology studies (STS and SSK) literatures, notably the work of Latour (1987), surveillance studies have embraced the idea of *surveillance assemblages* (Haggerty and Ericson 2000). That is, the combination of machines/equipment, techniques, procedures (all potentially *actants*), individuals, institutions, training, traditions and even cultures, as forming part of the assembly of constituent factors structuring the way in which interpretive activities are performed and understood. Although many of these features and dimensions tend to be omitted, or elided, in formal accounts and legal proceedings, their reintroduction provides a useful way of approaching the construction of surveillance and evidentiary artifacts and the *potential* for them to be opened up and pulled apart (or deconstructed, after Jasanoff 1995) in legal proceedings. The idea of the assemblage, combining human users, technologies, and traditions, reinforces the inescapability of human participation and the need for interpretation across the forensic sciences. Interpretation and risks of error occur across the spectrum of activities from the recognition and collection of traces, the analysis of results, to attempts to ascribe significance in the context of a case or administrative process. Human interpretation is perhaps most conspicuous on the margins: with low copy number DNA analysis, badly degraded DNA samples or results obtained at instrumental thresholds, partial or smudged latent fingerprints, and in responses to badly distorted or very old images.

Even sophisticated automated and semi-automated systems, such as DNA profiling machines or the automated fingerprint databases, require a human interface to interpret results as well as assess their potential significance to an investigation or prosecution. They also depend, as Lynch et al. (2008) explain, on mundane practices – chains of custody, collection and storage practices, training of personnel, accreditation of laboratories, the honesty of investigators and technicians as well as assumptions about the way traces may have been deposited. Rather than simply overcoming known problems, new and more powerful technologies (e.g., low copy number DNA profiling) may actually compound difficulties as smaller and smaller samples can be analyzed in ways that generate more mixed samples and introduce stochastic effects that require new forms of interpretation – and make the need for bias-reducing procedures, such as sequential unmasking, even more urgent.

Notably, fingerprint identification, as traditionally conceptualized, has lacked the "interpretative step," in which the analyst, having found correspondences between prints, assesses the significance of this finding by estimating the rarity of the corresponding features in some relevant population. Instead, assumptions about fingerprints lead analysts to equate a "match" with the positive identification of a particular individual to the exclusion of all others (i.e., individualization).

The interpretation of images represents an obvious example of the interpretative predicament. Whereas closed biometric systems relying upon images and/or other data such as fingerprints may perform reasonably well – especially on relatively small data sets, where the reference data and application are obtained in controlled conditions – when it comes to determining the identities of unknown individuals appearing in security and surveillance images, things are decidedly more complicated and not necessarily susceptible to algorithmic analysis – at least not without very significant levels of error (Introna and Wood 2004). In most investigations involving images, there are no relevant databases (e.g., *R v. Atkins* 2009). Rather, those recognized by courts as experts – because they are believed to be able to assist the tribunal of fact – are allowed to express their opinions about similarity and/or identity in the absence of any kind of systematic information about: the frequency of facial (or bodily) features; the independence of different facial features (e.g., lips and nose); and usually in the absence of methods capable of explaining how the analyst overcomes the distortion created by cheap cameras, poor positioning, bad lighting, image perspective, and the generally low levels of data retention.

Reliability Discourses

The epistemic value of many of the forensic sciences, particularly comparison sciences used for purposes of identification, was explicitly questioned after an inquiry by an eminent multidisciplinary committee (of the National Research Council, 2009) established by the National Academy of Science (USA). The committee's conclusions are revealing. Its report is not only a remarkably critical response to many comparison/identification techniques *in routine use*, but it also captures something of the light that scientifically predicated DNA techniques have cast on the other comparison "sciences."

Without wanting to suggest that DNA processes are infallible or even a "gold standard" to be faithfully emulated, it is useful to contrast the validation studies, sophisticated statistical work on population models and probability/likelihood ratio frameworks that have accompanied the largely extralegal negotiations surrounding the refinement of DNA evidence, with the credulous and accommodating reception of many other forensic science techniques – extending beyond latent fingerprint and image comparison to include, among others, ballistics, tool marks, handwriting, dental, hair, footprint, shoeprint, ear print, and tire mark comparison. This accommodating posture predates the introduction of DNA profiling and stubbornly survives its refinement in the 1990s. To varying degrees, non-DNA techniques have yet to produce, and courts yet to stipulate, the need for independent evidence of validation and reliability.

As things stand, and somewhat tautologically, investigators and experts tend to use prior admission, guilty pleas, and convictions as a basis for claims about the reliability of their techniques, interpretations, and evidence. In the absence of demonstrated validity and reliability studies (or independent evidence of proficiency), admission and convictions (however obtained) do not necessarily provide epistemic support for technologies and techniques. Moreover, the complex assemblages associated with "identification" are often obscured or "black boxed" and left to impecunious criminal defendants and their state-funded defense attorneys to consider challenging (or deconstructing) in the risky realm of the (adversarial) criminal trial.

Reviews of wrongful convictions suggest that techniques used to establish identity may sometimes fail to correct misleading investigative information and faulty assumptions, such as mistaken eyewitness accounts or confessions procured under duress (Garrett 2011). Where analysts are exposed to prejudicial information that is not required for their analysis (e.g., the suspect's prior criminal conduct and/or investigators' beliefs about culpability), these dangers are likely to be accentuated (Dror et al. 2006).

The Expression of Results

Considerable effort has been expended on the interpretation of DNA matches and the way results are expressed in reports and in courts. The results of DNA profiling are now routinely expressed in probabilistic terms based on widely accepted population models and statistics. Prominent, scientifically based, refinements to the reporting of DNA matches have created problems for other comparison sciences, including the interpretation of latent fingerprints and images.

Recently, in response to admissibility challenges to opinions based on latent fingerprints and images, several courts have required witnesses to qualify (i.e., read down) their results, sometimes restricting them to descriptions of apparent similarities (so-called splitting). This intervention is revealing. It reinforces the absence of validation and reliability studies able to support the historical form of expression (e.g., individualization and no errors for latent fingerprints) and exposes the willingness of these witnesses, legally recognized as experts, to express strong forms of incriminating opinion in their absence. It also evidences commitment to the admission of opinion evidence and naïve confidence in the ability of the trial to identify and convey limitations.

Curiously, it is highly unusual for forensic scientists to provide an indication of the error rate with the expression of results from most of these techno-legal assemblages. Rather, it seems to be the responsibility of those challenging "identification" evidence to retrospectively identity errors in the collection, storage, analysis, interpretation, and the expression of results.

Experience and the Reification (or Legal Construction) of Expertise

Courts have been responsible, to a considerable degree, through the legitimacy conferred by admission, along with the reliance placed on incriminating expert opinion evidence in supporting convictions (and upholding appeals), for recognizing and indeed reifying some forms of experience and/as expertise. Instead of requiring evidence of validity and reliability, courts have tended to accept weaker surrogates such as formal qualifications and experience. Many courts, including those in jurisdictions with formal reliability standards purportedly governing the admission of expert opinion evidence, have tended to place great store on formal qualifications and, particularly, experience along with earlier accommodating admissibility jurisprudence when approaching the admissibility of forensic science and medicine evidence (Edmond et al. 2013).

Rather than require evidence of ability and accuracy, in the form of published experimental studies, judges have preferred to look to practical experience and institutional affiliations (e.g., with the FBI, the FSS, and RCMP). While we accept that experience is an important dimension of expertise, we would contend that in most cases, and certainly with the kinds of technologies discussed in this entry, that experience alone (or even in conjunction with past "successes" and supplementary incriminating evidence – a strong case) cannot replace the need for demonstrable evidence of reliability. Experience is useful once the value of a technique has been demonstrated empirically.

In consequence, legal institutions have played an important if under-appreciated role in the construction and social legitimation (or "certification") of forensic science and medical evidence as "knowledge" through admission and allowing reliance to be placed upon techniques and opinions of unknown evidentiary value. Through their failure to impose credible restrictions on admission or adequately explore and convey limitations, courts – and lawyers, in particular – have facilitated admission and encouraged reliance upon techniques that were (or are) not adequately understood, nor demonstrably reliable. Somewhat iatrogenically, this accommodating posture may have actually inhibited study and testing. Disinterest in reliability has undoubtedly contaminated intelligence and investigative practice, actively contributed to wrongful convictions, and allowed serious offenders to remain undetected, free to re-offend (Garrett 2011).

The Limits of Legal Proceedings

In criminal justice systems, trial courts are conventionally characterized as the appropriate forum to contest and assess expert opinion evidence. They do not generally perform well in these capacities (Edmond and Roach 2011). Indeed, one of the reasons forensic scientists (and forensic medicine and dentistry) have been insufficiently attentive to the reliability of identification technologies and their various uses is that those managing the admission and presentation of evidence have been overconfident and accommodating because of their faith in the ability of legal processes to identify and convey limitations to lay tribunals of fact and courts of appeal. Such accommodating, and empirically indifferent, responses are difficult to reconcile with the expressed goal of "doing justice in the pursuit of truth" (Ho 2008).

Empirical evidence suggests that courts and jurisdictions vary dramatically in their ability to respond to forensic science and medicine evidence, and that individually and cumulatively trial safeguards and protections – such as prosecutorial restraint, (reliability-based) admissibility standards for expert opinion evidence, cross-examination, rebuttal experts, restrictions on the expression of results, directions and warnings to juries, and scope for appeals – are not particularly effective means of addressing problems with expert opinion (Edmond and San Roque 2012). Their limited value is compounded by under-resourced defense lawyers, the state's (near) monopoly of many types of "expert" evidence and experience (e.g., latent fingerprint analysts), excessive trust in police and investigative agencies, the complexity of many forms of statistical and probabilistic reasoning, and requiring lay persons to assess expert opinion evidence in the context of a criminal trial. There are relatively few well-resourced and technically sophisticated challenges to forensic science techniques and derivative opinions, and correspondingly few incentives for police and forensic scientists to study or improve their techniques.

Intelligence, Investigations, Prosecutions, Evidence, and Proof

In this entry, we contend that many of the technologies used routinely for surveillance, in investigations and as evidence in criminal proceedings, are not as unproblematic as routinely represented by investigative agencies, prosecutors, judges, and the media (e.g., CSI). Among commentators, considerable attention has been directed to the *frontstage*: of privacy concerns; and the ways surveillance technologies are adopted, used, and understood by institutions, operators, investigators, and various publics. Typically, less attention is dedicated to the *backstage* (or inside the "black box"): the value of the technologies and their evidentiary products, the capabilities of legal institutions and personnel, or the models of science, technology, and expertise embodied in the ways they are represented.

Following from the discussion of the epistemic value, particularly the uncertain validity and reliability of many "identification" techniques, we have to wonder about the use of terms such as "intelligence" and "evidence." Such terms are question begging: requiring further discussion about whether claims can be sustained and the kinds of models of science, technology, and expertise that might be used to support and understand their use in particular contexts and for specific uses. Without wanting to dismiss some kind of epistemic continuum, in practice, it will often be difficult to know precisely where techniques of interpretation might sit. In theory, there seems to be a spectrum from *uncertainty* (or ignorance) to *certainty*, with "intelligence," "evidence," and "proof," each respectively situated further along the spectrum toward "certainty." For the criminal justice system, there are risks, and a corresponding need for caution, if the probative value of the products of surveillance technologies is low or unknown – located toward the "uncertainty" end of the spectrum. This may require a protective attitude, formal protections, and possibly exclusion (or nonuse), particularly if technologies and derivative opinions are not demonstrably reliable.

Regardless of the nomenclature, there may be differences in the suitability of particular techniques, of varying degrees of reliability, to investigations as opposed to trials and criminal proof. Because of a range of explicit commitments and obligations – embodied in rules and procedures as well as constitutional and human rights protections – courts would seem to be constrained in the types of techniques and interpretations they might admit toward proof in criminal proceedings. In principle, criminal proceedings ought to be organized in a manner that embodies the desire for factual accuracy and fairness as well as an express commitment to avoid convicting the innocent.

Intelligence gathering and criminal investigations are not, for good reasons, constrained in the same way. Problems may emerge, however, when a range of speculative and error-prone technologies are available and relied upon uncritically by investigators and/or used as probative evidence in criminal proceedings.

Future Directions

This entry suggests that the value of surveillance technologies used routinely to observe, monitor, and interpret behaviors, and identify various publics and individuals, may be quite varied, necessarily moderating their suitability for investigations and criminal proof. There appears to be tremendous variation in what those using comparison techniques, whether based on DNA, latent fingerprints, or images (and extending to voice recordings, hair, handwriting, ballistics, tool marks, and so on), can credibly claim. Against expectations, we cannot assume that surveillance technologies, including those in routine use by investigative agencies and courts, are particularly effective. Interestingly, pervasive use and popular impressions reveal little about, and do not correlate with, evidentiary value.

This entry reveals complexity, and unevenness, in the ways institutions adopt, use, depend upon, and rationalize recourse to a range of identification technologies. It also suggests that even assemblages (including scientifically based technologies such as DNA profiling) unavoidably depend upon humans for the collection and interpretation of results and the attribution of meaning in particular investigative and prosecutorial settings. It seems likely that even with substantial advances in technological capabilities, whether through increasing sensitivity or whole genome sequencing, higher resolution cameras and greater data storage, or more accurate algorithms to enable automated comparisons, we will not eliminate – and probably not dramatically reduce – errors or the role of analysts, interpreters, and others. There may be technological advances, but there will be relatively fewer technological fixes. This seems to mean that the ability of the state (as well as the many corporate and private observers) to monitor, let alone effectively trace and identify citizens in a range of social, commercial, and criminal contexts, may be more constrained than is routinely suggested or believed. Scholars such as Lyon (2008) suggest that we need to develop more balanced responses to surveillance practices and capabilities – recognizing both the threats they may pose to traditions, privacy, and freedom as well as their ability to improve our lives and enhance safety and security. DNA profiling – with its diagnostic, discriminatory, and therapeutic possibilities, its ability to assist with investigations and identify criminals, as well as its exposure of wrongful convictions and the frailty of criminal justice processes – represents an example of the potential value of emerging empirically predicated technologies and their ability to produce valuable, if sometimes unexpected, insights.

This entry has adopted a somewhat unreflexive approach to technologies – particularly discussion of the validity and reliability of evidentiary products. We accept that the meaning of *reliability* is a social accomplishment, unavoidably extending beyond experts and domains of expertise to incorporate social, institutional, ideological, and practical dimensions (Bijker et al. 1987). Rather than adopting an essentialist or technocratic approach to the meaning of *reliability* or the effectiveness of a technology, we encourage analysts to shift focus to the particular use, the setting(s), institutional values, and traditions and even the way negotiations around the meaning and use of technologies ought to be conducted – in particular settings. It is our contention that in criminal justice settings, the state should be able to satisfy an onerous standard – guaranteeing basic trustworthiness – before interpretations derived from surveillance assemblages are admitted as incriminating opinions to assist with proof of identity and guilt. This is a response to the premium placed upon accuracy and fairness, but is also indexed to the frailty of many surveillance assemblages along with emerging evidence about the weakness of criminal trial safeguards. Legal systems have performed poorly in regulating and assessing identification technologies (NRC 2009).

Significantly, we would not necessarily suggest that the standards required of the state in relation to incriminating expert opinion evidence in criminal prosecutions should apply in other settings, such as civil justice, intellectual property, regulatory contexts, or even criminal investigations. Rather, models of science, technology, and expertise should be developed with sensitivity to goals, institutional values, and the risks associated with specific domains.

Identity Theft

Lynne Vieraitis[1], Heith Copes[2] and Ivan Birch[1]

[2]University of Alabama at Birmingham, Birmingham, AL, USA

Overview

Each year millions of people worldwide have their identities stolen or misused. As a result of these illegal actions, businesses and consumers lose an estimated $16 billion to $50 billion per year. Information available from public and private agencies that collect data on identity theft suggests that the crime is becoming more common and more costly. Indeed, many have referred to identity theft as the "fastest-growing crime in America." Not surprisingly, citizens worldwide have become concerned about falling victim to identity theft and fraud. These fears have led to a watershed of protective legislation and have stimulated private investors to develop monitoring and preventative products for identity protection. Consumers spend billions of dollars a year on credit monitoring, fraud alerts, and information monitoring to protect their personal information from theft and fraud. In fact, credit monitoring services alone are approaching a billion dollars a year in sales (Lieber 2009) with Experian leading the market with nine million consumers paying $650–700 million annually. In addition, sales of personal paper shredders, the fastest-growing segment of the total office products market, have grown by double-digit revenues for the past few years (Fetterman 2009).

Likely due to the increased prevalence of the crime, identity theft has garnered the attention of the media whose coverage of cases has risen dramatically since 2000. Media regularly report on the latest scams used by identity thieves to steal personal information, the dangers of conducting routine transactions involving personal data, and the newest products and services designed to protect consumers from becoming victims of identity theft. Although much of this attention is directed toward educating consumers and marketing products, the media regularly present identity theft as an ever-increasing, ever-threatening problem. Despite rising media attention on identity theft over the past several years, academic research on the crime is limited. This entry provides an overview of what is known about identity theft. Specifically, it discusses the nature of identity theft, characteristics of offenders and victims, techniques of enacting the crime, and what can be done about this seemingly "unstoppable problem."

Definition of Identity Theft

The *Identity Theft Assumption and Deterrence Act* (ITADA), passed in 1998, states that identity theft occurs when a person "knowingly transfers, possesses or uses, without lawful authority, a means of identification of another person with the intent to commit, or to aid or abet, or in connection with, any unlawful activity that constitutes a violation of Federal law, or that constitutes a felony under any applicable State or local law." The term "means of identification" is defined as "any name or number that may be used, alone or in conjunction with any other information, to identify a specific individual." Yet, despite the federal statute, "there is no one universally accepted definition of [it] as the term describes a variety of illegal acts involving theft or misuse of personal information" (Bureau of Justice Statistics [BJS] 2006: 2). In fact, the term "identity theft" has been used to describe activities associated with a variety of offenses including checking account fraud, counterfeiting, forgery, auto theft using false documentation, trafficking in human beings, and terrorism.

One issue that has impeded development of a universally accepted definition of identity theft centers on the concept of "personal information." For example, if an offender steals a credit card, makes a purchase, and then discards the card, has the victim's identity been stolen? Does the use of a financial account identifier constitute identity theft? Or does identity theft only occur when an offender uses personally identifying data? An offender can use a credit card number (financial account identifier) to make unauthorized purchases or use a social security number (personally identifying data) to open a new credit card account and make purchases. Furthermore, some argue that since the crime of identity theft involves two separate components, theft and fraud, they should be labeled accordingly. In this case, "identity theft" occurs when an offender steals a victim's personal identifying information, such as a social security number, birth certificate, or driver's license. Whereas "identity fraud" occurs when an offender uses the stolen information to open credit card accounts, bank loans, or to deposit counterfeit checks and make withdrawals from the victim's bank account (Koops and Leenes 2006). Although identity fraud cannot occur without identity theft, identity theft is not always followed by identity fraud, and the two components may be committed by separate offenders.

Patterns of Identity Theft

Inconsistent definitions of identity theft across agencies and organizations tasked with collecting data make gauging the extent and patterning of the crime difficult. Contributing to the problem of data collection is the sheer number of federal agencies that play a role in identifying and investigating it. The manner in which an identity thief obtains and/or uses an individual's identity usually determines which federal agency has jurisdiction in the case. Within the United States, the list of agencies with potential jurisdiction in identity theft cases includes the US Postal Inspection Service of the US Postal Service, the Social Security Administration Office of the Inspector General, US Securities and Exchange Commission, US Secret Service, the Federal Bureau of Investigation, the U.S. Department of State, the US Department of Education Office of Inspector General, and the Internal Revenue Service.

Measuring the extent of identity theft is further complicated by the problem of underreporting. It is estimated that 40 % of all crime victims do not report their victimization to law enforcement, but the rate of reporting varies by type of victimization with more serious crimes showing a greater level of reporting than less serious crimes. For a variety of reasons, some "unknown" number of identity theft victims do not report their crimes to law enforcement authorities. The 2008 Consumer Sentinel Report indicated that only 35 % of victims who reported identity theft to the Federal Trade Commission (FTC) also reported to their local law enforcement agencies (FTC 2009). According to the National Crime Victimization Survey (NCVS), only 17 % of all victims of identity theft reported their victimization to law enforcement. Of those who did not report the theft to law enforcement, almost half reported it to a credit card company or bank (BJS 2010). Identity theft victims may see no reason to report their victimization if they do not suffer much financial harm, as when a credit card company quickly dismisses the unauthorized charges made on the victim's credit card. Other victims may be reluctant to report their victimization if they know the offender for fear of retaliation or getting the offender in trouble with law enforcement, especially if the offender is a family member of the victim. With these limitations in mind, the most reliable data on identity theft in the United States come from the FTC and more recently the NCVS.

Extent of Identity Theft

In their report, the FTC estimated that approximately eight million people were identity theft victims in 2005 and total losses were nearly $16 billion (Synovate 2007). The number of victims estimated by the 2008 Identity Theft Supplement to the NCVS suggests 11.7 million people, or 5 % of persons age 16 or older in the United States, were victims of at least one type of identity theft in a 2-year period (2006–2008), with losses around $17.3 billion (BJS 2010). However, recent findings from the NCVS suggest identity theft has increased since the agency first collected data from 5.5 % of households in 2005 to 7 % of households in 2010 (BJS 2011). The change appears to be due to the increase in the misuse or attempted misuse of existing credit card accounts. The differences in the number of victims reported by the FTC and NCVS may be attributed to several methodological factors and do not necessarily represent an increase in victimization.

It is also difficult to ascertain the financial costs of identity theft since estimates vary across the available data, but all sources show that it is an extremely costly crime. According to estimates from the FTC, in 2006, the average amount obtained by the offender was $1,882, and the average victim loss (i.e., out-of-pocket expenses) was $371 (Synovate 2007). According to data from the NCVS survey, the estimated loss for all types of identity theft reported by victims who had lost at least 1 dollar averaged $2,400 with a median loss of $430 (BJS 2010).

The financial costs to victims vary depending on the type of identity theft. Victims who experienced misuse of personal information reported an average loss of $2,829, while theft of existing credit card accounts resulted in the lowest average losses ($1,105). Victims of new account fraud suffered the greatest financial loss with an average direct financial loss of $8,110 (BJS 2010). These figures represent losses that may or may not have been covered by a financial institution, such as a credit card company. In most cases, the victims are protected by a variety of federal and state laws that limit consumers' liability in these situations. For example, the *Truth in Lending Act* limits consumer liability for unauthorized credit card charges to a maximum of $50 and the *Electronic Fund Transfer Act* provides limits on consumers' liability for unauthorized electronic fund transfers (provided the consumer notifies the applicable financial institution within a specified time period). State laws typically but not always protect consumers from losses associated with checking account fraud and loan fraud. However, victims may incur expenses from time spent resolving problems created by the theft, including closing existing accounts and opening new ones, disputing charges with merchants, and monitoring their credit reports. Surveys suggest that the time victims spend resolving issues associated with identity theft has declined over recent years as the banking and credit card industries as well as federal laws have made it easier for victims to recoup their losses. Results from the NCVS show that about 42 % of victims spend 1 day or less resolving financial and credit problems associated with their victimization (BJS 2010).

Regardless of the time spent resolving problems created by the identity theft, victims may still experience a great deal of emotional distress, including feelings of anger, helplessness, and mistrust; disturbed sleeping patterns; and feelings of a lack of security (Davis and Stevenson 2004). In addition, some victims report work, school, and relationship problems as a result of their victimization (BJS 2011).

Getting a clear assessment of the actual costs incurred by other victims of identity theft such as banks, businesses, and companies is also difficult. In most cases, the victim whose information is misused is not legally responsible for the costs of the fraudulent transaction by identity thieves since typically it is the credit card company or merchants who lose money. Recent reports indicate that the costs to victims has been declining in the past few years perhaps due to greater awareness of identity theft, legislation directed toward making it easier for victims to regain their financial identity, and/or protection services for potential victims. Given that most banks and credit card issuers provide zero-liability fraud protection to customers, victims are usually not liable for the fraudulent charges. Since identity theft reports indicate the majority of identity theft is credit card fraud, the "costs" of identity theft have been shifted from the individual to the credit card companies and banks. But the extent of these costs is unknown as companies and banks may be reluctant to disclose financial losses due to identity theft and fraud. Despite the differences in the number of victims and estimated dollar loss to victims and companies, the data suggest that identity theft is a serious problem affecting a large number of people.

Although this entry focuses on identity theft in the United States, it is a crime that is a problem worldwide. International sources of data on the crime suggest that prevalence of the crime varies considerably by country. A multinational telephone survey conducted by Unisys (2005) found that victimization rates varied across countries participating in the survey, with the lowest victimization rates reported by Germany (3 %). The highest victimization rates were reported by respondents in the United States (17 %) and the United Kingdom (11 %). France and Mexico reported victimization rates of 8 %, while Australia's rate was 7 %.

More recent estimates from an online survey conducted by a private company in Australia in 2011 show that nearly one in six (or 16 %) of

Australians have been a victim or know somebody who has been a victim of identity theft or misuse (DiMarzio Research 2011). Findings from a survey conducted in 2007 by the Australian Bureau of Statistics indicated that nearly half a million Australians or 3 % of persons aged 15 years or more were victimized by some form of identity fraud in the preceding 12 months. In the same year, the Office of the Privacy Commissioner undertook a national survey, which found 9 % of respondents, aged 18 or older, were victims of identity theft. A 2004 survey by a UK consumer magazine indicated one in four British adults had been victimized by identity theft or knew someone who had been victimized.

Research from government agencies also provides limited data on the costs of identity theft. The Home Office estimates there are over 100,000 victims of identity fraud in the UK at a cost of £1.2 billion per year. A report from the Dutch Parliament in 2002 claimed identity theft resulted in over 5 billion euros a year in financial damage, but prevalence rates were not reported. Estimates from Australia suggest that identity theft costs its citizens $1.1 billion in 2005 (Rollings 2008). In Canada, estimates from victim reports suggest that it costs them $16 million (Canadian) in 2006.

Identity Theft Offenders

It is difficult to paint a portrait of the "typical" identity thief based on the lack of reliable data. To date, few have sought to collect data directly from offenders (for exceptions, see Copes and Vieraitis 2012; Duffin et al. 2006; Gill 2007). Thus, what little is known about offenders comes from police reports and closed case files of various law enforcement agencies. The fact that clearance rates for identity theft are low means caution should be taken when interpreting the findings, and available evidence suggests that offenders are seldom detected and rarely apprehended. Using data from a large metropolitan police department in Florida, Allison et al. (2005) reported an average clearance rate of 11 % over a 3-year period. Similarly, law enforcement officials interviewed by Owens (2004) and Gayer (2003) estimated that only 10 % and 11 %, respectively, of identity theft cases received by their departments were solved. Several obstacles make the investigation of identity theft cases and the likelihood of arrests difficult. Specifically, identity theft cases can be highly complex, and the offender may have committed the theft in a different jurisdiction than where the victim resides, making it difficult to secure an arrest warrant. In addition, limited departmental resources may be directed toward the investigation of violent and drug-related offenses rather than identity thefts.

The results of the analyses conducted by Allison et al. (2005), Gordon et al. (2007), and Copes and Vieraitis (2012) demonstrate relative consistency among the demographic characteristics of identity thieves, with the exception of gender. Gordon et al. (2007) examined closed US Secret Service cases with an identity theft component from 2000 to 2006. They found that most offenders (42.5 %) were between the ages of 25 and 34 when the case was opened and another one-third fell within the 35–49 age group. In their study of data from a local law enforcement agency in Florida, Allison et al. (2005) found that offenders ranged in age from 28 to 49 with a mean age of 32.

Both law enforcement-based studies found similar patterns about race. Gordon et al. found that the majority of the offenders were black (54 %), with whites and Hispanics accounting for 38 % and 5 % of offenders, respectively. Allison et al. found that the distribution of offenders was 69 % black, 27 % white, and less than 1 % were Hispanic or Asian. The two studies differed in terms of the gender of offenders. Gordon et al. found that nearly two-thirds of the offenders were male, whereas Allison et al. found that 63 % of offenders were female.

Copes and Vieraitis' (2012) sample of 59 identity thieves included 23 men and 36 women which is consistent with the findings of Allison et al.; however, this may be attributed to Copes and Vieraitis' sampling strategy and the higher response rate from female participants. The racial makeup of their sample was 44 % white, 53 % black, and 3 % other. The makeup for the full list of located inmates from which the sample was drawn was 50 % white, 46 % black, and 4 % other. This is a higher percentage of white offenders than found by either Gordon et al. or Allison et al. Offenders in the sample ranged in age from 23 to 60 years with a mean age of 38 years. The majority of offenders were aged 25–34 (34 %) or 35–44 (32 %). Only 7 % were aged 18–24 years and 5 % were older than 55 years. The age distribution matches closely with the larger sampling pool and that found by Gordon et al. and Allison et al.

Both Copes and Vieraitis (2012) and Allison et al. (2005) included information on the offenders' employment status. Most of the offenders in Copes and Vieraitis' study had been employed at some point during their lifetimes. The diversity of jobs included day laborers, store clerks, nurses, and attorneys. At the time of their crimes, 52.5 % were employed, and a total of 35.5 % of the sample reported that their employment facilitated the identity thefts. The majority of those who used their jobs to carry out their crimes committed mortgage fraud. The results from Allison et al. indicated that 47 % were employed.

Little is known about the degree to which identity thieves specialize in their offenses. Prior arrest patterns indicated that a large portion of the offenders interviewed by Copes and Vieraitis (2012) had engaged in various types of offenses, including drug, property, and violent crimes. Yet, the majority of them claimed that they only committed identity thefts or comparable frauds (e.g., check fraud). In total, 63 % of the offenders reported prior arrests, and most were arrested for financial fraud or identity theft (44 %), but drug use/sales (19 %) and property crimes (22 %) were also relatively common. This finding is consistent with that of Gordon et al. (2007), who found that while the majority of defendants had no prior arrests, those who did have criminal histories tended to commit fraud and theft-related offenses.

Copes and Vieraitis' (2012) interviews with identity thieves yielded information that helps provide a richer and more detailed profile of the persons who commit this crime. Through interviews with offenders, they show that identity thieves are a heterogeneous group. Their family backgrounds, educational attainments, work histories, and criminal histories run the gamut from poverty to wealth, less than a high school education to graduate degrees, and from no prior arrests to incarcerations for everything from fraud to drugs. Some are embedded in "street life" and resemble the profile of a typical street offender, while others live lives similar to those of the conventional middle-class citizen and share characteristics in common with middle-class fraudsters or white-collar offenders. Copes and Vieraitis' data suggest that it is difficult to create a "profile" of identity thieves because the crime may be more "democratic" than most other types of crimes. That is, there is not a "typical" profile that emerges from the data because identity theft is committed by a diverse group of people from all walks of life. Despite their diversity, however, they are similar in their motivations for why they choose to commit identity theft.

Motivations

The primary motivation for identity theft is the desire for money (Copes and Vieraitis 2012). Offenders estimate that they can earn several thousands of dollars in as little as 1 hour. The amount of profit gained from identity theft varies depending on the type of personal information stolen, the method an offender uses to convert a victim's information into cash and/or goods, and the financial status of the victim. Although official statistics estimating the dollar losses of identity theft to be in the billions each year support the notion that money is a primary motivation for identity thieves, data from interviews with offenders provide more understanding about the underlying motivational factors. While it is not surprising that money is the most commonly given reason for engaging in identity theft, what offenders do with the money may not be as obvious. As previously mentioned, identity thieves are a very diverse group, and the ways in which they steal information, convert it into cash and goods, and how they spend their profits demonstrate their various lifestyles. Many live self-indulgent lifestyles that are characterized by the mentality of "desperate partying" found among persistent street thieves. For these offenders, proceeds gained through illicit activities are seldom saved for long-term plans or to pay bills. Instead, identity theft is a way of getting money to buy drugs, to party, and spend frivolously. For other offenders, their lifestyles reflect their position among the middle class. Many hailed from middle-class backgrounds and sought to support and sustain lifestyles of the affluent. They use the proceeds of identity theft to finance comfortable middle-class lives, including paying rent or mortgages, buying expensive vehicles, and splurging on the latest technological gadgets. Many face increasing debt, looming financial problems, and/or fear of losing streams of income, which led them to identity theft as a way to solve their immediate financial crises.

Victims

Virtually anyone can become a victim of identity theft, including newborns and the deceased. Establishing a pattern of those most likely to be victimized, however, is difficult with existing data. First, the pattern of victims that emerges from victimization data is affected by the operational definition of identity theft employed in the survey. For example, including existing credit card fraud as a type of identity theft increases not only the victimization rate and the costs of identity theft, but it also changes the face of victims. Specifically, women and racial minorities are at a higher risk of victimization (relative to percent of population) for existing account fraud and new credit card fraud than existing credit card fraud (Copes et al. 2010). Second, victimization patterns are also difficult to establish if cases in which the victim and offender know each other are underreported. That is, official statistics on identity theft may suffer from the same problem as other forms of crime (e.g., forcible rape) in that incidents in which the offender is a stranger to the victim are more likely reported and thus overrepresented in victimization statistics.

The results of several studies indicate that a similar percentage of men and women are victims of identity theft each year (Allison et al. 2005; Anderson 2006; BJS 2010; Kresse et al. 2007). The lowest rate of victimization is among persons age 65 or older, while the majority of victims are in the mid-twenties to mid-50s in age. Recent data from the NCVS, however, show a younger demographic – households headed by persons ages 16–24 have the greatest risk of victimization although the difference in percentages with those ages 25–34 was minimal (BJS 2011). In addition, most data suggest that those with incomes greater than $75,000 are at higher risk than households in lower income brackets. Data from the NCVS on race/ethnicity and identity theft victimization show that households headed by whites, Hispanics, and Asians experienced increased victimization from 2005 to 2010. Those reporting "two or more races," Asians, and whites had the highest rates of victimization among race and ethnic groups (BJS 2011).

Although several studies suggest that child identity theft is relatively rare, this form of identity theft in particular may be underreported. Child identity theft occurs when an offender uses the identifying information of a person under the age of 18 for personal gain. Data from the Consumer Sentinel Network indicate that 7 % of all cases reported to the FTC involved victims who were 19 years old or younger (FTC 2009), though the study by Kresse et al. (2007) reported only half of that (3.5 %) for persons under the age of 20. The perpetrator of child identity theft is typically a family member who has easy access to personal information. According to Pontell et al. (2008), over three-quarters of those who stole the identities of victims under the age of 18 were the parents. Similarly, the Identity Theft Resource Center (ITRC) survey data indicated that in child identity theft cases, 69 % of the offenders were one or both parents or stepparent, and 54 % of these cases began when the victim was younger than the age of 5 (ITRC 2007). However, strangers also target children because of their "clean" credit histories as well as the lengthy amount of time between the theft of the information and the discovery of the offense. Evidence suggests the cost to the child whose identity is obtained illegally does not take place until the child applies for a driver's license, enrolls in college, or applies for a loan and/or credit. This also makes it difficult to detect and report.

Lastly, deceased persons are not immune to identity theft. Law enforcement officials have historically thought deceased victims were the targets of choice for identity thieves, as information stolen from the deceased are often used to defraud businesses or to hide from law enforcement with relative ease. Identity thieves obtain information about deceased individuals in various ways, including watching obituaries, stealing death certificates, and even getting information from websites.

Victim-Offender Relationship

Research on the relationship between the victim and offender has produced mixed results regarding whether the offenders knew victims before stealing their information. To date, the available data suggest that the majority of victims do not know their offenders. The FTC reported that 84 % of victims were either unaware of the identity of the thief or did not personally know the thief (Synovate 2007). Similarly, Javelin Research and Strategy Group (2005) found that only 14 % of all identity theft crimes were committed by someone known to the victim. When the offender is known, he or she is typically a family member, relative, friend, acquaintance, co-worker, or customer/client. Three other studies also reported that the majority (60 %) of victim-offender relationships involved individuals who did not know each other (Allison et al. 2005; Gordon et al. 2007; ITRC 2007). Although this figure is lower than the figures provided by the FTC and Javelin, overall the data suggest the majority of victims do not know the thief who stole their identity.

Techniques of Identity Theft

To be successful at identity theft requires that the would-be offenders secure identifying information and convert it into goods or cash. Identity thieves have developed a number of techniques and strategies to do just this. Researchers and law enforcement agencies have collected information, primarily from victimization surveys and interviews with offenders, on the techniques identity thieves commonly employ. Although media reports suggest that hackers and other cyber criminals are responsible for the lion's share of identity theft, most official reports suggest that this is not the case. For instance, a survey by the Javelin Strategy & Research suggests that only 10 % of identity theft occurred online (Javelin 2006). This finding is also supported by Gordon et al. (2007) and Copes and Vieraitis (2012).

Acquiring Identifying Information

The first step in the successful commission of identity theft is to obtain personal information on the victim, a relatively easy thing for offenders to do. Offenders obtain this information from wallets, purses, homes, cars, offices, and business or institutions that maintain customer, employee, patient, or student records. Social security numbers provide instant access to a person's personal information and are widely used for identification and account numbers by insurance companies, universities, cable television companies, military identification, and banks. The thief may steal a wallet or purse, work at a job that affords him/her access to credit records, purchase the information from someone who does (e.g., employees who have access to credit reporting databases commonly available in auto dealerships, realtor's offices, banks, and other businesses that approve loans), or find victims by stealing mail, sorting through the trash, or by searching the Internet. Some offenders create elaborate schemes to dupe victims into revealing their personal information both on- and off-line.

The FTC (2009) data have also shed light on strategies of offending from the victim perspective. Based on data from the 43 % who knew how their information was stolen, the report suggests that offenders obtain information from people they knew personally (16 %), during a financial transaction (7 %), from a stolen wallet or purse (5 %), from a company that maintained their information (5 %), or through stolen mail (2 %). Of the 4.5 million victims responding to the

NCVS, nearly 30 % believed their identity was stolen during a purchase or other transaction, 20 % believed the information was lost or stolen from a wallet or checkbook, and 14 % thought the information was stolen from personnel or other files at an office (BJS 2010).

Other techniques have been identified such as organized rings in which a person is planted as an employee in a mortgage lender's office, doctor's office, or human resources department to more easily access information. Similarly, these groups will simply bribe insiders such as employees of banks, car dealerships, government, and hospitals to get the identifying information. Offenders have reported buying information from other offenders such as prostitutes, burglars, drug addicts, and other street hustlers. Others have obtained credit card numbers simply by shoulder surfing, which involves peering over someone's shoulders while they type in a credit card number.

Another method of obtaining personal identifying information is through the use of computer technology. This involves hacking into businesses that maintain information legitimately or through the use of phishing, which involves spam email campaigns that solicit information from would-be victims. Underground websites and forums operate that sell stolen information for relatively cheap prices (Holt and Lampke 2010).

Converting Information

Offenders can use information to acquire or produce additional identity-related documents, such as driver's licenses or state identification cards, in an attempt to gain cash or other goods. Offenders apply for credit cards in the victims' names (including major credit cards and department store credit cards), open new bank accounts and deposit counterfeit checks, withdraw money from existing bank accounts, apply for loans, open utility or phone accounts, and apply for public assistance programs.

According to the FTC, the most common type of identity theft in 2006 was credit card fraud (25 %) followed by "other" identity theft (24 %), phone or utilities fraud (16 %), bank fraud (16 %), employment-related fraud (14 %), government documents or benefits fraud (10 %), and loan fraud (5 %) (Synovate 2007). Although not directly comparable due to differences in methodology, units of analysis, and definition of identity theft, data from the NCVS indicate the most common type was unauthorized use or attempted use of existing credit card accounts, which accounted for more than half (64 %) of victimized households, followed by unauthorized use or misuse of existing accounts other than credit card accounts such as banking, savings, or PayPal (35 % of households) (BJS 2011). Data from the National Public Survey on White Collar Crime show that existing credit card fraud is more common than existing account fraud and new credit card fraud (Copes et al. 2010).

The most common strategy for converting stolen identities into cash is by applying for credit cards. Most offenders use the information to order new credit cards, but they also use the information to get the credit card agency to issue a duplicate card on an existing account. They use credit cards to buy merchandise for their own personal use, to resell the merchandise to friends and/or acquaintances, or to return the merchandise for cash. Offenders also use the checks that are routinely sent to credit card holders to deposit in the victim's account and then withdraw cash or open new accounts. Offenders have been known to apply for store credit cards such as department stores and home improvement stores. Other common strategies for converting information into cash and/or goods include producing counterfeit checks, which offenders cash at grocery stores, use to purchase merchandise and pay bills, open new bank accounts to deposit checks or to withdraw money from an existing account, and apply for and receive loans (Copes and Vieraitis 2012).

Conclusions and Future Research

It is clear that identity theft affects a sizable portion of the population, is costly in both time and money, and is difficult to detect and prosecute. It is even difficult to define. To understand the crime of identity theft and thus increase the likelihood that policy makers and law enforcement are effective in reducing this crime, more research is needed. The first step is to address the problem of data collection. Currently, information on identity theft is collected and housed in multiple databases including both private and government agencies. Information on one incident may be reported to local, state, and federal law enforcement agencies; credit reporting agencies; credit card companies; financial institutions; telecommunication companies; and others. This makes the collection and sharing of information among agencies difficult. It also creates significant barriers to developing reliable estimates of the extent of identity theft, patterns in victimization and offending, and the true costs associated with this crime. There is also little data on the processing of identity thieves including clearance rates, conviction rates, and sentencing.

Second, a number of laws have been passed to provide help to consumers and victims of identity theft and to assist law enforcement. However, the effectiveness of these laws has not yet been assessed. Although much of this legislation is relatively new, future research should evaluate the degree to which legislation is an effective strategy in reducing identity theft. Information is also needed on citizens' awareness of identity theft including their awareness of the laws designed to assist them in protecting their information as well as those designed to assist those who have been victimized. Recent research from Unisys (2005) suggests that people's concern with, awareness of, and willingness to take steps to secure their information vary widely across countries.

Third, there is very little research on identity thieves themselves. To date, only a few scholars have examined offenders directly (Copes and Vieraitis 2012; Duffin et al. 2006). Researchers should consider further developing this line of inquiry by expanding the sample of identity thieves to include active offenders and offenders convicted at federal, state, and local levels. These efforts would also be aided by the development of a centralized database for the collection of identity theft data.

Developments in technology and the globalization of commerce also make coordination of international efforts to stop identity theft increasingly important. Lawmakers in various countries have been relatively slow to respond to the emerging threat of identity theft. According to a survey completed by the Perpetuity Group, countries such as France, the United Kingdom, the Netherlands, and Germany had no specific laws directly addressing identity theft and identity fraud (Owen et al. 2006). The Netherlands, for example, had over 30 different laws encompassing identity theft or fraud. In the absence of an explicit law, prosecutors had to be creative to ensure convictions. The study also found that only the United Kingdom and France had dedicated units specializing in noncash payment fraud. Most countries, however, had multiple, uncoordinated divisions each of which was partially responsible for detecting identity theft and apprehending thieves. The Department of Justice (DOJ) and the Department of State have undertaken several measures to increase awareness of and provide assistance to law enforcement agencies in an effort to organize a global strategy against identity theft. These efforts include the expansion of a "24/7 network" which communicates with agencies from approximately 50 countries to provide electronic evidence in emergency cases and the training of lawyers and law enforcement agents in other countries.

Impacts of Community-Oriented Policing

Antoinette Verhage and Paul Ponsaers
Faculty of Law, Research Group SVA, Ghent University, Ghent, Belgium

Introduction: The Deficit of Traditional Policing

The academic evaluative literature on police during the 1970s and 1980s concluded in an impressive consensus concerning the deficit of traditional police models (Bayley 1994; 1998). Summarized, following critiques can be considered as the most important: (1) The mere increase of the number of police officers is not an effective strategy to tackle crime or disorderly behavior. The quantitative assumption cannot resolve the necessary qualitative change of "how to do good policing" (Greene 1998). (2) The police cannot prevent crime, and more generally, cannot function without the help of the population, which means that the population is much more than "the eyes and ears" of the police (Rosenbaum 1998). (3) The classic tactics of traditional police models are too reactive, while they do not affect the circumstances that cause crime and disorder. (4) Police policy is frequently too broad and is applied to different problems in one and the same way ("one size fits all" – Skogan 1998). Observers advocated the need of "tailor-made responses." The need for linking different forms of policing to specific risks is probably the most energetic conclusion of police research during these decades.

COP as a Police Strategy

The most important attempt to the transformation and reform of policing during last decades was without any doubt the introduction of "Community (Oriented) Policing" (COP). The combination of focus on COP studies and the absence of ethnographers during the 1990s had as a consequence that the most influential books were studies on COP (Skogan and Harnett 1996), while this focus continued in the early years of this century (Skogan 2006). Without any doubt, this had a powerful and lasting effect on the image and the rhetorical capacity of the police (Manning and Yursza Warfield 2009).

Despite this evolution, Eck and Rosenbaum observe: *"There is no simple or commonly shared definition of community policing, either in theory or in practice"* (Eck and Rosenbaum 1994). Writing this, both authors suggest that COP over time became a container-notion. Bayley, who did a lot of research in different countries where COP was implemented, confirms this: "*Despite the benefits claimed for community policing, programmatic implementation of it has been very uneven. Although widely, almost universally, said to be important, it means different things to different people (. . .) Community policing on the ground often seems less a program than a set of aspirations wrapped in a slogan*" (Bayley 1988).

M. Moore states in this context (Moore 1994): *"Community policing is not a clear-cut concept, for it involves reforming decision-making processes and creating new cultures within police departments rather than being a specific tactical plan (. . .).*" He further states: *"Under the rubric of COP, American departments are opening small neighborhood substations, conducting surveys to identify local problems, organizing meetings and crime prevention seminars, publishing newsletters, helping form neighborhood watch groups, establishing advisory panels to inform police commanders, organizing youth activities, conducting drug education projects and media campaigns, patrolling on horses and bicycles, and working with municipal agencies to enforce health and safety regulations."*

Bennett arguments nevertheless that there appears to be some convergence of opinion in the recent literature that community policing is fundamentally a philosophy of policing or a policing paradigm, stating that *"It is generally agreed that these organizational structures and operational strategies do not in themselves represent community policing as they could exist* *equally well within the context of a different policing philosophy or policing paradigm. However, when they are implemented within a community policing paradigm they become community policing structures and strategies*" (Bennett 1994, see also Bennett 1990, 1998). Probably this conceptual blurring is to a large extent the consequence of the fact that COP is more a *prescriptive* model (on how police "ought to be") than a theory-based empirical statement (on how police "is").

Effects of Community-Oriented Policing

After more than twenty years now of promotion of this so-called police model (Ponsaers 2001) by governments, foundations, and leading universities, it is still not clear what effect this has had on police practice (Brodeur 1998b). The results of evaluative research seem to be unimpressive and in some cases nonexistent or immeasurable (Greene 2000; Fielding 1995). COP is stated to have little or no effect on police practice (Greene and Mastrofski 1988; Weisburd and Braga 2006), while, e.g., aging and years of service do (Mastrofski and Snipes 1995).

Impact on Public Opinion

Because COP tends to increase the contact between the police and the population, with a minimal use of compulsory measures, it is possible to improve the public satisfaction. But this coping strategy has only limited value, because those who are forced to stay in contact with the police (especially victims and offenders) seem to be precisely those who are mostly dissatisfied about the functioning of the police. This means that COP programs have a stronger impact on the improvement of the image than on the effectiveness of the police. This was also demonstrated in research; the most important effect of the implementation of COP was to be found in the improvement of the attitude of the population toward the quality of the service rendered by the police to the public (Brodeur 1998b). Moreover, it became clear that the improvement of the image of the police resulted in an intrinsic goal and was often misused to gain more (financial and personnel) facilities (Sacco 1998).

Impact on Crime

The most striking results were achieved in programs directed to intensive problem-solving strategies focused on so-called hot spots (Bayley 1994; Braga et al. 1999; Leigh et al. 1996). The realization of results nevertheless seemed almost impossible, while the police is confronted with problems they never can resolve (Brodeur 1998b).

The frequently used programs of "neighborhood watch" resulted in limited effects on crime. In the best case, the feelings of security and the communication between the public and the police are improving. As a result of that, the image of the police is reinforced and the job satisfaction of police officers is raised. But evaluative research demonstrated also that the majority of these initiatives were implemented in a defective way. Also it became clear that the involvement of citizens in these initiatives, also in England, was weak (Bennett 1998).

The difficulties to realize a more intensive collaboration seem to be more serious than most advocates expected. The empowerment of the public by means of a professional marketing strategy is certainly an interesting tool for the improvement of a more functional partnership between the police and the population. But the problems in mobilizing local inhabitants are often more structural of nature. In more deprived neighborhoods, the lack of collaboration by the public is often a result of feelings of despair and powerlessness, the fear for street gangs, and a deep embedded mistrust and conflict with the police (Rosenbaum 1998).

On the long run, COP would lead to a more or less important decrease of the number of emergency calls by the public (Brodeur 1998a). COP programs can have a regressive (instead of progressive) effect, while they are often directed toward the wrong target groups. Those groups within the population that are already organized succeed in using the police to their advantage, because the police feels themselves comfortable in this part of society. In spite of that, research evoked that COP, by means of locally initiated consultations, structures the active participation of the population in problem identification and prioritizing. It gives a channel for external accountability on police performance. Often it became clear that the initiatives were directed toward the wrong territoria and the target groups with the smallest needs (Skogan 1998).

Impact on Incivilities and Fear of Crime

Some authors come to the conclusion that COP can have some effect on the perception of crime by the population and on the appreciation of the quality of police care. Moreover, the feelings of insecurity seem to decrease, because of the increased visibility of the police in public space and the intensification of the interaction between the population and the police lead frequently to a better appreciation of the police service. COP seems to have an impact, when neighborhood problems are tackled and on the fear of crime. In any case, the results of COP are not worse than traditional policing in the control of crime, but the results in tackling incivilities and feelings of insecurity in the communities are better (Greene 1998).

Bayley, who did a lot of international comparative research on policing, concludes: "*We don't know if community policing works. Most of the time, a small effect can be detected, but sometimes also contradictory results. The best results can be observed in focused activities of problem oriented policing. It is not proven that citizens can act against insecurity in an effective way. Initiatives as "neighbourhood watch" don't have an effect on crime. Most of the time these initiatives work the best there were they are least needed and least where they are necessary. Nevertheless, most authors conclude that it is not the model that is failing, but in first instance the deficient implementation of it*" (Bayley 1994).

A Number of Positive Results

Pessimism should be avoided in this respect. Wycoff en Skogan (1994) state in this context that it *is* possible to bend granite. They report on the results of an evaluation of a successful internal reorganization of a police force, which has had a positive impact on the service of the police within a COP approach. One of the critical factors for successful intensive reform, they warn, is the creation of an instance outside and above the police, holding the police chief and his organization accountable for the realization of the new goals to achieve (Moore 1992).

Also Aronowitz (1997) points at positive consequences. He arguments that the approach has effects for the community: citizens are more involved in the identification of problems in the neighborhood and the relation with the police improves. Moreover, he stresses that the approach also increases the level of self-help of the citizens. They take a more active role in the maintenance of security and the quality of life in their own neighborhood. Another effect has a relation with the maintenance of legal order: not only are citizens more inclined to report to the police, but also the feelings of security improve.

One of the most prominent evaluative sources is the study *Preventing crime: What works, What doesn't, What's promising*. Sherman et al. conducted a systematic review, among others on COP (Sherman et al. 1997). The group of scholars introduce hypotheses on four levels concerning COP: (1) Neighborhood Watch programs are considered to be effective, while they encourage the level of surveillance by inhabitants of neighborhoods, which leads to the consequence that they have a deterrence effect on criminals. (2) The stream of information stemming from the communities is stimulated toward the police concerning suspects, offenders, and suspect circumstances, which leads to an increased probability to arrest offenders. This information exchange improves the problem-solving ability of the police. (3) The improvement of information from the police to the public empowers the population to protect oneself, certainly when it concerns recent trends in crime patterns and risks. (4) The credibility and legitimacy of the police is sustained and the population has more confidence in the police, which leads to more compliance to the law by the population.

Sherman et al. conclude that the results of tests concerning these hypotheses are ambiguous. Proof for the assumption that crime prevention is sustained by the increase of information from the population toward the police is not available. The second and third hypotheses are not supported by evidence either. The most important conclusion is nevertheless that there seems to be enough evidence for the fourth hypothesis concerning the legitimacy. There seems to be enough research and evaluation that sustains the presence of a strong correlation between COP on the one hand and the legitimacy of the police and law-abiding behavior by the population on the other hand (Sherman et al. 1997).

More recently, Sunshine and Tyler have concluded from their research on policing that the evaluation of police *legitimacy* is based on the perception of the way in which people are treated (Sunshine and Tyler 2003). Personal contacts between police and community are crucial – not the perception of the public with regard to how well the police handles crime.

In a study in Latin-American countries, Dammert and Malone (2006) indicate that the inclusion of the public in policing reduces public fear of crime. Although the authors are very careful in drawing this conclusion, they claim that this conclusion is very important in these "tough-on-crime-countries."

In this respect, procedural justice also influences the extent to which the public is *willing* to engage in crime prevention. The results of a study by Reisig (2007) show that citizens who judge police practices as fair and respectful are more open for participation in (property) crime prevention. This implies that it is not simply the assessment of effectiveness that influences willingness of the public to participate, but merely the way in which police practices are perceived. This conclusion could be made regardless of the level of property crime in the community. In this respect, the use of community policing as a police model can be seen as a crucial element in tackling crime. This finding was supported by empirical research in Australia, in which it was found that – when the police apply procedural justice – they are more likely to be judged as legitimate (Murphy et al. 2008). At the same time, social survey data showed that foot patrols – a typical practical element in community policing – meet the public demand and support "*the symbolic function of policing as a sign of social order*" (Wakefield 2007). Earlier studies had already showed that foot patrols lead to higher levels of citizen's satisfaction with police services *and* lower crime rates (except for robbery and burglary) (Trojanowicz 1982). A few years later, however, Pate showed that foot patrols did influence people's *perceptions* of safety and disorder problems, but did not influence the levels of reported crime (Reisig 2011).

Reisig (2010) concludes in his study on the effects of community- and problem-oriented policing, that in general, the results are encouraging. There is (though modest) evidence for the effects of these types of policing on levels of crime and disorder, and also for the perception of citizens with regard to their neighborhood (Reisig 2011). He also concludes that one of the important merits of the introduction of both community policing and problem-oriented policing is that it has instigated empirical research into police strategies and police practices, although of course a number of questions still remain.

A final and very recent (2012) impressive systematic review by Gill et al. (in progress) gathered both published and unpublished studies that focused on the effectiveness of community-oriented policing. This review based their final conclusions on 45 trials, published in 25 reports. Their findings show that community-oriented policing was associated with a statistically significant, but very small reduction in officially recorded crime. But, although the effect on crime figures seems to remain limited, findings for other intended effects, such as legitimacy, citizen satisfaction, fear of crime, and citizens' perceptions of local disorder, were very promising. The results showed a large increase in legitimacy and satisfaction with police, and a (more moderate) increase of odds of perceived social disorder and a decline in the fear of crime. The researchers hypothesized that short-term improvements in legitimacy may lead to longer-term effects on crime control, but emphasized the need for long-term research.

New Types of Policing Take Over

Some scholars, e.g., Manning, argument that the current attempt to consolidate and integrate research progress in community policing, problem-solving policing, hot spots policing, and crime analysis and crime mapping has collapsed into efforts of apparently preventive but actually active, aggressive- and arrest-oriented policing (Manning and Yursza Warfield 2009). This reading is supported tacitly by research (Weisburd and Braga 2006) containing little or no comment on the negative, unanticipated, or destructive impacts such types of policing have on order, sense of justice, and "community."

In addition to this, academic literature has also changed its focus and is increasingly moving away from the topic; in their review of police literature in 2007, Mazeika et al. conclude that although police strategies have remained the largest category in police literature, "community policing is no longer the most prevalent literature within this category" – for the first time in 6 years (Mazeika et al. 2010). Outcome-based research declined with over 32 %. The primary focus of research within the category of police strategies (which is, by the way, declining since 2005) is now research on target groups (Mazeika et al. 2010). A positive conclusion of their review was, however, that publications on policing have increased substantially, although it was not clear what the effect of this increase was on the distribution of research.

These developments have unfolded in the last twenty years. While many claims have been made, the cumulative progress in research based on deep and critical understanding of policing is modest in part because the research focus is far too narrow. It should therefore be emphasized that more research is needed for a good understanding of effects of police strategies and tactics, taking into account social processes that might influence the effects (Reisig 2011). It does, after all, affect our society in a fundamental way.

Epidemiology of cardiovascular disease; Incarceration; Racial disparities

Overview

More than 13 million individuals have a history of incarceration in the USA. In spite of their young age, current and former inmates are at increased risk for developing and dying from cardiovascular disease. In some US studies, current and former inmates have higher rates of hypertension, smoking, diabetes, and end-stage heart disease, compared to the general population and are thus more likely to die from cardiovascular disease.

Why is this the case? There are a number of plausible reasons. Current and former inmates are more likely to be ethnic minorities and poor. Between 50 % and 80 % of US inmates have a history of substance abuse of cardiotoxic agents, like alcohol, cocaine, and amphetamines. Many individuals do not exercise or eat a healthy diet in prison or on the street. And most do not have a primary care provider in the community. The focus of this entry is to delineate (1) the epidemiology of cardiovascular risk factors and disease among individuals with a history of incarceration, (2) to discuss mechanisms for this increased risk, and (3) to describe potential interventions that reduce the risk of disease in this at-risk population. Improving cardiovascular health of individuals with a history of incarceration may lower disease burden in the USA and reduce racial disparities in cardiovascular disease morbidity and mortality.

Fundamentals of Correctional Health Care

Incarceration is Common and Costly

The prison population has tripled in the past 20 years, and the USA now incarcerates more people per capita than any other nation. Worldwide, imprisonment ranges from 30 people per 100,000/year in India, 119 in China, 148 in the United Kingdom, 628 in Russia, to 750 in the USA (Wamsley 2006). Currently, 2.3 million individuals are incarcerated with an additional 4.6 million on parole or probation, such that one out of every 31 Americans is under the supervision of the criminal justice system (The Pew Center on the States 2009). An additional five million Americans are estimated to have a history of incarceration but are no longer under the criminal justice system jurisdiction (Wilper et al. 2009). In 2008, corrections was the fastest expanding segment of state budgets, with expenditures totaling $44 billion annually. Medical care is one of the principal drivers of cost, totaling $9.9 billion per year (Spaulding et al. 2011). By conservative estimates incarcerating individuals with chronic medical conditions like cardiovascular risk factors and disease by conservative estimates costs two times more than the average inmate.

Definition of Prison and Jail

Having a history of incarceration can range from a brief stay in jail (facilities that typically house those who are awaiting adjudication or serving sentences of less than 1 year) to longer sentences in prison (which house those who have been sentenced to more than 1 year). The median length of stay in jail is less than 7 days and in prison, 2 years. Despite the range of exposure to the correctional system, there are shared experiences that uniquely define the incarcerated population's health. To start, prisons and jails are one of the only places in the USA where health care is guaranteed by law. In 1976, the Supreme Court ruled in *Estelle v. Gamble* that it was "cruel and unusual punishment" not to provide basic health care in correctional facilities. Following the ruling, prisons and jails were mandated to provide acute care services. But as the prison population demographics have changed, health care services have adapted to provide chronic medical care. Between 1995 and 2010, the number of state and federal prisoners aged 55 or older nearly quadrupled (increasing 282 %), while the number of all prisoners grew by less than half (increasing 42 %). There are now 124,400 prisoners aged 55 or older. Many correctional facilities provide individuals their first access as adults to preventive and chronic medical care. An estimated 40 % of inmates are diagnosed with a chronic disease while incarcerated, and 80 % report seeing a medical provider while incarcerated. The correctional health care setting likely influences how ever-incarcerated patients understand their chronic medical condition and how to manage their disease condition.

Quality of Correctional Health Care

The quality of chronic medical care in correctional health care settings is variable, given limited state budgets or profit motives in privatized prisons. Unlike most free world health systems, which undergo annual quality measurement and public reporting of results, the quality of care within prisons and jails is not subject to government oversight or standardization. Standards of correctional health care are evolving for chronic conditions like hypertension, diabetes, and cardiovascular disease. National organizations such as the National Commission on Correctional Health Care (NCCHC) have established guidelines for accrediting prisons and jails, but it is voluntary whether prisons and jails agree to participate. Further, while the NCCHC and organizations like the American Diabetes Association have established screening, diagnosis, and treatment recommendations in prisons and jails, these have not been standardized in jails or prisons. Some prison systems, including Texas, Missouri, and California, have adapted free world measures of quality and have implemented quality improvement projects in the state prison systems (Damberg et al. 2011). For instance, California adopted 79 measures for quality of care, seven of which focus on cardiovascular risk factors and disease. Data on the performance of these prison systems are not publically available. Acute care for chronic medical conditions is typically contracted to outside community hospitals. Only one study has evaluated the quality of care for patients hospitalized with chest pain and found that on average inmate patients with heart disease stay in the hospital longer and receive treatment sooner compared to noninmate patients, indicating that inmates do not receive worse quality hospital care compared to noninmates (Winter 2011).

Transitions Between Correctional and Community Health Systems

Discharge planning does not fall under the constitutional guarantee for health care and nor does health care post-release. Among 33 states surveyed in 2004, all prisons offered some form of discharge planning to a limited number of patients and in most cases only those with HIV disease (Flanagan 2004). Patients with diabetes, hypertension, or cardiovascular disease are often released without medications or a follow-up appointment in the community (Mallik-Kane and Visher 2008). Even when provided medications upon release, many do not obtain them. Recently released inmates are less likely to have a primary care physician and disproportionately use the emergency department for health care compared to the general population. In one study, 90 % of individuals released from jail were uninsured or lacked financial resources to pay for their medical care (Conklin et al. 2000). Inmates with health problems may have a harder time returning to the community, as they are additionally confronted with the task of managing their health problems, obtaining health care, and keeping up with medications or appointments, while meeting their basic needs. Many return to the community without financial resources, housing, employment, or family support. And many individuals convicted of drug felonies are released from prison and prohibited from accessing safety net services, including food stamps, public housing, or federal grants for education.

Epidemiology of Cardiovascular Risk Factors and Disease

Cardiovascular Disease Mortality

Cardiovascular disease is one of the top causes of death of inmates in the incarcerated population. According to the Bureau of Justice Statistics, during the period of 2001–2004, 12,129 state inmates deaths were reported and 27 % of these deaths were attributed to heart disease (Mumola 2007). However, in spite of being a leading cause of death, the risk for death from cardiovascular disease is not higher than what would be expected if they were living in the free world (Spaulding et al. 2011). In contrast, recently released inmates have an increased risk for mortality compared to the general population (Binswanger et al. 2007; Rosen et al. 2008; Spaulding et al. 2011). In a retrospective study of 30,000 individuals released from Washington state prison, recently released inmates had a greater risk of all cause and cardiovascular disease mortality than the general population in the year following release (adjusted HRs 2.1, 95 % CI 1.7–2.6) (Binswanger et al. 2007). Evidence to date suggests that white inmates have an increased risk of dying compared to the general population, whereas blacks do not. A retrospective study of individuals released from North Carolina prison between 1985 and 2000 found that white ex-prisoners had 30 % greater than expected rate of death from diabetes and cardiovascular disease compared to the general population, although no difference was detected among black former inmates (Rosen et al. 2008). A study from Georgia, in which two-thirds of the prison population was black, also found no increased risk of cardiovascular death upon release (Spaulding et al. 2011). Importantly, there have been no national or prospective studies looking at the association between incarceration and cardiovascular disease mortality.

Incarceration Is Associated with Increased Cardiovascular Disease Risk Factors

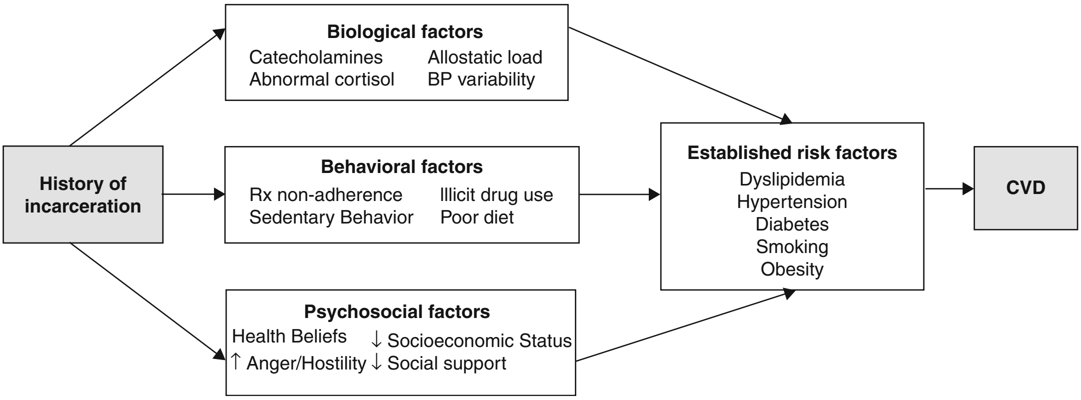
In US studies, current and former inmates have higher rates of hypertension (Wang et al. 2009), smoking (Cropsey et al. 2008), and left ventricular hypertrophy (Wang et al. 2009) than the general population. Analyses comparing diabetes in patients with and without a history of incarceration have yielded conflicting results (Leddy et al. 2009). Other studies have shown higher rates of cardiovascular disease risk factors among current and former inmates, but are based on extrapolations from noninstitutionalized Americans (2002), data from single institutions (Baillargeon et al. 2000), or limited to self-reported health outcomes, (Wilper et al. 2009) which may be subject to detection bias given that health care is constitutionally guaranteed in prison. In spite of these limitations, current and former inmates appear to have increased rates of cardiovascular risk factors, including hypertension, diabetes, and smoking.

Mechanisms for Increased Cardiovascular Disease Risk

Despite the evidence supporting the association between incarceration and cardiovascular risk factors and disease, it is not known why this association might exist. There are several plausible biological, behavioral, and psychosocial factors through which incarceration may lead to increased cardiovascular disease morbidity and mortality. No study has determined which or what combination of these potential mechanisms leads to poor health outcomes (Fig. 1).

Incarceration May Be Associated with Dysregulated Stress Responses

As early as 1971, psychiatrist George Engel published a paper reconstructing the events in



History of incarceration
Biological factors
Catecholamines
Allostatic load
Abnormal cortisol
BP variability
Behavioral factors
Rx non-adherence
Illicit drug use
Sedentary Behavior
Poor diet
Psychosocial factors
Health Beliefs
↓ Socioeconomic Status
↑ Anger/Hostility
↓ Social support
Established risk factors
Dyslipidemia
Hypertension
Diabetes
Smoking
Obesity
CVD

Imprisonment and Cardiac Risk, Fig. 1 Conceptual framework the hours before 170 people died and described the sudden death of a gentleman just released from prison as evidence that major stressful life events can lead to sudden cardiac death (Engel 1971). While researchers speculate that current and former inmates may have dysregulated stress mechanisms leading to increased risk for poor health outcomes (Massoglia 2008), no studies have examined the association between incarceration and various markers of stress – dysfunction of the hypothalamus-pituitary-adrenal axis, increased catecholamines, blood pressure reactivity, or physiological responses to chronic stresses, as measured by allostatic load. Alterations in these pathways may lead to cardiovascular disease, as elevated catecholamines have direct effects on the heart, blood vessels, and platelets. Catecholamines and cortisol have been implicated in the development of heart failure and cardiac ischemia. Blood pressure reactivity is associated with hypertension (Matthews et al. 2006). And allostatic load, a measure of cumulative stress burden, has been found to be a mediator for social disparities in cardiovascular disease (Sabbah et al. 2008). However, while life post release is stressful and may lead to dysregulated stress responses, this has not been studied.

Incarceration Is Associated with Behavioral Risk Factors That May Increase Cardiovascular Disease Risk

Higher rates of alcohol abuse and illicit drug use in patients with a history of incarceration are well documented and could contribute to increased cardiovascular risk. Injection drug use is associated with contracting HIV and hepatitis C, both of which are independently associated with developing cardiovascular disease. Whether substance abuse and its medical comorbidities contribute to the observed increased cardiovascular disease in this population is unknown. Epidemiologic studies looking at the association between incarceration and cardiovascular disease risk factors, either include measures of a single substance of abuse (Binswanger et al. 2009), do not explore it at all (Wilper et al. 2009), or find that it does not contribute (Wang et al. 2009).

Similarly understudied are the self-management strategies of current and former inmates – their physical activity, diet, pharmacologic adherence behaviors, and how the correctional system environment and its health care system might affect this. The average prison inmate spends an average of 2 years incarcerated, during which time there are limited opportunities for exercise, choice of diet, and self-management of medications. Limited studies have demonstrated that prison diet can either positively or negatively influence cardiovascular risk (Eves and Gesch 2003). Prison diets (inclusive of inconsistent timing and poor availability of sugar-free or fat-free alternatives) have been identified as a source of cardiovascular-disease-related complications in some prisons. Even fewer studies examine the association between physical activity and cardiovascular disease risk factors among incarcerated patients. These studies have found that being in prison is associated with a decrease in physical activity among women (Young et al. 2005) but an increase among men (Leddy et al. 2009). Studies examining body mass index during incarceration have found that inmates who serve shorter sentences had a nonsignificant trend for a reduction in body mass index while those who serve longer sentences have significant increases (Leddy et al. 2009). A study of older inmates reveals that being incarcerated can facilitate developing skills in managing one's cardiovascular risk factors; however, these skills may not be translatable to managing one's disease in the community (Loeb et al. 2007). In most correctional settings, patients do not manage their own medications. They do not pick up their medications at a pharmacy, dispense their own medications (for example, inject insulin or learn which medications to take at mealtime), nor develop the skills to manage complications of chronic medical conditions, including using a glucometer or sleep apnea machine. These are all skills that are essential to managing chronic conditions upon release to the community. No studies detail how best to provide chronic disease self-management support in correctional settings around hypertension, diabetes, and dyslipidemia, which is a cornerstone of cardiovascular disease risk factor management (Wagner et al. 2001).

Incarceration Is Associated with Psychosocial Factors That May Increase Cardiovascular Risk

Incarceration may augment socioeconomic disadvantage, which is independently associated with the development of cardiovascular disease. Individuals released from prison and jail often face additional barriers to obtaining employment, housing, and public entitlements and encounter various restrictions of their political rights (Travis 2005), which may further impede access to healthcare and medical treatment. Current and former inmates have been found to have higher levels of anger and hostility (Cuomo et al. 2008) which are associated with significant increases in angina, myocardial infarction, and angiographic severity of cardiovascular disease (Iribarren et al. 2000). Those with a history of incarceration may suffer from social isolation (Mallik-Kane and Visher 2008), which has also been linked to higher total mortality independent of cardiovascular risk factors. A related issue is that patients receiving psychotropic medications (e.g., olanzapine) are at increased risk of diabetes and, given the high rates of mental illness among the incarcerated, psychotropic medicine use is more common than in the general community. Another plausible mechanism that has not been studied is current and former inmates' health beliefs and attitudes about cardiovascular risk factors and disease. Research in minority and vulnerable populations has demonstrated that disparate patient adherence to health-supporting behaviors (exercising, eating a healthy diet, taking medications as directed, avoiding illicit substance abuse) is an important component of racial disparities in cardiovascular outcomes. Given the disproportionate incarceration of poor minority populations, this likely plays a role in the increased risk of cardiovascular risk factors and disease of ever-incarcerated populations.

Future Directions: Interventions to Reduce Cardiovascular Disease Morbidity and Mortality

Previous studies have demonstrated that recently released inmates have an increased risk of death from cardiovascular disease and current and former inmates are likely to have increased rates of cardiovascular risk factors. However, the reasons for this are unclear, making interventions that improve this population's health difficult to design. As the correctional population continues to age and correctional health care shifts from a focus on acute conditions and infectious diseases to noncommunicable diseases, like cardiovascular disease, important first steps are to understand why current and former inmates have increased rates of cardiovascular risk factors and disease, followed by design of prison and community-based interventions. To achieve this aim, we need more comprehensive studies that include patients with a history of incarceration and the correctional health care system.

Better Studies

Currently incarcerated individuals are not included in national surveys studying cardiovascular risk factors and disease, including the National Health and Nutrition Examination Study and the Behavioral Risk Factor Surveillance System (Wang and Wildeman 2011). Also, longitudinal cohort studies funded by the National Heart, Lung, and Blood Institute designed specifically to examine the epidemiology of cardiovascular risk factors and disease in minority populations do not follow individuals from the community into the correctional system, thus leading to loss of follow-up among minority populations, in particular black men and, thus, biased estimates of risk and disease. Why is this the case? In 1978, following decades of unethical prison research, the federal government instituted a moratorium on research in correctional settings. Recently, the Institute of Medicine revisited the issue at the behest of the Department of Health and Human Services and released a report on the ethics of conducting research on prisoners. It recommended the continuation of current restrictions but suggested updates to improve prisoners' ability to participate in limited clinical studies, particularly those with minimal risk and only interventions with demonstrated safety and efficacy. Despite these recommendations, the prohibition on prison research has not been lifted. Currently, individuals who enroll in studies while free may not be followed into prisons and jails (unless the researcher seeks OHRP approval under Subpart C) and in certain jurisdictions cannot be followed even upon release. Under the current guidelines, participants are removed from the study at the time of incarceration, unless specifications are delineated in the initial institutional review board application. Given this barrier, national surveillance systems may provide flawed estimates of cardiovascular risk factors and miss opportunities to understand how incarceration and the correctional health care system affect cardiovascular risk factors and disease. National policies should be created that allow incarcerated individuals to enroll in surveillance studies or continue their participation in a study they enrolled in prior to incarceration. Ever-incarcerated individuals, prison officials, researchers, and ethicists should be included in this dialogue so that such policies are patient-centered and acknowledge the unique logistics of conducting research in prison (or jail) without impeding good science or violating research ethics.

Understanding the Patient's Experience

Self-management is the cornerstone of treatment for patients at risk for or living with cardiovascular disease. Many studies have shown that a patient's health beliefs and experiences, medication adherence, or self-care behaviors are associated with improved blood pressure, diabetes, and cholesterol control. We know that individuals who are incarcerated are disproportionately comprised of minority racial groups and individuals from low socioeconomic environments. Additionally, given the established association between racial discrimination and hypertension, the incarcerated population has the added stigma of being incarcerated. How discrimination might impact their health and health care access has not been fleshed out. The determinants of ever-incarcerated individuals' cardiovascular disease outcomes are likely multifactorial, but their knowledge, attitudes, and health beliefs likely play a significant role and are shaped by the correctional health setting. Specific attention should be paid to studying the health knowledge, attitudes, and beliefs of ever-incarcerated individuals and how prison environmental issues, including access to healthy foods and health care in prison and upon release, affect self-efficacy for managing health in prison and upon release.

Include the Prison System

Given that around 60 % of inmates return back to prison within 3 years, understanding how the correctional health care system delivers care for individuals with cardiovascular risk factors and disease and particularly transitions of care are crucial to reducing cardiovascular disease morbidity and mortality in this population. A framework to improve the delivery of chronic care in the correctional system must be applied to study and improve care in the correctional setting. One such model, the Chronic Care Model, has already been applied in California (Wagner et al. 2001). The Chronic Care Model is a patient-centered model of care that identifies the essential elements of a health care system that encourages high-quality chronic disease care. These elements include the community, the health care system, self-management support, delivery system design, decision support, and clinical information systems. Redesigning systems of community primary care to the Chronic Care Model has led to improvements in health care outcomes for individuals with cardiovascular diseases. Adapting this model and appropriate metrics for assessing care delivery in correctional settings are underway and should incorporate corrections-specific needs (including security, transfers, and lock-downs) and the realities of the state of correctional medicine including the lack of robust informational technologies (Ha and Robinson 2011). These efforts will generate hypotheses about how prison health care, particularly self- management support and discharge planning, might impact inmates' long-term control of cardiovascular risk factors and management of disease. Moreover, current initiatives to improve quality of care in the correctional system should be mandated and overseen by state and local government entities, given that taxpayers pay for care behind bars. These initiatives may lead to lower costs and improved health for inmates with cardiovascular risk factors and disease.

Conclusion

Whether incarceration is independently associated with increased cardiovascular risk factors and disease remains unknown. However, what is clear is that prisons and jails house a disproportionate number of individuals who have or are at risk for cardiovascular disease. Acknowledging this reality and making attempts to both study and improve cardiovascular health in prison may mitigate disease among inmates.

Incapacitation

Shawn D. Bushway
School of Criminal Justice, University at Albany,
State University of New York, Albany, NY, USA

Overview

Criminologists typically consider four possible mechanisms by which incarceration can prevent crime: general deterrence, specific deterrence, rehabilitation, and incapacitation.

- General deterrence focuses on the changes in behavior created by the threat of punishment. Individuals may choose not to do a particular crime in order to avoid the possibility of incarceration.
- Specific deterrence focuses on the possible change in behavior after the experience of prison. An individual who has experienced prison may update their expectations about prison and decide, on the basis of that experience, to avoid criminal activity in the future. Of course, the experience of prison may also be less harsh than the person was expecting, leading to an increase in the rate of offending over what the person would have committed absent the prison experience.
- Rehabilitation refers to changes in the underlying "criminogenic" factors that the individual brings to prison, usually through targeted treatment programs, like drug treatment, cognitive behavioral programming, or work programs. These programs (and the resulting changes in the underlying propensity to offend) will lead to reduced crime by these individuals upon release. However, the prison experience itself may also increase criminal propensity, by reducing the person's pro-social human capital or increasing the person's criminal capital, such that the person is actually more likely to offend upon release.
- Incapacitation reduces crime by literally preventing someone from committing crime through direct control during the incarceration experience. While it is not impossible to commit a crime in prison, the possibility is greatly limited by the direct control exerted by the correctional system. People who are in prison will not be able to commit crime at the same rate as they did prior to their prison experience, and these prevented crimes should be a direct benefit to society. Unlike the first three mechanisms, incapacitation does not rely on creating changes in criminal propensity. Criminal propensity does not change at all – it simply is prevented from becoming reality. This direct, obvious connection between incarceration and crime reduction is the main attraction of incapacitation. The main drawbacks are that there are no efficiencies to scale and the effect is time limited. While one prison cell could potentially deter the criminal actions of many people or rehabilitate a person for a lifetime, one prison cell

can only incapacitate one criminal at a time for the time that the person is in prison.

The benefits of incapacitation depend directly on the offending behavior of those individuals who are incarcerated. Incapacitation benefits will be larger for policies that manage to incarcerate higher rate criminals. This is particularly true given that most criminologists believe that criminal offending is highly skewed among the offending population, with a relatively small minority of all offenders responsible for the majority of all crimes. Selective incapacitation focuses on the idea that policymakers can prospectively identify the most active offenders prior to their period of peak activity and prevent a great deal of crime through "selectively" incapacitating these high-risk individuals. However, incapacitation also implies declining marginal returns. If society starts by incapacitating the highest rate and most frequent offenders, additional incarceration will generate reduced benefits from incapacitation as society incarcerates lower rate, less frequent offenders.

Estimating Incapacitation

Historically, there are two basic approaches to the study of incapacitation that fall along basic disciplinary lines. The first, based in criminology's criminal career literature, relies on self-reported data from incarcerated individuals to generate estimates of lambda, the frequency of offending. The second, based in economics, relies on aggregate data from places to estimate the impact of prison on crime rates.

Criminologists use individual estimates to generate simulated estimates of the amount of crime averted by specific imprisonment policies. For example, inmates have been asked while incarcerated to describe their offending prior to the current term of incarceration. These responses are then used to generate estimates of the annual amount of crime committed while the person is free using the criminal career approach. The criminal career approach comes from operations research and involves the use of detailed equations which identify the specific parameters that contribute to an observed offending rate. Estimates of the underlying parameters are then used to generate an estimate of the benefits of a year of incarceration in terms of the number of crimes prevented.

Initially, research using this approach reported extremely high benefits from incapacitation, on the order of almost 200 felony crimes per prisoner year. But data on self-reported crimes is highly skewed, with a few offenders reporting a great many crimes. More recent research has reached a consensus around 15–20 felony or index I crimes per year in prison, on average. However, there is no way of knowing whether a given policy change will incapacitate the average offender or someone who commits less crime on average.

There is also no way of knowing whether the person placed in prison was simply replaced by someone else who would have otherwise not committed crime. The possibility of replacement is most plausible in the case of drug crimes, where dealers could be replaced by others. The problem of replacement is similar to the problem of displacement in the case of place-based crime prevention, which attempts to reduce crime by making a "crime-generating" place incapable of generating crime (by, e.g., increasing police presence). If criminals simply go to another place, then crime is displaced, and overall crime is not reduced by this policy, even though crime goes down in a particular place. By the same token, crime is not reduced by incapacitation if a person is incarcerated and is promptly replaced by another individual who now commits the same crimes the other person would have committed absent incarceration.

One way around the problem of replacement is to focus directly on the total amount of crime committed in a place rather than on the crime committed (or not committed) by a particular person. A change in the number of crimes committed in a certain place that can be directly tied to changes in the number of people in prison will generate an estimate of the incapacitation effect that is net of replacement. This idea of linking changes in incarceration to changes in crime for places is the approach of economists. While this approach has the twin advantages of controlling for replacement while linking policy directly to the outcome of interest, it also faces numerous empirical challenges, most notably the problem of endogeneity between prison policy and crime rates.

There is a positive correlation between aggregate crime rates and incarceration rates, not because prison causes crime but because places with higher crime rates also tend to put more people in prison. Attempts to causally identify the impact of prison on crime must therefore break this link by identifying exogenous variation in the incarceration rate. Experiments can cause this variation, although it is hard to create experimental variation in incarceration.

However, "natural" experiments can sometimes create exogenous variation. For example, Steve Levitt observed that some states in the USA were forced by the courts to reduce their incarceration levels due to charges of overcrowding (Levitt 1996). Initially, at least, states under court sanction could only meet this mandate by releasing prisoners. Likewise, the Italian government routinely releases up to 35 % of its prison population through periodic "collective pardons" (Barbarino and Mastrobuonie 2012). This creates variation in the incarceration rate over time and in different places, because the pardons release varying amounts of prisoners to each Italian region. In each case, researchers have observed an immediate increase in crime rates in the places that receive prisoners relative to places that do not, a change that that can be plausibly associated with the individuals who were just released from prison who otherwise would have been incapacitated. These papers generate estimates of between 15 and 20 more felony crimes per year in prison, a number that aligns well with the individual estimates from criminology.

It may not be completely correct to attribute all of these changes to incapacitation. In each case, the deterrent threat of incarceration has also changed as has the potential for specific deterrence and rehabilitation. For example, an individual contemplating crime in a state with a court-imposed cap on incarceration might plausibly assume that his chance of incarceration is less if he was to commit a crime. Individuals who are part of collective pardons might not be able to complete rehabilitation programs or might decide that incarceration is not as bad as they had previously thought and therefore commit more crimes than they would have without the collective pardon.

Some researchers have attempted to differentiate between incapacitative effects and deterrent effects by looking at the timing of effects on crime (Kessler and Levitt 1999). For example, three strikes laws impose long prison sentences for multiple or repeat offenders. These individuals would have been incarcerated even without the three strike provisions: the difference is that they may now have a 10- or 15-year sentence instead of a 5-year sentence. In the short term, there will be no additional incapacitative benefit to these particular laws. An immediate change in the crime rates after the implementation of the law can then plausibly considered to be a deterrent rather than an incapacitative effect. Long-term effects can be plausibly attributed to both deterrence and incapacitation.

Miles and Ludwig (2007) argued that reliable and valid estimates of incapacitation are too difficult to obtain and that time would be better spent generating estimates of the aggregate effects of prison using natural experiments. Although these aggregate measures would not enable the researcher to isolate the mechanism by which crime declined, it would give policymakers clear guidance with which to conduct cost-benefit analyses of prison. In a cost-benefit analyses, the cost of incarceration is compared with the monetized benefits of preventing a certain number of crimes. The monetary costs of crime are generated using direct accounting methods, compensatory damages from civil lawsuits, and methods that attempt to put an estimate on individuals' willingness to pay to avoid victimization. From Miles and Ludwig's perspective, generating a clean estimate of the crime-reducing benefits of a policy would then provide room to concentrate on generating good estimates of the costs and benefits of such a policy.

Recent work by economist Ben Vollaard (2012) looking at the "habitual offender" policy in the Netherlands is an exemplar of this tradition. He first estimates the reduction in crime due to the policy and then conducts a cost-benefit analysis to determine its viability as a crime prevention strategy. While Vollaard argues that the observed impact is due to incapacitation of chronic drug-addicted offenders who were no longer "deterrable" or amenable to treatment, he also acknowledges that it is still at least possible that there was also deterrent value to the statute. For example, good evaluations of "three strikes" laws in California using individual-level data have plausibly identified deterrence for individuals exposed to the risk of the third strike.

Regardless of whether or not the effects identified in the paper are entirely the result of incapacitation, the paper is important because it simultaneously highlights the attraction and limitations of incapacitation policies. Vollaard's estimates are huge, suggesting that the policy prevents over 50 reported crimes per prison year. This very large effect size is actually plausible because of the policy's laser focus on very high-rate habitual offenders in a country with a very low incarceration rate. The average offender sentenced under the law had 31 prior felony convictions, almost all for property offenses. The policy is implemented only as a last resort, after the person has shown no response to treatment. This makes sense, because in the long run it will be cheaper to simply remove the "cause" of the crime problem (the drug habit). Incapacitation only works while the person is in prison, while rehabilitation could last "forever." In cases where treatment does not work, Vollaard's paper appears to show that incapacitation could be a very cost-effective policy for reducing crime.

The problem arises when policymakers get greedy. If we can stop 50 crimes by incarcerating someone for a year, why do we not incarcerate more people? The reality is that only a few people commit crime at such a high rate. In the Netherlands, a country of 16 million, only 4,000 people are even eligible for the habitual offender label in a given year, and even fewer actually receive the penalty. Nevertheless, Vollaard shows that Dutch cities that used the habitual offender law more liberally also had smaller crime reduction per prison year. The reality of a strong positive skew is impossible to avoid – the only way to incarcerate more people is to incarcerate offenders who commit fewer crimes. This leads inevitably to diminishing marginal returns from increased incarceration. In the USA, which has seen a fourfold increase in the incarceration rate over the last 40 years, researcher after researcher has shown that the impact of incarceration on crime has declined during this period (e.g., Piehl et al. 2006). Incapacitation may work, but it is not scalable without a loss of impact.

Selective Incapacitation

The second way policymakers may get greedy would be to avoid waiting until someone reached "habitual offender" status. In the Netherlands, the habitual offender statute could only be used as an option of last resort for an offender with at least 10 felony offenses. As a result, individuals are only incapacitated after they have revealed through their own behavior that they are indeed prolific. However, it is tempting to avoid waiting until someone has committed so many offenses before identifying them as a high-rate offender. Imagine how many crimes could have been prevented in the Netherlands if these individuals could have been identified and incapacitated before they were convicted more than 10 times for felony offenses.

Prospectively identifying high-rate offenders, sometimes called selective incapacitation, holds out this tantalizing prospect of dramatic reductions in crime. It also carries with it some ethical ambiguity, since individuals are essentially being incarcerated for crimes they have not yet committed, and the inevitable cost of false positives. False positives are people identified as high-rate offenders who would have stopped without any additional intervention. Because of this concern about false positives, the debate about selective incapacitation can become quite heated, and people often make broad statements questioning whether criminologists can reliably predict high-rate offenders.

A reasonable read of the now large literature on identifying chronic offending and recidivism will necessarily conclude that criminologists can prospectively identify high-rate offenders at a rate significantly (and substantially) better than chance. It is also true that the accuracy is far from perfect. The open question is not whether criminologists can predict risk – they can – but whether the accuracy is good enough to create benefits that outweigh not only the costs of incarcerating the accurately identified high-risk offenders but also the costs generated by incarcerating the false positives.

There may also be inherent limits to the ability of researchers to prospectively identify high-risk offenders in the current environment. Empirical models require data on individuals followed over many years to validate risk prediction models. This is not a big problem in places like the Netherlands, since even the prolific offenders in the Netherlands who were subject to the habitual offender law had spent very little time in prison prior to receiving the sentence enhancement. However, in the USA, these people would have been incarcerated for substantial periods of time, drastically reducing the amount of time in which their behavior could have been observed. As a result, it would have taken them longer to accumulate the same number of offenses.

Despite the presence of these challenges, the use of risk prediction in the USA's criminal justice system, for sentencing, correctional placement, probation supervision, and parole release, has exploded and shows no sign of abating. Although not all risk prediction is used for selective incapacitation, many of the explicit goals of the risk, needs, and responsivity (RNR) model that now dominates the risk prediction field are at least consistent with selective incapacitation. For example, a central tenet of the RNR approach is the identification of low-risk offenders who will not offend even without treatment or supervision. This practice is simply selective incapacitation at the other end of the distribution – why incarcerate or otherwise restrict people who are at low risk for offending.

The Future of Research on Incapacitation

For decision makers, the most important question is the extent to which incarceration reduces crime; the path generating the reduction is irrelevant for those purposes. However, incapacitation has acquired prominence primarily because of its "obviousness." It is easy to question the power of deterrence in a world where people shoot one another over Nike sneakers. It is not easy to question that locking someone up will prevent the crimes he would have committed had he not been locked up. The debate, therefore, is not about the existence of the impact, but the relative costs and benefits of the approach. Within that framework, plausible estimates of the size of incapacitation benefits serve as useful lower bounds on the potential benefits of incarceration.

As previously discussed, there have traditionally been two approaches, one which relies on inmate surveys and the criminal career approach and the other which relies on policy changes and aggregate crime rates. The first approach, which relies on complicated calculations and expensive surveys, has not been used regularly for at least 15 years, and the second approach, taken to its logical end, reaches the conclusion that the incapacitation effect cannot be isolated from all the other mechanisms by which prison reduces crime.

A third approach has emerged in the last 5 years that combines the best parts of the two methods. The main advantage of the first approach is that it uses data from individuals and allows researchers to estimate a distribution of benefits from incapacitation. The main advantage of the second approach is that it provides a useful counterfactual, comparing the crime control effects of two different policies that can be described substantively.

These new attempts to estimate the benefits of incapacitation rely on individual-level data, like the first method, but, like the second method, attempt to create a reasonable counterfactual. In this approach, individuals are identified who are incarcerated. The researcher then creates a useful counterfactual using other observations in the data. The rate of offending generated by the non-incarceration counterfactual becomes the best estimate of the amount of crime prevented through the incarceration of the first individual.

The main attraction of this latter approach is that it does not force the researchers to assume that individuals who are not incarcerated will necessarily look like those who are. Rather, individuals are explicitly identified as comparable on the basis of their observed offending behavior and other characteristics.

For example, criminologists Gary Sweeten and Robert Apel (2007) studied the self-reported offending of a group of individuals in a contemporary USA sample. In contrast to most prior research, they do not generate estimates by relying on the reports of offending before incarceration by the same respondents. Rather, they rely on self-reported data from a matched control group (using propensity scoring) of other people who are otherwise similar but not incarcerated. This is the first time that a matched sample approach has been used to generate estimates of incapacitation.

Since it is likely that those who are incarcerated are different from those who are not in unobservable ways, it is also reasonable to assume that the Apel and Sweeten estimates also underestimate the incapacitative benefits. Their approach also has the merit of being tied to a specific change in imprisonment policy, namely, increasing the numbers who are given prison as a punishment as opposed to extending the lengths of those currently incarcerated.

Economist Emily Owens (2009) fashioned an identification strategy that should control for both unobserved and observed differences between those who are incarcerated and those who are not. It also fits nicely between the two approaches, because she uses individual-level data and a natural experiment to estimate the causal effect of incapacitation for a subsample of people affected by the policy. She takes advantage of a technical change in Maryland sentencing guidelines that had a substantial effect on the sentence for a subset of sentenced offenders.

The change involved the use of juvenile records in sentencing decisions. Until 2001, these records were included in the criminal history of all individuals up to the age of 25; after 2001, the age for which juvenile histories counted was lowered to 22. Thus, some of those aged 23–25 received shorter sentences than they would have received in the earlier years. Owens estimates that this reduced the average sentence under the Maryland guideline system by about 25 % (about 9–18 months). She also found that, during this time period when they were at liberty because of the change in rules, youths sentenced after 2001 were arrested on average 2.5 times per year. Taking account of the specific offenses for which they were arrested and the ratio of recorded arrests to recorded offenses of the same type, she estimates that they were responsible for 1.5 index crimes per year. This provides a relatively precise estimate of their recorded criminal activity during a period when they would have been incarcerated under the previous rules.

Unlike Sweeten and Apel, Owens' estimate uses information from other offenders to generate a counterfactual incarceration spell, rather than a counterfactual offending rate. Then, the individual's own offending during this time period after their initial period of incarceration is used to estimate the incapacitation effect. The estimate that Owens develops of crimes averted is smaller by an order of magnitude than the consensus estimate of 15–20 crimes previously cited in the literature. The difference comes from the fact that Owens has in all likelihood captured the lower tail of the distribution by her focus on young, relatively minor offenders.

The causal modeling in Owens' paper represents strong causal identification, but it only provides an estimate for a very narrow part of the population. This trade-off between generalizability and strong internal validity is probably typical of the research that might follow in this vein.

A final trend in this area is to extend the concept of incapacitation to include other policies besides incarceration. For example, research in economics has considered the incapacitative impact of school, which keeps youths out of the community and potentially reduces property crime, and of bad weather, which keeps people off the streets. It is also possible to talk about the incapacitative effect of police and even probation officers, who can detain and otherwise obstruct individuals from committing crime by their presence and actions. House arrest and electronic monitoring, which have become increasingly common in the USA, may serve as a deterrent but may also incapacitate people by making it more difficult to engage in criminal behavior. New monitoring policies which require individuals to check in daily for drug and alcohol tests may incapacitate offenders by requiring certain behavior (showing up for breathalyzer tests) when they would otherwise be drinking. Sex offender restrictions on housing locations are also another form of incapacitation. No attempt is being made to deter or change the underlying propensity of the individuals. Rather, policies are created which will make it harder for these sex offenders to actuate their underlying propensities.

These alternative forms of incapacitation might not be as complete as imprisonment, but they may also not carry with them the costs associated with concentrating large numbers of offenders in a prison. The costs of creating such potentially violent environments are not typically considered in the average incapacitation study, which only focuses on crimes in the community. In contrast, evaluations of alternative forms of incapacitation do consider the crimes that are committed while under supervision. For example, evaluations of electronic monitoring compare the behavior of people with the monitors to the behavior of people without monitors. No assumption is made that people with monitoring do not commit crime. A realistic appraisal of these new forms of incapacitation starts with a clear understanding of what the constraints placed on an individual can and cannot prevent. This same realistic appraisal could, and perhaps should, be applied to the constraint of prison. By broadening the definition of incapacitation, researchers may also start to question the fundamental assumptions underlying standard research on incapacitation.

Incarcerating Terrorists

Mark Hamm
Department of Criminology and Criminal Justice, Indiana State University, Terre Haute, IN, USA

Overview

An estimated 100,000 suspected terrorists are currently locked up in prisons throughout the world (Kruglanski et al. 2010). Some of the most influential terrorists are incarcerated in Western prisons, representing a significant security challenge: These prisoners have been known to conduct extensive outreach to other inmates and free-world extremists as well, instigating fear by claiming that anti-Western terrorists, including the 9/11 hijackers, should be remembered as martyrs and heroes.

A notable example is the Blind Sheikh, Omar Abdel Rahman, who has been in US custody since 1993 for his role in the New York City Landmarks plot – a plan to bomb the United Nations Building, along with the New York office of the FBI and the Lincoln and Holland Tunnels. Years ago the Sheikh issued a fatwa, calling on al-Qaeda to attack the United States should he die in an American prison, which is most likely inevitable. Not only has the Sheikh's fatwa reached worldwide audiences via the Internet, but from federal custody he has sent similar communiques to the Egyptian terrorist organization al-Gama al-Islamiyya.

Yet when it comes to the mythopoeia of modern terrorism – an essential element in understanding how extremists from different cultures create violence in similar ways – no one is more important than Ilich Ramirez Sanchez, better known as Carlos the Jackal. The first terrorist to achieve universal media fame for organizing a series of outstanding European and Middle Eastern terrorist attacks during the 1970s, Carlos played a definitive role in turning the terrorist into an incandescent celebrity, paving the way for Osama bin Laden's enlargement as a living myth at the turn of the millennium. And today, Carlos the Jackal is serving a life sentence in France's Le Sante prison where he periodically issues press releases praising al-Qaeda.

Key Issues

The imprisonment of influential terrorists therefore raises an important question for Western nations: What is the best practice for incarcerating terrorists? There are three models to consider: the *total segregation* model used by the United States, the *partial segregation* model used by Israel, and the *dispersal* model employed by the British. The challenges of comparative criminology are well known. Cross-cultural comparisons are subject to the vagaries of language and custom, politics, law, public policy, and criminal subcultures. Yet at the end of the day, the United States, Israel, and Great Britain share a common dilemma. Each country is struggling in its own way to work out the institutional methods and conceptual frameworks for controlling the threat of radicalization brought on by the long-term incarceration of Islamic terrorists.

United States: The Total Segregation Model

A total of 362 federal prisoners were serving sentences on terrorism-related charges in the

United States at the close of 2011 (out of a combined state and federal prison population of 2.3 million). Over half of these prisoners were non-US citizens (LaFree 2009). Most were involved in international terrorism (269 inmates) with an additional 93 inmates locked up on charges of domestic terrorism (Shane 2011). Another 171 suspected terrorists were being indefinitely detained without trial by the US military at Guantanamo Bay, Cuba, including five al-Qaeda operatives charged in connection with the 9/11 attacks.

Al-Qaeda has a solid presence in American prisons. Among the 362 terrorist inmates incarcerated by the Bureau of Prisons (BOP) were about two dozen al-Qaeda operatives, most of whom were trained in bin Laden's camps. They included terrorists involved in the 1993 World Trade Center bombing, the 1998 East African embassy bombings, the 1999 millennial plot to bomb the Los Angeles International Airport, and the 2000 bombing of the USS *Cole*. New York's BOP detention centers in Manhattan and Brooklyn held another dozen al-Qaeda members awaiting trial, including one high-ranking jihadist who was once bin Laden's bodyguard. These figures may be preliminary, however, given that federal prisons are experiencing what an official 2006 report called "a constant population of new inmates arrested on terrorism-related charges" (U.S. Department of Justice 2006, p. 49).

Moreover, these inmates are considered capable of radicalizing other prisoners into the cause of violent extremism. The danger to US security, then, is not the sheer number of Muslims in prison as some experts warn (Cilluffo and Saathoff 2006); rather, it is the potential for small networks of radical Muslim inmates to instigate terrorist attacks, either by other radicalized prisoners once released or by existing support structures in the community.

The threat of prisoner radicalization first surfaced several years after 9/11 when MSNBC news correspondent Lisa Myers reported that three federal prisoners – Mohammed Salameh, Mahmud Abouhalima, and Nidal Ayyad – incarcerated at the BOP's Administrative Maximum security facility (ADMAX or Supermax) in Florence, Colorado, for the 1993 World Trade Center bombing, wrote over 90 letters to Islamic militants outside the prison between 2002 and 2004. Fourteen of these letters were sent to prisoners in Spain who had connections to the terrorist cell responsible for the 2004 Madrid train bombings. Mohammed Salameh had also managed to smuggle several letters to Arabic newspapers praising bin Laden as a hero. The government's after-action report condemned the BOP in the strongest of terms, charging that it had failed to monitor terrorists' communications, including mail, phone calls, visits with family and friends, and cellblock conversations, resulting in "little or no proactive" intelligence on the activities of terrorist inmates in custody. "Consequently," the report concluded, "the threat remains that terrorist. . .inmates can use mail and verbal communications to conduct terrorist activities while incarcerated" (U.S. Department of Justice 2006, p. ii). Thus was born the total segregation model.

As a result of the Supermax affair, between 2006 and 2008 the Justice Department transferred all but the most highly secured terrorist inmates (e.g., Unabomber Theodore Kaczynski, shoe bomber Richard Reid, Zacarias Moussaoui, the 20th hijacker of 9/11) to two newly established maximum-security Communication Management Units (CMUs) within the federal prison system – one in the former death row at the US Penitentiary in Terre Haute, Indiana, and the other at the US Penitentiary at Marion, Illinois. (Both units were secretly opened in violation of federal law requiring public notice and comment). The little that is known of these prisoners and their conditions of confinement is due to the investigative reporting of journalists from National Public Radio and the *New York Times* (Johnson and Williams 2011; Shane 2011). According to these sources, prisoners are under 24-h surveillance in the CMUs. Guards and cameras record their every move and hidden microphones pick up every word they speak – a snooping operation that costs US taxpayers more than $14 million a year. Such information – along with data gleaned from the monitoring of phone calls, mail, and visits – is routinely gathered by prison intelligence officers who share their findings with counterterrorism experts at the Justice Department (Shane 2011).

Rules within the CMUs are strict and they are strictly enforced. The CMUs prohibit group prayer beyond the authorized hour-long Jumna services on Fridays and restrict inmate visitation to lawyers and immediate family members. Visits from journalists, human rights advocates, and volunteers are strictly off limits, as are researchers, who are routinely denied access to the CMUs; hence there is no primary criminological research on the incarceration of terrorists in the United States. Inmates are required to hold all conversations in English. Most of the CMU prisoners are Arab Muslims, yet the units also hold some African-American Muslims charged with radicalizing other inmates. Several environmental and animal rights activists are in the CMUs, along with a neo-Nazi, a tax resister, and a member of the Japanese Red Army. Also locked up in the CMUs are a few inmates who have threatened officials while in custody or ordered murders using smuggled cellphones.

In addition to virtually banning the prisoners' contact with the outside world, the objective of the CMUs is to fully segregate terrorist inmates from the general prison populations to prevent them from both converting other convicts to radical Islam and plotting terrorist acts behind bars. By fully segregating terrorists, the BOP argues that it can better concentrate its resources on language translation, content analysis of letters and phone calls, and intelligence distribution. Despite repeated media requests, authorities have refused to release a full list of the CMU inmates, although reporters have compiled a partial list based on open sources. Among them are three convicts who have previously waged terrorist attacks while confined to maximum-security prisons.

Nothing is known of the prisoners' psychological status in the CMUs, the criteria by which they have been chosen for incarceration in the CMUs, their conflicts with guards and other inmates, or their current threat to public safety. Nor is anything known about their rehabilitation, their preparation for community reentry, or their rates of recidivism. Yet many of the CMU prisoners will one day finish their sentences and return to society (some 300 terrorist-related prisoners have completed their sentences and been set free since 2001). Civil rights attorneys have filed lawsuits contending that CMU inmates are denied the right to review the evidence that sent them there or to challenge that evidence. Civil liberties groups claim that prisoners' rights are being violated by the policies that monitor phone calls and severely restrict visitation privileges, sometimes including access to lawyers which leaves prisoners unprotected against mistreatment. Other evidence shows that by creating Muslim-dominated control units, the BOP has inadvertently fostered solidarity and defiance among the CMU inmates, thereby increasing the potential for radicalization. Adding to these problems, the BOP has not instituted de-radicalization programs which are common in other countries. Because of the legal complaints, combined with the atmosphere of secrecy surrounding the disproportionate placement of Muslim prisoners in the CMUs, Terre Haute and Marion have become internationally known as "Guantanamo North."

Israel: The Partial Segregation Model

The most recently available figures indicate that Israel has approximately 10,000 terrorists in custody (out of a total prison population of 25,000), representing a 1,200 % increase over the 802 terrorists held in 2000. These prisoners are divided into two categories: those in administrative detention without formal charges and those with "blood on their hands" – including convicted terrorists who have killed Israeli citizens, terrorists who were en route to a suicide bombing mission but changed their minds, suicide dispatchers, masterminds of the attacks, those responsible for making the explosives, and senior members of terrorist groups. Roughly 700 terrorist inmates are serving life sentences (like most of the world, Israel does not have the death penalty) that are often "stacked" upon one another. It is not uncommon to find prisoners serving multiple life sentences. The majority are Islamic militants from the Palestinian territories. A reported 44 % are members of Fatah (which governs the West Bank), 26 % are members of Hamas (which rules in Gaza), and 14 % belong to Islamic Jihad which operates out of Egypt. They are spread out among 32 prison facilities and three detention centers in Israel proper. About 140 of the terrorist inmates are juveniles (some as young as 14 years old) who are held at two separate facilities.

Terrorists are physically segregated from the general prison populations, yet their confinement is not secret nor are they totally segregated from other prisoners or the outside world. Journalists, documentary filmmakers, legal aid groups, the International Red Cross, politicians, and human rights activists are permitted access to the inmates, as are researchers. Between 2002 and 2009, for instance, Ariel Merari (2010) conducted a series of important psychological studies on Palestinian would-be suicide bombers and their commanders inside Israeli prisons. Another research team led by Edna Erez conducted interviews with Arab/Palestinian women locked up in Israeli prisons on terrorism offenses, exploring their motivations for attempted suicide bombings (Berko et al. 2010). Terrorist inmates have been able to cooperate with criminal inmates inside Israel's prisons, pursuing various goals, both illegal and mundane. They are also allowed to receive food from family and militant groups during Muslim holidays.

Terrorists are confined to large dormitory-style units, holding as many as 40 inmates, where they manage a common money pool and keep decorations, books, magazines, and other personal items. (There is no documented evidence of electronic surveillance on these prisoners, though one can assume such measures are taken.) The inmates wear street clothes; women wear *hijabs*, or headscarves, as part of their traditional Muslim dress. The inmates are allowed to pray together in special areas. They are housed by militant faction; a good number of them were senior leaders of these factions prior to their incarceration. Their declared purpose is to continue the Israeli/Palestinian conflict within the prison system.

According to prison rules, each political faction appoints an inmate leadership council to negotiate with the guards for prisoners' rights. Each faction is organized hierarchically in accordance with the structure of the organizations on the Palestinian street. The prisoners present themselves in a clean and orderly fashion, yet there are distinct differences between the factions. Hamas is organized like an army while the more moderate Fatah reflects the looseness of a Middle Eastern bizarre. The outstanding feature of the Israeli experiment with locking up terrorists is its emphasis on rehabilitation.

Terrorist inmates are offered a 14-point rehabilitation program, beginning with point 1: religious de-radicalization, where mainstream Muslim clerics offer Koranic lessons on reversing Islamic fundamentalism. Point 2 involves educational, vocational, and occupational training and point 3 emphasizes psychological treatment designed to "heal the anger" from years of living under Israeli occupation. Point 4 involves social and family intervention, including flexible mail and visitation rights for Palestinian families. Families from Gaza are currently forbidden from making these visits, however, due to military restrictions on border crossings into Israel. In those cases, photographs of prisoners are sent to family members twice a year in an effort to show that they are being humanely treated. Other modes of rehabilitation include the creative arts, prison coping skills, and a mandated practice of holding congenial interactions between prisoners and guards.

These rehabilitative interventions are impeded, however, by a labeling process wherein imprisonment bestows a hero status on terrorists; some have been elected to the Palestinian legislature as prisoners. Reinforcing this status is a formidable ideology of resistance. Terrorists blatantly refuse to take part in the programs afforded to them by the Prison Service. Instead they spend time educating themselves in political science, international politics, and Israeli politics – often under the auspices of the Open University. They also study terrorism tactics, demolition, and other subjects relevant to their struggle. In so doing, they have turned Israeli prisons into de facto universities of Palestinian nationalism.

Contraband smuggling is a significant problem in Israel. Though forbidden by Fatah and Hamas leadership, heroin and alcohol are problematic among the rank and file, as is the smuggling of cellphones which can sell on the prison black market for as much as $10,000 (US) per phone. Yet their primary mode of communication is the *ashgarim* – crimped notes written on thin transparent paper tightly rolled into bindles ("kites" in the USA). Weapons – in the form of metal shanks, blow darts, and all manners of improvised explosive devices – present a major problem in the hands of terrorist inmates, as does intelligence on the security arrangements of the prisons, which is occasionally furnished to inmates by visiting family members and Palestinian lawyers acting as "mailmen" for Hamas and Fatah. Inmate leaders use this intelligence to both advance militant goals and ensure internal security by interrogating fellow prisoners and punishing those who deviate from the party line.

The security situation inside Israeli prisons began to take a turn for the worse in 2002 following the 9/11 attacks and the renewal of terrorist strikes by Hezbollah in Lebanon. The trend reached a tipping point in 2006 – a year marked by Hamas' landslide victory in the Palestinian legislative election followed by Hamas' decision to call off its truce with Israel and begin attacking the South with rockets, eventuating in the June 25 kidnapping of the 25-year-old Israeli soldier Gilad Shalit (released in 2011 in exchange for 1,027 Palestinian prisoners), prompting severe military reprisals by Israel. Amidst these tumultuous events, a United Nations study declared the humanitarian situation in Gaza "intolerable," with 75 % of its 1.6 million residents dependent on food and aid.

Since then a new generation of terrorists have flooded the prisons of Israel. They are younger than those who came before, more daring, belligerent, and proficient in the use of explosives. They reject all dialogues with the Prison Service. This generational shift has led to an increase in hunger strikes, disturbances, and security breaches involving violence. Since 2006, terrorist inmates have directed terrorist activities in the streets using *ashgarims* and cellphones. They have been involved in a range of attacks on staff, including stabbings, beatings, attempted murders and kidnappings, and throwing boiling oil into the faces of guards. Suicide bombing plots have been uncovered inside prisons, some carrying the mark of extraordinary criminal ingenuity. In one case, pigeons trained by Hamas flew from the Gaza Strip to the yard of an Israeli prison carrying explosives and cellphones strapped to their talons. On balance, prisons have become the center for terrorist planning and coordination with one goal in mind: destroying the State of Israel and replacing it with an independent Palestinian state. As a result, prison guards are primarily recruited from combat units within the Israeli military.

Great Britain: The Dispersal Model

A total of 150 terrorists are currently locked up in British prisons (out of a total prison population of 95,000). Eighty-nine of them are al-Qaeda inspired extremists who justify violence through distorted interpretations of Islamic texts. These terrorists are unknown to most Americans but their deeds are not. They include Abu Doha, once al-Qaeda's main European recruiter and a central figure in the millennium plot to bomb the Los Angeles International Airport, along with Saajid Badat and Nizar ben Trabelsi, accomplices to Richard Reid in a second bombing attempt on a US-bound aircraft in 2001. Other terrorists in custody include Irish Republicans, animal rights extremists, anarchists, and a growing number of far-right activists whose crimes were motivated by neo-Nazism.

There are 140 prisons in England and Wales, designated by security classification. Category A is the top classification (with three designations: standard, high, and exceptional risk). The escape of exceptional risk inmates, according to the Prison Service, "would be highly dangerous to national security." There are eight high-security prisons deemed suitable to hold Category A prisoners. Al-Qaeda terrorists are housed in these prisons, usually in single occupancy cells. For the most part, they are model prisoners: quiet, polite, clean, and often university educated. Most are ethnic minorities. In instructive contrast to the USA and Israel, in Britain terrorists are not segregated from the general prison populations. Rather, they are "dispersed" within those populations. As a result, al-Qaeda terrorists walk the cellblocks alongside murderers, rapists, drug dealers, skinheads, and old-school IRA members.

Al-Qaeda terrorists are subject to strict security precautions which are strictly upheld. They include restricted movements, pat down searches, daily strip searches, cell searches (called "spins"), and round-the-clock camera coverage. Guards, or "personal officers," are assigned individual terrorists and are required to monitor them for intelligence which is shared with Scotland Yard detectives apportioned to the facilities. To prevent them from building power bases, terrorists are required to change cells every 28 days. They are offered a full complement of rehabilitative services, including education, current affairs, history, and politics; library, inmate tutoring, and recreation; multi-faith worship allowing for group prayer and counseling by Muslim chaplains; psychological treatment; and creative workshops as well as visitation privileges, including the opportunity to meet with selected researchers from the Home Office.

The British dispersal model has two objectives. The first is to promote a sense of inclusiveness common to civil society. One facet of this mission is finding ways to enhance mutual accommodation between Western values and respect for the peaceful traditions of Islam. The second objective is more pragmatic. As a security matter, the dispersal model is intended to prevent the clustering of terrorists in cellblocks, thereby stopping them from forming paramilitary gangs.

The model has its roots in the Irish "Troubles" which began in 1969 as Irish Republican Army prisoners became the central focus of the decades-long conflict. IRA prisoners embarked on a campaign to challenge their status as ordinary criminals, seeking instead to be classified as political prisoners, through organized resistance against British prison authorities. This prison resistance movement eventually erupted in rioting, arson, hostage taking of prison staff and volunteers, and several high-profile escapes. By 1972, IRA prisoners at Belfast's Maze Prison were running their own paramilitary training and indoctrination programs. The campaign reached a tipping point with the 1981 Maze hunger strikes. When Prime Minister Margaret Thatcher refused to give in to IRA demands concerning the hunger strikers, she became the person most responsible for the painful deaths of Bobby Sands and nine other strikers. As a result, the IRA decided to kill Margaret Thatcher, leading to the spectacular 1984 assassination attempt against her at the Grand Hotel in Brighton, England, killing five and injuring over 30 others. Meanwhile, violence between different dissident groups also spilled over beyond the prison walls, with 29 prison officers being killed on the streets of Belfast and London during the Troubles (Pantucci 2008). The goal of the dispersal model is to prevent this violence from reoccurring with al-Qaeda.

Usually, the British dispersal model is successful. Prisoners charged with al-Qaeda-related offenses have been spread out over a number of institutions, thereby undermining their concentration of power. The dispersal model has also yielded increased intelligence, low rates of recidivism, and thus far no repeat of the violence against prison officers witnessed during the Troubles. But officials are nevertheless concerned about the long-term influence Islamic terrorists are having on other inmates. Al-Qaeda inmates have been found in possession of information relating to the bombing of passenger aircraft; some have been found with smuggled laptops and cellphones used to download al-Qaeda materials on how to manufacture explosives. Al-Qaeda inmates have also found ways of recruiting followers beyond the walls.

And despite the best of intentions, al-Qaeda inmates have been able to skirt security regulations and establish themselves as de facto gang leaders who use forced conversions and other forms of coercion (theft and intimidation) to recruit vulnerable inmates into the mix. This has occurred against the backdrop of a rise in minority religious groups in British prisons and fears of Islamic radicalization in the wake of the 2005 terrorist attacks on London's transportation system (the 7/7 bombings and the 7/21 follow-on attempt). System-wide, prisoners identifying themselves as Muslim rose 141 % between 1997 and 2007 (Liebling 2012). This growth was due mainly to the appearance of a younger, more ethnically diverse generation of convicts who have formed a new gang culture in British prisons which has not only imported the values and behaviors of street life into prisons (including drug and cellphone trafficking) but also glorifies Islamic terrorists and their extremist ideologies. Accordingly, in 2009 the security minister of the Prison Service proclaimed that Britain's high-security prisons had become "incubators of extremism" (Leppard 2009).

The confinement of al-Qaeda terrorists alongside Muslim gang members has therefore presented important challenges to high-security prison administrators in Great Britain. Most dauntingly, the dispersal model has led to increased levels of radicalization and in-prison violence that, some say, now rivals the challenges once posed by the IRA. As with most wardens in the United States today, the prison governors of Britain belong to a generation trained in what Feeley and Simon (1992) termed the "new penology." Whereas traditional penology stemmed from criminal law and criminology with an emphasis on punishing and rehabilitating individual prisoners, the new penology is based on a management style in which "specialists" think about criminal subpopulations as "aggregates" that need to be "herded" through "actuarial" risk assessments of danger. For Feeley and Simon, the new penologists provide an important "waste management" function for the state.

As a result, the primary focus of the British dispersal model is intelligence gathering and risk assessment of Islamic radicals. Officials rely on a set of radicalization risk factors which manifest themselves in prison behavior and communication. Of particular concern are overt "feelings of anger, grievance and injustice." In this regard, intelligence is gathered on dialogue and actions of prisoners which reflect a preoccupation with the injustices or the corruptness of the Prison Service and/or the British Government – particularly with the British-supported wars in Afghanistan and Iraq. Although some Muslim inmates "use prison to politicize everything," efforts are made to distinguish normal prison behavior from a larger grievance against Islam. For instance, a Muslim inmate who bangs on his cell house door because he is upset about a broken toilet is one thing; complaining that the broken toilet is evidence of Western imperialism and hatred of Islam is quite another.

A host of risk factors involving dominance and control are also used in intelligence collecting (e.g., appointing oneself as a leader or group spokesman; manipulating and controlling other inmates). Risk factors associated with correspondence and telephone calls include such things as giving commands and counsel to other prisoners, especially if the prisoner is ill-qualified to do so, and receiving requests for instructions from other prisoners. Intelligence is also assembled on susceptibility to indoctrination and groupthink. Here officials are on the lookout for sudden behavioral changes among inmates after coming into contact with charismatic leaders. The primary concern is with young minority prisoners who appear to be lost in the mix or are seeking a transformative experience.

An innovative feature of this control strategy is the identification of *jail craft* or an inmate's show of personal skills necessary to survive in high-security custody. Those with immature jail craft – inmates who have not yet learned how to "play the game" – are deemed susceptible to radicalization. The concept is also used as an anchor for counseling sessions intended to emphasize incongruities between an imagined jihad and actual life in a Western prison. Al-Qaeda's training manual offers several incongruities. For example, the Qaeda document stipulates: "Inside the prison, the brother should not accept any work that may belittle or demean him or his brothers, such as the cleaning of the prison bathrooms or hallways." However, as anyone who has ever worked in prison knows, one of the most coveted jobs among prisoners is that of a janitor or custodian – it is the one assignment that affords inmates the freedom to move around the cellblocks and often to enter security offices.

Finally, for a host of applied reasons, the dispersal model has become the subject of controversy. Prison officers required to be on "red alert" for signs of Islamic radicalization run the risk of alienating ordinary Muslims. The rise in Muslim extremism has created a power imbalance leaving other inmate groups in a state of anxiety. Increased tensions between staff and prisoners, combined with growing competition for state resources and official charges that high-security prisons have become "incubators of extremism," have led some officials and private prison companies to push for a specialized high-security unit for al-Qaeda terrorists and other extremists. Essentially, there is a mounting concern in Great Britain that it may be time to cast aside the dispersal model in favor of the total segregation model employed by the Americans.

Future Directions

The read-across from America to the United Kingdom may not be as obvious as some think. America's secret prisons of the post-9/11 era are hardly a model for forward-looking counterterrorism policy. By associating with the stain of Guantanamo and by insinuating the shame of Abu Ghraib, the British could attract recruits into radical Islamic networks by making the terrorist's cause appear a just response to an unjust enemy. It could also wreak havoc closer to home. Across Europe, Guantanamo has become a symbol of what many see as America's dangerous drift away from the ideals that made it a moral beacon in the post-World War II era. The British may want to reconsider the new penology first.

An often overlooked aspect of Feeley and Simon's argument is that it is not the new penology that has failed, but administrators who have failed to go beyond the new penology "to a new way of narrating the power to punish that can help shape the public and political discourse" (Simon and Feeley 2011, p. 78). Understanding the possibilities of de-radicalization as a "soft" weapon in the fight against Islamic extremism in prison may be such a narrative. It is a way to scale responses to a level appropriate to the real threat of radicalization without doing more harm militarily. This is not easy. Even in countries like Indonesia where de-radicalization programs are routinely offered to terrorist inmates, along with a strong community support structure, recidivism is a genuine concern as is the radicalization of criminal offenders and even Muslim prison officers who watch over them. As one Indonesian terrorist told a researcher after completing his de-radicalization program, if he was released from prison today, he would bomb the US embassy tomorrow (Ungerer 2011).

Decades of criminology shows that rehabilitation lowers recidivism rates when cognitive behavioral treatments target known predictors of crime (Cullen and Gendreau 2001). Although much remains to be done, research indicates that the predictors of prisoner radicalization are gang affiliations around Salafi-inspired Islam and one-on-one proselytizing by charismatic leaders with a violent agenda (Hamm 2008; Liebling 2012). Britain already employs treatment strategies targeting these predictors. Its counseling policy aimed at minority inmates with underdeveloped jail craft is one way of targeting the predictors of radicalization. Inverting al-Qaeda's training manual by using it as a teaching tool to dramatize incongruities between the jihadist dream and the reality of everyday prison life is certainly another. In fact, it is a brilliant example of undermining al-Qaeda's appeal among young prisoners without tackling ideology head on. De-radicalizing older jihadists is more difficult. One reason for this is that Islam's sacred law, the *shariah*, is essentially silent on the subject of incarceration as a rehabilitative venue. The crucial step in de-radicalization, then, is getting to young offenders near the time of their conversions to Islam when they are not yet settled into a commitment to jihad.

Israel's elaborate rehabilitation program for Palestinian terrorists will not work until the peace process is settled. But that does not mean that

Israel's strategies will not work with at-risk inmates in other countries. Employing Muslim clerics to challenge the tenants of Islamic fundamentalism has the potential to broaden transcendent horizons among the vulnerable to the point where serious discussions can be held about the meaning of such loaded concepts as *jihad* (struggle), *takfir* (blasphemy), *shahada* (martyrdom), and the establishment of the Islamic State or *caliphate*. But perhaps most importantly, discussions can be held about al-Qaeda's long-term future in the post-bin Laden era, thereby addressing al-Qaeda's failure to offer any positive vision for building a modern society as imagined by activists of the Arab Spring. Psychological interventions intended to "heal the anger" of prior victimization have the potential to reverse rigid anti-authoritarian views held by convicts at risk for radicalization, especially when tied to meaningful educational and occupational training. Indeed, changing ideological beliefs alone is unlikely to work unless combined with rehabilitative interventions aimed at desistance. And the mandated practice of forming congenial relationships between prisoners and guards can potentially take the air out of moral panics about the transgressive other.

If these are international standards by which a new de-radicalization movement is to be judged, the United States of America has little to offer. Its practice of incarcerating terrorists is secret. Not only secret but it is apparently void of any operating penal philosophy concerning the rehabilitation of anti-Western jihadists. Consequently, most of these inmates see their imprisonment not as justice but as US revenge against *all* Muslims for the attacks of 9/11. This will not change until the emblems of American injustice and abuse – Guantanamo and now "Guantanamo North" – are abolished and replaced with prisons that uphold America's core values.

Continuity and change; GST; Life course

Overview

When initially proposed, General Strain Theory's (GST) primary emphasis was on explaining why some people are more likely to offend than others. In more recent years, it has been extended to address within-person patterns of offending, or more specifically, why some individuals continue to offend well into adulthood while most limit their involvement in delinquency to adolescence. Explanations of both inter- and intra-individual differences rely on the same central principle: Patterns of offending can be accounted for by differences in exposure and reaction to strain between people and over time. This entry provides a brief review of the theoretical and empirical literature on GST explanations of between- and within-person differences in offending. Emphasis is on understanding the manner in which individual characteristics, such as personality traits, social support, and social control, affect the types and quantity of strains to which a person is exposed as well as their tendency to respond to strain using illegal coping mechanisms. After assessing the state of our knowledge regarding GST explanations of between- and within-individual differences in offending, some of the most pressing questions that remain to be answered on this topic are outlined.

Introduction

In 1992, Robert Agnew took traditional strain theory in a new direction with his General Strain Theory (GST). GST conceptualizes strain as a psychosocial concept that can explain individual-level offending. The crux of this theory is that strain – resulting from exposure to noxious stimuli, the removal of positive stimuli, or blocked goals – elicits negative emotions including fear, depression, and most importantly, anger. Illicit coping mechanisms, including offending, substance abuse, and other problem behaviors, may be used in an effort to relieve these negative emotions. As originally proposed, GST set out to explain between-individual differences in offending, or why some people are more likely to offend than others. Specifically, the theory states that people will be more likely to offend if they are exposed to higher levels of certain types of strain (e.g., victimization, work in the secondary labor market, abusive peer relations, negative secondary school experiences, poor parenting). Strains are most likely to lead to crime when they have the following characteristics: (1) are seen as unjust; (2) are viewed as high in magnitude; (3) are associated with low levels of social control; and (4) create pressure for criminal coping (Agnew 2001). People are also more likely to offend if they have a tendency to respond to strain with crime. Both exposure and reaction to strain are influenced by characteristics of the individual, including personality traits, social support, and social control; therefore, individual differences are critical to understanding between-person differences in offending. Socio-demographic and group characteristics such as race, gender, and socioeconomic status are important as well, but they are reviewed in another entry ("▶ Group Characteristics and General Strain Theory," by Stacy De Coster).

In recent years, GST has been extended to explain within-person patterns of offending or more specifically, why some individuals continue to offend well into adulthood while most limit their involvement in delinquency to adolescence (Agnew 1997, 2006b). Similar to GST explanations of between-person differences in offending, Agnew argues that for most individuals offending temporarily peaks in adolescence because youth are exposed to more criminogenic strains and are more reactive to the strains they experience during this period of their lives. Likewise, the small proportion who engage in chronic offending do so because they experience stable, high levels of strain and because they possess characteristics that make them more likely to cope with strain by using crime.

This entry provides a brief review of the theoretical and empirical literature on GST explanations of between- and within-person differences in offending. Emphasis is on describing the types of individual characteristics hypothesized to affect both exposure and reaction to strain, and outlining how these individual differences are key to understanding patterns of offending. This work is not intended to be an exhaustive review; rather, I focus on select characteristics that are most central to these issues, such as negative emotionality and low constraint. I also discuss in detail work that has received less attention in the literature, including GST explanations of offending over the life course.

Background

Between-Person Differences in Offending: Explaining Differences in Exposure and Reaction to Strain

Strain is often viewed as part and parcel of modern life. Given the pervasiveness of strain, one of GST's biggest challenges has been identifying why some people react to strain with crime, while others do not. GST argues that between-person differences in offending can be accounted for, in part, by individual differences that shape the types and amounts of strain to which people are exposed. They also affect the likelihood a person will respond to strain with criminal coping and moderate the relationships between strain, negative emotions, and offending.

Individual differences that are central to GST include social support and social control, associations with criminal others, coping skills, and the personality traits of negative emotionality and low constraint. The contributions of each of these characteristics to understanding why some, but not others, engage in offending are discussed below (see Agnew 1992, 2006b for a more in-depth discussion of these issues).

Agnew argues that individuals with low levels of conventional social support are more likely to react to strain in a criminal manner. Social support, which is defined as assistance that is used to meet an individual's needs, can come from many sources (e.g., parents, teachers, friends, intimate partners, employers) and may take the form of advice, comfort and assurances, direct assistance with problems, and material goods. Individuals who can turn to others for help will be less likely to respond to strains in a criminal manner because they have a conventional support system that can provide them with resources to cope with their problems using legal means. Although not discussed by Agnew, it is also possible that people with more social support will experience fewer strains because they are better able to extricate themselves from stressful situations before these situations affect other life domains. For example, someone with high levels of social support may draw on these resources to find work before unemployment leads to financial problems.

A second factor that can explain between-person differences in offending is social control. Individuals who are low in social control generally have less direct supervision, weaker emotional bonds with others, and do not believe in conventional social norms. People with these characteristics will be more likely to react to strain with illegal behavior because they experience fewer negative consequences as a result of their actions. Specifically, they are unlikely to get caught because their behavior is not monitored; their lack of attachment to others means that they have few people to disappoint with their behavior; and they do not believe crime is wrong, so they experience little guilt. It is also possible that individuals with low social control will experience more strains. For example, youth whose behavior is unmonitored have more opportunities to become involved in situations that are likely to lead to conflict with others.

Associating with criminal others can also increase the likelihood that a person will react to strains in a criminal manner. Drawing on social learning theory, Agnew argues that interacting with offenders can cause one to develop a disposition for crime because criminal peers model illegal behavior, provide reinforcements for criminal activity, and teach beliefs that are favorable to crime. In addition, as individuals observe their peers engaging in crime without being caught or sanctioned, they may come to believe that crime is a low cost endeavor. This belief is reinforced as peers fail to sanction the illegal behavior of group members and instead laud offending. Associating with criminal peers can also enhance one's exposure to criminogenic strains as criminal peer groups are more likely to engage in conflict with one another and with those outside the group.

Finally, individuals with few personal resources to draw upon, including poor problem-solving and social skills, are more likely to engage in crime because they have limited capacity to solve problems in a legal manner. Personal resources that may be particularly important for understanding between-person differences in offending are the personality traits of negative emotionality and low constraint. In fact, Agnew and others (Agnew et al. 2002) argue that these traits may be the primary factors moderating the relationship between strain and crime. Negative emotionality captures the likelihood a person will breakdown under stress. People with high levels of this trait have a tendency "to experience events as aversive, to attribute these events to the malicious behavior of others, to experience intense emotional reactions to these events. . ., and to be disposed to respond to such events in an aggressive or antisocial manner" (Agnew et al. 2002, p. 46). In comparison, low constraint characterizes individuals who "are impulsive, are risk-taking/sensation-seeking, reject conventional social norms, and are unconcerned with the feelings or rights of others" (Agnew et al. 2002, p. 46).

Negative emotionality and low constraint are moderately stable over the life span, but relative stability (i.e., maintaining rank order compared to others) is more common than absolute stability (i.e., sustaining the level of a trait over time) (see Miller and Lynam 2001).

According to Agnew (2006b), people high in negative emotionality and low in constraint are more likely to offend for two primary reasons. First, negative emotionality affects how people perceive, and therefore react to, stimuli. In situations where the intent of the actor is ambiguous, those with high levels of negative emotionality will be more likely to attribute harmful intent to the actor and blame others for their problems (Caspi et al. 1994). These cognitive processes increase the likelihood strain will lead to anger, which is the emotion most often associated with offending and aggressive responses. Because individuals with weak constraint tend to act quickly with little thought, low constraint may enhance the effect of negative emotionality on offending by encouraging the rapid translation of negative emotions into impulsive action (Caspi et al. 1994). There is also some evidence that people with low levels of constraint perceive stressors as more threatening or negative (Taylor and Aspinwall 1996). For these reasons, negative emotionality and low constraint increase the likelihood a person will respond to strain with criminal coping.

Second, people who are high in negative emotionality and low in constraint are more likely to experience strains that are associated with offending. This is due to the fact that they have problems getting along with others and are unlikely to exert the effort necessary to excel in conventional activities. In turn, failure in conventional pursuits can result in greater exposure to strain-producing environments, like delinquent peer groups. People with these traits are also more likely to evoke negative reactions from their social environments. These responses may be stressful in-and-of themselves, or they may introduce the individual to stressful situations. Finally, the search for interpersonal interactions with others they find compatible and stimulating may lead those who are high in negative emotionality and low in constraint to environments and relationships filled with stressors.

Differences in Within-Person Patterns of Offending

Originally, GST was formulated to explain between-individual variations in offending. More recently, it has been extended to explain within-individual patterns of behavior, including why some individuals engage in persistent offending over the life span while most others engage in normative delinquency that is limited to adolescence (Agnew 1997, 2006b). In his explanation of these within-individual patterns of offending, Agnew draws on many of the same concepts he uses to explain between-individual differences including poor problem-solving skills, lack of conventional sources of social support, low social control, association with delinquent peers, and negative emotionality and low constraint. Moreover, the fundamental explanation regarding the patterning of criminal behavior remains the same. Life-course persistent offenders experience high levels of criminogenic strains throughout their lives and have time stable characteristics that make them more likely to respond to strain with crime. In comparison, adolescent limited offenders experience a relatively short-lived peak in criminogenic strains and in the characteristics that promote criminal coping during their teenage years and will generally limit their offending to adolescence.

Life-Course Persistent Offending

GST posits four mechanisms that contribute to stability in offending over the life course. All but one of these mechanisms rely on the relatively time stable traits of negative emotionality and low constraint, directly or indirectly, to explain continuity. In the first explanation, people with these traits are theorized to be more reactive to potential sources of strain. As described above, during interactions, they will be more likely to attribute harmful intent to the actions of others, more likely to respond aggressively, and more likely to believe that aggressive responses will be effective. These perceptions increase the probability they will respond to any given strain with offending at all points in their life.

Second, individuals who are high in negative emotionality and low in constraint will persist in offending because they experience more strains over their life course. They have difficulty in getting along with others and succeeding in conventional pursuits, which generates strain and increases the likelihood they will end up in aversive environments and situations. People possessing these traits also actively seek out environments or relationships that are high in strain. In turn, experiencing strain contributes to the maintenance of negative emotionality and low constraint. In these first two explanations, it is the relative stability of traits overtime, and therefore continuity in exposure and sensitivity to strain, that accounts for persistent offending.

The third explanation Agnew proposes to explain continuity involves passive selection into an aversive home environment. Children who are high in negative emotionality and low in constraint are likely to have parents who possess these traits, partially because there is a hereditary component to these characteristics and partially because parents who are high in negative emotionality and low in constraint are likely create a family environment that promotes the development of these traits in their children (Rutter et al. 1997). Parents with these characteristics are impatient and irritable and typically create home environments for their children that are high in strain. Youth rarely have recourse to change their living arrangements, and therefore, stability in offending results from consistent exposure to criminogenic strains in the family environment.

The remaining pathway is the only explanation for continuity in offending outlined by Agnew that does not rely on the traits of negative emotionality or low constraint. Instead stability is attributed to state-dependent mechanisms in which offending and its negative ramifications have a causal effect on future behavior by increasing exposure and reactivity to strain. In this process, individuals facing persistent poverty and underclass status are initially more likely to offend because they are exposed to more strain, are more sensitive to the strain they experience, and are more likely to respond to strain with offending. Offending then creates its own set of consequences, like decreased social control. It can also disrupt the normative timing of life events, such as the birth of a child, making these events more stressful. These aversive circumstances increase exposure and reactivity to strain and make offending more likely. Therefore, offending is maintained over time by its reciprocal relationship with strain.

More recently, Slocum (2010a) has extended Agnew's explanations of stability. Drawing on the sociology of stress literature and the life-course perspective, she proposes two additional ways that GST may account for persistent offending. First, she argues that when experienced early in life, particularly before age 10, trauma and severe chronic strain can have long-lasting effects on how a person reacts to later strain. The size and force of these early stressors can be great enough to overwhelm available coping mechanisms, decreasing the amount of additional stress an individual can withstand. In this manner, early stressful experiences can lead to stability in offending through their lasting effect on stress reactivity.

The second explanation for stability proposed by Slocum is based on the process of stress proliferation, which occurs when initial stressors expand into aspects of the same life domain that were previously unaffected or when they disrupt patterns of social interactions, obligations, and expectations, leading to problems in other life domains (Pearlin et al. 1997). For example, the loss of a job may lead to financial problems which, in turn can create marital strain. Importantly, stress proliferation can lead to chronic strain, which Agnew (1992) argues is likely to be dealt with through illicit coping.

Adolescent Limited Offending

GST is also able to account for the fact that most individuals engage in normative delinquency beginning in early to mid-adolescence, but then leave this behavior behind as they move into adulthood. This theory attributes the adolescent peak in delinquency to two factors: (1) Compared to other age groups, adolescents are more likely to experience criminogenic strains and (2) they are more likely to react to these strain using criminal forms of coping. I discuss each of these explanations in turn.

Youth are more likely to encounter the types of strains associated with criminal behavior; therefore, the peak in crime during adolescence partially is due to greater exposure to strain. Adolescence is a time of great change. The center of youths' world shifts from their families to their peers, they become increasingly independent and mobile, and they transition from middle school to larger high schools. As a result "adolescents. . .experience a dramatic increase in the size and complexity of their social world" (Agnew 1997, p. 114). At the same time, they are less monitored by parents and their bonds with conventional adults become weaker. Therefore, these new relations are often accompanied by adversity because they require youth to engage in unchartered patterns of interactions without the guidance of their parents or other adults. Adolescents also have more interactions with delinquent peers who are likely to treat them poorly and initiate conflict with one another as well as with parents, teachers, and other adults. Agnew argues that another source of increased strain in adolescence is the blockage of goals. The most important of these goals are autonomy and popularity among their peers, both of which can be achieved through delinquent behavior. Moreover, the desire for autonomy brings youth in conflict with those who attempt to exert social control over them, namely, parents and teachers, and can lead to frustration and anger. Importantly, adulthood is associated with diminishing exposure to these types of strains. The social world of adults is often more limited compared to that of adolescents; adults settle down with a romantic partner, move into the more socially limited world of work, and have less contact with delinquent peers. In addition, adults get the autonomy that they so desired as adolescents and the importance of peer popularity and of other goals that can be achieved through delinquency declines with age. Therefore, according to GST, the decline in crime that accompanies adulthood is explained, at least partially, by a decrease in exposure to strain.

In addition, adolescents are also more likely than other age groups to define the events they experience and their relationships as aversive (Agnew 2006b). That is, not only are they more likely to experience objective strains (i.e., events and circumstances most people would find aversive), but they are also more likely to experience subjective strains. Important cognitive changes occur during adolescence. Compared to childhood, youth are capable of increasing abstract thought that enables them to empathize with others and take on their emotional burdens. At the same time, adolescents are egocentric, and thus, they feel that their actions are always being monitored and judged by others. This self-centeredness, combined with the fact that adolescents' lives are lived in the public sphere, makes it more difficult for them to cognitively reinterpret or minimize their strains. Youth are also more likely to blame their problems on others, which increases the likelihood they will react to strain with anger, and in turn, delinquency. The tendency to interpret events as aversive declines as youth mature, becoming less self-centered and learning not to blame their problems on others. This leads to a corresponding decline in illicit behavior.

The adolescent peak in offending can also be explained by the fact that this age group is more likely to respond to strain with delinquency than other age groups. As youth become more independent, there is an increased expectation that they will handle their own problems; however, they have little experience with coping since in their younger years, they could turn to adults to help them solve their problems. As a result, they may be forced to use less effective, illegitimate forms of coping mechanisms, such as delinquency. Adolescents also lack the resources and the power to escape from their problems, so this is one less coping mechanism that is available to them. Because adolescents have few social ties to prosocial adults and have more associations with delinquent peers, the costs of engaging in delinquency are lower and this behavior may even be rewarded. Thus, for youth, illicit behavior may be a relatively attractive way to cope with strains. As youth age, they have more opportunities to engage in prosocial coping and many of the factors that enhance the likelihood an individual will respond to strain with delinquency (e.g., low social control and exposure to delinquent peers) diminish.

In summary, GST explanations of between- and within-individual differences in offending are very similar – offending is more likely when individuals experience more criminogenic strains and when they possess the characteristics that increase the probability they will cope with strain in a criminal manner. The next section briefly reviews the research on these explanations.

State of the Art

Between-Person Differences in Exposure and Reaction to Strain

A number of tests using diverse samples have examined whether the effect of strain on negative emotions and criminal offending is stronger for individuals who possess certain characteristics, such as low social control, limited social support, and poor problem-solving skills, and for those who associate with criminal others. Support for GST has been mixed at best (see Agnew 2006a, b for a review). For example, in one study that looked at 96 interaction effects, only 6 of these were consistent with GST (Aseltine et al. 2000). In a more recent comprehensive test of GST that uses a sample of Korean youth, Moon et al. (2009) also found mixed support: Good problem-solving skills and high levels of social control mitigated the effect of strain on many types of delinquent behaviors, but contrary to GST, the effect of strain on offending was weaker for individuals with more delinquent peers. Looking across studies, there are few conditioning mechanisms that have received universal support. For example, some studies (e.g., Moon et al. 2009) have found that delinquent peers condition the effect of strain on offending, while others (e.g., Tittle et al. 2008) have not. There is some evidence, however, that conditioning effects may better explain the link between strain and affective responses than strain and delinquency (see Aseltine et al. 2000).

Research examining the conditioning effects of negative emotionality, low constraint, and related traits is generally more consistent with GST. For example, Agnew and colleagues (2002) found that the relationship between self-reported strain and delinquency was stronger for youth who had high scores on a measure that combined negative emotionality and low constraint. Additional research has examined whether related traits moderate the strain-offending link. For example, some studies indicate that individuals with low self-control are more likely to react to strain with delinquency (e.g., Hay and Evans 2006; Mazerolle and Maahs 2000), but other research has found that youth with low self-control are *less* reactive to strain (e.g., Ousey and Wilcox 2007). It is possible that self-control enhances the effect of strain on some outcomes, but not others (Peter et al. 2003). Methodological limitations with many of these studies including improper causal ordering and limited measures of key concepts make it difficult to reach a definitive conclusion regarding the moderating effects of negative emotionality and low constraint. Still, this is a promising avenue for future research.

Few tests of GST have examined whether individual characteristics affect exposure to the types of strain likely to lead to offending, but there is a good deal of evidence to support this idea (see Agnew 2006b for a partial review). For example, individuals involved in delinquent peer groups are more likely to be victimized and come into conflict with others, and negative emotionality, low constraint, and related characteristics have been linked to greater exposure to stressors.

Differences in Within-Individual Patterns of Offending

Compared to other aspects of GST, there has been relatively little research that has examined the ability of this theory to account for within-individual patterns of offending across the life span, although research on development generally supports Agnew's explanations of continuity and the adolescent peak in offending (see Agnew

1997, 2006b, and Slocum 2010a for reviews). Only one study has attempted to examine all of the pathways expected to promote stability in offending simultaneously. Using data spanning approximately 30 years, Slocum (2010b) examined whether individual differences, childhood experiences, and social location account for the continuity of strain and illicit drug use from adolescence through adulthood. As hypothesized by GST, negative emotionality/low constraint had a direct effect on adolescent drug use, and strain in adulthood had a stronger effect on depression and substance use for individuals with these traits. Contrary to theoretical expectations, individuals higher in negative emotionality/low constraint did not experience more stressors than other individuals and there was no support for the passive selection hypothesis. More support was found for dynamic processes including the reciprocal relationship between strain and offending and stress proliferation. Overall, the findings suggest that traits play a role in maintaining substance use from adolescence to adulthood, but that dynamic aspects of the stress process may be more important for explaining continuity.

Studies testing GST explanations of adolescent limited offending are also rare. Hoffmann and Cerbone (1999) used hierarchical growth curve modeling to relate increases in stressful life events to the escalation of delinquency in adolescence. Consistent with GST, they found that experiencing an increasing number of life events was related to intra-individual growth in delinquent activity. Although this study did not examine whether GST could explain the later decrease in offending observed in adulthood, other researchers have examined desistance from a GST perspective. Using seven waves of data from the National Longitudinal Survey of Youth, Gunnison and Mazerolle (2007) found that youth who reported lower levels of negative relations with adults were more likely to desist from minor delinquency even after controlling for other factors theoretically predicted to account for desistance. There was no relationship, however, between decreases in other types of strain and desistance, and none of the strain measures accounted for desistance from more serious delinquency.

Another study examined both GST explanations of desistance and persistence. Eitle (2010) used five waves of data collected from a sample of middle school males who were followed through age 25. He found that decreases in both chronic strain and negative life events were associated with decreases in the number of different types of delinquency in which a person reported engaging. This is consistent with GST, which posits that desistance is partially due to a decrease in strain. Eitle's study also provided some support in favor of GST explanations of stability: The effect of chronic strain on delinquency was exacerbated for individuals with an angry disposition, a trait similar to negative emotionality. Other predictions from GST were not supported. None of the measures of personal and social resources, including social support, moderated the effect of changes in strain on changes in delinquency nor did peer delinquency. Therefore, there was no support for the idea that adolescents desist from crime because they are better able to cope with strain in a prosocial manner or because factors that promote antisocial coping diminish over time. Moreover, strain was found to decrease during adolescence, rather than increase.

Finally, a study using data from the Great Smoky Mountains Study of Youth that covered ages 9 through 16 found support for GST explanations of intra-individual patterns of offending. Youth who experienced persistent poverty were more likely to have conduct disorder throughout the study period, while those who could be classified as desisters only experienced transitory poverty. Some of the findings are also consistent with the idea that stress is produced through a dynamic process, such as stress proliferation. Specifically, changes in the family configuration were associated with residential instability, suggesting that strain in one life domain can have a causal effect on strain in a different domain.

In summary, research suggests that exposure to strain is determined, in part, by characteristics of the individual. Although there are a number of studies that examine conditioning mechanisms, the results are too inconsistent to reach a definitive conclusion on the empirical validity of GST regarding this issue. In comparison, studies using GST to explain within-individual patterns of offending have been limited in quantity and scope, but they offer some support for this theory.

Open Questions and Controversies

There are a number of unresolved issues regarding GST and individual differences in exposure and reaction to strain. Perhaps the most pressing issue is that of moderating effects. Studies that examine whether the effect of strain on offending is contingent on the characteristics of the individual have produced markedly inconsistent findings. As Agnew (2006b) suggests, this might be partially due to the difficulty of detecting interaction effects in survey research. One solution to this problem is to use research designs that are better suited for detecting interactions (Agnew 2006a). For example, an experiment could be conducted in which the treatment group participated in a program intended to reduce stress exposure and reactivity by improving problem-solving skills, increasing social control and social support, and reducing exposure to delinquent peers. GST would be supported if, compared to the control group, individuals in the experimental group experienced fewer strains and were less likely to respond to the strains they experienced with delinquency.

Another potential explanation for the mixed support for conditioning effects is that the importance of specific moderators may vary based on the characteristics of the population being studied, the types of strain that are measured, and the outcome of interest. For example, the relationship between strain and offending might be stronger for youth with delinquent peers, but not for adults for whom friends take on a less important role in offending (Tittle et al. 2008). Therefore, to fully understand the contingent relationship between strain and offending, researchers might need to explore not just two-way, but also three-way interactions. The decision regarding what variables to explore in these complex interactions should be guided primarily by theoretical expectations, but might also be informed by the empirical literature on conditioning effects. This would require a systematic review of the studies that have tested hypotheses on why some people, but not others, react to strain with crime so that researchers can better specify the conditions under which individual differences are likely to moderate the effect of strain. A meta-analysis of the GST literature would be one way to conduct such a review.

It is also necessary to consider that important moderators may exist that have not yet been identified by GST or that have been identified but not well studied. Tittle et al. (2008) suggest that criminal opportunity is a potential moderator that has not received enough attention. Other potential moderators include past experiences with strain (Slocum 2010a) and coping styles (Aseltine et al. 2000).

Given the centrality of negative emotionality and low constraint to both between- and within-individual explanations of offending, understanding the role of these traits in shaping the strain-offending link is crucial; however, there remain a number of unresolved issues. First, most studies have combined negative emotionality and low constraint into one composite measure. Other studies have used measures that capture particular aspects of these traits, but not the full range of characteristics, such as angry disposition and low self-control. Therefore, it is not known if negative emotionality, low constraint, and related traits exert independent effects or whether they interact to produce even greater reactivity to strain. Second, although research on stress has found that individuals with traits similar to negative emotionality and low constraint experience more stressors, little work has examined whether strain mediates the effect of these traits on offending. Answering this question would provide a more complete picture of the relationship between traits, strain, and criminal coping.

More generally, the etiology of strain is typically overlooked in research on GST. Studies that do consider the sources of strain tend to focus on how strain emerges from poverty, family instability, or the neighborhood environment (e.g., Foster et al. 2010). While this work is certainly important, exposure to strain is also affected by access to personal resources as well as a person's actions and interactional styles, which partially originate from individual differences. As an emerging body of research (see Foster et al. 2010; Slocum 2010b) is beginning to make evident, strain is also produced through dynamic processes, such as stress proliferation. Given the importance placed on chronic strain in both GST and the larger stress literature, additional research is needed to understand the manner in which strain can restructure the life course to produce additional strain. Studying the etiology of strain will help to provide a more complete understanding of the causes of offending.

It is apparent that more testing of GST is needed before it will be known if this theory can explain patterns of offending over the life span. Most studies examine the relationship between changes in strain and changes in offending. With a few exceptions, they do not assess the mechanisms through which these changes are expected to occur nor do they examine the factors that cause changes in exposure to strain and the reaction to strain. In addition, most of these studies have very limited measures of emotions and therefore, they cannot assess one of the core propositions of GST – that emotions mediate the link between strain and offending. Yet, it should be noted that some (Tittle et al. 2008) have suggested that strain may have a direct effect on offending that is not mediated by affective responses. Data that are necessary to simultaneously test these mechanisms is hard to come by, especially if the interest is in moving beyond adolescence. Moreover, examining some of the mechanisms expected to lead to continuity and change in offending may be methodologically challenging. For example, future work will need to take into account the reciprocal relationships between strain, illicit behavior, and traits, which will require the use of more complex nonrecursive models.

But it is not just empirical work that is lacking; additional theoretical consideration is needed as well. Agnew's theoretical explanations for patterns of offending over the life course are primarily intended to explain the existence of two groups of offenders: the relatively rare life-course persisters and the much more common adolescent limited offenders. Research is accumulating that suggests this typology might be too simplistic and that even chronic offenders may eventually desist from crime. GST implies that these individuals will desist from crime because they are exposed to fewer criminogenic strains and are less likely to respond to the strain they experience with criminal coping mechanisms; yet, because stability is driven by stable traits and the increasing consequences of delinquency and strain itself, it is not clear how or why these necessary shifts in stress exposure and reactivity will occur. In other words, GST explanations for continuity leave little room for change. Therefore, a broader theoretical account of desistance that extends beyond adolescence and early adulthood is needed.

Conclusion

GST is a broad theory that incorporates concepts from a wide range of theoretical perspectives. Therefore, in order to understand patterns of offending, both across individuals and over time, it is not enough to focus only on strain. Rather, researchers must consider the characteristics of the individual and his or her social environment as well as the complex set of interactions that occur between these two spheres. People are not passive recipients of their circumstances, but instead make decisions or engage in behaviors that shape their exposure to strain. Their decisions and actions are shaped by their social world, past history, and family background, but also by their individual characteristics. These same factors also affect reactions to strain.

These complexities have made GST a difficult theory to test empirically. Examinations of individual differences in reactivity to strain have been hampered by the inherent difficulties associated with finding interactions using survey data. Studies of within-individual patterns of strain and offending have been limited by a lack of longitudinal data that contains the full range of variables needed to examine explanations of stability and change. Yet it is critical for the advancement of the theory that more attention be paid to these issues as well as the etiology of strain. GST is no longer in its infancy and in order for this theory to remain at the forefront of criminology, it must demonstrate that it can account for observed patterns of offending. This will require systematic reviews of the best studies, additional tests of the theory using more appropriate research designs and longitudinal data, and perhaps further refinement of the theory.

Overview

Crime mapping has become extremely popular as an analytic technique in the last 20 years and is arguably the default mode of analysis for law enforcement officers. Spencer Chainey (this volume) explores the driving forces behind this rise as well as what is current best practice. A more detailed treatment can be found at Chainey and Ratcliffe (2005).

The purpose of this entry is to outline a number of ways that the practice of crime mapping could be improved. Many analysts receive incomplete training in spatial analysis, and most in-house training consists of how to interrogate the various crime databases with very little or no time spent on theories of crime and criminality nor *how* to conduct analysis (generating and testing hypotheses, drawing inferences). There is currently a paucity of guidance on how to construct the analysis endeavor with notable exceptions being Ekblom (1988), Weisel (2003), and Hirschfield (2005). Two recent examples of hypothesis testing in crime analysis have been provided by Townsley, Mann, and Garrett (2011) and Chainey (2012).

A lack of analytical training has grave consequences for the quality of intelligence products. Without guiding principles, it is very easy to "uncover" patterns and relationships in data that are spurious. For instance, Diana Duyser, of Florida, found an image of the Virgin Mary in her grilled cheese sandwich (BBC 2004). While it is possible that this and other images are demonstrations of divinity, another explanation is *pareidolia*, when vague and random stimuli are perceived as clear and important. Sagan (1995) speculated that pareidolia may be a side effect of evolution as facial recognition is instinctive in humans.

A more germane example to law enforcement is the birthday problem: how many people would have to be in a room before you are confident that two people present share the same birthday? The answer is 23 for a 50 % chance and 57 to be 99 % confident (Saperstein 1972). Most people find this a surprisingly small number for a small initial probability. Yet intelligence analysts regularly construct social network graphs of individuals of interest trying to linking these to other individuals of interest. But the birthday problem demonstrates it is reasonably easy to establish connections once sufficient individuals are in the group. What no analyst can say, or even thinks to ask, is what they would expect to find for someone who has no connection to the criminal underworld.

Operational law enforcement relies on analysts that interpret the criminal environment, produce intelligence products that influence decision-makers, who then take action to impact the criminal environment (Ratcliffe 2008). The realities of operational law enforcement are that decisions need to be made with incomplete data, in imperfect conditions, and under significant time pressure. The intention of this entry is to offer broad guidelines to analysts on how to better construct hypothesis testing and draw inferences. Without a systematic approach to assessing evidence, there seems a high chance of misinterpretation. This entry contains five fundamental principles of analysis, influenced heavily by statistical reasoning and inspired by Dawid (2005). Statistical reasoning is the focus here because it is science of making decisions in the face of uncertainty.

Statistical Principle 1: Frequencies Versus Rates

A basic tenet of scientific enquiry is analysis using *rates* instead of frequencies. A rate is a frequency adjusted for the underlying population at risk. They are considered superior to count data because frequencies do not reflect the different exposure "at-risk" populations face. For instance, more crime is committed in the USA compared to the UK, but when the population of each country is controlled for, the USA has much a lower crime rate than the UK for nearly all crime classifications except murder (Langan and Farrington 1998).

In the context of crime, there are two underlying problems with the application of rates for measurement. First, the frequency of crime has tangible meaning for practitioners. For instance, while the property crime rate for the City of Omaha, Nebraska, is roughly the same as the City of Philadelphia, Pennsylvania (3730.7 and 3708.2 property crimes per hundred thousand population, respectively), their very different populations (464,628 versus 1,558,378, respectively) mean that the City of Philadelphia hosts roughly 3.3 the number of property crimes of the City of Omaha (FBI 2011). No one would suggest that both jurisdictions require the same level of resources for operational purposes, yet the crime levels, once the at-risk population is accounted for, are practically identical.

Second, locating valid denominators for crime rates is challenging because the population at risk is far from clear for many crime types. Criminal justice researchers are most familiar with crime incidence, the number of crimes per hundred thousand population, but residential population is not appropriate for certain crime types. Central business districts, night-time entertainment precincts, sporting arenas, and tourist locations have very low residential populations but have the potential to host large volumes of crime.

A related issue is the temporal relevance of the denominator. Vehicle crime has almost no connection with residential population; Rengert (1997), for instance, shows that the distribution of vehicle crime in Philadelphia can be explained by the time of day and not by residential population. At a larger scale, seasonal variation in crime rates (McDowall et al. 2011; Baumer and Wright 1996) suggests different limitations with conventional indicators of the population at risk.

A review by Harries (1981) found three main ways of reporting crime: (1) frequencies, (2) population-based rates, and (3) risk-related opportunity. As to be expected with any list of alternative measures, each has advantages over the others in particular circumstances. Frequencies make sense in an operational context or for highly focused, local research efforts. Population-based rates, where the residential population is used as the denominator, are suitable for interpersonal crimes at areal units around city size (Pyle and Hanten 1974). Units of analysis smaller than this do not typically have residential populations estimated with sufficient precision.

Opportunity-based rates use the population at risk as the denominator in rate calculation. For instance, to compute a commercial burglary rate the number of retail outlets could be used as the denominator. While there may be a strong correlation between residential population and shops, the scope of a crime problem is heavily influenced by the available targets in an area. As noted by Phillips (1973, p. 224, emphasis added) [] "[o]ne thing is certain, true risk-related crime rates reveal a far different pattern than had been previously described and *are a necessary starting point in any geographic research concerning crime* in urban areas."

Opportunity-based rates are difficult to calculate due to the wide variety of alternate denominators that could be chosen for any given crime type. Moreover, there are considerable logistical difficulties in compiling these indicators. To estimate vehicle crime rates, Boggs (1965) used the amount of parking space as a proxy for the number untended cars, the latter an impractical measure for routine crime analysis.

Another issue with opportunity-based crime rates is they largely represent the number of available targets, and R. V. Clarke (1984) argues convincingly that targets are not created equal and a simple count of targets does not correspond to opportunity. A number of crucial factors may operate to alter a given target's suitability, such as ease of exploitation, attractiveness, and defended perceptions. Moreover, available targets express different level of vulnerability over the course of a day (see J. H. Ratcliffe (2006) for a theoretic and empirical justification).

One of the methodological problems facing most police organizations is that information systems record crime incidents as point level information, with precision measured in meters when accurate property parcel databases are used. Rate calculation requires some level of aggregation to cruder levels of resolution (e.g., streets, beats, communities). For example, the following figure is taken from the Safe as Houses project in Enfield, UK (Enfield 2011), a finalist in the Herman Goldstein Problem-Oriented Policing Awards in 2011. Problem analysis showed concentrations in particular sections of the borough, one of which is depicted in Fig. 1. It shows frequencies of burglaries for electoral wards around the A10 motorway. The analysts inferred that because the crime count is much higher around the A10 that these properties face an increased risk of victimization, consistent with the empirical literature that more accessible streets host more crime because they are exposed to offenders at a greater rate than less accessible streets (Beavon et al. 1994; Johnson and Bowers 2010).

There are two issues with this figure and the inference drawn. First, it is impossible to gage the underlying population at risk. The difference in crime counts may simply be a reflection that there are many more residential dwellings in the electoral wards around the A10. Second, the Modifiable Area Unit Problem (MAUP) (Openshaw 1983) may be operating. MAUP is a pernicious problem in spatial analysis, occurring when arbitrary spatial units (such as administrative boundaries) are used to aggregate data. Different boundaries, especially when they have no connection with the phenomenon of interest, produce contrasting spatial patterns. Gerrymandering is a powerful illustration of the impact of the MAUP.

This project was selected because it is unusually thorough and is clearly the product of tremendous effort. The fact that it was a finalist is evidence that this represents an atypically nuanced and empirical treatment of a crime problem. The point is that if basic problems can be identified in an exemplar case study, then how prevalent are they in less rigorous analytic products?

There are a number of recent examples of opportunity-based rates in crime mapping. Chainey and Desyllas (2008) compute the pedestrian population in various London streets to generate assault rates per hour per street segment. This revealed that some areas that have a notorious reputation were actually some of the safest seats in London. A similar type of analysis, although used for a completely different purpose, was conducted by Kurland and Kautt (2011). They used street population data to quantify the level of crime around football stadiums in the UK. Ambient pedestrian population measures from LandScan (http:/www.ornl.govscilandscan) were used to estimate population at risk on certain days and times.

Statistical Principle 2: Making Comparisons

The next foundational principle of statistical reasoning is *making comparisons*. Comparative information features prominently in statistical reasoning, from baseline measurements, to the use of control groups, even to inferential testing (the null hypothesis provides an expectation and this is compared with reality; test statistics quantify the extent of differences in this comparison).

Crime figures, used in isolation, are meaningless without reference to a comparison area or some baseline crime level because they cannot be put into perspective. The newspaper headline declaring “Over 40 robberies this year” implies this is a high volume of incidents, but without reference to other statistics it is difficult to interpret the claim with confidence.

A common comparison choice is to use an area as its own “control”; that is, the area’s history serves as a baseline indicator to assess current performance. This is analogous to a *repeated measures design*, a type of analysis where a cohort is measured on more than one occasion. The advantages of this design are beyond the scope of this entry, but it has a number of highly desirable inferential features. The main point is that each observation in the sample is compared with itself to detect a change.

Even if a baseline period was established, a confounding issue is *regression to the mean*, a tendency for an area with an extreme score at one point in time to have a score much closer to the average on the next measurement period. This is a frequent problem in crime prevention where areas selected for attention because they contain a hot spot. When regression to the mean occurs, it is natural for analysts, decision-makers, and researchers to credit an intervention or tactical responses with curbing or suppressing a rising crime trend, after all a reduction was expected as a result of the tactics employed.

Another popular method of conducting comparisons is to use a *comparison group*. Pawson and Tilley (1997) provide a persuasive note of caution about their value. The argument is that interventions trigger mechanisms that fire in particular contexts. An intervention is designed explicitly for the particular area in question, yet comparison groups are conventionally identified through matching demographic and socioeconomic indicators, not the context. Two areas may be strikingly similar with respect to aggregate census indicators yet have neighborhood dynamics which would render some interventions infeasible.

The importance of making comparisons is reasonably straightforward, and spatial researchers could easily argue that crime maps actually possess an inherent comparison; crime maps contain simultaneous displays of hot and cold spots. However, this does not entirely capture the statistical principle of making comparisons. A map of crime density displays the *where* of crime, serving simply as a form of analytical triage indicating where attention should be placed. What next? What should law enforcement attempt to do to the criminal environment to change to reduce the level of crime?

The overarching goal of analysis is to make some causal claim or inference. For example, poor place management leads to more assaults is a causal statement that links the presence or absence of place management with varying degree of assaults. Statisticians would formally label poor place management as an *independent variable* (sometimes explanatory variable) and assaults as the *dependent variable*. The volume of assaults is said to "depend" on the amount of place management.

In order to *make comparisons*, analysts need to demonstrate that the spatial pattern of some independent variable is closely aligned with the observed pattern of crime incidence (the dependent variable). Explanatory factors are rarely a feature of crime mapping products (Eck (1997) provides a rare example of crime mapping that fully incorporates theory).

Statistical Principle 3: Retrospective Versus Prospective

Many risk factors are expressed in terms of a *retrospective proportion*. This is where the prevalence of risk factors among an interest group (victims or offenders, say) is computed. For instance, a study claims that 80 % of sexual assaults take place on the public transport system. The inference drawn is that there is a high chance of victimization if you use public transport. Notice the shift in emphasis between the data and the inference:

- If victimized, there is a high chance of using public transport (data).
- If using public transport, there is a high chance of being victimized (inference).

It is clear there is a difference between these two statements, yet the vagaries of language make it easy to slip between these two distinct meanings. In statistical parlance, each of these statements is a *conditional probability* of the form, $P(A \mid B)$ where the probability of outcome A is conditioned on (or constrained by) the necessary occurrence of B. The conditioning event is always located to the right the "|" symbol.

To clarify, a conditional probability is the probability of event A occurring if B also occurs. A simple form of inference is to compare conditional probabilities with simple probabilities, probabilities of a single event – $P(A)$. The extent of difference between simple and conditional probabilities implies an association between A and B. Of course, this just establishes an association, a type of correlation. This is not the same as claiming that A *causes* B. In order to do this, the analyst needs to demonstrate (1) the temporal sequencing such that a change in B corresponds to a change in A and (2) dismissing competing explanations. The statements can be expressed in formal statistical terms:

- $P(PT \mid V)$ the probability of public transport use among victims (data)

Inferential Crime Mapping, Table 1 Frequencies of victimization status versus public transport use

	Victimized	Not victimized	Total
Public transport	80	10,000	10,080
Not public transport	20	11,000	11,020
Total	100	21,000	21,100

- $P(V \mid PT)$ the probability of victimization among public transport users (inference)

These are two entirely different quantities as demonstrated in the following table.

It is reasonably straightforward to see that of those people who have been sexually assaulted, 80 % (=80,100) were on public transport. It is equally easy to see that for those people who are not sexually assaulted, 48 % (1,000,021,000) used public transport. These suggest an association between victimization and public transport and are consistent with the first two statistical principles – these quantities are rates and comparisons are being made. Importantly, these quantities relate to the likelihood of public transport patronage for victims and non-victims.

Unfortunately there is a further problem with retrospective proportions as they give an inflated sense of the association. The statistic of immediate interest is the likelihood of victimization among public transport users, the *prospective proportion*. Referring to Table 1, this prospective proportion is .8 % (=8,010,080). The corresponding percentage for nonpublic transport users is .2 % (2,011,000).

Two points should be obvious. First, prospective proportions maintain the same order as their retrospective counterparts. The association between public transport and victimization is preserved such that the presence of public transport does correspond to a higher victimization rate regardless of which type of proportion is used.

Second, the prospective proportions are considerably smaller in magnitude than the retrospective proportions, yet this is of more relevance. The problem is that retrospective proportions create the impression that there is a high chance of crime, yet they quantify the likelihood of observing the risk factor (public transport), not the outcome measure (crime). The prospective proportion is about the likelihood of crime.

Analysts need to be aware that due to the nature of crime, they will invariably be calculating retrospective proportions about crime risk factors. Following individuals prospectively when the event of interest is rare or has low frequencies is time and cost prohibitive. Instead, it is far simpler to take a sample of individuals that have observed the event of interest and examine their antecedent attributes. These are useful but are limited in their inferential insight. Retrospective proportions will point to associations, but the strength of those relationships is not immediately apparent. As seen in the example here, quoting the retrospective proportion implies that victimization is a near certain occurrence if one was foolish enough to use public transport, yet the prospective proportion seems far, far less alarming.

Statistical Principle 4: Selection Bias

This principle reflects the observation that forces influencing the data collection process shape the results of analysis performed on the data. Selection bias occurs when the process of data collection is non-probabilistic. Celebrated examples of selection bias occur in election polling (Squire 1988; Jowell et al. 1993), leading to inaccurate estimates. Increased use of mobile telephones has further compromised telephone polling, with some households having no landline telephone (Keeter 2006).

Selection bias occurs naturally whenever *secondary data analysis* is performed. This is a well-recognized problem that accompanies *all* crime analysis. Maguire (2012) writes in the most recent volume of the Oxford Handbook of Criminology of the differences between victimization surveys and official statistics. Commonplace problems – which offences are reported to police, which get recorded by police – act as filters on the information contained in police information system. The cumulative impacts of these and other recording practices are to skew the crime analyst's depiction of the criminal environment.

With respect to spatial analysis, there are a number of additional pressures on crime data which may further impact selection bias. J. H. Ratcliffe (2001) writes that the process of *geocoding*, where spatial reference information is assigned to crime event data, could be faulty due to a number of reasons:

- *Out of date cadastral map*. Cadastral maps are a register of property parcels in a region. They contain validated, government information about spaces. Cadastral information is very useful for geocoding because street addresses can be linked to known land survey information. However, if this information is out of date, such as buildings have been demolished or property parcels have been combined to form larger spatial units, then it is likely that geocoding will be inaccurate if applied to new spatial units that do not appear in the cadastral map.
- *Abbreviations and misspellings*. Reported crime may be misspelled, mispronounced, or incomplete in some way, such as an absent street number. Under these conditions, geocoding is unlikely to operate correctly, with addresses either failing to find a match or being mismatched to a separate address.
- *Local name variations*. Certain places develop a nickname or local business name which may not appear in an address database. Geocoding works on known street addresses, which victims may be oblivious of if they are not an employee or local community member. Tourists are often unaware of street addresses of locations they visit, for instance.
- *Address duplication*. Certain street names are more common than others and, without ancillary suburb or community level information, can easily be placed in another area.
- *Nonexistent addresses*. Mistakes in data entry can easily modify the reported address so it is positioned out of range of a street segment. For example, 18 Baker Street can be transcribed as 80 Baker Street.
- *Non-addresses*. Public space is a notoriously difficult to record and/or capture reliably, and there are a number of locations that may not exist in a cadastral map. For instance, public parks may be defined as a polygon of the geographic extent of the park, yet it is difficult to see how any geocoding engine could distinguish where any incident would have occurred. In most cases, anything occurring in the park is "recorded" at a single location for the entire park such as the centroid of the polygon.

Bichler and Balchak (2007) show that address matching procedures in the major mapping software applications are prone to distinctive systematic biases in geocoding errors. J. H. Ratcliffe (2001) demonstrates geocoding inaccuracy of between 5 % and 7 % in a dataset where crimes recorded in an incorrect *census tract*. This level of inaccuracy seriously undermines any spatial analysis performed at all but the crudest of spatial resolutions.

Statistical Principle 5: Simpson's Paradox

This principle operates when patterns of rates (or proportions) calculated for an entire sample are not consistent for patterns for subgroups of the data. The paradox is a reflection of changing denominators in crime rates and is a result of only relying on proportions or rates as indicators of activity. The contradiction is that Simpson's Paradox directly contradicts the first principle listed here. Of course, it really underlines the importance that counts *and* rates need to be incorporated in analysis.

To illustrate, consider you were responsible for two policing jurisdictions and the crime rates for three priority crimes were as listed in the following table. Being a diligent analyst you compute rates for each of these based on appropriate denominators. It appears that Area 2 is safer than Area 1, in aggregate (Table 2).

Inferential Crime Mapping, Table 2 Aggregate crime rates for Areas 1 and 2

	Area 1	Area 2
Total	7.75	7.20

Inferential Crime Mapping, Table 3 Subgroup crime rates for Areas 1 and 2

Crime type	Area 1 freq	Area 1 denominator	Area 2 freq	Area 2 denominator	Area 1 crime rate	Area 2 crime rate
Assault	256	41,250	430	54,000	6.21	7.96
Commercial burglary	178	2,800	30	350	6.36	8.57
Car theft	69	20,850	66	18,750	3.31	3.53
Total	503	64,900	526	73,100	7.75	7.20

Given that Area 2 has the lower crime rate, it would be worth considering what examples of best practice might be transferred to Area 1. Exploring differences across different crime types will aid in identifying areas worth targeting. However, examining each crime type shows that Area 2 has a *higher* crime rate for all crimes (Table 3).

The reason this apparently contradictory result occurs is due to differences in the denominator that are used to compute the rates as well as a reliance on only rates to assess relative risk. Examining either the "at-risk" populations or the volume of crime would indicate that the two areas have certain fundamental differences which may need to be incorporated in addition to considering crime rates.

This principle is a reflection that variation is unequally distributed among locations and facilities. Aggregate summaries of crime may not be representative at finer levels of resolution. For instance, Brantingham, Dyreson, and Brantingham (1976) provide a nice depiction of the changing nature of crime patterns viewed at different levels of resolution. National patterns differ greatly from regional patterns which are different still from local patterns.

Even the use of sophisticated modeling techniques does not protect research findings from Simpson's Paradox. Roncek and Maier (1991) found a positive association between the presence of licensed venues and the volume of crime. They use the technique which estimated the average impact of a bar on an average block. However, the frequency of crimes for individual bars shows that the effect of an "average" bar is atypical and that only a minority of bars account for the majority of alcohol-related crime and instabilities (Eck et al. 2007).

Spatial Principles

The five principles outlined pertain to any quantitative analysis. Spatial data and analyses in particular have a number of unique attributes that need to be controlled for, or at least accounted, in order to provide valid findings. These are mentioned briefly here:

- *Modifiable area unit problem* (Openshaw 1983). This is an issue that occurs when point level information is aggregated to areal spatial units that are defined by arbitrary administrative boundaries. If the boundaries used do not have a clear alignment with the social phenomena in question, it is possible to generate a depiction of crime that is a reflection of the properties of the boundaries. For instance, a hot spot located close to the border between two police beats will appear diluted if the hot spot is bisected by the border of the police beats. Using a different set of spatial units will probably "undercover" this hot spot.
- *Spatial autocorrelation*. Tobler's first law of geography states observations that located close tend to be more similar to each other than far observations (Tobler 1987). This is a problem because it suggests that observations that are proximate are not statistically independent. This is a fundamental assumption of many inferential techniques in hypothesis testing. Michael Townsley (2009) provides a list of techniques useful for incorporating spatial autocorrelation in analysis or investigating whether is present.

Conclusion

The purpose of this entry has been to outline fundamental principles of statistical reasoning with a view to informing operational crime analysts about better ways of approaching pattern detection. The target audience for this entry may very well ask exactly how should analysis be conducted in order to observe these principles. There are three main strategies:

1. *Be more scientific*. The discipline of crime science has emerged in the last decade and is focused on ways to make crime harder to commit and how to catch offenders quicker. It emphasizes that practitioners should think more scientifically, generate hypotheses, test them, and collect high-quality data. One of the missing gaps in this literature is an acknowledgement of how to conduct analysis in a scientific way. Recent studies by M. Townsley, Mann, and Garrett (2011) and Chainey (2012) put forward methods and examples of how to carry this out.
2. *Employ more sophisticated methods*. One of the advantages of more sophisticated statistical techniques is that many of the principles of statistical reasoning are "baked in," especially regression models. There needs to be much more investment in increasing the training of analysts so that they can exploit well-developed quantitative methodologies. If crime science is analogous to medical science, at present there is no analogue to epidemiology in the study of crime.
3. *Be more focused and use crime theories*. Analysts need to define their problem precisely, restricting their attention to a finite set of behaviors to analyze. For instance, analysts should not study assaults by criminal classification (aggravated assaults, grievous bodily harm, assault with a weapon); rather, they should focus on the relationship between the parties involved. These will range typically from spouses or partners (domestic violence), road rage incidents, school pupils, bar patrons and door staff, and strangers. Each of these assault types has a unique opportunity structure and probably different space-time signatures. Failure to partition each of these discrete problems means that aspects of each are consolidated into an aggregate uninformative blob.

Informal Guardianship

Danielle M. Reynald
School of Criminology and Criminal Justice,
Griffith University, Griffith, Australia

Overview

Guardianship is the process by which citizens function as effective informal crime prevention and control agents. The concept was first introduced in Cohen and Felson's (1979) routine activity approach and was originally defined as "any spatio-temporally specific supervision of people or property by other people which may prevent criminal violations from occurring" (Felson and Cohen 1980). In spite of the capable guardian's central role in determining criminal victimization, research focusing exclusively on guardianship and the mechanisms that facilitate and inhibit it is limited, particularly compared to that of offending and victimization. Recent research has begun to address this gap in the criminological literature to reveal that guardianship against crime is effective when citizens are available and is boosted when they engage in monitoring or supervision of their surroundings and intervene when necessary. Empirical evidence demonstrates that guardianship intensity in residential environments is a place-based characteristic, as it is critically determined by the opportunities available for supervision generated by spatio-physical and sociodemographic contextual factors.

Fundamentals

The Concept of Guardianship

Within criminology the concept of guardianship first surfaced as a critical component of Cohen and Felson's (1979) routine activity approach. This theory put forward the perspective that in order for a crime event to occur, it requires the convergence of three minimal elements: a likely offender, a suitable target (defined as a person, object, or place), and the absence of a capable guardian. In doing so, they draw attention to the capable guardian as the ultimate protector and defender of people and property against criminal violations. Felson and Cohen (1980) define guardianship as "any spatio-temporally specific supervision of people or property by other people which may prevent criminal violations from occurring." In spite of the fact that the capable guardian is one of the only actors within the crime event model who has the power to prevent criminal violations from occurring, it has been argued that "the issue of guardianship lags in theoretical development and empirical testing" (Tewksbury and Mustaine 2003, p. 203).

The Capable Guardian

In their original formulation of routine activity theory, Cohen and Felson (1979) explained crime as the product of the convergence of three minimal elements in time and space: (1) likely offenders, (2) suitable targets, and (3) the absence of capable guardians. Thus, the routine activity explanation of crime rate trends identified the capable guardian as one of the only actors within the crime event who has the power to prevent a crime from being executed. The theory defines a capable guardian as any person or thing that discourages crime from taking place (Cohen and Felson 1979). Cohen and Felson (1979) and Felson (1995) emphasize that guardians "keep an eye on potential crime targets" and serve "by simple presence to prevent crime, and by absence to make crime more likely" (Felson 1995). Felson (1995, pp. 53–54) goes on to further clarify the concept by providing examples of who capable guardians are and how they may serve to prevent crime: "a retired person at home might well discourage daytime burglary of his or her own home or even the home next door. Conversely, someone working away from home during the day contributes to a greater risk of burglary by their absence. Two persons walking down the street might serve as effective guardians for one another against a mugging or other attack, while each individual serves as a guardian for his or her own immediate property."

With these examples, Felson reveals that guardians may be household residents (who can act as guardians over their own as well as nearby properties) and/or passersby (who may act as guardians over others in their presence). Who fulfills the role of a guardian, therefore, is dependent in the first instance on who is present within the context of the crime opportunity. Felson (1995) argues that his conceptualization of the guardian within the crime event model is not a formal policeman or security guard but an informal person or ordinary citizen whose presence, during the course of their daily routines, provides security to potential targets/victims of crime. It is therefore informal guardians like residents and passersby who are more likely to be present to discourage crime than formal guardians like police officers and security guards.

Guardians and Other Crime Controllers

Recent developments in routine activity theory highlight the various roles assumed by the actors who are responsible for crime control, of which guardians represent just one. These roles have been expanded to include handlers who supervise potential offenders (Felson 1995), and managers who supervise places (Eck 1994), to accompany the original group of guardians who supervise potential crime targets (people or property) (Cohen and Felson 1979). Felson developed the concept of the "handler" by linking the routine activity approach and Hirschi's control theory to explain how parents and others in a community who have knowledge of and close proximity to a likely offender can serve as "intimate handlers" who can exert control over them if they are aware of their rule-breaking. Eck (1994) identified another group of controllers – place managers – who have the power to discourage crime at places through the effective supervision of those places. Place managers can be restaurant managers, apartment building managers, doormen, or concierges – all have the ability to keep an eye on places due to their close proximity to or frequent presence at places, as well as the responsibility they have been assigned to manage those places. These developments in the routine activity approach point to the convergent mechanisms that may come into play for those who exercise control over likely offenders, defined (micro) places, and individual people and/or property targets.

Crime Prevention and Control Through Guardianship

Guardianship and Situational Crime Prevention

Clarke (1997) highlights the importance of increasing guardianship as one of the core situational crime prevention techniques. Based on the premise that specific situational characteristics help generate opportunities for offenders to commit crime, Clarke (1997) explains that crime can be prevented by systematically manipulating situational elements in order to block these opportunities using a range of situational crime prevention strategies and techniques. Situational crime prevention is designed to affect the offender's decision-making process by manipulating the perceived costs and benefits associated with a particular crime opportunity. The aim therefore is to manipulate situations so that the costs of committing crime outweigh the benefits, thereby discouraging the offender from committing the criminal act. Thus, Clarke (1997) explains that the ultimate goal is to create unfavorable circumstances for the offender through "discrete managerial and environmental change" (1997, p. 2) in order to reduce opportunities for crime and prevent its occurrence.

With this objective in mind, one of the central strategies of situational crime prevention is to *increase the risks* for offenders to get caught. The key techniques associated with this strategy include extending or increasing guardianship, using place managers, and providing assistance for guardians or tools to facilitate natural and other forms of surveillance including improved street lighting and use of CCTV. Clarke explains that the implementation of these guardianship (and related) techniques is fundamental to crime prevention as it heightens the offender's perception that he or she will be detected and subsequently puts him or her off from offending in that situation. In short, guardians serve to discourage crime and protect targets through their presence and through supervision.

Support for the role of guardianship as an effective crime prevention technique comes from offender self-reports on factors affecting target selection. In Bennett and Wright (1984), for example, qualitative interviews with burglars reveal that factors related to guardianship in terms of household occupancy and the risk of being seen or detected by others played a significant role in the targets selected for burglary. In selecting their targets, burglars explained that they would look for signs or cues that a dwelling was occupied, in which case the dwelling would be deemed "unsuitable for burglary" (Bennett and Wright 1984, p. 65). Similarly, offenders were also concerned with the proximity of neighboring houses and the presence of neighbors who might act as guardians (Bennett and Wright 1984, p. 63). Offenders were discouraged not only by the presence and proximity of guardians in the form of neighbors but also by their capability as guardians, that is, whether offenders would be noticed by neighbors and whether neighbors would take action upon noticing their presence. They admitted being concerned about "being seen by someone familiar with the property who might intervene if something suspicious occurred" (Bennett and Wright 1984, p. 64).

Guardianship and Informal Social Control

The three groups of controllers or supervisors identified in the routine activity approach – guardians, place managers, and handlers – draw attention to the fact that crime can be prevented by controlling potential targets, crime sites, or offenders themselves through supervision. In this way, the concept of guardianship is subsumed under the umbrella of informal social control, where supervision by the guardian over the target, the handler over the offender, and the place manager over the place is enhanced by social bonds and informed by social norms, which leads ultimately to crime control. Felson and Cohen's (1980) definition of guardianship as spatio-temporally specific supervision of potential crime targets emphasizes the function of supervision – that is, looking out for, keeping an eye on, monitoring, and natural surveillance – of people or property that is likely to prevent victimization. This definition also explains that guardianship is place and time specific, highlighting that guardianship as a crime prevention technique is situational; it needs to be targeted at specific places and times in order to maximize its effectiveness.

Availability of Guardians

Citizens' capability to guard against crime is defined, in the first instance, by their routine activities as this dictates a person's availability to act as a guardian. Guardianship for crime prevention thus rests on the notion that any individual can serve as a guardian against crime by being present at the scene of a potential crime event (Felson 1995). Local residents, for example, can guard their residential communities against crime through frequent presence in their residential locale. Routine activities that involve a higher proportion of time spent at or around the home rather than away from home help increase the likelihood that guardians will be available if necessary. The mere presence of a guardian has the potential to discourage offenders who are in search of low-risk opportunities to commit crime. Availability therefore can be viewed as the primary dimension of guardianship.

This is corroborated by empirical evidence which shows that household occupancy or frequency of time people spend at home is a negative correlate of burglary victimization. Garofalo and Clarke (1992) used a survey measure of residential guardianship asking household members how often they were at home, as well as indicators such as the presence of a dog, an alarm system, a timer for lights or radio, informal arrangements with neighbors, and other security measures. Results showed that the combined measures of guardianship contribute to reducing the likelihood of residential burglaries, with the strongest effect when they are used together. Similarly, Miethe et al. (1990) operationalized guardianship in terms of household occupancy, using the number of persons in a household over the age of 12 as its measure. Results showed that individuals who had a decreased level of guardianship over time showed an increased risk of victimization. Time spent away from home not only decreases property guardianship by leaving properties unattended but also increases individual exposure to the risk of personal victimization. In some situations, more important than being present is the *evidence* of availability. "Traces of household occupancy" in the form of visual or auditory cues inform potential offenders that guardians are present and therefore are likely to play a vital role in discouraging offenders.

As such, the majority of empirical research on guardianship utilizes proxy measures for home occupancy to measure guardianship. Indicators such as the number of owner-occupied households, percentage of labor-force participation, and number of household members have traditionally been used to approximate the level of guardianship at places in lieu of direct measures. The British Crime Survey (BCS) and Garofalo and Clark (1992) provide notable exceptions, as they use self-report survey items to measure the amount of time people spend at home as an approximation of the level of guardianship at the property level. Availability, however, is just one dimension of guardianship and conveys little about actual supervision by the guardian who may be present or whether they would take action to stop a crime in progress. It has been argued that this reflects the tangible problem of the inadequacy of some of the proxy measures of guardianship that have traditionally been used in tests of the concept (see Miethe and Meier 1994, for discussion). While availability is a necessary condition for guardianship, the visible presence of guardians is merely the starting point of the spectrum of capability that citizens can draw upon to guard against crime.

Guardianship in Action: Including Supervision and Intervention

While presence/availability is arguably its most fundamental dimension, Reynald (2009, 2010, 2011a) demonstrates that capable guardianship is intensified through monitoring and intervention when necessary (*see* Cohen and Felson 1979). Given availability, effective guardianship can be enhanced by actual supervision or monitoring of residential space and property. Felson (2006) explains that the absence of actual supervision determines when and where crime occurs since offenders primarily seek to escape supervision by finding targets and places that are not well attended to. The power to guard against crime can be further intensified when guardians take action to intervene upon observing untoward activities in their surroundings. Intervention can be defined as any action taken to disrupt or prevent a crime event and can encompass a range of actions including shouting out to perpetrators, calling the police, or physically intervening to stop a crime. Intervention as a form of guarding against crime is supported by Brown and Bentley (1993) who explain that the risk of being seen is not always sufficient to deter a burglar since "burglars also need to know whether potential onlookers would care about their presence. . .Burglars also may decide that some neighbours will intervene and others will not" (Brown and Bentley 1993, p. 52).

Reynald (2009, 2011) elaborated on these action dimensions of capable guardianship, arguing that these components of supervision and intervention are directly observable and provide a more ecologically valid measure of the core dimensions of guardianship than traditionally used proxy measures. Measuring these action components of guardianship through observation revealed that guardianship intensity is strongest and is significantly associated with lower property crime rates when guardians are (1) available, (2) engage in supervision/monitoring/surveillance over targets in their surroundings, and (3) take action by intervening when necessary in order to prevent or disrupt crime or related violations. These findings were replicated by Hollis-Peel and Welsh (forthcoming). Together, availability, monitoring, and intervention have been established as a reliable and valid integrated measure of guardianship and can therefore be viewed as the dimensions of guardianship in action (GIA).

Decision Making by Guardians: Willingness to Supervise and Intervene

In support of the premise that guardianship can extend beyond the availability of guardians, an interview study with available residential guardians revealed that neither supervision nor intervention when necessary is an inevitable consequence of availability (Reynald 2010). In fact, of a sample of 255 available guardians, 15 % admitted to choosing not to supervise or pay attention to occurrences in their surroundings. Moreover, supervision was shown to enhance guardianship capabilities, as residents explained that monitoring enhanced their contextual awareness by helping them to recognize people and situations that were suspicious and out of the ordinary in their particular residential context. These findings support the results from the GIA studies showing that monitoring or supervision boosts the intensity of guardianship at places.

Consistent with the social psychology literature on bystander intervention, only 16 % of the 217 residents that reported witnessing crime or related events in their surroundings in the past also reported being willing to intervene directly, irrespective of the type of crime event they witnessed. Of equal interest was the fact that 20 % of this subsample admitted they would not take any action to intervene, either directly or indirectly, upon observing suspicious, crime-related activity. The majority of the sample reported indirect intervention by calling the police for help as their chosen response to a crime event, with many residents explaining that their choice of direct or indirect intervention would depend on the severity of the crime event in progress. Through their discussion of these varying responses to crime, some of the core stages involved in guardians' willingness to take action to disrupt crime events – that is, to supervise and/or intervene – were able to be elucidated.

Results also revealed that once a crime event is observed by an available guardian, his/her responsive action is decided through an assessment of a range of individual and situational factors that can be broadly categorized as (1) perceived risk to personal safety, (2) perceived capability, and (3) perceived responsibility. When the perceived risk to safety is low and the perceived capability and responsibility is high, available guardians expressed a greater willingness to take some form of direct or indirect action to intervene. Clarke (1997) suggests that guarding against crime within the situational crime prevention context is about encouraging guardians and place managers to take responsibility for monitoring and guarding the places they inhabit. For residents it means taking responsibility, not just for private residences, but also for public areas around residences, while for place managers like shop assistants, parking lot attendants, or train conductors, it means taking responsibility for monitoring their workplaces (Clarke 1997). Felson (1995) builds on this premise by identifying varying levels of responsibility that guardians take for guarding against crime which are determined by physical distance to potential targets/victims, as well as social distance in terms of familiarity and attachment (see Reynald 2011b).

Interviews with available guardians reveal that there are distinct decision-making stages that determine the critical action dimensions of guardianship – supervision and intervention. In particular, they suggest that once a crime event is observed, the responsive action taken by an available guardian is the product of a series of rational choices and the evaluation of the costs and benefits involved. By determining the intensity of guardianship available within particular contexts, these decisions ultimately have an indirect effect on the crime levels within defined contexts. Whether or not guardians take the necessary action to supervise and, in particular, to intervene is affected by individual, contextual, and situational factors which are often interrelated (see Reynald 2010). In order to develop this line of research, these guardianship decision-making stages need to be further extrapolated by developing an understanding of the mechanisms that facilitate intervention by guardians, as well as those that hinder it. A systematic construction of how these mechanisms interrelate to produce the decision to intervene or not is a critical first step in realizing how effective forms of intervention by guardians can be encouraged.

Guardianship and Environmental Support

The aforementioned results point to the importance of contextual factors in generating opportunities for effective guardianship. Wilcox et al. (2007) argue that guardianship is a multidimensional concept which is affected by contextual factors not appropriately considered by most of the previous studies in this area. Alongside the behaviors required to guard against crime as described in the GIA model, the local environment or the characteristics of a place play a critical role in supporting efforts by local citizens to guard against crime. Physical, spatial, social, and demographic factors all make a significant contribution to what is perceived holistically as the residential environment. In turn, each of these groups of factors affects the (visible) availability of residents, their monitoring capabilities, and whether or not they are willing to intervene to disrupt or prevent crime events. Citizens can therefore be empowered to guard against crime through opportunities that are generated by their environment.

The following section will explain which environmental factors have emerged as most influential when it comes to guarding against crime, as well as the mechanisms through which the environment and guardianship likely interrelate. Relevant theoretical perspectives will be highlighted along with empirical evidence to explain the relationship between the environment and the dimensions of guardianship depicted in the GIA model. This comparison will reveal how the same environmental cues vital for crime prevention may be conversely interpreted by the offender in search of crime opportunities.

Guardianship Opportunities and the Spatio-physical Context

Natural Surveillance

Both the visible availability of guardians and their monitoring capabilities are critically mediated by the opportunities for surveillance that are provided by the design and layout of the built environment. Newman's (1972) defensible space theory explains how the spatio-physical environment affects residents' capability to act as guardians by either facilitating or blocking opportunities for natural surveillance. According to Newman's theory, residents can maximize their ability to monitor their surroundings if windows and doors of properties are oriented towards public space and designed to face each other along a street, and by ensuring that the lines of sight between private residences and public space are clear and unobstructed. This makes it easier for residents to oversee their property, neighboring properties, and public space immediately surrounding them. With the support of these features of environmental design and layout, residents can supervise their surroundings purposely or inadvertently while carrying out regular household activities (Newman 1972). Felson (2006) reinforces this argument, suggesting that supervision is maximized when guardians can see as much of their residential space as possible. These natural surveillance opportunities function as a tool for crime prevention as they increase the risk that potential offenders will be seen by increasing the observability of residential areas as well as the visibility of residents who are at home.

Image and Maintenance

The image of a residential environment reflects the extent to which it is controlled, maintained, and well cared for by its residents (Newman 1972). Image provides information about the management of a residential place and whether or not its residents are effective place managers. The extent to which residents take responsibility for keeping a place clean and well maintained determines the image of residential places. Residents can help guard against crime through the regular upkeep of properties and the wider residential environment. Broken windows theory corroborates this perspective as it suggests that cues reflecting poor management and maintenance, such as broken windows and graffiti, promote an image of vulnerability and encourage crime. Empirical evidence also shows how physical incivilities like graffiti, broken windows, litter, and general disrepair encourage social incivilities and lead to increased crime, fear of crime, and withdrawal from the community by residents (e.g., Skogan 1990). This evidence reveals the ways in which the image of a place can determine resident participation as it can affect the frequency with which residents are present, as well as their willingness to monitor and intervene when necessary.

Accessibility, Land Use, and the Routine Activities of Place

While residents can contribute to the maintenance of their physical environment, image is also generated by the routine activities of that place. The social organization of behavior at a particular place determines its routine activities and therefore its risk of being targeted for victimization. The routine activities of a place can be viewed as a function of the level of activity and the type of activity encouraged therein. The accessibility of a place and its land-use patterns in turn contribute to the level and type of activity that is routine at a place. Accessibility and land use affect residents' ability to guard against crime through their capacity to either generate or inhibit opportunities for effective monitoring and direct intervention when necessary. Taylor et al. (1995, p. 122) explain that the presence of nonresidential land use on a block essentially "alters the ratio of outsiders to regulars on a block, lessening the familiarity of faces residents see around them."

Similarly for areas that are highly accessible, a high proportion of users are likely to be outsiders and this diminishes residents' monitoring capabilities by reducing the likelihood that they will be able to detect suspicious activity or individuals who are there for illegitimate purposes. Empirical studies have shown that crime tends to be higher in more accessible, highly utilized areas of the street network. High accessibility and activity level at a place also generates increased opportunities for crime by encouraging opportunities for physical and social incivilities (Taylor et al. 1995). The image of the place that is generated as a result of the number of external users that are attracted to it can have a negative effect on resident's place attachment, participation, and their territorial behavior. Taylor et al. (1995) explain that the lack of familiar faces and the physical deterioration that is encouraged by the high usage cause residents to withdraw from public spaces and become much less engaged in place management. This consequently serves only to reinforce the negative place image. Exacerbating the issue further still is that nonresidential land uses on a residential block create "holes" in the residential fabric that residents do not take responsibility for (Taylor et al. 1995, p. 122).

There is, however, some debate over the effect of accessibility and mixed land use on residents' guardianship capabilities and on crime in general. Built on the work of Jane Jacobs (1961), New Urbanism promotes residential developments comprised mixed land use that includes public transportation stops and other amenities. Jacobs (1961) argues that mixed land usage and the flow of people it attracts at various times of the day are factors that encourage, rather than detract from, opportunities to guard against crime since more people means more available guardians.

The Sociodemographic Context and Guardianship

The Density of Acquaintanceship and the Social Context

Citizens' willingness to monitor and their willingness to intervene are both influenced by their sociodemographic context. Freudenberg (1986) argues that while monitoring by residents in an area discourages offenders and helps control crime levels, this is likely to be mediated by the social context and the degree to which residents know each other. Thus, he argues that the *density of acquaintanceship* or the degree to which residents in a community know each other is the critical factor as it determines the degree of "watchfulness" by residents in areas with stable population (Freudenburg 1986). Likewise, Sampson et al. (1997) found evidence to suggest that residents' willingness to intervene is linked to social cohesion among neighbors and is negatively associated with neighborhood variations in violent victimization. These studies emphasize the importance of the social environment in encouraging residents' capability to guard against crime.

Residential Mobility, Ethnic Heterogeneity, Income, and Social Ties

Residents' immediate social environment is fundamentally shaped by demographic characteristics of the broader neighborhood context. Sampson and Groves' social disorganization model predicts that neighborhood demographic characteristics, including ethnic heterogeneity, low income, and residential mobility, contribute to high crime and delinquency rates by weakening informal social control and disrupting social organizations and networks within neighborhoods. This has been corroborated by micro-level empirical studies. Xie and McDowall's (2008) study showed that residential turnover independently increases the risk of property victimization due to changes in the opportunity structure for crime that result from constrained capabilities to guard against crime.

According to Xie and McDowall (2008), high residential turnover on streets increases the vulnerability of households to crime through the confluence of several mechanisms that highlights the relationship between the sociodemographic environment and the guardianship dimensions of monitoring and intervention: "Residential moves sever local ties and weaken social control, so newcomers tend to have fewer friends in the neighbourhood who might act as guardians of their homes. . .Long-term neighbours are more likely to recognize unusual patterns and unfamiliar people that may be signs of criminal activity. They will also be more likely to intervene, ask questions, and notify the police of clear indications of unusual activities" (Xie and McDowall 2008, p. 543). High rates of resident turnover mean high numbers of new residents whose lack of knowledge of their residential area has a negative effect on their monitoring capabilities and perhaps even on their confidence to intervene. Xie and McDowall (2008, p. 543) suggest that "potential offenders may perceive the vulnerabilities of newcomers," including their diminished capacity to distinguish outsiders from their own neighbors.

Alternative Applications and Extensions of the Guardianship Concept

Mechanical Surveillance

Cohen and Felson (1979) explain that while capable guardians are usually people, the function can also be served to some extent by mechanical objects. As such, CCTV cameras have been used increasingly as technological/mechanical replacements for the supervision and control provided by human guardians. When guardians are not able or available to provide supervision over targets, people, and places, it has been proposed that CCTV cameras are an effective form of surveillance. Moreover, whether manned or not, CCTV cameras are said to create the perception that someone is watching. It is therefore meant to have a similar effect as a guardian who is watching by discouraging offenders in search of crime opportunities because of the elevated risk of detection (see Clarke and Eck 2005).

Guardianship and Physical Control

Target Hardening

Another dimension of the guardianship concept to be introduced is that of *physical guardianship* or the protection of targets through physical control. Physical guardianship has been defined as "routine activities that provide physical protection of homes" (Wilcox et al. 2007, p. 774) or other property targets. According to Wilcox et al. (2007), these include target hardening measures that overlap with guardianship and are consistent with situational crime prevention, such as the use of alarm systems and locks. One of the principles of SCP is that target hardening can be used effectively to block opportunities for crime by increasing the effort required to commit crime. Several studies have distinguished these types of target hardening measures as a specific form of guardianship (e.g., Miethe and Meier 1994; Garofalo and Clark 1992). It is again important to note, however, that this is distinct from the routine activity concept of guardianship, and even within the situational crime prevention literature, target hardening and guardianship are considered separate techniques for crime prevention. Increasing guardianship is categorized as a technique that helps prevent crime by increasing the risk for offenders that they will be identified or caught. On the other hand, increasing target hardening is a separate technique designed to increase the effort required by offenders to illegally acquire or access a target (Clarke 1997). Though related, these are viewed as distinct techniques that operate successfully individually and in combination to prevent crime through separate strategies.

Self-Protection Measures

The fusion of the routine activities approach with the lifestyle-exposure perspective of Hindelang et al. (1978) inspired the birth of another branch in the conceptualization of guardianship, one that remains distinct from the original form it takes in the routine activity approach. Moving away from the perspective of guardianship as an expression of social control, studies by Mustaine and Tewksbury (1998) and Tewksbury and Mustaine (2003) conceptualize guardianship in terms of specific behaviors geared towards self-protection and target protection. Starting with the perspective that individual lifestyle or routine activities determine "differential exposure to dangerous places, times, and others" (Miethe and Meier 1994, p. 32), Mustaine and Tewksbury (1998, p. 834) define guardianship as "the degree of protection afforded to property or persons." In keeping with this definition, guardianship is operationalized by the use of self-protective behaviors by individuals, including weapon possession (e.g., carrying a knife or gun) and possession of body alarms or mace (Tewksbury and Mustaine 2003). There remains, however, a great deal of debate about the extent to which personal protection measures like these are synonymous with the original concept of guardianship and reduced risk of victimization (*see* Wilcox et al. 2007; Reynald 2009).

Conclusions and Future Directions

"Private citizen's involvement in crime prevention is being given a high priority as a public policy issue" (Geis and Huston 1983, p. 398). This has fuelled debates about whether or not private citizens are capable of guarding against crime, whether or not they have the expertise to do so, and the dangers inherent in involving citizens at this level. These concerns are especially interesting in light of the fact that private citizen involvement in crime control is not a novel phenomenon and actually is an historical antecedent of formal policing in westernized states (Zedner 2006). In fact, crime prevention through guardianship in the form of informal surveillance and shared responsibility has been put forward as an alternative to the ideals of the present-day formal state police (Zedner 2006). This informal guardianship by citizens preceded formal policing as it now exists within the modern criminal justice state. Indeed, the technique of guardianship as a form of situational crime prevention would thus fit in well with what Zedner (2006, p. 85) describes as the eighteenth-century policing experts who "regarded prevention as more important than the retrospective functions of arrest, detention and prosecution that later came to characterize modern policing." Critical for the development of research on guardianship is understanding the ways in which informal guardians can enhance the functioning of formal guardianship processes and, as a consequence, have a positive impact on crime control (see Reynald 2011b, for further discussion).

While a recent empirical focus on understanding the mechanisms that facilitate and inhibit effective informal guardianship has revealed the importance of environmental/contextual factors in determining guardianship intensity, further microlevel research is needed to elucidate ways in which situational and individual factors interact to affect the intensity of guardianship at places. In his article on communities, crime, and neighborhood organization, Skogan (1989, p. 437) asserts the claim that "the ability of individuals to act in defense of their community is shaped in important ways by the opportunities for action that are available to them." This highlights the importance of mobilizing citizens to take action through guardianship by raising their awareness of the active role they can potentially play in crime prevention. Aside from continuing to develop our understanding of the function of informal guardians as crime control agents in their residential environments, much needs to be explored about guardianship in other domains. Research on guardianship is dominated by a focus on the way it functions in the residential context, but very little is known about how citizens function as capable guardians in domains away from home.

Informal Social Control

María B. Vélez
Department of Sociology, University of
New Mexico, Albuquerque, NM, USA

Overview

Research in sociology and criminology consistently indicates that crime clusters in places characterized by adverse conditions such as neighborhood disadvantage and residential mobility. Scholars draw on social disorganization theory and its idea of community social organization – the capacity of local communities to solve commonly experienced problems and realize collective goals – to help explain this clustering of crime. In neighborhoods characterized by high levels of informal social control, social disorganization is comparatively low, suggesting the importance of informal social control as a strategy to achieve community social organization. Informal social control reflects the ability of local neighborhoods to *supervise* the behavior of their residents and the capacity of neighborhoods to *socialize* their residents conventionally (Bursik 1988; Bursik and Grasmik 1993; Sampson and Groves 1989). In addition to promoting social organization, a predominance of evidence shows the crime-controlling effect of informal social control. Not only do these neighborhoods have lower crime rates, such contexts also translate into lower levels of offending and victimization risk among individuals. Put simply, the impact of informal social control in shaping neighborhood crime is "widely accepted" (Kubrin and Weitzer 2003, p. 376).

Fundamentals

Crime is unevenly distributed across neighborhoods, and research suggests that it tends to cluster in those communities with adverse conditions such as poverty, racial/ethnic heterogeneity, and residential mobility (Bursik and Grasmik 1993; Kubrin and Weitzer 2003; Sampson et al. 1997; Sampson and Groves 1989; Shaw and McKay 1942; Sampson 2012). Scholars draw on social disorganization theory and its idea of community social organization to help explain this clustering of crime. Community social organization refers to the ability of local communities to solve commonly experienced problems such as crime and realize common goals important to their residents such as achieving a crime-free environment (Bursik 1988, p. 521).

A major strategy to achieve community social organization is for neighborhood residents to exert informal social control. Informal social control is thought to have two central elements: the ability of local neighborhoods to *supervise* the behavior of their residents and the capacity of neighborhoods to *socialize* their residents conventionally (Bursik 1988; Bursik and Grasmik 1993; Sampson and Groves 1989). *Supervision* occurs through a variety of activities including resident's surveillance of public spaces, a shared sense of responsibility for taking care of the neighborhood and its residents such as calling parents when kids are misbehaving or neighbors taking care of each other's property especially when out of town, providing information to fellow residents about which parts of the neighborhood are unsafe and should be avoided, and directly intervening such as breaking up street fights, questioning strangers in the neighborhood, or admonishing fellow residents for behavior defined as unacceptable (Bursik 1988; Bursik and Grasmik 1993). *Socialization* occurs in the presence of strong conventional institutions such as two-parent families or well-funded and viable schools, which help to provide a setting where support for conventional processes of socialization can take hold. Neighborhoods characterized by extensive supervision and effective socialization are well situated to ensure norm compliance. As such, they enjoy little crime.

The goal for this encyclopedia entry is to provide a preliminary introduction for readers to the concept of informal social control. This entry is by no means exhaustive but is designed to outline the major contours of the concept and how it fits within the larger literature on communities and crime. This entry begins with a brief sketch of social disorganization theory, which serves as the theoretical footing for the role of informal social control in reducing community-level crime rates. Then, current conceptualizations and operationalizations of informal social control are discussed. The entry provides the current state of knowledge on its distribution and impact on local levels of crime and victimization as well as individual-level offending and victimization risk. The entry concludes with directions for future research.

Theoretical Background. Social disorganization theory serves as the primary theoretical backdrop of our understanding of the role of informal social control in shaping community crime rates. It is a long-standing theory in criminology originally pioneered by Shaw and McKay (1942), researchers grounded in the Chicago school, who sought to understand the neighborhood ecology of social problems such as juvenile delinquency. Utilizing a variety of secondary data sources including Cook County court information, they found that high delinquency rates associated positively with a variety of adverse neighborhood conditions including poverty, racial/ethnic heterogeneity, and residential mobility. They also found that high delinquency rates persisted in certain Chicago neighborhoods for several decades despite change in racial and ethnic composition. They drew on life-history data and argued that the uneven pattern of crime across urban neighborhoods and its persistence over time were rooted in adverse neighborhood conditions that impeded community social organization. In particular, they proposed that neighborhoods with economic deprivation tended to have high rates of population turnover (or mobility) and racial/ethnic heterogeneity, which in turn socially disorganized a community, and increased delinquency rates as well as other social problems.

Shaw and McKay (1942) argued that two key processes accompany the structural mechanisms that characterize disorganized areas and reinforce neighborhood disorganization. First, disorganization creates a context in which there is a wide diversity of values and attitudes with respect to conformity to the law. Because delinquency as a way of life competes with conventional ways, disorganized areas are characterized by divergent systems of values. This aspect of social disorganization theory aligns with cultural deviance theories. Second, because of weakened conventional institutions, socially disorganized communities are unable to control the behavior of residents and facilitate socialization processes so that they comply with conventional norms, especially those relevant for law-abiding behavior.

Shaw and McKay's emphasis on the need for neighborhood structures to regularize norm compliance is consistent with notions of social control, one of the most widely discussed concepts in sociology (Meier 1982). Social control is considered to be a collection of mechanisms (a social process) to induce compliance to norms (Meier 1982). Controls can be invoked internally with feelings of guilt or shame (products of effective conventional socialization) or commitment in conformity. The logic is that people feel good when they adhere to conventional norms, allowing them to continue a conventional life. When they do not adhere to these universal beliefs, they feel bad, self-critical, and guilty, deterring such norm violations in the future. Controls can also be induced externally by others in direct ways such as with scrutiny or surveillance engaged in by formal agents like the police or informal agents like neighbors. Others like family, school officials, or the community can exert control via the withdrawal of sentiment. The logic is that people conform to norms or rules because they are rewarded with things like status, prestige, money, and freedom when they do adhere to them and are punished with the loss of them when they do not. Taking this logic to the macro level, social units by way of their social relationships can regularize norm compliance by providing rewards for compliance and prompting high costs for deviance.

Social disorganization theorists took the above logic to heart when they reframed the theory in the 1970s and 1980s. They contended that neighborhoods vary in their ability to exert social control; they vary in their ability to provide awards for compliance and punishments for deviance. As such, contemporary articulations of this theory are basically a "group-level analog of control theory and is grounded in very similar processes of internal and external sources of control" (Bursik 1988, p. 521). The current entry focuses on contemporary discussions of social disorganization (see Bursik 1988; Bursik and Grasmik 1993; and Kornhauser 1978 for historical accounts of social disorganization as well as greater elaboration on the re-articulation as a macro-control theory).

This encyclopedia entry centers on the *informal* ways neighborhoods exert social control in urban communities; the informal level also is where the bulk of theorizing and research has taken place (Bursik 1988; Bursik and Grasmik 1993; Carr 2003; Kubrin and Weitzer 2003; see also Hunter 1985; Bursik 1988; Bursik and Grasmik 1993 for discussion of two other levels of networks and social control: private and public). How do neighborhoods informally provide rewards for enforcing norms and engender high costs for engaging in deviance so that they ensure a crime-free environment? The logic is that social disorganization arises in contexts of adverse neighborhood conditions such as – residential mobility, racial/ethnic heterogeneity, family disruption, and neighborhood disadvantage. These adverse neighborhood conditions translate into less informal neighboring such as fewer people getting together to chat and neighbors not knowing the names of their fellow residents. When residents have limited social interaction, it makes it difficult for a community to develop mutual trust and shared expectation among residents, impinging on the community's ability to provide the rewards for adhering to norms and the punishments for deviant behavior. This means that residents are unlikely to intervene during suspicious activity, admonish residents and local youth for deviant behavior, or watch out for one another's property. In turn, public spaces are not supervised effectively and crime rates increase. Empirically this logic also means that the intervening mechanisms of informal networks and social control will absorb much of the effects of neighborhood adverse conditions on crime and victimization. Discussed below is how researchers study informal social control and its impact on levels of crime.

Conceptualizations of Informal Social Control. Informal social control is hypothesized to emerge and facilitate reductions in crime by way of three neighborhood-level processes: social interaction, collective efficacy, and community organizations. First, the dominant approach termed the systemic model views communities as a "complex system of friendship and kinship networks and formal and informal associational ties rooted in family life and ongoing socialization processes" (Kasarda and Janowitz 1974, p. 329). As such, informal social control is conceptualized as the regulatory capacity of a neighborhood, presumed to arise from the community's affiliation, interactional, and communication networks among residents (Bursik 1988, 1999; Kasarda and Janowitz 1974). From this vein, larger, interconnected, and active associational networks provide the rewards for adhering to norms and the punishments for deviant behavior. The systemic model argues that poverty, residential instability and racial heterogeneity are expected to hamper the establishment of relational network structures that serve to facilitate mechanisms of informal social control. In turn, crime is expected to increase (Bursik 1999, p. 87). Importantly the systemic model assumes that places with strong ties among neighbors and to local institutions will bring about informal social control.

Empirical work suggests that strong informal ties among neighborhood residents do not always translate into low crime rates. For instance, ethnographic work on disadvantaged and minority communities indicates that although strong bonds exist among neighbors, they do not translate into reductions in crime (Pattillo 1998; Wilson 1996). Wilson (1996) finds that despite high levels of neighboring, inner-city residents in Chicago reported feeling they had little informal social control over their children. Wilson (1996, p. 64) states that "A primary reason is the absence of a strong organizational capacity or an institutional resource base that would provide an extra layer of social organization in their neighborhoods." In her research about a predominantly

African-American middle-class neighborhood in Chicago, Pattillo (1998) found a socially cohesive neighborhood characterized with abundant ties among residents. However, these ties did not always translate into an effective exercise of informal social control; rather, they often inhibited the ability of residents to admonish the behavior of other residents such as local youth hanging out in the street corner. Pattillo (1998, p. 763) argued that "… the more people are familiar with one another; the more illicit networks are absorbed into mainstream connections and thereby normalized." She found this reluctance especially pronounced when it came to residents calling the police. As one resident said about a young man's gang-affiliated behavior to Pattillo (1998, p. 763), "I didn't wanna give this young man's name to the police because his mama is such a sweet lady." Bellair (1997) in a study of Seattle neighborhoods finds that social interaction among neighbors that takes place at least once a year or more has consistent and negative effects on rates of burglary, motor vehicle theft, and robbery across Seattle neighborhoods. He, however, finds that if social interaction is frequent such as once a week, it does not have consistent effects on crime rates. Bellair (1997) suggest that in terms of the regulatory and sanctioning capacity of local networks, it may matter very little whether neighbors are close friends as long as they interact with one another enough to provide the mutual support needed for "doing something" on behalf of the community.

Such findings set the stage for another conceptualization of informal social control. The focus here shifts to collective efficacy, which highlights the *nature* of social ties rather their presence or absence (Warner and Rountree 1997; Wilson 1996; Pattillo 1998). It may be that networks originating in churches, after school clubs, or schools may not lead to the social control of crime because these networks are not strictly focused on reducing crime. Whereas networks that result from being involved in a neighborhood watch group where neighbors meet once a month to talk about crime issues do lead to the social control of crime because the content or nature of the network is focused on crime. This logic is consistent with notions of social capital – networks are used in part to transmit group norms and expectations pertaining to appropriate behavior for neighborhood residents and to impose a wide variety of informal negative sanctions if those expectations are violated. So in the case of crime, ties have to be geared towards collective action to secure a crime-free environment. The concept offered to address this issue is collective efficacy, a form of informal social control, measured as mutual trust, social cohesion, and a willingness to intervene (Sampson et al. 1997). Collective efficacy thus only counts informal ties among neighbors when they are coupled with high levels of informal social control; otherwise, they are not assumed to reduce crime from this perspective.

A third strategy for conceptualizing informal social control is to account for the presence of or resident participation in community organizations. Community organizations, especially those that have indigenous roots, act as a central vehicle for neighborhoods to bring about informal social control (Bursik and Grasmik 1993; Sampson and Groves 1989; Skogan 1989, 1990). For instance, community organizations provide spaces and events for the fostering of informal networks, the planning out of collective action to address crime and other neighborhood problems, and the supervision and socialization of neighborhood youth with programming. Moreover, community organizations help to minimize isolation by linking primary (i.e., family and friends) and secondary institutions (i.e., neighborhood watch groups and local businesses). Thus, community organizations help to organize neighborhoods so that they can "protect and defend their interests and values" (Kornhauser 1978, p. 79). It is important to note that the above literature is not clear on what types of organizations are most consequential for the control of crime.

Operationalization of Informal Social Control. To study informal social control, researchers have focused primarily on secondary relational networks (relationships among neighbors) and the exercise of informal (parochial) control. The bulk of studies on informal social control is quantitative and uses questions from community surveys that sample residents across neighborhoods in a particular city. In most cases, researchers compile a multiple-item index to capture informal types of social interaction among residents that take place in the neighborhood. Responses are usually aggregated to the community level (i.e., census tracts, police beats, community areas, and neighborhood clusters).

Informal Neighboring. Some researchers measure social interactions among neighbors that are presumed to yield informal social control. Social interaction among neighbors is usually captured by a variety of aspects related to informal neighboring such as how often respondents get together with their neighbors either in their neighbor's or their own home, how many people respondents know by sight or by name in the neighborhood, do respondents ask neighbors for favors such as borrowing tools or looking out for each other's property, and how many neighborhood kids are known by name (Bellair 1997; Elliott et al. 1996; Simcha-Fagan and Schwartz 1986, Warner and Rountree 1997). Further, Bursik (1988) points to the importance of residents patronizing local business establishments as a strategy for integrating residents into the social life of a community. As such, Bursik (1999) measured informal networks with a six-item factor that tapped into how often (range from nearly always to never) respondents do their shopping for groceries, medical goods, and clothing; do car repairs; went out to eat; and did their banking in the neighborhood.

Direct Intervention. Other papers attempt to capture neighborhood levels of direct intervention by residents with the extent to which residents "do something" or that they can count on their neighbors to "do something" about crime. Specifically, respondents are asked how likely it is they can count on their neighbors to intervene to solve problems in the neighborhood like someone breaking into a house in plain sight, someone is trying to sell drugs to a child in plain sight, a fight in front of the house and someone is getting beaten up, and their kids are getting into trouble. As an early example, Maccoby et al. (1958) asked respondents hypothetical questions about whether they would step in and try to do something if they observed children using abusive language, engaging in property damage, fighting, or drunkenness. Bellair (2000) captures informal social control with a two-item factor scale that combines neighborhood percentages on whether respondents watch their neighbor's property when the neighbors are out of town and if neighbors watch out for the respondent's property when the respondent is out of town. Silver and Miller (2004) use a four-item Likert scale that asks respondents the likelihood they can count on their neighbors to take action if children were skipping school or hanging out on a street corner, children were spray painting on a local building, children were showing disrespect to an adult, or if there was a fight in front of the house and someone was being beaten up. In another study, Sampson et al. (1999) utilize a similar measure as Silver and Miller (2004) to capture child-centered control by asking respondents the likelihood that neighbors would take action if children were skipping school or hanging out on a street corner, children were spray painting on a local building, and children were showing disrespect to an adult. It is important to note that most measures capturing the extent that residents do "doing something" or that they can count on their neighborhoods to "do something" are based on hypothetical situations.

Collective Efficacy. To operationalize collective efficacy, scholars often replicate Sampson et al. (1997) who combine two factors that were closely associated across neighborhoods: (1) social cohesion and mutual trust are part of this construct because residents are unlikely to intervene when the rules are unclear or people mistrust or fear one another and (2) the willingness to intervene (informal social control). Sampson et al. (1997) state that the two measures tap aspects of the same latent construct, which they term collective efficacy (see also Sampson 2012). To measure the willingness to intervene on behalf of the neighborhood, Sampson et al. (1997) used a five-item Likert-type scale that asks residents about the likelihood (ranging from very likely to very unlikely) that their neighbors could be counted on to intervene in various ways if children were skipping school and hanging out on a street corner, children were spray-painting graffiti on a local building, children were showing disrespect to an adult, a fight broke out in front of their house, and the fire station closest to their home was threatened with budget cuts. To capture "social cohesion and trust," respondents were asked how strongly they agreed that "people around here are willing to help their neighbors," "this is a close-knit neighborhood," "people in this neighborhood can be trusted," "people in this neighborhood generally don't get along with each other," and "people in this neighborhood do not share the same values" (the last two statements are reverse coded). Note that had Sampson et al. (1997) only used their willingness to intervene measure, it would have been consistent with above work on direct intervention. But to capture the notion of collective efficacy, they combine direct intervention with social cohesion and trust into one measure.

Community Organizations. Researchers measure the role of community organizations in one of two ways. First, using survey data, some researchers examine the extent of resident reported participation in community organizations. For example, Sampson and Groves (1989) computed the percentage of residents in a neighborhood that had attended a committee or club meeting in the week prior to the survey. As another example, Morenoff et al. (2001) measure the extent residents report participation in voluntary associations such as local religious organizations, neighborhood watch programs, block group associations, community councils, business or civic groups or ethnic/nationality clubs, or local political organizations. Second, scholars attempt to capture the presence of organizations in a community by either counting their presence with a directory or by asking respondents in community surveys about their knowledge of organizations present in their neighborhoods. For instance, Morenoff et al. (2001) put together an index of the number of resident reported organizations and programs in the neighborhood such as a community newspaper, block group, crime prevention program, alcohol/drug treatment program, mental health center, or family health service. Skogan (1989, p. 445) created an index that summed resident responses to three questions concerning respondent's awareness of "volunteer citizens patrolling residential areas," "groups that encourage citizen to undertake crime prevention efforts," and "groups that work to improve police-community relations" within two to three blocks of their houses.

The State of Evidence Regarding Informal Social Control

The Distribution of Informal Social Control. Extant work from the systemic or collective efficacy approach shows that informal social control is harder to achieve in neighborhoods characterized by adverse neighborhood conditions including concentrated disadvantage, immigrant concentration, racial/ethnic heterogeneity, and residential mobility. In the now classic assessment of the systemic model, Sampson and Groves (1989) using data from the British Crime Survey find strong support for the idea that adverse neighborhood conditions like low economic conditions dampen informal strategies to control crime across neighborhoods in Great Britain. In particular, they find that neighborhoods characterized by low socioeconomic status, ethnic heterogeneity, family disruption, and urbanization have relatively high levels of unsupervised peer groups, their measure of a community's diminished capacity to supervise youth. They also find that poor neighborhoods report less organizational participation than their more affluent counterparts. Similar patterns emerge from studies grounded in collective efficacy. In the first study on collective efficacy, Sampson et al. (1997) find that concentrated disadvantage and immigrant concentration decreases levels of neighborhood collective efficacy across Chicago neighborhoods while residential stability increases its presence. Morenoff et al. (2001) find that collective efficacy is significantly lower in Chicago neighborhoods characterized by concentrated disadvantage, immigrant concentration, and with prior high rates of homicide, whereas affluence, resident participation in voluntary associations, the presence of organizations, and strong kin/friendship ties increase collective efficacy levels across Chicago neighborhoods.

Although the above work establishes support for the idea that adverse structural contexts do not foster informal social control as successfully as more advantaged contexts, theoretical and empirical work has yet to fully articulate the source of this gap. In research directly addressing this question, Silver and Miller (2004) argue that if residents feel that local institutions have not met their needs or aspirations, which is often the case for disadvantaged neighborhoods, they will feel more like they are "passing through" and thus be less willing to intervene on behalf of the community. Moreover, when resident satisfaction with the police is low, typical in disadvantaged neighborhoods, residents will be reluctant to take personal risks to safeguard the community and so will be less willing to exert informal social control. Silver and Miller (2004) find support for this logic in that relatively higher levels of neighborhood attachment and satisfaction with police contributed significantly to increases in neighborhood levels of informal social control. Moreover, they find that neighborhood attachment and police satisfaction help to mediate a substantial portion of the effects of concentrated disadvantage and immigrant concentration on levels of informal social control.

Evidence for the Impact of Informal Social Control on Crime. Though more theoretical and empirical work needs to be done to account for the uneven distribution of informal social controls across neighborhood contexts, the fact that it is more limited in disadvantaged communities serves to compound the crime problem in these communities. At the same time, research also suggests that informal social controls can act as a protective factor, buffering the criminogenic influence of disadvantage. Evidence suggests that weak informal social control mechanisms increase neighborhood levels of crime and victimization. Early work by Maccoby et al. (1958) compared two Cambridge, Massachusetts neighborhoods that were similar in terms of socioeconomic status but with different levels of juvenile delinquency. One neighborhood had relatively high levels of juvenile delinquency, while the other had relatively low rates of juvenile delinquency. They find that area differences in informal social control at least partly explain differences in juvenile delinquency across the two neighborhoods. Specifically, they find significant area differences in informal social control, measured as the percentage of residents who "would do something about it" in hypothetical instances of fighting and drinking. They also found a higher percentage of interventions among non-victims in low versus high delinquency areas. At the same time, they did not find significant neighborhood differences in informal social control when it pertained to children involved in property damage or being openly rude such as using insulting language.

Recall that during the 1970s and 1980s, social disorganization was reframed as a systemic model, which emphasized the role of informal social networks as precursors of informal social control. In the first contemporary assessment of the systemic model, Sampson and Groves (1989) examined the impact of unsupervised peer groups, conceptualized as a neighborhood's inability to regulate youth in public spaces, and local participation in formal and voluntary organizations (a measure of informal networks among neighbors) on 12 different victimization and offending rates across a large number of local British areas. They found strong direct effects of unsupervised peer groups in increasing crime and victimization rates, while participation in local organizations lowered crime and victimization rates. They also found strong support for the mediation arguments of social disorganization theory in that the intervening measures of informal social control absorbed much of the effects of poor socioeconomic conditions, ethnic heterogeneity, residential mobility, family disruption, and urbanization on crime and victimization rates.

Sampson and Groves (1989) strong support for the social disorganization framework paved the way for subsequent tests within the systemic and collective efficacy approaches to informal social control (Bellair 1997, 2000; Elliott et al. 1996; Simcha-Fagan and Schwartz 1986; Warner and Rountree 1997). Elliott et al. (1996) in an analysis of Chicago and Denver neighborhoods found neighborhood levels of informal social control significantly lowered juvenile delinquency rates across Chicago but not Denver neighborhoods. Supporting expectations of social disorganization theory, they also find that informal social control mediated the effect of neighborhood disadvantage on adolescent reports of delinquency in both Chicago and Denver. Two additional papers demonstrate the impact of collective efficacy on neighborhood levels of crime. In the first paper to advance the concept, Sampson et al. (1997) finds that higher levels of collective efficacy yield lower levels of homicide across Chicago neighborhoods. In a second paper, Morenoff et al. (2001) find that collective efficacy decreases both local levels of homicide victimization and homicide offending across Chicago neighborhoods.

Research has also examined the role of community organizations in shaping neighborhood levels of crime. Simcha-Fagan and Schwartz (1986) in a study of 12 neighborhoods in New York City found that neighborhoods with relatively high levels of organizational involvement had relatively lower levels of rates of delinquency. Similarly, Sampson and Groves (1989) investigate the impact of resident participation in community organizations on various types of crime. They find that neighborhoods with relatively high levels of organizational participation have lower levels of burglary, auto theft, mugging, street robbery, stranger violence, and total victimization across British neighborhoods. Other research suggests that the reason organizational participation reduces crime is because it fosters collective efficacy (Morenoff et al. 2001). This research indicates that beyond participation, the number of organizations available to community members matters. In fact, Morenoff et al. (2001) find the presence of community organizations is important for producing collective efficacy which, in turn, brings about decreases in homicide in Chicago neighborhoods. Regardless of how community organizations are measured, research suggests that they play a role in bolstering informal social control and thereby help to reduce crime.

Scholars also investigate how informal social control at the neighborhood level shapes individual-level offending or victimization risk using multilevel analytical strategies. For example, Elliott et al. (1996) find that, under some circumstances, informal social control decreases the likelihood of youth engaging in problem behavior. Though they find this to be the case among youth in Chicago, this pattern did not hold for youth in Denver. Simcha-Fagan and Schwartz (1986) find that community organizational participation, a composite of factors meant to capture informal social control, at the neighborhood level decreased the likelihood of self-reported delinquency for youth across 12 neighborhoods in New York City. Sampson et al. (1997) find that increases in neighborhood levels of collective efficacy translated into decreases in individual perceptions of neighborhood violence and individual-level victimization risk.

In the end, a preponderance of empirical evidence shows that residents in adverse neighborhood conditions struggle to engage in the kinds of informal social control necessary to reduce crime such as organizing neighborhood watches, intervening when suspicious activity occurs, or making the police more accountable to resident needs. Concentrated disadvantage, racial segregation, and residential mobility are powerful forces that dampen the ability of neighborhoods to provide (in informal ways) rewards for conformity and punishments for deviance. In turn, neighborhoods with relatively low levels of informal social control, measured in a variety of ways as outlined above, are the kinds of places that experience relatively high levels of crime. Such contexts can translate into higher levels of offending and victimization risk among individuals.

Future Directions for Informal Social Control

As established above, social disorganization research has focused almost exclusively on what residents can do inside the neighborhood to address crime (Bellair 1997; Bursik and Grasmik 1993; Sampson and Groves 1989; Sampson et al. 1997; Warner and Rountree 1997). As such, high rates of neighborhood crime are viewed as largely a result of the inability of residents within a neighborhood to organize collectively against crime. But a growing body of criminology shows that the ability of a community to control crime is shaped profoundly by its relationship with local political and economic actors. Favorable ties to political and economic elites are thought to translate into the allocation of lucrative resources to improve local public spaces, increase police presence in a community, and speed-up city approval for resident-driven initiates related to crime control. This process is often termed public social control. Recall that Silver and Miller (2004) found that neighborhoods with strong ties to the police and local public officials have high levels of informal social control. As another example, Carr (2003) documents how informal social control efforts are facilitated when cities enact policies that reinforce these efforts. He describes that when Chicago implemented a community policing program, it provided the resources and support for residents to coordinate two crime control programs: (1) the Beltway Night Patrol, the neighborhood problem-solving group that orchestrated the closing down of a troublesome tavern, and (2) the Court Advocacy Program that organized residents to attend hearings and pressure local judges to hand down harsher penalties for residents charged with criminal/delinquent acts. This growing body of work offers evidence that external actors from outside the neighborhood can facilitate informal social control. Criminologists should further investigate the interplay between informal dynamics of social control with local political and economic entities. Doing so should help to make more central the idea that broader political and economic forces are consequential for the ability of residents to control crime.

The bulk of our understanding of the role of informal social control on neighborhood crime is cross-sectional and thus does not adequately take into account that the relationship between informal social control and neighborhood crime is likely multifaceted, non-recursive, and dynamic. Two issues are particularly important. First, cross-sectional research designs do not handle very well the possibility of reverse causality: crime possibly influences the ability of a community to exert informal social control. For instance, research finds that disorder and incivilities often go hand-in-hand with high-crime areas, and residents often view these conditions as troublesome and threatening (Skogan 1990; Taylor 1995). In particular, violence, disorder, and incivility correspond to a variety of negative emotions felt by residents – fear of victimization, mistrust of others, desire to move, and general dissatisfaction with the neighborhood – that fuel an unwillingness to intervene on behalf of the common good. In a study of neighborhoods across five cities, Skogan (1990) finds that disorder decreased neighborhood satisfaction, the percentage of residents who planned to stay in the neighborhood, and the percentage of residents reporting that neighbors help each other. As another example, Hipp (2009) finds that households that perceived more social and physical disorder reported lower levels of satisfaction with their neighborhood, especially in communities where residents perceived crime as a problem. Clearly, crime itself can be a disorganizing force that can impair informal social control. A handful of studies have found support for this claim with cross-sectional designs (Bellair 2000; Markowitz et al. 2006; Sampson et al. 1999). But without longitudinal data, these findings must be taken cautiously. Future research should utilize longitudinal data that allow for a more careful examination of the informal social control – crime relationship. Specifically, longitudinal data will allow for the assessment of the sequencing of the relationship between informal social control and crime. By better incorporating strategies for feedback processes among informal social control and crime, a more definitive assessment of this causal relationship can be established.

Second, cross-sectional data are not well suited for providing information on how informal social control evolves over time. But there is reason to believe that informal social control is a dynamic process that changes within a neighborhood over time as events take place, policies are enacted, new populations move in or leave the neighborhood, and crime fluctuates up or down. Work by Carr (2003) and Small (2002) is instructive here. Carr (2003) spent 5 years conducting field work in a working-class Chicago neighborhood (Beltway). He found that although traditional forms of informal social control were low such as the direct supervision of youth, a hybrid version called new parochialism had evolved partly because of the introduction of a community policing program. He argues that new parochialism is a set of strategies of ongoing informal social control that are enabled and stimulated by the actions of city officials. Successful implementation of informal social control, Carr finds, only happens when there is intervention by institutions and groups from outside the neighborhood. Carr suggests that such a complex process would not have been discovered if he had used a shorter time frame. Similarly, Small (2002) attempts to understand why community participation declined in Villa Victoria, a poor Puerto Rican housing project in Boston. He finds that the decline in local participation in the housing project was driven by changes in cohorts (different generations of residents) and not changes in structural conditions and that the most important of these changes was the transformation in the cultural categories through which the cohorts framed their neighborhood. In particular, Small (2002, p. 25) finds that the first generation of residents framed the neighborhood positively "as a success, something beautiful to cherish and preserve" and so were willingness to participate in local community activities that enhanced informal social control. In contrast, the younger generation of residents framed their neighborhood poorly as "physically dirty and deteriorating . . .above all, a ghetto" and were less compelled to participate in local community activities, hindering most efforts at informal social control (Small 2002, p. 25). Had Small (2002) taken a single snap shot of one time period, he would have concluded that participation was either high or low depending on the cohort under observation. But by taking the long view, he is able to map out the process by which a disadvantaged community goes from being an efficacious one to a marginalized and socially isolated one. Longitudinal designs are a critical strategy for incorporating the dynamic and evolving nature of informal social control and assessing how this dynamism is consequential for neighborhood crime or victimization risk.

In sum, crime rates tend to cluster in neighborhoods characterized by adverse conditions such as disadvantage, residential segregation, and mobility. To explain this pattern, the bulk of social disorganization research has focused on the roles of informal neighbor networks and their attendant social controls. Informal social control reflects the ability of local neighborhoods to *supervise* the behavior of their residents and the capacity of neighborhoods to *socialize* their residents conventionally. As such, informal social control is a process by which norm compliance is achieved. Since Shaw and McKay's (1942) early work, a majority of evidence shows the crime-controlling effect of informal social control. Neighborhoods with relatively high levels of informal social control are the kinds of places that enjoy relatively little crime and lower levels of offending among individuals. Put simply, the impact of informal social control in shaping neighborhood crime is "widely accepted" (Kubrin and Weitzer 2003, p. 376).

Overview

This entry addresses the role of information technology in shaping policing organizations and police practices. It is comprised of five parts. The first part is a brief overview of police and technology. The second part outlines types of technology in police organizations. The third part discusses current police innovations in information technology. The fourth sets out the problematic collocation of data in police organizations. The fifth part discusses the focus on the incident, the core of operational policing, and the ways in which it controls and shapes *how* whatever technology is available is used (or not). The entry concludes with some propositions that might guide future research. Overall, while there are abundant capacities based on information technology available, they are selectively used and patterned by traditional notions of the job and the occupational culture of the patrol division.

Introduction

Literature on technology and organizational change in management science, organizational theory, and social theory more generally reflects a long history of what has been called the "iron cage" thesis of Weber (Weber 1958: 181–182). In compact form, this states that rationality in its various forms drives and shapes all modern bureaux, and that this rationalization process, linked to capitalism, is inevitable, universal, and unidirectional. Implicit in this statement is the notion that organizations in their dance with rationality, forward and back, are much the same in their adaptive and environmentally sensitive maneuvers. This thesis remains a proposition, something of an assumption, such that research short circuits the general proposition and then proceeds to examine the extent to which it is true. Assuming the rational nonproblematic nature of the organization permits investigation of putative innovations in policing, corporate life, schools, and the military as if the rationality of these innovations and their success is merely a question of goodness of fit with the current practices within the organization. At the heart of this powerful assumptive assemblage is the role of technology, a sponge concept whose definition remains as elusive as any other of the treasured social science concepts on which we trade.

Inevitably, the introduction of technology into discussions of innovation always raises questions because technology is not a thing, but an imagined process and a product of practices. The term "imagined process" refers to the fact that technology is a *social object* that is created by actions directed toward it and responses that are made to these actions by those involved in the installation, maintenance, and use of such a social object. It is a collectively created and sustained matter with many facets. Granted that "technology" has a variety of connotations and is always embedded in an organizational structure, it can be succinctly summarized as the ways in which work is accomplished including both material and symbolic matters, the understanding of which is required to get this work done. "Technology" has a visible, material aspect (weight, shape, and size), a symbolic or representational aspect (it stands for something as shown in the actions of people who use it), a logic, as well as a range of connotative meanings – implied attitudes toward it and talk about its functions (Roberts and Grabowski 1996). What is rarely discussed (although see

Manning 2008) is the cognitive and imaginative work required to understand, fix, maintain, and use the technology routinely. The imaginative and cognitive aspects are situated and situational in their unfolding, and the workings of technologies, including information technologies, are best seen or revealed by looking at how people use them in key or *thematic situations* that are directly and indirectly relevant to their work tasks. *Technologies are situationally and contingently relevant*. Their use while in some sense is routinized is always touched off by a work-situation and in that sense is *occasioned*. This is true because information technologies, as noted above, are invisible in their interior workings, complex in their effects, not all of which are understood, appreciated, or anticipated, and viewed with some degree of mystification. Thus, it is important to keep an eye on what is out of sight – both within the machinery as well as in the minds and bodies of users. In addition, since whatever "technology" is introduced will often be in conflict with current practices, dialectic and associated technological dramas are inevitable (Manning 1992). Information technology (IT) in particular produces response and counter-responses which are attempts by those in power to stabilize the organization. The time frame of introduction and response to new technology will shape the types of responses the organization makes (Manning 1992, 2008). Technology is a plastic or sponge concept, one that soaks up meaning and reflects the meanings attributed to it. It could be said also that technology is a blank screen onto which ideas, hopes, and dreams can be projected. In this way, the ambiguity of technology and its far-reaching consequences make defining a "technological innovation" and evaluating its effects difficult (Byrne and Marx 2011). Finally, the technology of an organization speaks to the socially constructed environment, the *external realities*, in which the organization operates. The organization officially only knows what is recorded and officially sanctioned; bureaucracies are webs of secrets, and what is known is a function of the channels by which the information of interest is sought processed, encoded, stored, and retrieved. External realities, globalization, and political trends shape the framing of technology, how and when the technology is used. Technology also speaks to, and is shaped by, the *internal realities*, or the pattern of power in the organization.

The position adopted in this entry is that while technology may alter specific organizational processes, the null hypothesis should be that organizations shape and alter the impacts of technologies. Placing technology in organizational context as such requires also interrogating the matter of what is being "produced" and the related decision-making. The process reproduces the patterned and conventionally sanctioned deciding that takes place and into which the technology is slotted. Policing is in fact a process. Policing is a people-processing system, above all and in that sense alone cannot be judged by the criteria or standards of economic organizations with a product, a market, and conventional standards for judging "profit" and "loss." Certainly, "people work" is complex and daunting because of the roles and statuses of the people who are dealt with. Ostensively, their social class, gender, ethnicity, and occupational status are relevant to the incident at hand, regardless of the basis for the negotiation; the standards employed are flexible and situational as people morally are defined as ends in themselves, rather than merely tools of the trade. The assumption of technological rationality, that technology has exclusively positive, systematic, predictable, and endearing consequences, is untenable. The craft of policing, archaic as it may be, is predicated on managing the vagaries of the human condition.

Technologies have powerful and seductive appeal to police departments. Large departments in particular routinely acquire new technologies, the most central of which are variations on computer-based activities and analysis. Thus, *prima facie*, the topic of police technology or technologies used by the police is a topic of growing interest to scholars (Nunn 2001; Chan 2003; Chan et al. 2001; Manning 2008; Byrne and Marx 2011; Mastrofski and Willis 2010; Willis and Mastrofski 2011). Some reviews of technology in police organizations are benignly optimistic and naively hopeful, but conclude with rather disappointed summaries (Willis and Mastrofski 2011; Mastrofski and Willis 2010), while others are dystopian (Nunn 2001; Byrne and Marx 2011). But because these reviews are descriptive, accept generalizations about reported changes, for example, from LEMAS data of dubious credibility, and lack any theoretical framework, it is unclear what explains the absence of "innovation." The tendency in practitioner-law enforcement journals is to be benignly positive about all new technologies, absent any systematic evaluation. Chan (2003) critically and systematically reviewed technology in police organizations using a framework adopted from Bourdieu. She concluded in a balanced overview that not only are there negatives associated with increased technology, but that ironically, increased technology may exacerbate the problems of factual overload, noise, stored data of modest validity, and resistance to change among patrol officers. Manning's study of crime mapping and crime analysis in three cities concludes that little has changed in the routines and practices of police as a result (See also Willis and Mastrofski 2011).

Consider now, prior to review of the topic of police and technology, two fundamental ideas that should shape any research on policing as an organization. Egon Bittner, in many respects the theorist of record in regard policing, states at the beginning of his well-regarded classic, *The Functions of the Police in Modern Society* (1970): "The [function] of the police can't be understood by working down from broadly conceived programmatic idealizations." (p. 4), He continues, arguing that the task of his book is ". . . to elucidate the role of the police in modern American society by reviewing the exigencies located in the practical reality which give rise to police responses *and* [italics in the original – ed.] by attempting to relate the actual routines of responses to the moral aspirations of a democratic polity." (p. 5). By "programmatic idealizations," Bittner is referring to social theory of the Weberian sort, disconnected from the exigencies and routines of organizational life. This means in turn that technologies are situationally contingent and relevant, rather than concretely obvious in their functions, meanings, and uses. Insofar as it is possible, then this framework requires an examination of the relationships between technology and the police organization to be ethnographically rich and textured, and somewhat reticent to accept evidence that does not acknowledge this ground in the contingencies and routines of police work. This postulate is explored below. It would appear that technology has replaced craftwork as the domain means by which work is accomplished (Bittner 1983). An ideal technology would be one in which the worker was not required to have any knowledge or interest in the task, only to follow instructions (Bittner 1983: 254). This creates an everyday contradiction with the practice of policing. Police work, in contrast, is above all a craft, a craft rooted in the intuitive grasp of contingencies, demonstrating collective trust using shared routines to manage the endlessly problematic, and connecting the ethics of the work with craft-like standards. These standards are disconnected with the technological efficiency. Policing in many respects is based on a "reading" of local knowledge, subjective knowledge of persons and places, and nonstandardized ways of knowing and doing.

This entry has several parts. The first part is a brief overview of police and technology and outlines types of technology in police organizations. The second part outlines innovations in police technology. The third part discusses current police innovations in information technology. The fourth sets out the problematic collocation of data in police organizations. The fifth part discusses the cynosure of the incident, the core of operational policing, and the ways in which it controls and shapes *how* whatever technology is available is used (or not).

Police and Technology: An Overview

The notion that scientific or technological innovations in police organizations would fundamentally alter the nature of policing and, in turn, social security and safety is almost 100 years old. It was set out as a principle of policing by August Vollmer and has long been associated with "professional policing." The steady march of more efficient communicational devices, the telegraph, call box, radio and two-way radio, telephone and cell phone (with the numbers for reaching police as 911, 999, and 311 in addition to routine local numbers), computer, and mobile digital terminals, have had impact. All have reduced the "pass through or processing time" of requests for service, escalated demand for policing, and stimulated a variety of ways in which the police screen, set aside, delay, and otherwise manage demand that is sometimes, albeit rarely, overwhelming. On the other hand, the long history of innovations suggests the following: active and passive officer and civilian resistance to innovations; abundant short-term and abandoned nonevaluated projects; on the ground cynicism about the latest-soon-to-be-abandoned "new thing;" a devotion to the craft-like nature of the work; **and** a slow creeping intrusion of some technological innovations that build on already processed facts-as-knowledge. These changes are overlays or superficial elaborations upon the truculently guarded craft skills.

Nevertheless, let us step back and recognize that many technologies are in operation in policing, and some of them are quite new. In general, and without question, *the most obvious and salient "technology," or means of accomplishing police work tasks, is talk* – face to face verbal communication. This is the baseline "information-processing system". The efficacy of what might be called "tactical talk" has not been researched by social scientists. While most social science attention has been paid to information technology and its role in shaping the police organization and police practices, and that is the focus here, there are four other types of technology at work. It could be argued that *weapons technology* – both lethal and nonlethal – is understudied by social scientists. *Transportation technology* is also assumed to be gradually improving in some sense, but emphasis has been placed on speed, presence, and availability, rather than economy or environmental prudence. *Training technologies* are used in the academy. The core remains symbolic (shaming, harassing, conditioning, and rapid response to orders) and secondarily, lengthy lectures, "academic learning" about the law, diversity, interpersonal relations, and problem-solving, combined with rote learning and exams. Police are also adopting *sensory processing and extending technologies*, transformative devices, means to enhance the senses: sight, hearing, smell, taste, and touch. They include radar guns, listening devices, night sights, crime scene and accident scene technologies, DNA, CCTV, fingerprinting, and ballistics, as well as the breathalyzer (See Nunn 2001). Increasingly, police are adopting these sense-extending devices to monitor events and track ex-offenders and the general population (Nunn 2001; Byrne and Marx 2011). While these last named technologies decrease time spent on tasks, and increase reliability, they are dependent on the quality of the input and interpretation, usually scientific, to convert facts or data, placing it in a context, thus creating information. The primary interests of social scientists are in the *information technologies*. The central operating information technologies have expanded rapidly in the last 40 years since the introduction of 911 systems and computer-assisted dispatch (CAD). The primary systems are: records management system (internal matters such as employee records – payroll, attendance, leaves, and illness); jail booking system; criminal histories and offender identification; CAD data; mobile digital terminal (MDT) records; GIS; crime analysis and crime mapping; UCR/NIBRS, AFIS, NICS, data and links to the Internet, search engines, national databases such as NCIC, and the FBI's new (2012) N-Dex, a national data exchange system and website [**http://www.fbi.gov/about-us/cjis/n-dex**]. Also national are UCR/NIBRS, AFIS, NICS, and the FBI's various crime lists. Not all states participate in submitting data to these databases, the quality of data varies widely and is unaudited, and the lists are frequently redundant and contain useless or dated information (Geller and Morris 1992). The maxim is that the more the better, regardless of the quality of the input. It must be said that the use of cell phones, police-issued, multiple private phones, "personal assistants," "smart phones," and other private communication – computer devices, including handheld cameras, scanners, and in-car fax-machines and mapping capacities, for example – have not been researched and their impact on practices not well understood.

Recent Police Innovations

Technologically driven management-based innovations are sprinkled across the many departments in the USA and elsewhere but their effect is not known. Research with known results has been carried out briefly, in only a few cities, and has not been widely and consistently evaluated and diffused (Willis and Mastrofski 2011). Police departments are:

- Developing and publishing on accessible websites and in hard copies strategic plans, annual reports, mission statements, and the like. Organizations may submit and revise annually a policing plan with goals, objectives, and a broad mission statement. These are overwhelmingly focused on "crime" and based upon unaudited and unreviewed data generated by the departments or Constabularies themselves. In recent years, especially in the UK, these may be related to performance criteria for ranks and linked in turn to bonuses or other perks.
- Offering varied communication channels to and from the public. Websites now display descriptive materials, some data on calls for service or crime patterns, and hyperlinks to other websites. Often headlined is a current crime, wanted offender, or seasonal concern, for example, traffic and school closures for holidays. Some are appropriately mundane such as warnings about drinking and driving, congestion as a result of sporting events, community activities, and local holiday celebrations. Chan et al. suggest that these channels, including crime reporting, are growing in use in the UK, but they are limited for the same reason that reporting in general is sociologically constrained.
- Assembling more integrated databases and systems. This process may include linking software and geocoded databases and computer-assisted dispatching (CAD) data that facilitate crime analysis and crime mapping (Manning 2008).
- Managing tactical deployment including short-term efforts directed to manage known problems of crime or disorder or longer programs based on crime analysis. The rise of an experimental criminology devoted to controlled, randomized experiments focused on crime control has resulted in a number of such research projects in Boston, Jersey City, Lowell, Massachusetts, and St. Louis.
- Adopting tools for career-assessment of young officers while also monitoring complaints to identify high-risk officers and guide supervisors in their evaluation tasks.
- Supporting a modest research capacity. In part as a result of Community Oriented Policing Services agency (COPS) funding, growing political pressure to demonstrate and be seen as "efficient," and pressure to employ systematic and unrelenting "smart management," large departments now have a "research and development office." Many departments receive and manage state and federal grants. For the most part, the research units are in fact merely data entry and tabulation centers.
- Establishing public relations units with explicit policies, specialized, nonsworn personnel, equipment, and offices (Mawby 2002). These units and their spokes persons are increasingly sophisticated and well-funded and are designed not only to respond to queries but also to propagate "good news." They communicate with media and the public routinely, in a noncrime-focused as well as in a crisis modality.
- Arranging institutionalized communicational channels by which public can contact police, such as providing business cards, e-mail addresses, and voice mail for uniformed officers as well as sites by which police can contact villains, victims, or witnesses on a case by case basis. Some departments have introduced programs to target groups, neighborhood associations, corporations, and other governmental agencies (Mawby 2002). There has been a move toward more communication from the public to the police. These include

incompatible *channels of communication* that connect the public to the police and between units within the police department. Police use websites, e-mail, cell and land-based phones, "snail" mail, personal visits to stations, face to face encounters, network communication via fiber optic cables, paper documents, and "blogs." None of these data is assembled or checked for overlap, inconsistency, validity, or utility. Included and increasingly important are the social media. In particular, Facebook, YouTube, MySpace, Twitter, and variations on these are used by the Police Service of Northern Ireland, Greater Manchester Police (UK), and New York City Police Department. These can be used, of course proactively to solicit information as well as reactively to be in receipt of useful information.

- Organizing internal management-oriented meetings of a compstat-like character that involve presenting crime maps, recent trends in crime, quality of life issues, current problems of police interest such as gang activity, changes in drug use, or guns fired. These have become wide-spread but their functions and the depth of analysis presented varies. The relationship between these meetings and the drop in crime in New York City in the 1990s is now seen as problematic (Eterno and Silverman 2012).
- Presenting data routinely to public meetings, in some places required by law. As a part of political changes brought on by the Patten Report, PSNI officers are required to report in local districts patterns of crime and disorder. Similar meetings are also held regularly in Chicago.
- Linking with city governments and private corporations to monitor public areas via CCTV (Goold 2004). These may include parks, train stations, bus stations, airports, and harbors, as well as areas of the city deemed trouble spots. A few police departments have added the aural and visual monitoring equipment designed to detect shots fired in high crime areas (Mares and Blackburn 2012).
- Developing some information-based operational infrastructures. This includes transforming management information systems into networks linking electronically created and sustained databases; making these networks accessible wirelessly; as well as seeking integration of various nonlinked (typically) paper databases such as criminal records, juvenile records, CAD data, and social facts about neighborhoods (Dunworth et al. 2000).
- Increasing the number of nonsworn employees. Demands for service as well as management by objective approaches, crime analysis, and some augmented research capacity, has led to an increasing civilianization. The present composition of police departments shows about 27–30 % of their employees are civilians (LEMAS 2000 survey). This figure is some 5–7 % higher in the UK.
- Innovating in regard to thinking about crimes that are planned, politically imagined, and organized, and belief-based such as human trafficking, anti-terrorist, and homeland security programs mounted by the NYPD and other large departments. These are funded by massive infusions of money through federal and state-based grants.
- Introducing more systematic database access and storage for investigative work. These systems also include the possibility of exchange of information concerning crimes that have area-wide significance. Formalized systems are used in the UK, such as HOLMES and HOLMES 2; they provide a format for entering data on serious crimes and enable sharing of key facts and evidence (See website http://www.holmes2.com/holmes2/index.php).
- Engaging in networks of data internationally while developing dedicated systems for specialized crime and investigative work. For example, in the UK, the Serious Organised Crime Agency (SOCA), established in 2006 the Home Office, which operates within the UK and collaborates (through its network of international offices) with many foreign law enforcement and intelligence agencies (www.soca.gov.uk/). It is the result of the merger of the National Crime Squad, the National

Criminal Intelligence Service, the National Hi-Tech Crime Unit, the investigative and intelligence sections of HM Revenue and Customs that investigate serious drug trafficking, and the Immigration Service, and the Assets Recovery Agency.

- Linking data and analysis through the Internet. The FBI has a massive network of data including phone calls, e-mails, addresses, and other information that is available for police agencies, and is working on linking the many state agencies including police, corrections, and social services in this database. (N-Dex cited above). There are also planned databases in the UK centered at GCHQ to monitor all cell phone, e-mail, and web-use, while the UK national database of DNA data includes 3.4 samples, and the fingerprint database includes 5.5 million prints. There are large datasets based on number plate recognition in the UK, and these are used for enforcement, fines, and other penalties assessment. It is estimated that there are four million CCTV sites in the UK although research suggests they have limited value (Welsh and Farrington 2009). Some of these are monitored directly in police stations, for example, in Belfast, while others are either privately owned or owned by local authorities.

Each of these examples is built upon a core of information processing. The new information channels operate embedded in a structure, strategies, and values largely unchanged since the 1920s. As Chan et al. (2001: 113) have argued correctly, these new channels produce more work, more paperwork, and more data within organizations already awash with uncollated facts. The fantasy of efficiency of course has not been validated. There have been no structural changes, setting aside 911 and computer-assisted dispatch (itself a means), since the mid-nineteenth century when detective work was added. The rest are add-ons to the basic model developed by Sir Robert Peel prior to 1829 – the model featuring reactive, uniformed, visible, full time patrol. The pastiche that has resulted has not been systematically evaluated; that is, an evaluation that assessed the extent of integrated functioning with respect to clear and established criteria and valid and reliable data in one or more police organizations over time.

The Problematic Collocation of Police Data

While the term system is used to describe the information modalities within a police organization it is better seen as an *occasioned assemblage* based on "need to know" and patterned by use and power. While many police departments have acquired new information technologies, and most departments typically possess many, they remain fragmented and scattered throughout the organization even if electronic, scarcely used beyond daily needs, and marginal to the core of the job as seen by working officers. They serve many functions and are assumed to perform in connection with certain assumed rationalities. These rationalities, connecting ends and means, are incompatible in theory and are mediated and ignored in practice. It is not surprising that any given system or facet of the information system is so intertwined with others that it cannot be distinguished for research purposes. This makes evaluation very imprecise and narrow, while the impact of information technology is amplified throughout the organization and its practices.

Consider these features of current modern information systems in policing. As Bittner wrote (1970: 64), "... police departments accommodate a colossally complicated network of secret sharing combined with systematic information denial." A reflection of this, among other structural aspects of the craft, he also avers (1970: 65), correctly "... even the most advanced among our police departments are not anywhere near the objective of developing adequate information and storage retrieval systems." His point is that the majority of information known is seen as personal knowledge, not shared, may not even be written down, a product of a combination of individualism and defensive occupational solidarity (p. 65). If this position is definitive, and it is consistent with my fieldwork, whatever technology shapes and is used to enter, store and retrieve information, is a modest part of what is known.

The stated *capacity* to gather and process data quickly, to store them in an accessible and orderly fashion, and to develop vast fact-based files of fingerprints, criminal records, lab reports, arrest documents, and cases, most of which are still in written and printed form (or both), is considerable. There is vast storage capacity and it is increasing, but storage capacity and use are not calibrated. The growth in storage capacity absent access and use reveals the tendency within policing and perhaps other public agencies to acquire systems without clear standards or stated purposes, and without considering the complexity of creating usable, and simple modes of interface, collocation, and analysis. What is useful is not fact, but fact in a context or information.

While the systematic use of databases such as the Internet is growing and linked to trends in policing new forms of crime such as human trafficking, white collar and Internet-based crime, these are not connected within and between police departments, or done so unsuccessfully, for example, HOLMES. Individual cases crossing police boundaries are rarely connected and investigated systematically.

Given these databases and their related platforms, it is not surprising to find that numerous *software* systems exist (e.g., ArcView, for geocoded material; Pop TRAK, for monitoring problem-solving; specialized programs for workload management; many spread sheets for accounting and noncriminal records maintenance). Changes in software are seldom done well "in house" and when out-sourced, lead to confusion because training is not provided, new systems have new "bells and whistles," and the oral culture for actually using them well may not exist. A parallel matter is that when federal or state funding expires for a given software, it is abandoned in time because those who knew the routines were transferred or retired, and no one knows how to run it (Nesbary 2001).

Many inconsistent user and backside *technology interfaces* are in place. A large police department will house: several servers, diverse and uneven mainframe access and work-place terminals as well as Internet connections via fiber optic cables. These work-place terminals have varied and varying memory and memory capacity. Perhaps as a result of the ad hoc accretion of these via technologies, uneven and unplanned purchasing, the influence of grants, vendors, trends, and fads, and now abandoned failed innovations, police possess disparate information technology clusters. These are not additive or cumulative in their effects. Unlike technology-sensitive organizations, such as universities and corporations, they do not systematically and routinely, that is, every 2–3 years on a rotated basis, replace software, laptop, and desktop computers. The work stations are often acquired ad hoc and used by several officers over the course of a 24 h period of three or more shifts. Large departments have diverse work stations, running software of various generations (several versions of Microsoft) and a sprinkling of MACS and IBM clones that do not "speak" to each other. Research suggests that they are rarely and poorly utilized (Dunworth et al. 2000; Manning 2008); and data transfer, especially of large data sets, is awkward and flawed. A variety of limited and many nonlinked access points exist.

The Incident Cynosure and Police Beliefs

The ground of policing is the work of the patrol officer. Ideas about the what, why, and how of the work is surrounded by and protected by beliefs about it. *These beliefs are the most profound impediments to information-based technologically driven change*. These beliefs vary within and across the segments of the organization, among civilians and sworn officers, and probably vary by years of service and gender, but they underlie the powerful world view of the uniform patrol segment. They are in many respects the primary interface – where the organization's boundaries are maintained, expanded, or contracted over time – between the police and the public.

Consider the incident itself: a situated face to face encounter. This matter of some interest to the police may arise from an on-view matter; from a call to that unit or another; from a cell phone, or a decision to make a stop. These incidents, especially those of most public importance, are seen as perceived as distributed in time and space, as semi-autonomous and bounded, and have little if any connection except as they are clustered within an area. These are here and now moments, and the future alone can tell whether some level of crime or disorder will arise and have to be dealt with, but it is believed that without some action, things will get worse. Officers believe one cannot predict the occurrence of any given event as regards time, even given local knowledge of an area and its residents or habitués. A general policing proposition is: social life is odd; "things happen." The patrol culture and cops' stories, a vague set of configured resources, are loosely fitted to guide response to a given incident confronting an officer. The somewhat heroic yet quixotic world of the officer is always at risk from society's oddities. One might say, "society is what it is, and changes little." Correcting such lasting and troubling things as homelessness, mental illness, poverty, crime, and inequality are beyond the necessarily limited scope of policing, and of a given officer, and to some degree their causes and consequences are beyond the understanding of the average police officer. This is not a comment on intelligence or education, but seeing the "big picture" is regarded as a hindrance, and ignoring it a logical necessity, given the pressing, repeated, anomalous demands of police work. Policing is about practical, decisive action that minimizes the consequences of the visible and present here and now incident. Thus, ratiocination, reflection, and paperwork are secondary to "real police work." Details, abstractions, reflection, and cogitation may in fact impede accomplishing this work, extend the job, and add unnecessary complexity. This concern, the **defined incident**, is itself a flexible and elastic matter. Many events can be overlooked, ignored, or made irrelevant, but those in which the police intervene are truly multidimensional, could be handled in a number of ways, and as argued above, are governed by forces largely out of control of the officer. Once defined, the incident shapes the needed information: that which is accessible and useful in the incident at hand, and arrives "just in time" for use by an officer. The extent to which the incident extends to other matters is problematic and an information search, if undertaken, is guided by past success with the source, whether personal or technological in nature. Inquiries from patrol officers or investigators tend to be restricted to referring to or querying a handful of trusted (external) data sources: vehicle registration and driving licenses, outstanding warrants and/or criminal records, and other field stops. It follows, then, that the defined incident and its contours drive the nature, number, and types of records kept. It may not be written up, or may be dismissed by a number of routine modes of closing an open incident. Officers emphasize: "keeping up the numbers," "output," or showing what counts: processing calls, moving on quickly to the next, making the odd traffic stop and citation, and showing one is part of a team. This means, by extension, that some information will be passed on often verbally, about dogs, guns, dangerous alley ways, and "cock-ups" that are heard as cautionary tales. Always, the technologies and related information sources required or used are matters for the officer at the scene to best determine. The cynosure of the incident is combined with the notion that "you had to be there" and the reluctance of officers to judge others officers' decisions.

While there are technologies that actively circumscribe action – the mobile digital terminal in the car and the cell phone if used – the technologies used by officers are not used for the intrinsic merits ascribed by computer scientists, sociologists, or other experts; they are occasioned or used when an incident is fraught with rich and troubling potentialities. They are used as and when, by the needs of the moment, interpersonal trust, and a subtle assessment of the audiences to which the information might be presented. The imagined audience for the report, for example, a sergeant or a prosecutor, or internal affairs officer, shapes the written report. If the record associated with a technology is to serve the immediate situation, one's partner, citizens, and on-lookers, it may have a lower horizon than something written for management. If it is seen as having broader, media-based attention, it has a longer and more uncertain horizon of possibilities. How problems are defined, approached, managed, and disposed of is situational, governed by context, and what is seen as a resource shifts as contexts change.

The incident cynosure reduces the likelihood of open channels of communication between the public and the police. Consider these beliefs that are intimately related to patrol work. The focus on "doing something" shapes interactions with the public, and is based on a distrust of the public. Police are often lied to, misled, and subject to provocative dramas. They learn to keep some distance from what is said, make quick judgments, trust their "gut feelings" and learn from experience, and to honor the oral traditions of the job. The cloud of the media, their preoccupations and biases are misleading and public fears, insecurities, and concerns are generally inconsistent with police interpretations of these problems. They are obligated to act, as Bittner (1970: 40) writes, in *spite* of the citizens' natural attitude (Citizens' requests, definitions of solutions to the situation) about a possible solution. There is parsimony about the job and its craft. It is assumed that what is written is just enough and just in time to accomplish what the officer anticipates accomplishing, no more. This often limits radically additional comments, asides, observations, and other matters that might, if included, link this incident to others. Although it is most entrenched and honored in the patrol segment, the ideology of the power of the present and the incident is not restricted to the patrol segment. It is revealed in the focus of detective work on the case and its clearance, and the ideology of crisis management at the command level.

The Fundaments of Police Information Technology: Some Propositions

What are the *grounding fundamentals* of the police organization and of policing as a practice? One might argue that police organizations shape the uses of technology, that is, simple assumptions about the "what" and the "how" of policing – the basis for the craft, what is seen as "the job." In this sense, the rationality of the worker, poised between work control and rate-busting, persists and determines production, for example, the speed and quality of responses to calls for service, clearance of crimes, visits to schools and neighborhood meetings, clearance rates, and cold cases. In the same sense, technology in use, whether in the communications center, patrol, or investigation, produces pressures to speed up deciding. Operators are monitored by several means to coerce them to rapid processing of calls for service and for categorical "by the numbers" dispatching. Patrol officers are encouraged to "keep up their numbers," for example, running number plates, making traffic stops, and returning to service promptly (Meehan 1998). Detectives are pressured to "produce" clearances; they quickly focus on cases that can be cleared. Technology compresses deciding time and simplifies complexity. There is a "group think" aspect to deciding because the greater the time constraints on action, given ambiguity in technological human interaction, the greater the tendency for coping based on collective cues. Nevertheless, work fills the time available to do it. One aspect of this (Goffman 1959: 110–111) is "make work," activities that maintain the appearance of working, whatever the actual level of activity, as well as the appearance accuracy, involvement, pace, and personal interest. In every police department, detectives claim they are overloaded regardless of the workload; patrol officers complain of the same. As MDTs are installed in patrol cars, officers with patrols increase their inquiries to databases (Meehan 1998; Meehan and Ponder 2002), especially if they have a partner in the car. Police technologies stimulate and shape work *routines* which in turn shape roles (Goffman 1959: 16). The segments of the police organization, for example, top management, middle management, and the lower participants, tend to be loosely connected through occasioned routines. Management dicta flow down, but little information flows upward. Given this segmentation of the organization communication networks, technology has different meanings and functions when the police organization is in a crisis mode. The influx of information about a riot, a disaster, or a flood of calls for service may require changes in command authority (it moves up in emergency), resources available ("assets"), and tactical deployment. In an emergency mode, the organization communicates internally and externally quite differently, more quickly and with less reflection and anticipation of outcomes. Technology amplifies police communications in crises and emergencies and increases uncertainty (matters that cannot be answered factually and are contingent and contextual). Police organizations have more images, facts, and records than ever before. As the police organization increases its capacity to make short-term surveillances and interventions, it increases the use of "high tech"-based activities, for example, heavily armed and elaborately uniformed SWAT teams for relatively benign incidents. These encounters increase the chances for a mistake in judgment, a bad shooting, a false entry, a response to an exaggerated risk. As has been emphasized above, information technologies are variously rewarding to the officer. Those with features that decrease effort in respect to valued routines – checking data from traffic stops, running field stops, credit checks by detectives, ad hoc retrievals – are used and praised; those that are associated with unwanted efforts or disvalued routines, "paperwork," whether electronic, typed, or handwritten, are ignored, sabotaged, or seldom used. Uneven performance of the IT is frustrating and leads to reduced use of the technology. As Chan has shown (2001), skill and knowledge of the workings of information technologies is not randomly distributed within police departments. It is used for different purposes by the command, patrol, and investigative units; varies by age and gender; and increasingly is a source of social distance between young patrol officers and senior officers. When a form of IT violates the zone of indifference at the bottom, that is, when monitoring and surveillance are seen as "big brother" activities, the relevant IT will be sabotaged, damaged, turned off, or not used. It is resisted. This is seen in connection with audio and video monitoring in patrol cars, transponders, and GPS devices used to track the movements of unit (Meehan 1998). While technology strives for unity in the face of complexity, it separates content or "propriety" from efficiency (Bittner 1983: 258). As Bittner points out (1970: 55), policing is a means to deal with complexity and with exceptions or contradictions. Rules for organizing are bureaucratic and formalized, but cannot define when and how to intervene. Quality of response is less valued than pragmatic resolution of incidents.

The illusion of technological advance is made murky by those who use the technology, and define the utility of its apparent capacities. Bittner (1970: 64) states this succinctly "...police departments accommodate a colossally complicated network of secret sharing combined with systematic information denial." And later, in a phrase that no evidence has yet contradicted since he observed this pattern in the late 1960s (1970: 65): "... even the most advanced police departments are not anywhere near the objective of developing adequate information storage and retrieval systems. Even is present efforts to make modern electronic technology would succeed in coding existing information, this would not encompass the knowledge that is currently neither shared nor recorded." His point is that much knowledge is "local knowledge" gathered by officers and occasionally shared within the oral culture; that much knowledge is not recorded or written down in any form, and that this body of knowledge is more useful in practice than that which is seen as centralized, administrative, stored, and formatted (Brown and Brudney 2003). The reticence is in part ignorance and lack of training, in part due to the here and now incident focus; and in part due to a resistance to sharing information that might advance the career of a given officer. The working rules that govern policing include a set of contradictory themes in action – information is personal property of a kind to be guarded and protected; the most useful technologies are those that have visible, useful, local, immediate, and consequential properties: checking on driving licenses, insurance; ownership and registration of the vehicle, databases concerning previous stops, arrests, and criminal record of driver and passenger; watch your back and avoid close surveillance (Chan et al. 2001). These join other reliable and trustworthy technologies such as vehicles, weapons, and everyday tools of the job (logbooks, second gun, accident scene equipment, cell phones, and the radio-computer when help is needed). Those technologies seen as functioning to carry out surveillance, track and monitor (and perhaps to punish) workers such as in-car videos, sound recording capacities, and traffic stop records, are untrustworthy and might be sabotaged, turned off or on as need be in the situation, or used as self-protective devices in problematic circumstances.

Conclusion

The focus and implicit purpose of police technology is somehow to increase efficiency, or the level of resources, effort, and time required to accomplish a given task or set of tasks. Policing, however, is ill-suited to considerations of efficiency minimally, because it acts in a turbulent rapidly changing environment, responds to complex, problematic, human situations, and is "people work." It requires slack resources in anticipation of a complex, lasting, and engaging emergency, natural or man-made, such as a hurricane, earthquake, riot, terrorist attack, or power loss. Patrol officers, the front line and most powerful segment politically in the organization, spend more than 50 % of their time doing "nothing," driving around randomly (Famega 2005) and this is valued and lauded as the essence of police work, and much admired by the public. The emphasis in technological innovation has been upon time saving, yet the most fundamental waste of time is random, unfocused, and aimless patrol. The work, on the other hand, is viewed to some considerable degree as a sacred, representative entity rather than as an industry. It produces at best trust. It is not surprising, furthermore, that innovations in policing vary widely in their purpose, focus, cost, and utility, and that they are rarely evaluated internally. This ensemble of technological add-ons can only at best be an augmentation of the fundamental technology, interpersonal skills, verbal and nonverbal, that are the tools of policing everywhere. The ensemble also reflects the *competing rationalities* within a police organization: the focus on various ends such as crime, on crime prevention, public trust and respect – the mandate itself – or on means of policing, more patrol officers, more arrests, more partnerships, and better and faster equipment.

This review has set out types of technology and focused on the information technology-based innovations that have been most visible in the last 30 years or so that are typically called "technology." They are numerous. The framework presented here, a concern for practices that constitute the social objects that are considered technology, has identified how the data and information systems are loosely coupled within police organizations, rarely integrated, inconsistent in detail and format, varying as to content and form, and widely scattered in many locations. Thus, claims for capacity are misleading as they do not consider actual usage and outcomes of such utilization. The incident or case and how to handle it is the focal concern of policing; technologies that are seen as reducing paperwork, surveillance, time and energy, and supervisory intervention in entrepreneurship on the ground are valued.

On balance, the research on the impact of technology on police practices is thin and there is very little systematic evaluation of force-level impact available except the work of Chan in Australia. It is very likely, however, that the primary impacts are subtle, not directly affecting the work on the street or anything resembling "crime," but on the following: the speed and availability of response, given a call for service from a land line or cell phone; the availability of records for jail occupancy, arrests, field stops, CAD, and MDT inquiries for the previous year or so (others tend to be destroyed or stored); the skill of younger officers with various forms of e-communications, and the quality and quantity of internal communications, for example, e-mails.

The resistance to innovative thinking, for example, problem-solving (Brown and Brudney 2003) and the power of the patrol segment to define the nature of the job remain. The ways in which the lower participants work around, with, and innovate in their usage of, technology remain unexplored (see however, Meehan 1998; Meehan and Ponder 2002).

Criminal Cases Review Commission

Overview

Increased attention paid to wrongful convictions over the last quarter of the century has led to the formation by the state of permanent commissions that have powers to refer convictions back to the courts after ordinary appeals have been exhausted. The best known of these commissions is the Criminal Cases Review Commission (CCRC) of England and Wales. It was created by statute in 1995 and has been operating since 1997. Before its creation, it was necessary to convince an elected official and a member of the executive to refer a conviction back to the courts once appeals had been exhausted. Indeed, such petitions to the executive remain the norm in Europe and North America.

Commissions with powers to refer convictions back to the courts after appeals have been exhausted are sometimes called innocence commissions (Roach 2010a, b) because of their concern about the wrongful conviction of innocent people. At the same time, the criteria that various commissions apply in referring convictions back to courts depend on the precise form of their enabling statute. The CCRC, for example, applies criteria relating to the safety of the conviction that are used by appeal courts in England and Wales, and such criteria may not directly address the question of innocence (Naughton 2010).

The phrase "innocence commission" has been used to describe a wide variety of very different institutions including (1) self-appointed study commissions with an interest in systemic reform of the criminal justice system (Gould 2007), (2) volunteer civil society groups that investigate or advocate on behalf of the wrongfully convicted (Roberts and Weathered 2009), (3) temporary or permanent state-appointed inquiries into specific cases and/or systemic causes of wrongful convictions (Roach 2010a), and (4) permanent state-appointed commissions with a mandate to investigate claims of miscarriages of justices and to refer convictions in individual cases back to the court after ordinary appeals have been exhausted. This entry will focus only on the fourth category, namely, state-based commissions with a power to refer convictions back to the courts after the exhaustion of ordinary appeals.

This entry will examine the background of the formation and composition of various commissions. It will then examine the state of the art in the scholarship and identify areas of controversy within that scholarship. Finally, the entry will conclude with an examination of issues for future research.

Background

Most jurisdictions do not have independent commissions with powers to refer convictions back to the courts after appeals have been exhausted. The background of the creation and composition of the few commissions that operate at present will be reviewed in this section.

The Criminal Cases Review Commission

The pioneer of commissions is the Criminal Cases Review Commission (CCRC) created for England, Wales, and Northern Ireland in the Criminal Appeal Act of 1995 c. 35, s. 8. The CCRC was created following recommendations by two Royal Commissions and after successive applications had been made to the Home Secretary as an elected official to refer several suspected wrongful convictions in terrorist cases back to the court. In 1992, Lord May in his second report concerning one of many wrongful convictions in terrorism cases discovered in the late 1980s and early 1990s recommended that new independent machinery be established by statute that would have the power and resources to investigate cases of suspected miscarriages and refer them to the Court of Appeal (May 1992, 92ff). The next year, the Runciman Royal Commission on Criminal Justice made more elaborate recommendations for the creation of what was to become the CCRC. It recommended that the power to refer cases of suspected miscarriages of justice to the courts should be removed from the Home Secretary and be given to a body that was independent from the executive and the courts. The body would be composed of both lawyers and lay people and have the power to appoint police and others individuals such as forensic scientists to investigate cases of suspected miscarriages of justice. It contemplated that decisions made by the body would not be subject to appeal or judicial review, but that applicants whose cases were not referred to the courts could reapply to the commission (Runciman 1993).

Although there was much support for the creation of an independent commission to replace the role of the elected Home Secretary in referring convictions back to the Court of Appeal and this proposal was eventually put into effect by Parliament in the Criminal Appeal Act, 1995, c. 35, some reservations were expressed about the commission from the start. One reservation was a concern that the commission would be too closely tied to the Court of Appeal because the Court of Appeal would have the ultimate power to overturn the conviction. This concern was heightened by the fact that the Court of Appeal had expressed some reluctance to overturn convictions in the terrorism wrongful conviction cases that led to the creation of the CCRC in the first place. Concerns were also expressed that applicants would not have a hearing or even full disclosure before the CCRC and that the CCRC might have to rely on the police for investigations even though police misconduct had been a contributing cause of the wrongful convictions that had led to the creation of the CCRC in the first place. There were also concerns that the new body would not act as an advocate on behalf of the wrongfully convicted (Pattenden 1996: 407–408, 421; Thornton 1993). These concerns have all resurfaced in later scholarship critical of the CCRC (Naughton 2010).

In the Criminal Appeal Act of 1995, the CCRC was created as an independent body appointed by the Queen on the advice of the Prime Minister. It consists of at least 11 commissioners, one third of whom must be lawyers with 10 years of experience and two thirds of whom must have knowledge or experience of the justice system (Criminal Appeal Act 1995, c. 35, s. 8). The CCRC has subpoena powers, but only with respect to public bodies such as the police (Criminal Appeal Act 1995, c. 35, s. 17). It can appoint police officers when necessary to conduct investigations (Criminal Appeal Act 1995, c. 35, s. 19), although this is rarely done. More commonly, the CCRC relies on its own caseworkers as well as its ability to commission reports from experts (Criminal Appeal Act 1995, c. 35, s. 21).

The CCRC has the power to refer a conviction to the Court of Appeal where it considers that there is a "real possibility" that the conviction will not be upheld (Criminal Appeal Act 1995, c. 35, s. 13). The "real possibility" standard has been defined by the courts "as more than an outside chance or a bare possibility but which may be less than a probability or a likelihood or a racing certainty. The Commission must judge that there is at least a reasonable prospect of a conviction, if referred, not being upheld. The threshold test is carefully chosen: if the Commission were almost automatically to refer all but the most obviously threadbare cases, its function would be mechanical rather than judgmental and the Court of Appeal would be burdened with a mass of hopeless appeals; if, on the other hand, the Commission were not to refer any case unless it judged the applicant's prospect of success on appeal to be assured, the cases of some deserving applicants would not be referred to the Court and the beneficial object which the Commission was established to achieve would be to that extent defeated. The Commission is entrusted with the power and the duty to judge which cases cross the threshold and which do not" (R. *v*. *Criminal Cases Review Commission ex parte Pearson*, [1999] EWHC 452 at para 17 (Admin.) (Eng.)).

One commissioner can make a decision to reject an application, but three commissioners must agree to a referral to the Court of Appeal. The CCRC rejects over 95 % of the approximately 1,000 applications it receives each year (Walker and McCartney 2008: 198). The CCRC does not publicly release its decisions on whether or not to refer a case to the Court of Appeal, and it is an offense for the CCRC to disclose information it has collected except in relation to its own statutory functions or for purposes of criminal, civil, or disciplinary proceedings (Criminal Appeal Act 1995, c. 35, §§ 23–24).

The basis for a conclusion by the CCRC that a conviction should be referred to the Court of Appeal will generally be "an argument, or evidence," not raised in the proceedings, but a reference can be made in "exceptional circumstances" in other cases (Criminal Appeal Act 1995, c. 35, § 13). Originally, the accused was able to raise any ground of appeal once a case had been referred back to the courts by the CCRC, but this was amended in 2003 to only allow appeals on grounds certified by the CCRC or on other grounds where the Court of Appeal has granted leave (Criminal Appeal Act 1995, c. 35, § 14). The CCRC's reasons for making a referral are not released publicly, and it has a discretion not to refer a case even if the statutory requirement of a "real possibility" that the conviction will be not be sustained on appeal is satisfied. In one well-publicized case, the courts upheld the CCRC's decision not to refer a case to the Court of Appeal because the applicant had already received a posthumous pardon and compensation (*Westlake v. Criminal Cases Review Comm'n*, 2004 EWHC (Q.B.) 2779 (Admin)).

Despite having some lay representation, the CCRC ultimately makes its decisions on legal criteria relating to the hearings of appeals. The CCRC does not directly consider factual innocence and has referred cases back to the Court of Appeal on technical legal grounds relating to changes in the law and procedural irregularities (Elks 2008, Chap. 1; Naughton 2010).

As of May 31, 2012, the Court of Appeal had heard 461 referrals from the CCRC, quashing 324 convictions but upholding 137 cases (CCRC 2012). Although the CCRC is not a party in cases that it refers to the Court of Appeal, it has a 70 % success rate in the cases it refers to the Court of Appeal. The courts have generally been receptive to the role of the CCRC, but in some cases have expressed reservations about the CCRC's decisions to refer historical cases or cases where there was no new evidence to consider (Elks 2008).

Since its inception in 1997, the CCRC has completed a review of over 14,000 applications, but has referred only 503 cases (CCRC 2012). In other words, the CCRC has rejected just over 96 % of the applications it has received. The difference in cases referred by the CCRC and those decided by the Court of Appeal is explained by the delays in preparing and hearing the new appeals ordered by the CCRC. The cases that the CCRC has referred to the Court of Appeal and the convictions that have been quashed cover a wide range of cases, but only two cases in the first 10 years of the commission have been classified as DNA exonerations (Elks 2008: 83) of the type that often characterize exonerations in the United States, which are much more dominated by murder and sexual assault cases (Garrett 2011; Elks 2008).

The Scottish Criminal Cases Review Commission

There is a separate criminal case review commission for Scotland, which has a different legal system than the rest of the United Kingdom. The Scottish commission has nine members. Like the CCRC, they include both lawyers and lay representatives. The Scottish commission may refer a case back to the courts on the basis that a miscarriage of justice may have occurred and that it is in the interests of justice that the case be referred (Crime and Punishment (Scotland) Act 1997, c. 48, § 25). A miscarriage of justice is the sole ground of appeal in Scottish law. Thus, the Scottish commission, like the CCRC, essentially applies the test for a successful appeal when deciding whether to refer a case back to the courts.

The Scottish commission has broader investigative powers than the CCRC, which include the ability to obtain a judicial order to examine any person with relevant information under oath as well as to require production of relevant material from any person, not just public bodies as is the case for the CCRC (Elks 2008). As of July 2012, the commission had referred 111 of 1,489 completed applications since the start of its work in April 1999 (Scottish Criminal Cases Review Commission 2012). This referral rate of 8 % is considerably higher than the CCRC's. The High Court has allowed a successful appeal by the accused against either a conviction or sentence in 59 of these cases.

The Norwegian Criminal Cases Review Commission

In 2004, Norway established its own Criminal Cases Review Commission by an amendment of Chapter 27 of its Criminal Procedure Act. It can refer cases back to the court if new evidence or new circumstances may lead to an acquittal or a more lenient sentence or if an international court has determined that a conviction violates international law. It can also refer cases if a participant in the case such as a judge, prosecutor, juror, or witness has been convicted of a criminal offense in such a way that might affect an applicant's conviction or sentence. Unlike in the CCRC and the Scottish commission, the Norwegian commission refers cases for new trials as opposed to new appeals.

The commission has five permanent members, three of which must have law degrees. They are appointed by the King in Council and are assisted by investigating officers with legal and police backgrounds. The Norwegian commission may summon witnesses to appear before it and subpoena evidence. It also can, and frequently does, appoint expert witnesses. It can also hold formal hearings, though this has only been done in one case. Although the commission does the investigation, it can and does appoint lawyers to represent the applicant especially in complex cases or in cases where the applicant may not be guilty because of mental disorder. More recently, the commission also has the power to appoint lawyers to represent victims of sexual offenses who may be interviewed as a result of an application to the commission. The most common ground for reopening cases is evidence of mental disorder and that occurs in about 40 % of case where the commission sends the case back for a new trial (Stridbeck and Magnussen 2012). The cases reopened include not only crimes of violence including sexual offenses but also financial, drug, and minor offenses (Stridbeck and Magnussen 2012).

Except in its first years of operation when there were higher numbers, the commission receives about 150 applications each year. Since 2004, the commission has reviewed 1,045 cases and has reopened 120 or 11 % of the applications. The conviction was quashed in 80 % of reopened cases, and the sentence was reduced in another 14 % of cases, suggesting a higher success rate for the Norwegian applicant than is found in the other commissions.

The North Carolina Innocence Inquiry Commission

The first, and at the time of writing only, jurisdiction in North America to create a CCRC-type body was the state of North Carolina. In August 2006, legislation was enacted creating the North Carolina Innocence Inquiry Commission (NCIIC) to determine claims of factual innocence from living persons (N.C. Gen. Stat. §§ 15A–1460–75 (Supp 2006)). This legislation grew out of recommendations made by another body, the North Carolina Actual Innocence Commission, which was a self-appointed body chaired by Chief Justice Lake of the North Carolina Supreme Court. The legislation creating the NCIIC was originally subject to a 4-year sunset provision imposed by the legislature, but this has now been extended indefinitely.

The North Carolina Innocence Inquiry Commission (NCIIC) is composed of eight voting members appointed by the Chief Justices of the North Carolina Supreme Court and Court of Appeals. The membership of the NCIIC must include a superior court judge, a prosecuting attorney, a victim advocate, a defense attorney, a sheriff, a person who is not an attorney or employed by the judiciary, and two others (N.C. Gen. Stat. § 15A–1463).

Unlike the British, Scottish, and Norwegian commissions, the NCIIC is limited to claims of factual innocence, which are defined as "a claim on behalf of a living person convicted of a felony in the General Court of Justice of the State of North Carolina, asserting the complete innocence of any criminal responsibility for the felony for which the person was convicted and for any other reduced level of criminal responsibility relating to the crime, and for which there is some credible, verifiable evidence of innocence that has not previously been presented at trial or considered at a hearing granted through postconviction relief". (N.C. GEN. STAT. § 15A–1460.) Thus, unlike the other commissions examined above, the NCIIC is also precluded from considering applications on the behalf of deceased persons (N.C. GEN. STAT. § 14–1467(a)).

Like the commissions examined above, the NCIIC screens out most applications made to it, but also has extensive investigative powers that include the power to issue subpoenas and compel the attendance of witnesses (N.C. GEN. STAT. §§ 15A 1467(d)–(f)). The NCIIC can refer a case to the courts for review by a majority vote on the basis that there is "sufficient evidence of factual innocence to merit judicial review"; a unanimous decision is required if the convicted person pled guilty (N.C. GEN. STAT. § 15A–1468). This is a narrower standard than that used by the CCRC or the Scottish commission, which as discussed above can refer cases on the basis that they will be overturned on any existing legal standard for appeals, including miscarriages of justice that are not related to factual innocence.

The NCIIC has discretion whether to hold public hearings when it decides whether to refer a conviction back to the courts; however, if it does hold a hearing, the transcript of these hearings must be released in cases that are referred back to the courts. If a case is referred back to the courts, the case will be heard by a three-judge panel with no previous involvement in the case. The judicial panel can dismiss all charges on the basis of a unanimous decision that there is a clear and convincing case of innocence (N.C. GEN. STAT. § 15A–1469(h)). Both the decisions of the NCIIC and the three-judge panel are deemed to be final and not subject to appeal or judicial review (N.C. GEN. STAT. § 15A–1470(a)).

As of January 2012, the NCIIC had closed 953 applications of 1,102 applications since it started operating in 2007, effectively denying relief in all but four of these cases. The commission has held four formal hearings and referred three of those cases to the special three-judge panel. Of those cases, the special three-judge judicial panel concluded that factual innocence had been established in two of the three cases with one of the two successful cases resulting in the exoneration of two previously convicted persons. Thus, the North Carolina process has so far resulted in the judicial exoneration of three previously convicted persons on factual innocence grounds (North Carolina Innocence Inquiry Commission 2012).

State of the Art and Current Controversies in the Literature

There is a growing amount of scholarship on the commissions, and a number of themes and controversies can be identified.

Commissions are often seen as "inquisitorial" institutions that allow state-financed but independent persons to investigate claims of wrongful convictions. The exact extent to which a commission engages in proactive investigation or relies on the result of investigations by others is not known, but research conducted on the role of legal representatives for applicants before both the CCRC and the Scottish commission engages with some of these issues. A study has found that while about one third of applicants to the CCRC have legal representation, almost two thirds of the small number of applicants who are successful in the sense that the CCRC refers their case to the Court of Appeal have legal representation (Hodgson and Horne 2009). This finding reveals only a correlation between legal representation and success in the form of a referral and might be inconclusive given the fact that applicants with stronger cases might be more likely to attract legal representation. Nevertheless, the qualitative part of this research revealed a number of cases where legal representatives for the applicant were able to change initial decisions made by the CCRC to dismiss the application. This suggests that lawyers can have a determinative effect in some cases, especially those in which the CCRC reverses its initial decision not to refer a case (Hodgson and Horne 2009).

A study of applications made to the Scottish commission from 2007 to 2009 found that the applicant was represented in 155 applications and unrepresented in 99 applications and that applicants with representation fared better at each stage of the proceedings before the commission (Scottish Criminal Cases Review Commission 2010: 19). The problem of whether this measures a simple correlation between strong cases of miscarriages of justice and representation is not resolved in this research (Scottish Criminal Cases Review Commission 2010). The Norwegian commission also encourages representation of applicants in more serious cases, again complicating the idea that commissions are purely inquisitorial institutions (Stridbeck and Magnussen 2012). More research is needed into how the commissions operate and the role that representatives play in determining the strength of applications made to the commissions.

Much of the literature on the CCRC has from the start focused on its relation with the Court of Appeal. From the creation of the CCRC, commentators have raised concerns that it will be too dependent on the relevant tests used by the Court of Appeal to accept new evidence and to quash convictions (Nobles and Schiff 2001, 2005). More recent literature in this regard has argued that the CCRC is not truly independent because of its reliance on the Court of Appeal and that it is not concerned enough about factual innocence (Naughton 2010). These arguments have not gone unchallenged in the literature, and others have argued that the Court of Appeal's rejection of a significant number of referrals by the CCRC and its occasional criticisms of the CCRC referrals demonstrates that the CCRC is not captive of the Court of Appeal (Zellick 2006). As discussed above, the Court of Appeal quashes convictions in about 70 % of cases referred by the commission. The controversy in the literature over whether commissions are or should be independent from the legal system is likely to continue. Michael Zander, however, had made the important point that "some of these criticisms of the CCRC... could perhaps with more justice be directed at the Court of Appeal" (Zander 2010: xviii). Future research into commissions should not be conducted in isolation but rather should study how commissions interact with other parts of the justice system.

A common feature of all four commissions reviewed above is that they reject the vast majority of applications that they receive. Concerns have been expressed with respect to the CCRC that "many failed applicants are now voicing their dissatisfaction with the paucity of reasons given for the Commission's refusal to refer their case" (Walker and McCartney 2008: 198). There is a need for more research about why applications are rejected and the response of the rejected applicants. Such research will contribute to better understanding of whether commissions enhance the legitimacy of criminal justice systems by admitting of the possibility of error or whether they may actually increase dissatisfaction with the justice systems among those convicted of offenses and other affected persons including crime victims.

The Runciman commission contemplated that the CCRC would be well placed to make recommendations on the basis of its cases about how to prevent wrongful convictions in the future (Runciman 1993: 185). Other commentators have made similar predictions (Findlay 2009). Some research suggests, however, that the annual reports of the CCRC have failed to address issues such as the regulation of forensic experts and the use of anonymous witnesses that may increase the risk of wrongful convictions and have instead focused on matters that affect the case review process including feedback it has received from the Court of Appeal and budgetary matters (Roach 2010a, b). This research also suggests that there may be a tension between a commission's quasi-judicial role in deciding whether a conviction merits referral back to the court and less impartial advocacy for systemic reforms. This research found that the CCRC intervened in matters of legislation before Parliament only once and more from the perspective of how a proposed narrowing of the grounds of appeal would affect the commission's own work and has stayed silent with respect to other legislative initiatives that arguably have increased the risk of wrongful convictions.

Other research has also found a decrease in press coverage of wrongful convictions since the creation of the commission (Mason 2010). This suggests that the CCRC may have bureaucratized and regularized miscarriages of justice. Before the creation of the CCRC, extensive media campaigns had often proven necessary to convince the Home Secretary as an elected official to refer convictions back to the court, whereas this power is now exercised by the independent CCRC. The media campaigns previously designed to persuade the Home Secretary created a sense of crisis that some commentators observed undermined the criminal justice system's legitimacy (Nobles and Schiff 2001).

Much can be gained by comparing the profiles of cases referred by a commission to the courts to the profile of wrongful convictions addressed without a commission. Britain has opted for a state-financed error correction model which has enjoyed considerable success both in processing large numbers of applications and in referring close to 500 cases back to the Court of Appeal. A striking feature of these cases is that two thirds are non-homicide cases and only two cases in the first 10 years apparently involved DNA (Elks 2008: 184). This profile of cases can be contrasted with those found in the United States where DNA evidence plays a much larger role and most exonerations have involved homicide/sexual assault cases. Much work remains to be done in comparing the profile of reversed convictions generated by publicly subsidized commissions with those produced by the volunteer work of innocence projects and lawyers, who may quite understandably focus on the most serious cases, and those in which it is easiest to find new evidence to overturn a conviction. Such research should examine the interactions and frequent tensions between volunteer innocence projects and commissions that are not limited to work for the factually innocent (Roberts and Weathered 2009; Naughton 2010). Such research also poses questions about the larger purposes of the criminal justice system and the influence that increased concerns about the conviction of the factually innocent have on the traditional law and politics of criminal justice systems normally focused on crime control and due process (Findlay 2009).

Future Directions for Research

The issue of the relationship between commissions and the courts to which they refer cases is likely to continue to command scholarly attention. The present state of the literature has focused on competing viewpoints about whether the CCRC is sufficiently independent of the Court of Appeal. Perhaps a more productive approach would be to identify particular areas where Court of Appeal decisions have presented obstacles to possible referrals. This could expand scholarship beyond the commissions themselves to the courts and their receptivity to the idea that convictions should be quashed after ordinary appeals have been exhausted.

Commissions in all jurisdictions reject the vast majority of applications made to them, and there is a dearth of research on these rejected applications. Relevant questions are whether the applications are frivolous and should be screened out or whether they provide an important safety valve in the system. Qualitative and quantitative research about the attitudes of unsuccessful and successful applicants to the process would be promising. Another question is whether the jurisdiction of the CCRC and the Scottish commission over sentences as well as convictions should be retained or whether the focus should be more squarely placed on wrongful convictions.

There is a continued need to conduct research on the proper definition and approach to wrongful convictions. Arguments have recently been made that the CCRC is not concerned enough with factual innocence (Naughton 2010). The existence of the North Carolina commission that is limited to factual innocence claims provides a fascinating natural experiment; some early comparisons suggest that the North Carolina process may overturn fewer convictions than under the broader approaches used in the England and Scotland (Sangha et al. 2010: 351–356). Although all the commissions decide not to refer the vast majority of applications that they receive back to the courts, the North Carolina commission refers an even smaller percentage of its applicants back to the courts, and this may be related to the difficulties of establishing factual innocence on clear and convincing evidence (Roach 2012). Research comparing North Carolina's factual innocence commission with other commissions will also engage with broader questions about the purposes of the criminal justice system.

Comparative research between jurisdictions that have commissions and between jurisdictions that do not have commissions is promising. So far, much of this research has compared England and the United States; it demonstrates how most American states (except North Carolina) have been reluctant to create commissions and instead have committed resources to extensive but frequently futile habeas corpus review (Griffin 2001, 2009). Comparative research should not just focus on commissions but take into consideration other aspects of the criminal justice system that may make it easier or more difficult to reverse convictions (Griffin 2009). There is a need to expand the universe of countries that are the subject of comparative review especially to include countries with both adversary common law backgrounds and those from more inquisitorial systems (Roach 2010b).

Other research based on a natural experiment approach could compare the profile of convictions that are overturned as a result of a commission process as opposed to the profile of cases that are overturned in jurisdictions that do not have commissions such as Australia, Canada, most of Europe, and most of the United States. One hypothesis that finds some support in the case profiles of convictions overturned after referral by the CCRC (see Elks 2008) is that commissions are more likely to overturn convictions in non-murder and sexual assault cases than those that occur in jurisdictions without a commission. Jurisdictions that rely on volunteer lawyers and innocence projects and that do not have publicly funded commissions may understandably prioritize murder and DNA cases over less serious cases where the accused is less likely to be subject to long-term imprisonment and where it may be more difficult to find new evidence to undermine the conviction. More research also needs to be done on the subsets of cases referred by commissions. Almost a quarter of the CCRC's referrals are in sexual cases (Griffin 2009: 123; Elks 2008, Chap. 9), and this high referral rate may in part be related to the CCRC's powers and practice of reviewing victim compensation and other claims for post-conviction statements that can impeach the complainant's credibility (Griffin 2009: 124). This raises the question of whether different standards are applied in different types of cases.

The different commissions that now exist should be compared on a number of grounds relating to issues such as the transparency of their processes. The CCRC in particular may be less open than the North Carolina commission. The investigative powers and resources of each commission can be compared with an eye to determining the optimal model for commissions that may be created in new jurisdictions. Similarly, the composition of each commission can be compared as can their engagement with systemic reform that attempts to prevent wrongful convictions in the future.

Another area of future research that should be pursued is whether the existence of a commission bureaucratizes miscarriages of justice. The routine work of those who process and reject the vast amount of applications sent to the commissions needs to be examined. The relation between commissions and civil society groups that advocate on behalf of the factually innocent and also with the media needs to be examined. At the same time, the ability of commissions to act proactively, for example, where the practices of a particular police force or expert witness have come into question, needs to be carefully examined. In such cases, commissions may not necessarily wait for applications but could conduct proactive audits (Roach 2010b).

Conclusion

Commissions with the power to refer convictions back to the courts after appeals have been exhausted have emerged as interesting and innovative new criminal justice institutions in a number of jurisdictions. Much of the first generation of scholarship on these commissions has undertaken the necessary steps of describing the basic composition and operation of each commission. The next generation of scholarship should use the work of commissions as a window into wrongful convictions and into the larger purposes of the criminal justice system.

One research priority should be to compare the profiles of convictions reversed as a part of a state-financed commission process and those that are reversed by the efforts of innocence projects and other volunteers. These cases can be compared with each other and with the systems of petitioning the executive to reopen convictions that are still used in most American and European states. In general, the next generation of research and scholarship on commissions should focus on situating commissions in the larger context of the criminal justice system.

Overview

The UK Cox Report on creativity in business (HM Treasury 2005: 2) identifies three key interlinked terms:

"Creativity" is the generation of new ideas – either new ways of looking at existing problems or of seeing new opportunities, perhaps by exploiting emerging technologies or changes in markets.

"Innovation" is the successful exploitation of new ideas. It is the process that carries them through to new products, new services, new ways of running the business, or even new ways of doing business.

"Design" is what links creativity and innovation. It shapes ideas to become practical and attractive propositions for users or customers. Design may be described as creativity deployed to a specific end.

Innovation, creativity, and design of course occur not just in the scientific and technological domains but also in the social, institutional, economic, environmental, commercial, and legal domains. And the business in question could be a criminal enterprise, whether run by a lone, casual thief or the Camorra. Design is covered in Entry "▶ Designing Products Against Crime" of this encyclopedia; this entry focuses on innovation and creativity.

Why should criminologists and crime scientists be interested in these concepts? Simply put, there is a dynamic such that innovation regulates both the quantity and the quality of crime opportunities and crime reduction solutions. Examples are given of obsolescent crimes and the process whereby they become obsolete. The metaphor of co-evolution or arms race between offender and preventer is found helpful in understanding the dynamic. It is noted that the consequence of this insight is the relative unhelpfulness for understanding crime trends of statistics of recorded crime, since the same crime label is attached to crimes whose nature and method has changed with the profile of presenting opportunities. The crime drop experienced throughout the Western world in the last decade of the twentieth century is interpreted in terms of a temporary advantage enjoyed by preventers, notably via enhanced security of motor vehicles. The integration is advocated of this understanding into the crime reduction enterprise and into the strategy and tactics that follow.

The scope of this entry encompasses three strands of thought. First, innovation may be taken to refer to deliberate changes in economic, technological, and social arrangements in society. These in turn change the supply of opportunities and wider opportunity structures

(Clarke and Newman 2006) for crime and/or influence the prevalence of precipitating factors such as prompts and provocations (Wortley 2008 and [this encyclopedia]). Second, innovation may be taken to refer to changes in offenders' repertoire and application of resources (Ekblom and Tilley 2000), organizational and business models, tactics and strategies for committing crime, and actively *generating* opportunities. Third, it may be taken to refer to counterpart changes in crime reduction. Clearly, the three strands are yoked together, with the first opening avenues in the second and requiring responsive changes in the third, which will in turn reverberate back on the others.

Fundamentals

Obsolescence

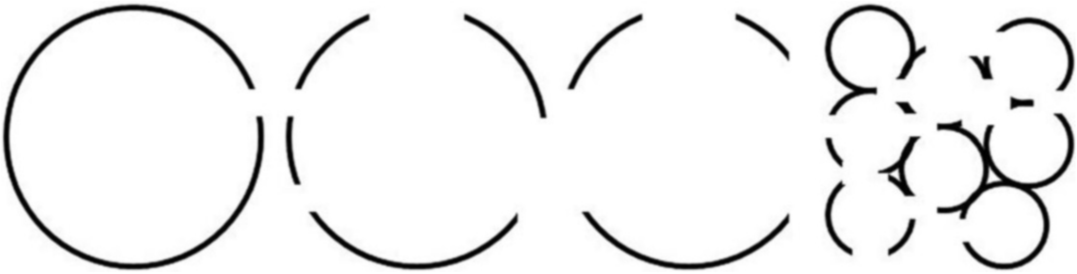
Given that criminals have a finite amount of time available to offend, new methods and targets of crime must drive out some of the old. Dermot Walsh, in an early attempt to describe the "obsolescence of crime forms" (Walsh 1994), distinguished a number of reasons for crime obsolescence (the classification given here is slightly reworked from the original). They were:

1. Legal abolition: legislative changes in permissible sexual behavior represent the most obvious examples here, with the decriminalization of suicide, eavesdropping, and challenging to fight affording more arcane examples.
2. Court action: Walsh is properly skeptical that claimed effects of court action were real, with the closest to an example he found persuasive being the decline of garrotting (strangling with cord or wire) following the passage of the Garrotters Act (1863) which enabled exemplary sentences. This instance is of course vulnerable to the criticism that legislators, acting when things are at their worst, are condemned to success by the operation of regression to the mean (Campbell 1969; Ekblom and Pease 1995).
3. Changes in Police and Forensic Science: "Forensic science has been most notably successful in thwarting the crime of poisoning. This has been accomplished through the techniques of small sample identification, and through co-ordinated knowledge, which meant that there ceased to be such a thing as an unknown poison" (p. 152).
4. Economic change: Walsh identifies the shift in transport from horses to cars as making crimes concerned with the market in horses obsolescent. Because of his focus, he omits to mention the corresponding rise in crimes linked to motor vehicles. Safebreaking was deemed a casualty of control of explosives and increased surveillability. The diminished need for companies to keep cash on the premises to pay wages could also have been mentioned.
5. Social change: A less censorious attitude to sexual proclivities and adventures was taken to reduce the scope for offences like blackmail, as well as to the decriminalization of some sexual acts, as mentioned above.
6. Population density: More contentiously, Walsh claims that increased population density "unfavourably affects the prospects for the commission of some crimes, for example bribery of voters or nomad-related crimes" (p. 154).

While one may not agree with all Walsh's conclusions, his work is a useful first review of the association between innovation, social change, and crime.

Innovation and Crime Statistics

The dynamic of innovation and desuetude has, as a little-acknowledged consequence, the relative meaninglessness of some aspects of aggregated crime statistics. This is because the practical actions which constitute offences with the same legal label have changed. At the simplest level, the targets of "theft" have changed from, say, pocket watches in the nineteenth century to mobile phones in the twentieth century. More subtly, for example, at one point in time, the offence of "unlawful abstraction of electricity," originally associated with consumers getting free energy by bypassing the point at which the electricity supply was metered, had to be used



Innovation and Crime Prevention, Fig. 1 Schematic representation of opportunities in terms of obviousness and effort

to prosecute some early instances of computer hacking. This thereby illustrates innovation not only by criminals but also by the crime control authorities, faced as they were with agile offenders on the one hand and arthritic legislative responsiveness on the other. The recorded crime landscape likewise changed with the advent of one-to-very-many digital communication, where the techniques of fraud and pedophilic grooming are adjusted almost beyond recognition. With these changes have come huge increases in the number of potential victims (which of us has not received online invitations to profit in exchange for helping to release a bequest held in a foreign bank?) and the scope for joint offending, with illegal encounters being arranged from the comfort of one's home.

Innovation and Criminal Opportunity

While "criminal opportunity" is normally considered solely as a property of the *situation*, in reality (Ekblom 2011), it is an ecological concept, co-generated by the resources of the *offender* to exploit the vulnerabilities, gain the rewards, and handle crime preventers. An open window three floors up is only an opportunity to an offender equipped with courage, agility, and a ladder. One important kind of resource for innovation is J.J. Gibson's concept of *affordance* (Gibson 1979), the ability of some offender (say) to perceive opportunity and utility as they go about their environment (in a terrorist context, see Taylor and Currie 2012).

To take things further, Clarke and Harris (1992) distinguish between criminals who are opportunity *takers* and those who are opportunity *makers*. This concept is best described graphically in Fig. 1, which schematically shows a range of opportunities. At the left end is the perceptually obvious and logistically simple – an easy chance to steal an unattended laptop from a library desk, say. Moving towards the right, the shape of the opportunity becomes progressively less distinct, and progressively more causal preconditions for success have to be actively created by the offender (copy the key, time the guard patrols, prepare an excuse for being in the factory at the weekend. . .). Here, ingenuity is required to thread the crime technique between tricky multiple constraints and manufacture/exploit numerous simultaneous or sequential opportunity factors. At the far right, it is not even clear *which* if anything is the opportunity in question – what possible desired criminal event can be made to happen from what manipulable causes. Quite easy opportunities could be hidden in this tangle of possible conjunctions if only they could be discerned. One can think of talented entrepreneurs spotting a gap in the market that nobody else has. And the difference can also be noted between "regular earners" – criminal techniques that once invented continue to deliver for some time – and spectacular "silver bullets" that can only ever be used once, as with the 9/11 terror attack, where retrospective preventive action ensures opportunities are never the same again.

One presumes that, as in honest walks of life, there are more creative and less creative criminals. Studies of the former are rare although the issue is dealt with (Cropley et al. 2010) (Gamman and Raein 2010), who draw interesting psychological parallels between criminals, designers, and artists (in terms, e.g., of dyslexia). Whatever the proportion of creatives, the dissemination tools of the modern age enable the less well endowed to pick their brains (and indeed their locks – a quick check on Google reveals many lock-picking sites and even a lock-pickers' T-shirt!).

In the Industrial Revolution, the advent of machine tools was a bellwether of the "evolution of evolvability." A possible machine tool for the next generation of skilled offenders is the 3D printer which can manufacture realistic and effective scanning ports to be attached to the card slots of cash machines or reproduce high security handcuff keys. Another is the "script kiddie" – computer virus-making kits readily available to empower Internet criminals lacking their own expert knowledge to write the source code themselves. In today's open-source, open innovation (Chesbrough 2003) society, turning the clock back to an era of tools restricted to expert use or confined to professional guilds cannot be envisaged. Preventive interventions have to be put together which have a reasonably long effective life despite criminals' knowledge of their limitations and vulnerabilities and despite attempts to create countermeasures. The key strategic question then becomes one of how it might be possible to reduce the innovative capacity of offenders while building it up with preventers and/or designers.

A consideration of what is truly innovative serves as a counterpoint to the above comments on the flux-concealing nature of crime statistics. The UK government Foresight project "Cyber Trust and Crime Prevention" (Collins and Mansell 2004) wrestled with the issue of whether there were ever truly novel kinds of crimes – introduced in that case due to the arrival of the cyber world – or merely familiar techniques in new guises. Was online "phishing," for example, something entirely novel or merely the latest variant of a familiar "social engineering" con trick designed to extract personal details from an unsuspecting victim? In most cases the novelty is at the level of technical detail, but at a certain level of abstraction, the "crime script" (Cornish 1994) – the organized sequence of actions necessary to prepare, undertake the crime, cover tracks, and handle the proceeds – is similar. Following on from this, it may be helpful to systematically document changes in the nature and volume of modus operandi or perpetrator techniques over time to complement the numbers falling into given legal offence categories.

Offender Versus Preventer: Co-evolution and Arms Races

Change always presents new crime opportunities, which in turn call forth new preventive responses. There are usually three stages linking new products, and new ways of doing things, with crime. They are:

1. Innovation without considering the crime consequences
2. Reaping the crime harvest
3. Retrofitting a solution, usually partial

This sequence has been common. The Penny Black postage stamp was introduced in 1840 and withdrawn in 1841. This is because it was canceled by red franking ink, which in 1840 was water soluble, leading people to wash the franking ink off and reuse the stamp. The Penny Black was replaced by the Penny Red, canceled by black ink, which could not be washed off. Similar sequences are universally evident, most recently seen in mobile phones and laptop computers, where the mass manufacture of small, anonymous, valuable items, and the complexities surrounding numbers used for their unique identification, meant that they became a target for robbers and in thefts from cars. The magnetic stripe on credit cards was secure until thieves discovered techniques for "skimming," where data from the stripe on one card is copied without the cardholder's knowledge and placed on another card (to be combined with the cardholder's PIN number, obtained, e.g., by "shoulder surfing" in the cash machine queue). When silver mining opened up in California, silver was cast into conveniently sized ingots for transport to the East. These were stolen en route, despite protection by guards. The thefts ceased when the metal was cast in the largest available cannon ball mold. This was conveyed East on unprotected wagons without further problem (Lingenfelter 1986). Pocket watches were fastened to one's waistcoat by a rigid circular eye around the winder. This was a boon for cutpurses, who could simply snap the rigid eye and make off with the watch. The design response to this involved making the circular eye swivel, rendering it extremely difficult to steal and providing an interesting example of "target softening." Daguerreotype photographs can apparently be dated by this change.

The coin clipping example is particularly interesting because of its historical associations, namely, that Sir Isaac Newton was Warden of the Royal Mint when recoinage occurred. So the sequence was as above, first with smooth-edged (hammered) coins susceptible to clipping, the inevitable clipping problems, and replacement by milled edge coins whose well-defined perimeter apparently solved the initial problem. On his first morning at the Mint, Newton had to take an oath that:

> You shall swear that you will not reveal or discover to any person or persons whatsoever the new invention of rounding the money and making the edges of them with letters or graining or either of them directly or indirectly, so help you God. (White 1998 [229])

Unfortunately, the replacement coins were melted down and sold abroad as bullion because the metal commanded a higher price than the value of the coin set by the Treasury. Thieves were also inducing people to give up their old coins at unfavorable rates, then exchanging the old coins for new. Newton instituted official exchange mechanisms, and the recoinage eventually succeeded, but it illustrates that solutions to one crime are themselves untested innovations and can reap crime harvests of their own if not well thought through. It also illustrates the iterative nature of innovation, whether by criminals or crime preventers, because human ingenuity and social complexity (Chapman 2004) hinder getting things right first time and usually engender unforeseen consequences in what may be a "complex adaptive system" of diverse agents, each pursuing their own agendas in response to, or in anticipation of, the actions of the others.

A recent example of the neglect-harvest-retrofit sequence is the story of the Europrofile lock. This form of lock is almost ubiquitous in more recently built homes (or older homes with replacement doors) in Western Europe. In time, burglars realized that it could be easily overcome by the use of a wrench or a hammer and screwdriver. Once the protruding elliptical face of the lock is removed, the door will open. This form of attack is depicted through You Tube (another innovation making for communication with the effect of reducing the period between design and crime harvest). The increasing use of the technique in burglary led to the design of hardware devices to make disabling Europrofile locks more difficult.

Arguably the best metaphor for the dynamic linking innovation of crime is that of an arms race or the process of coevolution (Ekblom 1997, 1999). Offenders, over shorter or longer timescales, adapt their methods of attack to circumvent current preventive measures. They do so in several ways:

- Making tactical countermoves in situ – spraying quick-setting foam in car alarm speakers to deaden the sound.
- Turning crime prevention devices to their own advantage – antishoplifting mirrors work both ways; communal CCTV in blocks of flats has been misused by residents to spot which neighbors are going out, prior to burgling their flat.
- Turning designer themselves and developing tools – perhaps doing sophisticated reverse engineering of locks to understand and defeat the mechanisms of protection.

Preventers in their turn readjust by creating new devices or employing new methods of defense. The offenders then make further countermoves, and the process spirals on indefinitely. Safebreaking was one of the examples used by Dermot Walsh to illustrate obsolescent crime. The evolutionary struggle between safe manufacturer and safebreaker was described in more detail by Neil Shover (Shover 1996). The safebreaker, erstwhile skilled artisan of the crime business, is now an endangered species if not extinct.

Shover's story of the safe design and breaking "arms race" can be taken up in the mid-nineteenth century. By the turn of that century, safe cracker skills had required safe designers to turn to manganese steel in safe manufacture by dint of its resistance to drilling and fire. The spread of the oxyacetylene torch left even safes so constructed vulnerable to attack. The next countermove involved the development of laminated safes with alternate layers of manganese steel and copper, the better to conduct heat away from the point of attack. With safecracking by torches effectively rendered obsolete, offender attention switched to the locks, developing techniques to exploit vulnerabilities (sometimes analyzed by "reverse engineering" – careful dismantling of legitimately purchased mechanisms to see how they worked and how to overcome them). In some cases specialist tools to extract an entire lock became favored. After World War II, carbide and diamond-tipped drill bits briefly rendered the safe walls vulnerable again, forcing manufacturers to develop new laminates, on which most drill bits shatter. The production of ever-more sophisticated intrusion alarm systems placed time pressure on the safebreaker. Thieves who were unable to acquire expensive electronic equipment and specialist expertise to defeat the alarms had to give up safecracking. In a parallel development, electronic banking meant that many companies kept little in safes, so there were usually slim pickings for the endangered safebreaker species who had recently invested heavily in specialist equipment (overspecialization to best exploit what turns out to be a temporary niche or opportunity is a classic route to biological extinction).

But any such "victory" by one or other side remains forever provisional and precarious. Some new technology, for example, could appear which again tips the scales the other way. Like the frog which has evolved an enzyme which currently manages to protect its skin against fungal attack, society's currently functioning security measures may be just one or two "mutations" of criminal ideas away from susceptibility. And there are some grounds for pessimism here. To continue with a biological parallel, coevolution between pathogen and host, or predator and prey, has been likened to the Red Queen's Game, from *Alice through the Looking Glass* – you have to keep running just to stay on the same spot (Ekblom 2005; Schneier 2012). Worse, Schneier maintains that criminals have a natural advantage because they can usually come up with innovations faster than society can invent and deploy theirs; he also refers (p. 229) to von Clausewitz' nineteenth century military concept of the "position of the interior," wherein defenders have to protect against every possible attack, while the attackers just have to find one vulnerability in the defenses.

The rate of obsolescence will depend on the kinds of offenders involved and their resources and the kinds of social and technological changes that occur. And the rate of change is constantly accelerating. This means that the "breathing space," which society gets from a new preventive method before it is bypassed, is tending to diminish. In the face of this, Cohen, Vila, and Machalek wrote in 1995 that "contemporary crime control policies are hopelessly static" (p216).

Implications for Crime Control

If the arms race/coevolution characterization of the relationship between innovation and crime is accepted, there are a number of implications for how would-be crime preventers should act. The first thing is to address the pessimist position just stated. One could take the arms race to mean that coming up with new preventive measures is ultimately futile because, in time, criminals will inevitably find a way to defeat them. At the *tactical* level, many crime prevention approaches are undoubtedly a wasting asset (although this applies over a rather longer timescale than conventional displacement). Nevertheless, they cannot be abandoned. The long term can only ever be influenced via a succession of actions in the short term provided they are intelligently concerted. Led by responses to the rapidity of changes in criminal targets and techniques within the information and communications technology

(ICT) world, it is fair to say that the "hopelessly static" critique of 1995 no longer fully applies, though there is still far to go.

Viewed *strategically*, it must be accepted that crime reduction is *not* about individual innovations and their sometimes limited shelf life; it *is* about maintaining a dynamic imbalance between creativity and innovation by preventers and that by offenders.

In an earlier paper (Ekblom 1997), it was argued that those responsible for developing crime prevention policy and practice have to recognize the time-limited nature of security products and procedures and learn to cope with innovative, adaptive offenders, changing opportunities for crime and arms races by *gearing up* to become innovative and adaptive ourselves. (The concept of developing and building innovative capacity among preventive designers and crime prevention practitioners more generally is further considered in Entry "▶ Designing Products Against Crime" in this encyclopedia.) Strategies for gearing up include:

- Exploiting new technology for prevention (Ekblom 2005).
- Avoiding rigidity – where crime changes but the installed security system cannot.
- Encouraging variety (in contrast to the "Europrofile" lock – crack one, crack all).
- Basing the generation of *plausible* variety (i.e., that which has a good chance of working) on some combination of tested theoretical principles, research into what works at the level of detailed practical methods, and "think thief" imagination; here, integrated theoretical models such as the Conjunction of Criminal Opportunity Framework (Ekblom 2010, 2011) and design frameworks such as the Security Function Framework (Ekblom 2012) can help, where simple slogan-type frameworks hinder the creativity and innovation needed to customize specific interventions to crime problem, evidence of what works, and context.
- More generally getting crime prevention practitioners of all backgrounds and responsibilities to "draw on design" in generating good quality interventions with a strong chance of being cost-effective, practically implementable and acceptable, durable, and devoid of undesirable side effects; interventions which address the messy and complex nature of the constraints and requirements in crime prevention and the not unrelated prevalence of "implementation failure" in rolling out mass crime prevention programs.
- Designing products, places, procedures, and systems to performance standards rather than fixed technical specifications – enhancing "design freedom."
- Studying offender resources (Ekblom and Tilley 2000), current and future, to aid anticipation of what the product and its owner or guardian is up against (resources may be tools, as with a bolt cutter for defeating a bike chain; skills, such as deft movements for pickpocketing a music player, or more cognitive and social ones, such as intimidation or distraction techniques; more systematically professional preventers can consult or prepare "technology roadmaps" to get an idea of upcoming tools for attack).
- Making "attack testing" the default position in relation to the security of new products.
- Undertaking future proofing – whether of products (Armitage 2012) or even of laws (as with new drugs designed to circumvent too-specific proscriptions in law, by alteration of some nonfunctional part of the molecule – the answer here being to describe such drugs generically or even by their mechanism).
- Creating "pipelines" of new security arrangements to deploy as soon as current ones fail (as with satellite TV revenue-protection encoders, which have the rare advantage of immediate, "broadcastable" transmission of security upgrades to all users; with the increasing tendency to pervasive computing and networking, or "chips and wifi with everything," this strategy may become progressively more available to protect all kinds of property, though one can expect offenders to find ways to misuse the facility).

The above strategies center on crime preventers outracing offenders by innovation of their own or heading them off by anticipation. But, like Dick Dastardly in the *Wacky Races* cartoons covertly tying an anchor behind competitors' vehicles, it may be possible to thwart offenders by actively disrupting their innovative capacity. In effect, this could be done by turning all that is known about supporting legitimate enterprise and innovation into reverse or sowing uncertainty and distrust to reduce the level of networking that enables open innovation-type sharing of knowledge and other resources among offenders. Needless to say, this can only be done by subtle design and continuous response to feedback, because it is simultaneously necessary to avoid disrupting legitimate business.

Innovation and the Crime Drop: A Key Issue

The image of the crime/crime prevention struggle as a process of coevolution is consistent with one account of the crime drop which has characterized the Western world in the last decade of the twentieth and the first decade of the twenty-first centuries. Because the trend is common across nations, it cannot be the result of (divergent) national policies. The account with which it is consistent is the security hypothesis, still modestly characterized as an hypothesis despite its greater plausibility than its rival accounts. The hypothesis (Clarke and Newman 2006) is that change in the quantity and quality of security was a key driver of the crime drop:

> the one thing in common amongst all these countries, including the United States, is that they have all made a huge investment in security during the past 25 years, affecting almost every aspect of everyday life (p. 220).

Jan van Dijk and colleagues (van Dijk et al. 2007) independently reached the same conclusion:

> Perhaps a more significant factor inhibiting crime across the Western world is the universal growth in the possession and use of private security measures by households and companies over the past few decades. ICVS [International Crime Victimization Survey] -based trend data on the use of precautionary measures confirm that in all Western countries, without exception, the use of measures to prevent property crimes such as car thefts and household burglaries has risen drastically over the past 15 years (p. 23).

From evidence relating to vehicle theft in two countries, it was concluded that electronic immobilizers and central locking were particularly effective. It is suggested that reduced car theft may have induced drops in other crime including violence. Rival accounts, including demographic or economic change, better policing, gun legislation, the death penalty, lead levels in blood, and crack cocaine use, have all been subject to doubt after empirical analysis (Farrell et al. 2008; 2011). These authors point out that previous analyses focused on crimes of violence. They thereby failed the "phone theft test." They cannot therefore parsimoniously explain why many crime types fell in the 1990s while others including phone theft and e-crimes increased. They note the (inverse) coincidence of vehicle theft and security measures. Other trends, for example, in temporary relative to permanent theft, age of vehicle taken, and method of entry, yielded a "signature" consistent with the security hypothesis. Graham Farrell and his colleagues plausibly extend their vehicle crime analysis to other crime types, seeing car theft as a debut crime for young offenders and vehicle availability being the facilitator for many other crime types.

Overview

What began as a monograph aimed at accounting for the excessively high rate of violent crime in the United States (Messner and Rosenfeld 1994), Messner and Rosenfeld's *institutional anomie theory* (IAT), an identity provided by Chamlin and Cochran (1995), is perhaps the quintessential sociological theory of crime among the more recently minted theoretical approaches over the past two or three decades. The theory is a purely macro-social theory of crime and is in fact a cross-national theory of crime stressing the interplay of social structural and cultural feature of modern nation-states as the ultimate cause of crime. The entry below traces the origins of the theory, describes the theory in detail, reviews the empirical work testing key propositions of the theory, and discusses current controversies surrounding the development of the theory.

In 1994, Messner and Rosenfeld published their book entitled Crime and the American Dream where they first introduced their conceptualization of anomie.

Building on the work of Durkheim, Merton, and others (or building upon the Mertonian paradigm), Messner and Rosenfeld proposed the institutional anomie theory (hereafter, IAT) arguing that anomie is derived from the interplay between the culture and social organization of a society. Their theory shifts the focus away from Merton's development of individualized strain theory and toward the expansion and reformulation/clarification of the macro-level relationships articulated by Merton throughout his career. Thus far, empirical support for IAT has been mixed. The purpose of this entry is to describe Messner and Rosenfeld's institutional anomie theory and its theoretical underpinnings, review the empirical support for this theory, and discuss some of the controversies in the literature surrounding this theory as well as the policy implications derived from this theoretical perspective.

Origins of the Theory

Messner and Rosenfeld draw heavily upon the works of Emile Durkheim and Robert K. Merton to lay the foundation for their theory. Durkheim first introduced his concept of anomie in the late 1800s when he was describing the division of labor in societies as they transformed from the simple mechanical societies to the more complex organic societies of today. Durkheim noted that as societies become more complex and increase in size and density, the division of labor becomes more specialized and the capacity of societies to regulate behaviors weakens. Durkheim was not particularly concerned with explaining crime rates, but rather sought to explain conditions of deregulation or normlessness, which he termed "anomy" that he felt led to various forms of deviant behavior.

Durkheim believed that humans had insatiable desires and it was the responsibility of society to provide the appropriate restraints. Durkheim thought, "human activity naturally aspires beyond assignable limits and sets itself unattainable limits" (Durkheim 1951: 247). Durkheim proposed that in mechanical societies, the society exercised a relatively high degree of control over individuals. In societies undergoing rapid change, such as those evolving toward organic societies, this degree of regulation or control was weakened. In these situations, society loses the ability to regulate man's aspirations, and they can escalate beyond their abilities to fulfill them. If man's desires exceed his ability to satisfy them, then he will be in a state of anomie (Durkheim 1951: 246). Therefore, Durkheim was proposing that both the type and occurrence of deviance (including crime) is tied to changes in social conditions. Durkheim also described other situations where a society might lose its ability to regulate individual goals and therefore might lead to increases in anomie, including those of both economic prosperity and economic distress.

Merton, setting out to explain the relatively high crime rates present in the United States, attributes his initial ideas to the writings of Durkheim. While Merton borrowed the concept of anomie from Durkheim, he greatly expanded its meaning and proposed a slightly different interpretation. Merton's concept of anomie differed from Durkheim's in several important ways. First, Merton believed that it was society, not man's innate desires or human nature, that ascribed man's aspirations. Merton and later theorists recognized that American society was uniquely different from other societies. He believed that the distinctive feature of American society was its emphasis on what has been termed the "American Dream." He contended that American society placed an overemphasis/exaggerated emphasis on monetary success. As a result, all citizens are taught that success is measured by the achievement of monetary or material goals. Therefore, it is the society, not a biological drive, that provides man's aspirations. Society is also responsible for prescribing the acceptable means of achieving these cultural goals. Merton (1938) refers to these methods as the institutional norms. The institutional norms emphasized in America include means that are primarily based on what is referred to as the "Protestant work ethic." These include education, hard work, perseverance, etc. A balanced society, Merton contended, is one in which there is an equal emphasis or a balance between the cultural goals and the institutionalized means of achieving these goals (1957: 134). In such a society, utilizing these means should in and of themselves provide citizens with success or a sense of achievement. Further, in such a society, there would be a variety of values through which citizens could achieve/obtain culturally validated virtue or worth (Kornhauser 1978: 162).

In American, however, there is an overemphasis on the goals to the detriment of the means, setting up an environment where the achievement of the goals (winning) is more important than the process (playing the game) (Merton 1938). It is this disjunction between the goals and the means that Merton referred to as anomie. American society is, therefore, an imbalanced culture (Kornhauser 1978; Merton 1938). Kornhauser (1978: 163) points out that our culture is imbalanced because it does not provide a "sufficient variety of values whose achievement carries public recognition of moral worth." In American society it is the accumulation of wealth that is correlated with the moral values of stability, hard work, thrift, discipline, ambition, diligence, etc. (Kornhauser 1978: 165). In other words, achievement of the monetary goal affirms the existence of these other virtues. A balanced society would provide other ways to demonstrate these virtues. As Kornhauser points out in our society, there are no rewards for "hero of production" or "heroine mother of the year" (Kornhauser 1978: 163). In addition, Merton maintained that citizens are also taught to believe that this universal cultural goal is available to all and prescribes the acceptable means of achieving these goals. In reality, this is not the case. He believed that the availability of the institutional means varies by social class and is not equally available to all. In particular, the institutionalized means are restricted to those in the lower class structures. As Kornhauser (1978: 165) describes when items such as a "diploma, job title and bank account provide the only public insignia of moral worth, large numbers of people are shut out of the moral community defined by these achievements."

Although Merton proposes a variety of methods in which individuals can adapt to this strain or the inability to achieve the culturally prescribed goals through the institutionalized means, his theory is most useful in explaining utilitarian, profit-motivated crimes. Individuals who engage in these types of criminal behaviors, termed innovators, are simply utilizing the most efficient means available to them to achieve the universally accepted cultural goals. Individuals who engage in this type of criminal behavior accept and believe in the culturally induced goals. In fact, it is society that has pressured them into engaging in this type of conduct, by limiting their access to the institutionalized means of achieving these goals. Merton's proposed theory was, therefore, a theory of societal anomie. Bernard (1987: 268) simplifies Merton's cultural argument to the following propositions:

1. "The value attached to the goal of monetary success varies in different cultures and
2. At a cross-cultural level, variations in the value attached to monetary success are positively related to rate of utilitarian, profit-oriented criminal activity."

Institutional Anomie Theory

It is upon this foundation that Messner and Rosenfeld developed their version of anomie theory. Much like Merton, they developed their theory to explain the disproportionately high crime rates in America compared to other countries. Also similar to Merton, Messner and Rosenfeld believe that America places a high value on monetary success. However, they expand upon this idea by proposing that American society is unique in its emphasis on the cultural values embraced in the "American Dream." According to Messner and Rosenfeld, the cultural ethos of the American Dream refers not only to the goal of material and monetary success but also to the ideal that this goal can be pursued by everyone under conditions of open and individual competition (Rosenfeld and Messener 1995). This high level of crime coupled with a strong belief in the American Dream is termed "American exceptionalism" by Messner & Rosenfeld (2005).

The American Dream as envisioned by Messner and Rosenfeld embodies four fundamental value orientations: (1) individualism, (2) universalism, (3) achievement, and (4) materialism. Individualism is a highly prized value that stresses not only individual rights and freedoms but also the belief that individuals should be self-reliant and that success or achievement is individually accomplished.

Universalism is the belief that all individuals, regardless of their social class and background belief, are encouraged to aspire to the goal of monetary success. These two values combined underscore the belief that with hard work, anyone has the ability to succeed. Achievement stresses the importance of this success. One is ultimately judged by the achievements he or she has accumulated. Success in America is defined by the accumulation of monetary rewards. This belief that money is the ultimate reward in our society is the value of materialism. These four values together promote what has been referred to as the Horatio Alger ideal of rags to riches.

Embracement of the American Dream has had a number of benefits for the United States leading to an expanding economy, technological innovation, and social mobility (Messner and Rosenfeld 2007: 8). However, this value orientation, along with the capitalist economy present in the United States, also operates to influence citizens toward the unrestrained pursuit of materialistic and monetary goals. It is both the exceptionally high crime rates, along with the strong emphasis on the American Dream that sets the United States apart from other nations.

However, these cultural values in and of themselves are not what lead to exceptionally high rates of serious crime. IAT theory postulates that it is the interaction between culture and the social structure that leads to crime. The social institutions highlighted by Messner and Rosenfeld include the economy, polity, family, and educational system. These institutions assist societies in (1) adapting to the environment, (2) mobilizing and deploying resources for the achievement of collective goals, and (3) socializing members to accept society's fundamental normative patterns (Messner and Rosenfeld 2007: 72).

Each of these social institutions assists with one or more of these goals. For example, the economy, in its responsibility for the production and distribution of goods, helps in the adaptation to the environment. The family assists in propagating society and in caring and socializing the children. The political system is responsible for protecting members of society as well as mobilizing the resources to assist in attaining the normative goals. The education system not only helps to prepare members of society for assuming adult roles but also shares responsibility with the family to socialize society's youth. The relationship between these institutions is both dependent and antagonistic. For a harmonious society to exist, these institutions must cooperate with one another. For example, the economy is reliant on both the family and the educational system to produce quality citizens who will make efficient and effective workers. On the other hand, they are in competition with each other for resources and value orientations.

This interplay between these social institutions is crucial to IAT. One of the central assumptions of IAT is that a dominant economy coupled with weakened controls from the other social institutions in society produces a state of anomie conducive to serious crime. Economic dominance is expressed in a number of ways. First, the role of noneconomic social institutions is devalued in comparison to the economy.

For example, the role of the educational system in imparting knowledge is devalued, as the system is more valued for its role in training future workers. The second way this is expressed is by accommodation of economic norms by other institutions. This is exemplified by the family sacrificing family time for the sake of work schedules. Finally, economic values penetrate these other domains. For example, Messner and Rosenfeld point to terms such as "accountability" and "consumer-driven classroom" as evidence of the penetration of economic values into the educational system.

When the institutional balance of power is skewed, these noneconomic institutions are weakened in terms of their ability to regulate social behavior. When the economy is dominant, this can lead to crime by both stimulating anomie and by simultaneously weakening the organizational controls associated with the noneconomic institutions. IAT not only predicts anomic offenses when the institutional imbalance of power is in favor of the economy but also predicts criminal behavior in situations of imbalance. For example, corruption is expected to result in situations where the polity is the dominant institution. Likewise, "crimes in defense of the moral order" result in situations where family or religion dominates (Messner and Rosenfeld 2001). In sum, anomie results from "a strong cultural emphasis on ends over means" that is not guided by a strong moral foundation (Rosenfeld and Messner 1997: 214). In this type of situation, the type of means selected, including criminal behavior, is dependent on a cost-benefit or utilitarian analysis. Consequently, a society where the economy is dominant and the culture is anomic is expected to also have high crime rates, particularly serious and utilitarian or instrumental offenses.

Messner and Rosenfeld expanded upon Durkheim and Merton's concept of anomie by both refocusing on the macro-level causes of anomie and by examining the connections between the cultural ethos of the American Dream and the interrelationships among social institutions (Rosenfeld and Messener 1995). In more recent iterations of their theory, they have discussed how IAT explains the racial and gender distribution of crime. For instance, they suggest that females are less involved in criminal behavior because of their greater investment in noneconomic institutions such as the family as well as gender differences in value orientations (Messner and Rosenfeld 2007). In contrast, Messner and Rosenfeld argue that African-American investments are different with struggling attachments and alienation from the major institutions in our society.

Policy Implications

The policy implications derived from this theory are typically outside of the control of the criminal justice system. For instance, one way that societies can mitigate the influence of a dominant economy is by reducing its citizen's reliance on the market economy for their well-being. This is typically accomplished by welfare policies such as unemployment, social security, and health insurance. These policies help to restore the institutional balance of power as well as protecting individuals from market fluctuations (Batton and Jensen 2002).

IAT theory also suggests more complex initiatives that would be difficult and that many might be unwilling to undertake. Because the source of high crime rates lies within the tenets of the American Dream, reducing crime significantly would necessitate rethinking the basic tenets of the dream – many of which are responsible for the innovation and success that is often considered uniquely American. Likewise, crime would be reduced if we strengthened the noneconomic institutions in our society. Messner and Rosenfeld, for example, suggest strengthening the family by promoting initiatives such as paid family leave, flexible work schedules, and employer-provided child care (2007: 112). The primary criminal justice reform associated with IAT theory is to reduce our reliance on mass incarceration and to promote effective prisoner reentry programs (for a thorough discussion of this issue, see Rosenfeld and Messner 2010).

State of the Art (Empirical Tests of IAT)

While IAT theory is relatively new to the field, there have been a number of empirical tests conducted to determine the efficacy of the theory. These studies have primarily focused on examining the impact of the institutional balance of power between the social institutions and its effect on crime rates. Comprehensive and frequent investigations are most likely hampered by the methodological difficulties involving both the measurement of and collection of empirical data on the key concepts in the theory.

One of the first tests of IAT's main propositions was conducted by Chamlin and Cochran (1995). They examined 50 states in the USA to determine the impact of institutional imbalance on property crimes. They utilized the percentage of families below poverty level as their measure of absolute economic deprivation. In addition, they included measure for the polity, family, and religion. They examined the institutional balance by testing interactions between their poverty measure and measures for the church, family, and polity. They found all of these interactions to affect property crime rates in the directions predicted by the theory. They found that in the presence of strong noneconomic institutions, the influence of poverty on property crime was lowest. With one exception (family disruption), they also found that these results held up when they utilized alternate measure of income inequality in place of poverty rate.

Piquero and Piquero (1998) also examined property and violent crime rates using cross-sectional data from the United States. They also measured the strength of the economy by the percentage of persons below the poverty level. They likewise measured the strength of the polity (percent receiving public aid and percent voting in presidential election), education system (proportion of population enrolled full time in college, percentage of high school dropouts, teacher's salary relative to the average pay), and the family (percent of single parent). They explored whether the strength of these institutions moderated the effect of the economy on crime while varying their operationalization of the key concepts. They found mixed support for the theory. The percentage of persons in college (education) and the percentage receiving welfare (polity) decreased both property and violent crime rates. Also consistent with the theory, the percentage of the population below the poverty level (economy) and the percentage of single-family homes (family) increased both types of crimes. When examining the interactions, they found the cross-product term of economy and education to be significantly related to crime rates. Specifically, when more persons were enrolled full time in college, the economy had its weakest influence on property crimes and violent offenses. Similarly, the interaction between the economy and the polity significantly influenced the violent crime rate. However, when they utilized alternative measures for these concepts, the results were not replicated. They concluded that such tests of the theory are sensitive to the operationalizations of the key concepts.

In 2003, Maume and Lee predicted homicide rates in US counties with populations of 100,000 or greater. They examined the influence income inequality (economy), voter turnout for presidential elections (polity), the average educational expenditure per person (education), rates of divorce (family), and rates of adherence to civically engaged religious dominations (religion). One of their primary focuses was on determining the exact nature of the relationship between the economy and non-economy institutions on crime rates. Specifically, they tested whether noneconomic institutions mediated or moderated the influence of the economy on homicide rates. They also disaggregated homicide rates to predict both instrumental and expressive homicides. They found the economy to be a strong predictor of both types of homicides. In their analysis they found more support for the notion that noneconomic institutions mediated the relationship between income inequality and homicide. They found only limited support for the notion that they moderated this relationship as only the level of welfare expenditures interacted with income inequality.

Kim and Pridemore (2005b) advanced the literature by examining the utility of IAT theory in explaining homicide rates in 78 regions in transitional Russia. They measured the strength of the economy using a ratio of the top 20 % of income to the bottom 20 %. They also examined the impact of socioeconomic change on homicide. They only found limited support for direct effects on crime and no indication that the noneconomic institutions of the polity, education, or family interacted with change to affect crime. When they substituted their socioeconomic measure for the change measure and then looked at absolute deprivation (population below poverty line), their findings remained the same. Therefore, in this setting, social institutions did not help ameliorate the effects of poverty and social change on violence.

Schoepfer and Piquero (2006) expanded the discussion to examine the efficacy of IAT theory in predicting embezzlement rates between states in the USA. They found their measures of the economy (percent unemployed), policy (percent of registered voters who voted in general state and local elections), and education (percent that did not graduate from high school) to all be directly related to embezzlement rates. They also tested several cross-product terms and found the economy polity to be associated with embezzlement such that high levels of voter participation reduced the impact of the economy on embezzlement rates.

In 2008b, Bjerregaard and Cochran as well as Frerich, Munch, and Sanders assessed IAT utilizing cross-national data sets. Frerichs et al. (2008) predicted robbery and homicide rates among twenty developed, post-welfarist nations. They evaluated the institutional balance of power between several measures of the economy (Gini coefficient, P90/P10 ratio, union density rates, public social expenditures, unemployment, and mass imprisonment). Contrary to the expectations of IAT theory, they found that low female employment, high levels of union density, and low unemployment sometimes increased crimes. Likewise, they found that decommodification also increased crime. In contrast, low divorces and high public social expenditures and high imprisonment rates reduce crime. Bjerregaard and Cochran (2008b) also investigated homicide and theft rates across 49 nations. They found that the family and education institutions moderated the relationship between the economy and homicide. Likewise, education and the polity tempered the relationship between the economy and theft rates. Similar to Piquero and Piquero (1998), they found these results to be sensitive to the various operationalizations of the key concepts.

Collectively the results of these studies provide moderate support for IAT theory. The majority of the studies support the notion that noneconomic institutions moderate the relationship between the economy and crime (for an exception, see Maume and Lee 2003). Utilizing indirect measures of the key theoretical concepts support for the various propositions exists. The most common finding is that various measures of the economy including income inequality, poverty, and unemployment are related to crime rates. The findings regarding the influence of the noneconomic institutions are more mixed with various studies confirming these relationships and several refuting them. In addition, these results appear to be sensitive to the measurements utilized in the studies.

Another set of studies has focused on the idea that decommodification or welfare policies ameliorate the impacts of a dominant economy. This was first addressed by Rosenfeld and Messner themselves in 1997 when they studied the influence of Esping-Andersen’s measure of welfare expenditures (decommodification) on homicide rates in 45 nations. They found decommodification to be negatively related to homicide controlling for a variety of demographic and socioeconomic factors.

Hannon and DeFronzo (1998), integrating IAT with social support theory, looked at whether welfare assistance moderated the relationship between income inequality and crime in the United States. Confirming IAT theory, they found that high levels of welfare assistance did reduce the impact of economic deprivation on crime. Pratt and Godsey (2003) assess this relationship cross-nationally by measuring both social support (GDP spent on health care) and economic inequality (ratio of median incomes of the richest to poorest 20 % of citizens). They found economic inequality to have a strong, positive effect on homicides and social support to have a negative effect. Looking at the interaction between these two concepts, they found the effect of economic inequality on homicides to be lessened in situations of high levels of social support.

Savolainen (2000) went a step further and looked at sex-specific homicide rates using two cross-national data sets including the one previously used by Rosenfeld and Messner (1997). Income inequality (Gini coefficient) interacted with decommodification to influence homicide. Specifically, in situations with high levels of decommodification, income inequality reduced homicide rates for both men and women. These findings were supported in both samples. However, they also found the influence of income inequality on homicide to be restricted to nations with low levels of decommodification. Taking a slightly different approach, Stucky (2003) found the effects of economic deprivation on crime to be weakest in those metropolitan areas with strong local political structures.

Messner et al. (2002) studied this issue longitudinally investigating 150 countries over a 20-year time period. Confirming previous findings, they noted that income inequality had a positive impact on homicide rates. They also supported the notion that well-developed social welfare institutions mitigate the effect of income inequality on homicide. Batton and Jensen (2002) likewise researched this issue longitudinally across the United States, but they found that high levels of decommodification did not reduce homicide rates. They also examined these relationships across various time periods and found a negative relationship between unemployment and homicide for recent years. They attribute this finding to increasing levels of juvenile violence, potentially rising nonemployment rates and more females joining the workforce. Again, the findings from these studies are mixed, although the majority shows support for the proposition that decommodification buffers the influence of market forces on crime rates.

The above-discussed studies have been criticized in the literature for failing to test the fundamental assumptions underlying IAT. The studies discussed below have all focused on a different approach to researching IAT theory by attempting to confirm the notion of American exceptionalism. Specifically, they sought to determine both whether the values associated with the American Dream are universally supported and whether or not the United States is unique in its value system.

Value Orientations

Jensen (2002) was one of the first to decry the lack of empirical data on the degree to which societies embraced the goals and values described by Messner and Rosenfeld. Utilizing data from the World Values Survey, he examined value orientations across 38 nations. He found that the USA did not rank as high on materialistic values or normlessness compared with other nations. In fact, the United States scored toward the top in terms of rating the family, religion, and leisure as important. The USA also ranked sixth in agreement with the statement that “less emphasis on money and material possessions would be a good thing” (p. 59). In addition to ranking value orientations, Jensen also analyzed the extent to which decommodification influenced crime rates by strengthening the family. He discovered that the higher the investment in decommodification, the less likely citizens were to have children and the more likely they were to divorce (p. 62). Decommodification was also positively related to the importance of leisure and negatively related to the importance of religion, and not significantly related to the importance of family. Ultimately decommodification was found to significantly increase burglary rates. The findings from this study are clearly contrary to the expectations of institutional anomie theory.

Chamlin and Cochran (2007) followed suit and utilized the World Values Survey to measure cultural attitudes and ultimately determine how they correlated with homicide and robbery rates.

They also do not find evidence that the United States is particularly materialistic. In fact, they find that the "fledgling, market economies that emerged from the dissolution of the Soviet Union most enthusiastically embrace the so-called 'American Dream'" (p. 53). There was also no significant correlation between the importance of work and homicide and robbery rates. Interestingly, they found that if they limited their analysis to the economically developed nations, this correlation became strong and significant, implying that IAT may have salience only among developed nations.

In order to determine cultural values, Muftic (2006) took a unique approach and compared American to foreign-born college students. She asked the students several questions designed to tap into core value orientations such as individualism, achievement, and fetish for money and then correlated those values with cheating behaviors. Consistent with IAT theory, she found that students born in the USA indicated higher dedication to universalism and monetary fetishism and higher levels of cheating behaviors. These value orientations were also found to be related to cheating behaviors (except for the value of achievement). She also investigated attachment to and importance of family, polity, education, and the economy. In a multivariate analysis, the family and polity were found to be significant and negatively related to cheating. However, students who were employed (involvement in the economy) were less likely to cheat. Finally, attachment to or involvement in noneconomic institutions were not found to moderate the influence of values on cheating. Cullen et al. (2004) applied IAT to explain unethical business practices. Their findings were also mixed. The findings with regard to the values of universalism and pecuniary materialism support IAT, while the results for individualism and achievement do not.

Baumer and Gustafson (2007) also looked at geographic areas in the United States. They used individual-level data from the General Social Survey to measure commitment to pursing monetary success and the legitimate means of achieving that success and macro-level measures of the polity, education system, family, and religion. They found broad support for IAT. Their interactive models showed that when there are strong beliefs in the cultural goals of monetary success coupled with low attachment to legitimate means, higher rates of instrumental crimes result. When they considered the impact of social institutions only, the family and welfare assistance reduced this effect.

Controversies in the Literature

While these studies advance certain tenets of IAT, the findings overall are mixed with several propositions finding support and others not. All in all there is more support for the notion that social institutions moderate rather than mediate the influence of the economy on crimes. It is important to note that several studies find these results to vary depending on the operationalizations utilized.

Despite the advances made in empirically testing the theory in the past decade, a number of issues remain unresolved. For instance, the exact nature of the causal relationship between social institutions and the economy in affecting crime rates is somewhat uncertain. While the majority of studies have supported the notion that social institutions moderate the relationship between economy and crime, a few have refuted this perspective instead finding that these institutions play a mediating role (e.g., Maume and Lee 2003).

Another controversy that currently exists is the extent to which the core values of the American Dream central to IAT are universal. Findings surrounding this question have been mixed, with several researchers refuting this claim (e.g., Jensen 2002). Further, some research appears to suggest that the values held by Americans are not as unique as the theory suggests failing to provide support for the notion of American exceptionalism (Chamlin and Cochran 2007; Jensen 2002).

One of the most challenging issues facing the advancement of this theoretical perspective is the fact that IAT is not readily amenable to falsification. In general, the studies reviewed imply partial support for IAT. This may be in large part due to the fact that researchers are only indirectly testing main propositions of the theory due to the difficulty in both operationalizing the key concepts (e.g., economic dominance) and data challenges inherent in cross-national research. In the future, we need to find adequate sources of measuring crime rates cross-nationally. It would be especially helpful if we could disaggregate homicide offenses so that researchers could focus on the violent acts committed for instrumental or utilitarian purposes. Better data sources would allow future researchers to expand the scope of the dependent variables utilized.

Open Questions

There are still several open questions that exist in determining the efficacy of IAT. One of the primary issues involves the extent to which IAT is compatible with other theoretical perspectives. Rosenfeld and Messner (1997: 218) acknowledge that they are "heavily indebted to insights associated with traditional bonding and social-disorganization theories." They also recognize that "Mertonian insights about the social structuring of criminal incentives and opportunities have yet to be incorporated systematically and formally into the framework of IAT" (Messner and Rosenfeld 2006: 144).

Relatedly, Jensen (2002) has pointed out that other theoretical perspectives could likewise explain several of the findings from the literature testing IAT. For example, he points out that the mediating structure relating economic dominance to crime is consistent with social control and social disorganization perspectives. Further, he criticizes previous empirical tests of IAT for failing to incorporate variables central to other criminological theories into the analysis (p. 56). Future research needs to more fully incorporate key concepts from other theoretical perspectives in order to disaggregate the impact of IAT.

Another issue is the degree to which IAT can be integrated with micro-level explanations of crime. Both Durkheim and Merton advance individual-level explanations along with their structural focus. In fact, Messner et al. (2008: 177) point out that in integrating these two levels of analysis in research on IAT, it will be necessary to include indicators from other theoretical perspectives, and they encourage further efforts along these lines.

Finally, the applicability of the theory to explaining offenses other than serious crimes such as robberies and homicides is not well developed. Although these offenses were clearly the focus of Messner and Rosenfeld's presentation of the theory, it is unclear the extent to which the theory would apply to other types of crimes. Researchers have started to explore this issue predicting unethical business practices (Cullen et al. 2004), cheating behaviors among college students (Muftic 2006), and embezzlement rates (Schoepfer and Piquero 2006).

Messner and Rosenfeld offer us a unique reformulation and expansion of Merton's original anomie theory. In doing so they focus on the role of cultural values, social institutions, and the ability of these institutions to regulate behavior. Their theory helps describe the role of anomie in explaining cross-national variations in crime in general and high rates of serious crimes in the United States in particular. Finally, they refocus policy initiatives toward the wider cultural and social structure issues. The challenge will be to operationalize the key concepts in the theory to better advance our empirical tests of this theory. Messner and Rosenfeld have introduced an intriguing explanation for America's serious crime rates and presented a challenge for future researchers to develop the means to empirically assess its validity.

Institutional Theories of Punishment

Joachim J. Savelsberg
Department of Sociology, University of
Minnesota, Minneapolis, MN, USA

Synonyms

Comparative Punishment; Criminal Punishment; Institutions (political, legal, knowledge); Rates of Punishment (spatial and temporal variation)

Overview

Long- and midterm changes in punitive attitudes and penal practices can only be understood by taking complex interactions between multiple social forces into account. Statistical analyses show that many factors are at work (Jacobs/Jackson 2010), while theoretically informed studies provide an in-depth understanding of the role played by specific conditions such as everyday life experiences (Garland 2001), including economic conditions and racial/ethnic conflict (Wacquant 2009), elite strategies (Beckett 1997; Simon 2007), and long-term cultural patterns (Melossi 2001; Savelsberg 2004; Whitman 2003). Recent literature, following earlier suggestions (Savelsberg 1994, 1999), has drawn special attention to the institutional arrangements under which ideas regarding crime and punishment are generated and penal decisions are made (Barker 2009; Campbell 2011; Garland 2010; Lacey 2008; Miller 2008; Page 2011; Savelsberg et al. 2004; Savelsberg and Flood 2011; Schoenfeld 2010; Sutton 2000; Whitman 2003). This entry begins with an illustration of what is to be explained: massive divergences in midterm trends in punitive attitudes and penal practices, illustrated for Europe and the United States. The main body of this text introduces competing (and mutually complementing) factors and approaches, each supported by distinct literatures, that seek to make sense of penal variation across time and space. While each of these approaches proves to be insufficient by itself, a synthesis is more promising, especially if it takes institutional conditions seriously.

What is to be Explained: Cross-National Patterns and Trends

Differences between crime concerns, penal attitudes, and intensities of punishment in Europe vis-à-vis the United States are substantial. The United States of the last third of the twentieth and the early twenty-first centuries is home to considerable fear of crime. Such fear and related cognitions inform not only adaptations in everyday behavior but also political attitudes and behavior. They are a precondition for the extraordinarily high rate of public support for capital punishment that has been hovering between 70 % and 80 % for most years since the late 1970s, for America's continuing use of the death penalty (the only Western country), albeit not in all of its states, and for rates of imprisonment that are unparalleled in American history and in any Western democracy.

A closer look shows that punitive attitudes and tough punishment practices are not a constant feature of the United States. Populations of other countries, for that matter, are not consistently mild-minded. A comparison of longer-term trends in support of capital punishment in Germany and the United States, for example, shows that both populations strongly supported the death penalty in the immediate post-World War II era. Support among Germans was even higher, despite (or because) of the most recent experience of the murderous Nazi regime. The 1960s witness a considerable weakening of support in both countries. Analyses for Germany show that this decline is primarily the result of cohort effects, only secondarily of period effects. It reaches new lows in the 1980s and 1990s. The United States, on the other hand, experience rising support of capital punishment, beginning in the mid 1970s, reaching new heights within a few years, and remaining at a very high level ever since.

Penal practice shows some parallels to, but also marked differences from, attitudes. Rates of executions in the United States, for example, are closely associated with trends in public opinion. They declined through the 1960s until a Supreme Court-mandated moratorium brought executions to a standstill from 1968 through 1976, but they increased steadily from there through the late 1990s to almost 100 executions per year in 1999, followed by a drop in most recent years. In European countries, by contrast, the death penalty is now abolished. In Germany, for example, it has been unconstitutional since the foundation of the Federal Republic in 1949, a time when public support for the death penalty was still high. Here, public opinion followed political decisions and constitutional norms, rather than vice versa.

The trend line for incarceration rates in the United States shows a similar development to that of executions. It decreased through the early 1970s and then began its dramatic increase that culminated in levels never seen before by the turn of the millennium (from just above 100 per 100,000 population to a rate of above 600). The new increase beginning in the 1970s is not just associated with the renewed support for the death penalty but also with increases of other indicators of punitiveness. For instance, a growing number of people supported the proposition that courts in their region are too lenient in their practices.

In Europe, on the other hand, long-term imprisonment rates were relatively stable and less in line with changes in public opinion. Consider again Germany. Even though the last decade of the twentieth century shows a marked 50 % increase in imprisonment rates, this trend built on a historical low of around 50 inmates per 100,000 population in 1992. Recent increases in punitive attitudes among Germans have been diagnosed, but they are relatively moderate (Reuband 2003).

How can we explain the syndrome of fear, punitive attitudes, and increasingly severe penal practice in the United States? What about the long-term trends toward leniency and recent moderate shifts in the opposite direction in Europe? Can we develop a theory that is congruent with these patterns and general enough to explain distinct trends in different countries alike? Several explanatory approaches have been offered in recent years, each with its own promises and limits.

Explanatory Controversies: Toward Multiple Factors

Crime as a Basis for Punitiveness?

Looking at the extraordinary rates of punitive attitudes and practices in the United States, some point at high American crime rates as the likely cause. Yet, American crime rates for most offenses are quite comparable with rates in other Anglo-Saxon countries and not dramatically higher than those in most European countries. Important exceptions are particular types of violent crime such as robbery and homicide. These are concentrated, however, in poor inner-city ghettos, where dealing with illegal drugs constitutes one remaining opportunity to earn a living after the cities began to deindustrialize in the 1950s. When conflicts develop in the world of illegal markets, the resolution of resulting grievances is not left to the state's monopoly of force, but is carried out through self-help, thus contributing to high rates of violence in these areas.

Punitive attitudes, on the other hand, are highest not among those who are most exposed to the risks of violent crime but rather among residents of America's suburbia. Also, the increase in punitive attitudes in the United States is far from synchronized with crime trends. Similarly in Germany, while crime rates increased for the first half of the post-World War II era, support for capital punishment declined during this period. Patterns and trends of crime and victimization risk thus neither offer a simple and direct explanation for punitive attitudes in the United States nor for international differences. In short, crime rates are not direct determinants of punishment trends, especially not in Europe. It is still conceivable though that they play an indirect role once translated into fear through different ways of cultural processing and political instrumentalization (Garland 2001). Such processing is thus to be considered below.

National Culture?

Others point to cultural particularities of different countries as a basis for their patterns of punishment. For the United States, it has been suggested that a profoundly religious culture with clear distinctions between "good" and "evil" may dramatize evil and thus produce fear and punitive attitudes. Research finds some supporting evidence. For example, judges who are members of fundamentalist congregations tend to sentence more harshly than other judges; also members of fundamentalist Protestant congregations are more likely to support imprisonment, corporal punishment, and capital punishment (e.g., Grasmick et al. 1993). Not just religion, also other aspects of culture may encourage punitive attitudes. Some suggest that American individualism advances an individual as opposed to collective attribution of guilt, thus encouraging punitive rather than social reform responses.

A closer look shows, however, that reference to enduring national cultures by itself does not suffice. Historically, the USA is the country in which the Quakers promoted the replacement of corporal punishment for the sake of a rehabilitation-oriented prison system already in the early nineteenth century. Also in the nineteenth century, Gustave de Beaumont and Alexis de Tocqueville traveled to America to learn about this system and its potential benefits for Europe. Further, the American imprisonment rate varied considerably in the course of the twentieth century, and Americans' support for capital punishment tended to fall below that of Germans for much of the 1950s and 1960s. A simple reference to American culture is thus equally misleading as the reference to American crime rates when we seek to explain fear and punitive attitudes and practices.

Reference to a long-term culture as a straightforward explanation of punitiveness elsewhere is just as simply cast into doubt. Consider again Germany as a convenient example. The post-World War II era of the Federal Republic experienced considerable variation in support of capital punishment. A look beyond this Republic's history reveals the most dramatic shifts in penal attitudes and practices. While we do not have good measures for public attitudes during the Nazi era or for the German Democratic Republic (the Communist part of the divided Germany), we do know that penal and police practice in the former were unspeakably harsher and in the latter considerably more severe than in the Weimar Republic or in the Federal Republic. Again, enduring national culture surely is unable to provide a straightforward explanation of penal practices and probably not for penal attitudes either, neither for Germany nor for the United States or any other country.

And yet, the role of culture should not be discarded altogether. Instead, the concept of culture as "tool kit" provides help, a notion developed by sociologist Ann Swidler. A tool kit is a collection of tools from which actors can draw in a situation of need. It is then decisive what tools are available in a given national context. Whitman (2003) suggested that aristocratic sensibilities played a part in Europe's historically less shaming and ferocious punishment regimes. Others highlight dominant religious traditions in different countries that provide distinct penal tools (Savelsberg 2004). More broadly, Philip Smith (2008), in his Punishment and Culture, develops a neo-Durkheimian argument that alters us to notions of the sacred, of rituals, and of myths that feed penal practices. The question then arises: What types of myths, sensitivities, religious doctrines, and other tools are available in different societies?

Culture as a tool kit thus means that certain tools are available and can be drawn on depending on a given situation. Cultural tools are necessary but not sufficient conditions of the use of penal strategies. Further, tools also need to be legitimate. It is noticeable that the use of force by government appears to have been delegitimized in countries such as Italy and Germany after the brutal misuse by the Fascist and Nazi regimes (albeit with a time lag) but that it remained intact in liberator and victor countries (Melossi 2001).

In short, long-term cultural traditions affect punitive attitudes and practices in complex interaction with the shorter-term legitimization of the state's use of force. They further interact with actions by concrete actors, such as elite campaigns and support by the populace that is associated with concrete living conditions.

Concrete Actors 1: Conservative Elites

The social science literature has shown that a focus on concrete actors is highly promising. Katherine Beckett's (1997) work, for example, successfully links increases of punitive attitudes and practices to activities of members of conservative elites, beginning in the 1960s. Her historical account quotes from political campaigns in which conservative Southerners equated support for the civil rights movement (as expressed in tactics of passive resistance and limited law violations) with the promotion of lawlessness generally to thus explain the dramatic increase in crime rates during this period. Charles Whittaker, a former US Supreme Court Justice, for example, argued that the 1960s crime wave was "fostered and inflamed by the preachments of self-appointed leaders of minority groups . . . [who told their followers] . . . to obey the good laws and to violate the bad ones. . . This simply advocates the violation of the laws they do not like. . . and the taking of the law into their own hands" (as quoted in Beckett 1997:31). More recent work has thus rightfully highlighted racial dimensions of the punitive turn in the United States (Wacquant 2009), especially in the context of the "war on drugs" (Tonry 1995).

Conservatives applied the same logic when they fought President Johnson's expansion of the welfare state through his Great Society programs. A quote from a 1964 speech by the Republican presidential candidate Barry Goldwater may serve as an illustration: "If it is entirely proper for the government to take away from some to give to others, then won't some be led to believe that they can rightfully take from anyone who has more than they? No wonder law and order has broken down, mob violence has engulfed great American cities, and our wives feel unsafe in the streets" (as quoted in Beckett 1997:35).

Insights gained from such historical narratives are supported by evidence from systematic data collection and hypothesis testing, including multivariate tests of the relationship between political initiatives, media coverage, and public perception. Examining when respondents to public opinion surveys consider crime or drug use the most important problem the nation faces, Beckett's (1997):14–27 work yields four insights: First, the reporting of drug and crime issues by the media and their ranking in public opinion surveys are highly uneven across the years, even within 2–4 year spans. Second, neither media reporting nor public opinion is clearly associated with the actual seriousness of the problem as measured by the crime rate and the incidence of drug use. Third, the fluctuations of media reporting are closely associated with political campaigns that highlight crime or drug issues. Fourth, public opinion tends to be motivated by media reporting. In short, the causal path leads from elite strategies through media reporting to public opinion. Americans tend to think of crime or drug use as the most important problems when politicians raise these topics in their campaigns and when media report about the issues raised by politicians. Yet, an important factor is missing from this account which is now to be addressed.

Concrete Actors 2: Everyday People and Their Fears

New critics within the constructivist tradition of social problems research, with which authors such as Beckett are affiliated, have noted that the public is not always receptive to the campaigns of political elites. Such campaigns may thus be necessary, or at least important, conditions of social problem careers, but not sufficient ones. Elite campaigns are effective only if they touch a sensitive nerve of the public. This sensitivity is a central theme in David Garland's (2001) book *The Culture of Control*. Garland argues here that people, under conditions of late modernity, are exposed to extraordinary challenges that produce severe anxieties. Old certainties about stable jobs, streamlined work careers, and social security have been lost. Arrangements of everyday life become more complicated as people are confronted with longer commutes; more single parent or dual income situations; longer periods of study, training, and retraining with less secure career expectations; and a weakening of the welfare state's safety net. In addition, and in line with routine activity arguments, public space is ever less secured by informal social control, which helps explain actual increases in crime rates in most Western societies in recent decades, and has thus contributed to further insecurities among the public. In short, Garland argues that we can understand the public's receptivity for punitive elite campaigns only against this background of general insecurity under conditions of late modernity.

Such arguments are supported by empirical investigation. Social psychologist Tom Tyler and collaborators examine public support for the "three strikes" law in California (Tyler and Boeckman 1997). This well-known law, passed through a public referendum, demands that offenders convicted of a third felony offense be given a life prison term with no possibility of parole. Tyler's research indicates that California's "three strikes" law was most strongly supported not by crime victims but by those who feel that the basic foundation of their social life has become undermined as the stability of their families is threatened or as immigrants move into their neighborhoods.

Conditions of everyday life and resulting public sensitivities must thus be taken seriously when we seek to explain punitive attitudes generally and people's receptivity to punitive campaigns by conservative elites specifically. Yet, this argument too faces an important limitation. The United States is not the only country whose residents experience conditions of late modernity. Consider the small and seemingly peaceful alpine country of Austria where, according to new survey results, the majority of young people no longer believe that their retirement benefits are secured. In some of its states, almost half of all children are born out of wedlock. Or consider

Germany where family life has abandoned its traditional and standardized patterns. Statistical trends show an almost double divorce rate by the end of the twentieth century compared to two decades earlier. In the same time span, the number of non-married cohabitating couples quadrupled, accompanied by a massive increase in the rate of out of wedlock birth. Finally, the participation of women in institutions of higher learning and in occupational life has increased dramatically in most European countries, albeit not to the same degree as in the United States.

In short, life has become less certain and life courses less predictable in the United States, in other Anglo-Saxon countries, and in continental European countries such as Austria or Germany. Late modernity has arrived in all of these places. Yet, most countries do not show the same intense increases in punitive attitudes and practices as do the United States (for common law countries, see Sutton 2000).

Institutional Particularities 1: The Weight of Knowledge Markets in the United States

The puzzle of country-specific responses to the challenges of late modernity can only be solved if we consider nation-specific institutions that process the insecurities people experience, that produce knowledge and ideas on how to respond to these insecurities, that promote or inhibit attitudes, and that channel those processes in the political and judicial worlds where punitive decisions are made (Savelsberg 1994). Such institutions differ considerably even across Western style democracies. Consider mass media as one institution through which information and knowledge are generated and diffused. Mass media in the United States are largely steered through market mechanisms, while most European countries, at least until a few years ago, were served by parallel public radio and television stations. Mass communication research has shown that market-driven media tend more toward dramatized and sensationalized presentation of hot news items, including crime, thereby enhancing fear of crime and cultivating punitive attitudes.

Further, public opinion surveys have been institutionalized in the United States for many decades. Media regularly report survey results back into the public, thus contributing to a positive feedback slope that further intensifies public sentiments. The regular publication of public opinion survey results in mass media has become more common in European countries as well; yet, it was the exception for much of the post-WW II era.

Institutional arrangements even in the world of scholarship as it contributes to knowledge about crime and punishment open up this field to market pressures much more in the United States than in European countries. The resource distribution to universities and academic departments depends on how well they do in the competition for student enrollment and research grants. Signs of competitiveness are annual rankings of department members according to their achievement in research, teaching, and service and the rankings of academic programs and universities alike that are widely known across the country. It is not surprising then that the past decades of growing public concern about crime have also witnessed a rapid growth of specialized programs of criminology and criminal justice studies. This specialization has been partly driven by funding from Justice Departments and by the creation of demand for higher education among law enforcement personnel.

This institutional adaptation of academia to concerns of its environment has also resulted in the incorporation of punitive ideas. Content analyses of large sets of scholarly journal articles on issues of crime and crime control in leading sociology and criminology journals, combined with in-depth interviews with scholars, show that research in specialized programs is more closely oriented toward themes and theoretical perspectives that dominate in the increasingly conservative political sector. This effect is further enforced where research is funded by political institutions (e.g., Savelsberg et al. 2004; Savelsberg and Flood 2011). These findings may partly be due to the facts that funding has shifted away from (1) departments dealing with health, housing, or human services to the Justice Department and (2) from researcher initiated to strategic funding programs. While comparable studies do not exist for other countries, it is likely that less competition-oriented European academic institutions will not adapt as readily to their political environment as their American counterparts do.

Institutional Particularities 2: The Weight of Political Markets in the United States

Not only institutions of knowledge production but also institutions of political and legal decision-making play crucial roles in the unfolding of penal practice. In a recent series of publications, Nicola Lacey (e.g., Lacey 2008) directs our attention toward the weight of political decentralization, the dynamics of different electoral systems and cycles. Her work leads her to challenge the notion that globalization leads to a simple convergence of criminal justice policy across nation states. Instead, she stresses that several nation-level institutional and cultural particularities filter global processes, dislodging them before they prove effective at the national level.

Applying these insights to a European-US comparison informs us that political institutions too are more market driven in the United States (Savelsberg 1994). One decisive factor is the relatively weak position of political parties that are not guaranteed a place in the American constitution, in contrast to some European countries. Candidates for elected office, for example, who are selected by the public in primary elections in the USA, are chosen through party committees and assemblies in Europe. American political candidates who seek to advance their political careers thus have to orient their positions at least as much toward opinions and sentiments of the electorate as toward enduring positions of their party. Not only legislators, but also heads of the executive branch, president, and governors alike, are elected through direct popular elections, not through a vote within the legislature as is the case in parliamentary democracies. Again, public opinion is more likely to translate into political decision-making in the United States. Further, high-ranking civil servants in the USA are much more frequently political appointees, selected by the president. They will return to their prior positions in the business world, academia, foundations, or law firms once the administration changes. Here too public sensitivities make their way into public administration more easily than in most of Europe. Finally, in the judicial branch of government, the public is represented in court through the American jury system, and most prosecutors and judges are also selected through popular elections. They depend on reelection if they wish to keep their position for a subsequent term. It is likely that such judges and prosecutors will orient their decisions more toward concerns of the public than their life tenured civil servant colleagues in most continental European countries.

It is decisive that all of these institutional spheres are more open to adapting to public opinion in the United States than in Europe. As a result, anxieties and punitive public attitudes are more likely to be reflected in the production and diffusion of knowledge and in political and legal decision-making. And they become communicated back to the public through a positive feedback slope to thus reinforce the initial expression of public opinion. Sutton's sophisticated and theoretically guided statistical analyses provide empirical support for this type of institutional argument in his comparative study of common law countries (Sutton 2000). Such institutional arguments are not meant to answer the "chicken or egg" question as to what comes first, public opinion about crime and punishment or punitive programs. It is decisive instead that those relatively "open" institutions of knowledge production and decision-making characteristic for the United States tend to lead to a mutual reinforcement of both poles, while Europe's relatively "closed" institutions are more likely to support stability.

Two modifications to this typological cross-national argument are needed. First, the American War on Crime has contributed to a transformation of America's democratic institutions, as Jonathan Simon (2007) has aptly documented. Prominent among them is a shift toward the use of executive power. Further, Joshua Page (2011) has powerfully demonstrated for the case of California that the imprisonment boom has strengthened an important group in the penal field, the corrections officers union. In turn, this union constituted an effective lobbying group on behalf of the passage of penal laws.

Second, the above argument, focusing on nation-level characteristics, has been challenged in recent years as states below the nation-level show remarkably different trends in their penal practice. David Garland (2010), in his recent book on capital punishment, highlights the fact that the United States, while retaining the death penalty longer than other Western democracies, is constituted by states, some of which abolished this penalty when no European country even considered abolition. It is exactly the decentralization of political power and localized decision-making that account for this country simultaneously being an early abolitionist and a late retainer of the death penalty.

Rightfully then, others have taken the next step by studying punishment at the state level. A comparison of penal practice in the states of California, New York, and Washington shows, for example, that state-level differences in political institutions and participatory practices help explain the distinct penal patterns in these three states (Barker 2009). Specifically, Barker argues that "polarized populism" in California contributed to a retributive penal regime. This pattern starkly contrasted with Washington State's "deliberative democracy" that fostered de-escalation and New York's "elite pragmatism" that advanced a managerial practice of punishment. Others have explored institutional particularities of individual states to explain their specific patterns of punishment (e.g., Lynch 2010 on Arizona; Schoenfeld 2010 on Florida). Campbell (2011) finds for Texas that a period of unsettled and contested change generated a highly punitive penal code and created an additional layer of prison facilities to manage lower-level offenders. His analysis suggests that the patterns he identifies reflect institutionalized conflict between state and local governments. Campbell further alerts the reader to interactions between such institutional arrangements and contextual factors that are deeply embedded in the history of the state. Finally, examining differences in the institutionalization of civil society between the local and the national levels, Miller (2008) shows that anti-punitive interest groups are generated at the local level, where residents are in fact most affected by crime but where political pressure has little influence on penal policy making. State- and nation-level organization of interests, on the other hand, representing those least affected by crime, tends to be punitive and effective.

Clearly thus, institutional arrangements, characteristic of particular levels of government, and even of particular states must be taken seriously. This does not mean, of course, that higher-level factors become obsolete. The next step in this institutional line of scholarship should thus aim at theorizing – and examining empirically – the interaction between global-, national-, state-, and local-level institutions as they jointly filter social structural and cultural forces and thus shape penal practices.

In short, a growing body of literature has shown that institutional arrangements are a crucial factor in the equation that explains practices of punishment. Open institutions, at least in some contexts, tend to communicate public concerns and punitive demands into legal and political decision-making. Yet, the question remains unanswered why people under conditions of insecurity, provoked by the strains of late modernity, resort to punitive demands. It is not at all certain, after all, that punitive strategies will actually create security and improve living conditions. Much to the opposite, evidence indicates considerable destruction of human, social, and cultural capital as a consequence of massive imprisonment. Alternative responses to insecurity such as increased unionization or demand for new welfare protections may be much more effective in fighting insecurity. Here, institutional arguments need to link back to the notions of tool boxes and interested actors discussed above. Open institutions are especially receptive to punitive turns where popular pressure suggests the use of punitive tools and where political leaders and members of the judiciary have an interest in using these tools.

Institutional Change and Transnational Convergence?

Given the impressive differences between Europe and the United States in terms of cultural repertoires, institutional arrangements, and social structure, should we still see a convergence as many globalization theorists would predict? There are some reasons to follow their argument and even stronger challenges that caution us.

First, institutions in Europe have been undergoing considerable change. The safety net of the welfare state is weakening and some functions are being passed on to the market, even if changes in Europe are much slower and meet more resistance than they do in the United States. Also, the weight of public radio and television stations has been declining over the past two decades as private channels, operating under the pressure of markets, have become more prominent. Simultaneously, the number of programs that address crime, especially violent crime, in movies and reports has multiplied. Consumers of such programs tend to overestimate crime as a problem, perceiving serious increases even for types of crime that have been on the decline as documented by German criminologist Christian Pfeiffer. Finally, leading politicians are increasingly exposed to public pressure due to a growing media presence in combination with increased public opinion polling. They are thus likely to be more oriented toward public opinion.

Finally, institutional shifts in Europe are supplemented by one change of a different sort. New cohorts of judicial decision-makers are socialized under conditions of late modernity and new institutional arrangements. Future cohort studies may measure effects of this turnover in judicial personnel on changing penal practices in Europe.

Despite such changes, however, many institutions in Europe maintain their distinct character and continue to differ markedly from those in the United States. The role of public media is still more prominent in Europe. Platform parties remain strong. Candidates for political office continue to be selected by parties, rather than by the public in primary elections. Heads of the executive branch continue to be elected by the members of parliaments rather than in direct popular votes in most countries. Prosecutors and judges still do not get elected by the general public; the proposal of such selection mechanism would in fact continue to appear strange to most Europeans. Due to these institutional specifics, I expect that increases in punitiveness in Europe will not reach American dimensions. Empirical opinion data seem to support this contention as recent studies by German sociologist Karl-Heinz Reuband (2003) have shown. The percent of residents of the (old) West German states who demand prison terms in response to burglary convictions, for example, increased from 13 % to 19 % between 1989 and 2002. Fifty-nine percent demand community service (down 1 %), 7 % suggest fines (down 2), 10 % probationary terms (down 2), and 5 % “other” penalties (up 3) (others “don’t know”). The increase in demand for prison terms is surprisingly modest in light of the advent of late modernity, a high rate of unemployment for much of the 1980s and 1990s, the burden of the 1990 German unification with its cultural clashes and dramatic demographic and economic transformations, and the institutional changes sketched above. Each of these factors by itself might, according to substantial bodies of social science literature, result in massive increases in punitiveness, was it not for the continuing features of Europe’s institutional outfit.

In line with these observations about public opinion, the 50 % increase in German imprisonment since 1992, beginning from a historic low, and similar prison growth in other European countries, has been significant but modest compared to the American experience of recent decades, where the 1970s and the 1980s each experienced almost 100 % increases in imprisonment rates; the 1990s, despite steep declines in serious crime, saw another increase of around 50 %. Again, distinct cultural repertoires and institutions and important institutional differences in the legislative, executive, and judicial branches of government are likely to account for this contrast between the USA on the one hand and Germany (and most European countries) on the other.

Concluding Thoughts: Toward Synthesis

Punitive attitudes and practices, especially pronounced in the United States, have been increasing in Europe as well. Changes in crime are only a very limited and indirect explanation for this trend. Crime needs to be culturally processed before it can cause anxiety and punitive attitudes. Conservative elites may play a major role in this process as the American case indicates. Their effect, however, is partly contingent on the growing insecurity of many segments of the population under conditions of late modernity. Both effects of elite strategies and of conditions of late modernity on punitive attitudes and practices have been shown by researchers in the United States.

Yet, punitive responses to insecurity are not a natural outcome. They are more likely where respective cultural repertoires are available and legitimized, which (during the post-World War II period) seems to apply more to the United States than to Europe. One additional factor, too frequently overlooked in earlier scholarship, is the profoundly different institutional arrangements in the United States vis-à-vis most continental European countries. This applies to institutions for the production and dissemination of knowledge as much as for institutions of political and legal decision-making. The more open political and legal institutions are for public sentiments, the more will public concerns affect political and legal decision-making. Anxieties will often not be calmed by punitive decisions, but instead may even be reinforced as the American case seems to indicate. This does not mean, of course, that democracy accounts for punitiveness but that some forms of democratic institutions may have that effect. Autocratic regimes, in fact, are characterized by particularly severe and arbitrary practices. Fortunately, the earlier neglect of institutional forces has been corrected by a wave of recent research at the national, state, and local levels. We now face the challenge of understanding the interaction between global forces and national, state, and local institutional conditions.

In sum, an appropriate theory of punitive attitudes and practices must be conceived as a multifactorial, historically, and institutionally grounded theory, as Max Weber would have suggested. Such a theory must take seriously crime, changing living conditions, elite strategies, cultural repertoires and experiences with the state's use of force, and finally institutional patterns through which knowledge is produced and diffused and through which decisions on punishment are made.

Integrated Cognitive Antisocial Potential Theory

David P. Farrington
Institute of Criminology, University of Cambridge, Cambridge, UK

Synonyms

Antisocial potential; Developmental criminology; ICAP theory; Life events; Life-course criminology; Risk and protective factors

Overview

Developmental and life-course criminology (DLC) focuses on the development of offending and antisocial behavior, risk and protective factors, and the effects of life events. The ICAP theory specifies the risk and protective factors that influence the development of long-term antisocial potential (varying between individuals) and the situational factors that influence short-term antisocial potential (varying within individuals over time). It also specifies the cognitive processes that influence whether the antisocial potential becomes the actuality of offending in any situation and the consequences of offending that have feedback influences on antisocial potential. Tests of the ICAP theory and its research and policy implications are described.

Developmental and Life-Course Theories

Developmental and life-course criminology (DLC) is concerned mainly with three topics: (a) the development of offending and antisocial behavior from the womb to the tomb; (b) the influence of risk and protective factors at different ages; and (c) the effects of life events on the course of development (Farrington 2003). Whereas traditional criminological theories aimed to explain between-individual differences in offending, such as why lower-class males commit more offenses than upper-class males, DLC theories aim to explain within-individual changes in offending over time, such as why males commit more offenses when they are unemployed than when they are employed.

DLC theories aim to explain offending by individuals (e.g., as opposed to crime rates of areas). "Offending" refers to the most common crimes of theft, burglary, robbery, violence, vandalism, minor fraud, and drug use and to behavior that in principle might lead to a conviction in Western industrialized societies such as the United States and the United Kingdom. These theories aim to explain results on offending obtained with both official records and self-reports. Generally, DLC findings and theories particularly apply to offending by lower-class urban males in developed countries in the last 80 years or so. To what extent they apply to other types of persons (e.g., middle-class rural females) or offenses (e.g., white-collar crimes or sex offenses against children) are important empirical questions that cannot be addressed here.

In conducting research on development, risk and protective factors, life events, and DLC theories, it is essential to carry out prospective longitudinal surveys. I have directed the Cambridge Study in Delinquent Development, which is a prospective longitudinal survey of over 400 London males from age 8 to age 56 (Farrington et al. 2013). The main reason why developmental and life-course criminology became important during the 1990s was because of the enormous volume and significance of longitudinal research on offending that was published during this decade. Particularly influential were the three "Causes and Correlates" studies originally mounted by the US Office of Juvenile Justice and Delinquency Prevention in Denver, Pittsburgh, and Rochester. Other important longitudinal projects that came to prominence in the 1990s were the Seattle Social Development Project, the Dunedin study in New Zealand, the Montreal Longitudinal-Experimental study, and the further analyses by Laub and Sampson of the classic study by the Gluecks. (For reviews of all these studies, see Farrington 2013.)

What Do We Know?

There are ten widely accepted conclusions about the development of offending that any DLC theory must be able to explain. (For references, see Farrington and Loeber 2013.) First, the prevalence of offending peaks in the late teenage years – between ages 15 and 19. Second, the peak age of onset of offending is between 8 and 14, and the peak age of desistance from offending is between 20 and 29. Third, an early age of onset predicts a relatively long criminal career duration and the commission of relatively many offenses.

Fourth, there is marked continuity in offending and antisocial behavior from childhood to the teenage years and to adulthood. What this means is that there is relative stability of the ordering of people on some measure of antisocial behavior over time and that people who commit relatively many offenses during one age range have a high probability of also committing relatively many offenses during another age range. However, neither of these statements is incompatible with the assertion that the prevalence of offending varies with age or that many antisocial children become conforming adults. Between-individual stability in antisocial ordering is perfectly compatible with within-individual change in behavior over time. For example, people may graduate from cruelty to animals at age 6 to shoplifting at age 10, burglary at age 15, robbery at age 20, and eventually to spouse assault and child abuse later in life. There is also continuity in offending from one generation to the next.

Fifth, a small fraction of the population (the "chronic" offenders) commit a large fraction of all crimes. In general, these chronic offenders have an early onset, a high individual offending frequency, and a long criminal career. Sixth, offending is versatile rather than specialized (although specialization increases with age). For example, violent offenders are indistinguishable from frequent offenders in childhood, adolescent, and adult risk factors. Seventh, the types of acts defined as offenses are elements of a larger syndrome of antisocial behavior, including heavy drinking, reckless driving, sexual promiscuity, bullying, and truancy. Offenders tend to be versatile not only in committing several types of crimes but also in committing several types of antisocial behavior.

Eighth, most offenses up to the late teenage years are committed with others, whereas most offenses from age 20 onward are committed alone. This aggregate change is not caused by dropping out processes or group offenders desisting earlier than lone offenders. Instead, there is change within individuals; people change from group offending to lone offending as they get older. Ninth, the reasons given for offending up to the late teenage years are quite variable, including utilitarian ones (e.g., to obtain material goods or for revenge), for excitement or enjoyment (or to relieve boredom), or because people get angry (in the case of violent crimes). In contrast, from age 20 onward, utilitarian motives become increasingly dominant. Tenth, different types of offenses tend to be first committed at distinctively different ages. For example, shoplifting is typically committed before burglary, which in turn is typically committed before robbery. In general, there is increasing diversification of offending up to age 20; as each new type of crime is added, previously committed crimes continue to be committed. Conversely, after age 20, diversification decreases and specialization increases.

The main risk factors for the early onset of offending before age 20 are well known (Farrington and Welsh 2007):

- *Individual factors*: low intelligence, low school achievement, hyperactivity-impulsiveness and risk taking, and antisocial child behavior including aggression and bullying
- *Family factors*: poor parental supervision, harsh discipline and child physical abuse, inconsistent discipline, a cold parental attitude and child neglect, low involvement of parents with children, parental conflict, broken families, criminal parents, and delinquent siblings
- *Socioeconomic factors*: low family income and large family size
- *Peer factors*: delinquent peers, peer rejection, and low popularity
- *School factors*: a high delinquency rate school
- *Neighborhood factors*: a high crime neighborhood

By definition, a risk factor predicts a high probability of offending, whereas a protective factor predicts a low probability of offending in a group who are at risk. Less is known about protective factors. (For reviews of risk and protective factors, see Farrington et al. 2012.)

The main life events that encourage desistance after age 20 are getting married, getting a satisfying job, moving to a better area, and joining the military. The distinction between risk factors and life events is not clear-cut, since some life events may be continuing experiences whose duration is important (e.g., a marriage or a job), while some risk factors may occur at a particular time (e.g., loss of a parent). Other life events (e.g., converting to religion) may be important but have been studied less.

While the focus in DLC is on the development of offenders, it is important not to lose sight of factors that influence the commission of offenses. It is plausible to assume that offenses arise out of an interaction between the person (with a certain degree of criminal potential) and the environment (providing opportunities and victims). Existing evidence suggests that people faced with criminal opportunities take account of the subjectively perceived benefits and costs of offending (compared with other possible activities) in deciding whether or not to offend. DLC theories should explain the commission of offenses as well as the development of offenders.

Contentious Issues

I now turn to some more contentious issues. (For reviews of knowledge about these more or less contentious issues, see Piquero et al. 2003.) First, while it is clear that the prevalence of offending peaks in the late teenage years, it is much less clear how the individual offending frequency (i.e., the frequency of offending by those who offend) varies with age. Some studies suggest that the individual offending frequency accelerates to a peak in the late teenage years and then decelerates in the twenties, whereas others suggest that the individual offending frequency does not change with age. Second, it is not clear whether the seriousness of offending escalates up to a certain age and then de-escalates or whether it does not change with age.

Third, while it is clear that an early age of onset of offending predicts a long criminal career duration and many offenses, it is much less clear whether an early age of onset predicts a high individual offending frequency or a high average seriousness of offending. Nor is it clear whether early onset offenders differ in degree or in kind from later onset offenders or how much there are distinctly different behavioral trajectories. Fourth, while chronic offenders commit more offenses than others, it is not clear whether their offenses are more serious on average. Nor is it clear whether chronic offenders differ in degree or in kind from nonchronic offenders.

Fifth, it is clear that certain types of offenses occur on average before other types and hence that onset sequences can be identified. However, it is not clear whether these onset sequences are merely age-appropriate behavioral manifestations of some underlying theoretical construct (e.g., antisocial potential) or whether the onset of one type of behavior facilitates or acts as a stepping-stone toward the onset of another. In other words, onset sequences could reflect persistent heterogeneity or state dependence (Nagin and Farrington 1992). Similarly, little is known about onset sequences in which childhood antisocial behavior has some kind of influence on later offending, which might suggest opportunities for early prevention.

Sixth, while the main risk factors for the early onset of offending are well known, the extent to which these risk factors have causal effects on offending is not clear. Seventh, many risk factors could either be causes of offending or indicators of the same underlying construct, or even both. For example, heavy drinking could reflect the same underlying construct as offending (e.g., antisocial potential) in comparisons between individuals but could be a cause of offending in comparisons within individuals (e.g., if people committed more offenses while drinking than while not drinking). In other words, heavy drinking could be a factor that influenced short-term within-individual variations in offending: why people commit offenses in some times and places but not in others.

There are many other unresolved issues concerning risk factors for offending. While a great deal is known about family risk factors (especially) and individual risk factors, much less is known about biological or neighborhood risk factors. Little is known about risk factors for continuation of offending after onset, for later onsets after age 20, or for persistence or desistance of offending after age 20. Little is known about risk factors for the duration of criminal careers. Little is known about the causal processes that intervene between risk factors and offending. And little is known about protective factors, whether defined as factors that are opposite to risk factors (e.g., high school achievement compared with low school achievement) or as factors that interact with and counteract the effects of risk factors (Farrington and Ttofi 2012). While the main life events that encourage desistance are well known, much less is known about life events that influence onset or continuation after onset. Also, the effect of the criminal justice system (police, courts, prison, and probation) on desistance is highly controversial. The labeling effects of convictions, in increasing the probability, frequency, variety, or seriousness of subsequent offending, are also controversial. Few DLC theories include specific postulates about the effects of interventions.

DLC Theories

Several DLC theories have been proposed to explain findings in developmental and life-course criminology, of which two of the most famous were proposed by Moffitt and by Sampson and Laub (see Farrington 2005a). My “ICAP” theory is described here.

For many years, I did not attempt to formulate a wide-ranging DLC theory of offending. In line with Bernard and Snipes (1996), who advocated a risk factor approach, I focused on identifying independently predictive risk factors, testing specific hypotheses (e.g., about the effects of unemployment on offending), and on investigating possible causal mechanisms linking risk factors and offending (e.g., mediators between criminal parents and delinquent sons). However, I was criticized for being "atheoretical" (and sometimes described as a "dust-bowl empiricist," whatever that means) for focusing on empirical variables rather than underlying theoretical constructs. Therefore, encouraged by Joan McCord, I proposed a tentative theory in 1992 (Farrington 1992).

My theory tries to overcome some of the perceived deficiencies of classic criminological theories. First, they focused primarily on offending during the teenage years, on factors that correlated with offending, and did not focus on development through life. They emphasized immediate influences on offending, as opposed to longer-term influences from infancy and early childhood. Second, they neglected the continuity between offending and antisocial behavior, and the continuity in antisocial behavior from childhood to adulthood. Third, they focused on a limited number of influences on offending (especially those connected with socioeconomic status) and did not include biological or psychological factors. Fourth, they focused on differences between individuals rather than on changes over time within individuals.

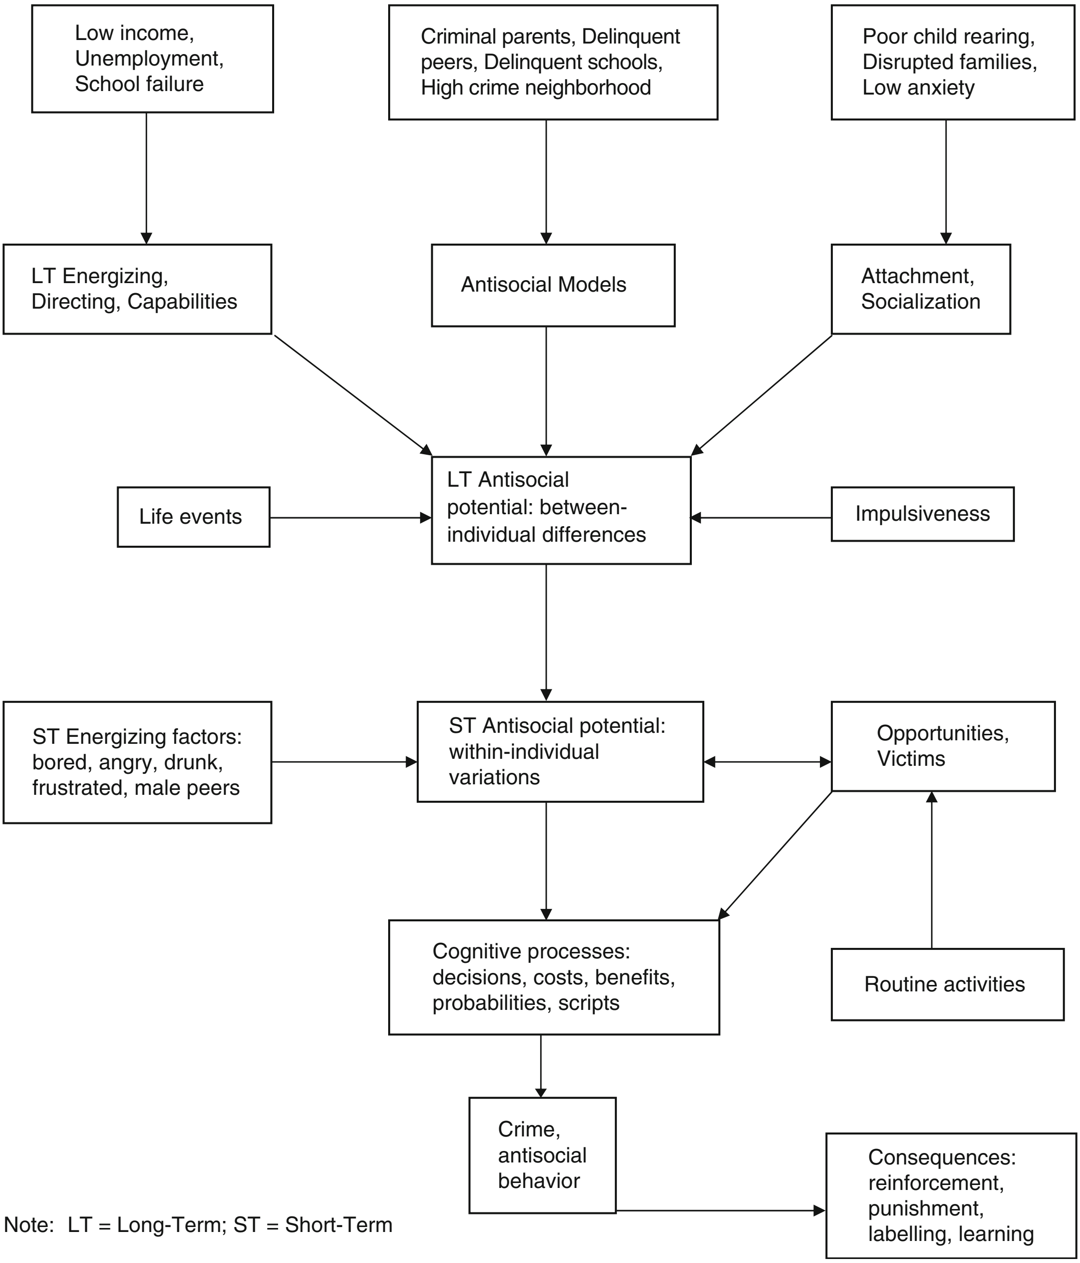
The ICAP Theory

My "Integrated Cognitive Antisocial Potential" (ICAP) theory was primarily designed to explain offending by lower-class males, and it was influenced by results obtained in the Cambridge Study (Farrington 2005b; Zara 2010). It integrates ideas from many other theories, including strain, control, learning, labeling, and rational choice approaches; its key construct is antisocial potential (AP); and it assumes that the translation from antisocial potential to antisocial behavior depends on cognitive (thinking and decision-making) processes that take account of opportunities and victims. Figure 1 is deliberately simplified in order to show the key elements of the ICAP theory on one page; for example, it does not show how the processes operate differently for onset compared with desistance or at different ages.

The key construct underlying offending is antisocial potential (AP), which refers to the potential to commit antisocial acts. Long-term persisting between-individual differences in AP are distinguished from short-term within-individual variations in AP. Long-term AP depends on impulsiveness; on strain, modeling, and socialization processes; and on life events, while short-term variations in AP depend on motivating and situational factors.

Regarding long-term AP, people can be ordered on a continuum from low to high. The distribution of AP in the population at any age is highly skewed; relatively few people have relatively high levels of AP. People with high AP are more likely to commit many different types of antisocial acts including different types of offenses. Therefore, offending and antisocial behavior are versatile rather than specialized. The relative ordering of people on AP (long-term between-individual variation) tends to be consistent over time, but absolute levels of AP vary with age, peaking in the teenage years, because of changes within individuals in the factors that influence long-term AP (e.g., from childhood to adolescence, the increasing importance of peers and decreasing importance of parents).

A key issue is whether the model should be the same for all types of crimes or whether different models are needed for different types of crimes. Because of their focus on the development of offenders, DLC researchers have concluded that, because offenders are versatile rather than specialized, it is not necessary to have different models for different types of crimes. For example, it is believed that the risk factors for violence are essentially the same as those for property crime or substance abuse. However,



Low income, Unemployment, School failure
Criminal parents, Delinquent peers, Delinquent schools, High crime neighborhood
Poor child rearing, Disrupted families, Low anxiety
LT Energizing, Directing, Capabilities
Antisocial Models
Attachment, Socialization
Life events
LT Antisocial potential: between-individual differences
Impulsiveness
ST Energizing factors: bored, angry, drunk, frustrated, male peers
ST Antisocial potential: within-individual variations
Opportunities, Victims
Cognitive processes: decisions, costs, benefits, probabilities, scripts
Routine activities
Crime, antisocial behavior
Consequences: reinforcement, punishment, labelling, learning

Note: LT = Long-Term; ST = Short-Term

Integrated Cognitive Antisocial Potential Theory, Fig. 1 The integrated cognitive antisocial potential (ICAP) theory

researchers who have focused on situational influences have argued that different models are needed for different types of crimes. It is suggested that situational influences on burglary may be very different from situational influences on violence.

One possible way to resolve these differing viewpoints would be to assume that long-term potential was very general (e.g., a long-term potential for antisocial behavior), whereas short-term potential was more specific (e.g., a short-term potential for violence).

The top half of the model in Fig. 1 could be the same for all types of crimes, whereas the bottom half could be different (with different situational influences) for different types of crimes.

In the interests of simplification, Fig. 1 makes the ICAP theory appear static rather than dynamic. For example, it does not explain changes in offending at different ages. Since it might be expected that different factors would be important at different ages or life stages, it seems likely that different models would be needed at different ages. Perhaps parents are more important in influencing children, peers are more important in influencing adolescents, and spouses and partners are more important in influencing adults.

Long-Term Risk Factors

A great deal is known about risk factors that predict long-term persisting between-individual differences in antisocial potential. For example, in the Cambridge Study, the most important childhood risk factors for later offending were hyperactivity-impulsivity-attention deficit, low intelligence or low school attainment, family criminality, family poverty, large family size, poor child-rearing, and disrupted families. Figure 1 shows how risk factors are hypothesized to influence long-term AP. This figure could be expanded to specify protective factors and to include influences on onset, persistence, escalation, de-escalation, and desistance.

I have not included measures of antisocial behavior (e.g., aggressiveness or dishonesty) as risk factors in the ICAP theory because of my concern with explanation, prevention, and treatment. These measures do not cause offending; they predict offending because of the underlying continuity over time in AP. Measures of antisocial behavior are useful in identifying risk groups but less useful in identifying causal factors to be targeted by interventions. Similarly, I have not included variables that cannot be changed, such as gender or ethnicity. I assume that their relationships with offending are mediated by changeable risk factors (Farrington et al. 2003).

A major problem is to decide which risk factors are causes and which are merely markers or correlated with causes (Murray et al. 2009). Ideally, interventions should be targeted on risk factors that are causes. Interventions targeted on risk factors that are merely markers will not necessarily lead to any decrease in offending. Unfortunately, when risk factors are highly intercorrelated (as is usual), it is very difficult to establish which are causes in between-individual research. For example, the particular factors that appear to be independently important as predictors in any analysis may be greatly affected by measurement error and by essentially random variations between samples.

It is also important to establish how risk factors or causes have sequential or interactive effects on offending. Figure 1 shows how risk factors are hypothesized to influence long-term AP. Following strain theory, the main energizing factors that potentially lead to high long-term AP are desires for material goods, status among intimates, excitement, and sexual satisfaction. However, these motivations only lead to high AP if antisocial methods of satisfying them are habitually chosen. Antisocial methods tend to be chosen by people who find it difficult to satisfy their needs legitimately, such as people with low income, unemployed people, and those who fail at school. However, the methods chosen also depend on physical capabilities and behavioral skills; for example, a 5-year-old would have difficulty in stealing a car. For simplicity, energizing and directing processes and capabilities are shown in one box in Fig. 1.

Long-term AP also depends on attachment and socialization processes. AP will be low if parents consistently and contingently reward good behavior and punish bad behavior. (Withdrawal of love may be a more effective method of socialization than hitting children.) Children with low anxiety will be less well socialized, because they care less about parental punishment. AP will be high if children are not attached to (prosocial) parents, for example, if parents are cold and rejecting. Disrupted families (broken homes) may impair both attachment and socialization processes.

Long-term AP will also be high if people are exposed to and influenced by antisocial models, such as criminal parents, delinquent siblings, and delinquent peers, for example, in high crime schools and neighborhoods. Long-term AP will also be high for impulsive people, because they tend to act without thinking about the consequences. Also, life events affect AP; it decreases (at least for males) after people get married or move out of high crime areas, and it increases after separation from a partner (Theobald and Farrington 2009).

There may also be interaction effects between the influences on long-term AP. For example, people who experience strain or poor socialization may be disproportionally antisocial if they are also exposed to antisocial models. In the interests of simplicity, Fig. 1 does not attempt to show such interactions.

Figure 1 shows some of the processes by which risk factors are hypothesized to have effects on AP. It does not show biological factors, but these could be incorporated in the theory at various points. For example, the children of criminal parents could have high AP partly because of genetic transmission, excitement-seeking could be driven by low cortical arousal, school failure could depend partly on low intelligence, and high impulsiveness and low anxiety could both reflect biological processes.

Many researchers have measured only one risk factor (e.g., impulsiveness) and have shown that it predicts or correlates with offending after controlling for a few other "confounding factors," often including social class. The message of Fig. 1 is don't forget the big picture. The particular causal linkages shown in Fig. 1 may not be correct, but it is important to measure, analyze, and explain all important risk factors in trying to draw conclusions about the causes of offending or the development of offenders.

Ideally, protective factors should be included in the ICAP theory as well as risk factors. The risk factor prevention paradigm (Farrington 2000) suggests that risk factors should be reduced while protective factors are enhanced. Often, programs focusing on protective factors (e.g., building on strengths, promoting healthy development) are more attractive to communities and consequently easier to implement than programs focusing on risk factors (which seem to emphasize undesirable features of communities and hence imply blame). Of course, a key question is whether the risk and protective factors for offending (or for the onset of offending) are the same as or different from the risk and protective factors for reoffending (or for the persistence of offending). Perhaps different models are needed in Fig. 1 for onset, persistence, escalation, de-escalation, and desistance.

Explaining the Commission of Crimes

According to the ICAP theory, the commission of offenses and other types of antisocial acts depends on the interaction between the individual (with his immediate level of AP) and the social environment (especially criminal opportunities and victims). Short-term AP varies within individuals according to short-term energizing factors such as being bored, angry, drunk, or frustrated or being encouraged by male peers. Criminal opportunities and the availability of victims depend on routine activities. Encountering a tempting opportunity or victim may cause a short-term increase in AP, just as a short-term increase in AP may motivate a person to seek out criminal opportunities and victims.

Whether a person with a certain level of AP commits a crime in a given situation depends on cognitive processes, including considering the subjective benefits, costs and probabilities of the different outcomes, and stored behavioral repertoires or scripts. The subjective benefits and costs include immediate situational factors such as the material goods that can be stolen and the likelihood and consequences of being caught by the police. They also include social factors such as likely disapproval by parents or female partners and encouragement or reinforcement from peers. In general, people tend to make decisions that seem rational to them, but those with low levels of AP will not commit offenses even when (on the basis of subjective expected utilities) it appears rational to do so. Equally, high short-term levels of AP (e.g., caused by anger or drunkenness) may induce people to commit offenses when it is not rational for them to do so.

The consequences of offending may, as a result of a learning process, lead to changes in long-term AP and in future cognitive decision-making processes. This is especially likely if the consequences are reinforcing (e.g., gaining material goods or peer approval) or punishing (e.g., receiving legal sanctions or parental disapproval). Also, if the consequences involve labeling or stigmatizing the offender, this may make it more difficult for him to achieve his aims legally and hence may lead to an increase in AP. (It is difficult to show these feedback effects in Fig. 1 without making it very complex.)

A further issue that needs to be addressed is to what extent types of offenders might be distinguished. Perhaps some people commit crimes primarily because of their high long-term AP (e.g., the life-course-persistent offenders of Moffitt 1993), others primarily because of situational influences (e.g., getting drunk frequently) and high short-term AP, while still others offend primarily because of the way they think and make decisions when faced with criminal opportunities. From the viewpoint of both explanation and prevention, research is needed to classify types of people according to their most influential risk factors and most important reasons for committing crimes.

Predictions About Contentious Issues

The ICAP theory makes the following predictions about the contentious issues listed earlier. First, it predicts that the individual offending frequency and the seriousness of offending should increase to a peak in the teenage years and then decline, because both reflect AP. Second, the theory predicts that an early age of onset of offending predicts a high individual offending frequency and a high average seriousness of offending, again because both reflect AP. An early age of onset indicates a relatively high level of AP, and the ordering of people on AP tends to stay relatively consistent over time. Similarly, chronic offenders should have both a high frequency and a high seriousness of offending. Third, the ICAP theory predicts that onset sequences generally are age-appropriate behavioral manifestations of AP and therefore that they reflect persistent heterogeneity. However, the theory also incorporates learning and labeling processes following offending, so this would predict some state dependence effects.

Fourth, the ICAP theory predicts that within-individual changes in the major risk factors should be followed by within-individual changes in AP and hence in offending. Fifth, the theory predicts that short-term energizing factors such as heavy drinking influence short-term within-individual variations in offending: why people commit offenses in some times and places but not others. Sixth, the ICAP theory predicts that different risk factors would influence early onset before age 20, continuation of offending after onset, later onset after age 20, and persistence or desistance of offending after age 20. This is because it assumes that risk factors have different effects on AP at different ages. Seventh, the theory predicts that the criminal justice system should have deterrent or labeling effects on future offending. Future research should aim to establish to what extent these predictions are correct or incorrect.

Testing the ICAP Theory

The first independent test of the ICAP theory was carried out by Van Der Laan et al. (2009) in the Netherlands. Nearly 1,500 youth ages 10–17 completed a survey that enquired about long-term and short-term (situational) risk factors for delinquency. Nearly 300 of these answered questions about the circumstances of their last offense. In agreement with the ICAP theory, Van Der Laan and his colleagues found that long-term individual, family, and school factors correlated with serious delinquency, and the probability of serious delinquency increased with the number of factors. However, after controlling for long-term factors, short-term situational factors such as the absence of tangible guardians and using alcohol or drugs prior to the offense were still important. While the results of this test are very encouraging, it would be useful in the future to test the theory in a longitudinal survey.

The ICAP theory could be tested in the Cambridge Study by using antisocial attitude scores at different ages as measures of long-term antisocial potential. These could be related to individual, family, peer, and school risk factors to investigate the relative strength of relationships at different ages. They could also be related to self-reported and official offending at different ages. Different causal models could be tested at different ages. For example, in the Pittsburgh Youth Study, Defoe et al. (2013) concluded that hyperactivity and low socioeconomic status led to low school achievement, which led to delinquency, which in turn led to depression. In the Cambridge Study, the importance of long-term risk factors and short-term situational influences should be compared.

Conclusions

The ICAP theory, like other DLC theories, explains the widely accepted findings that I have listed above. However, more efforts should be made to compare and contrast the ICAP theory point by point with other DLC theories in regard to their predictions and their agreement with empirical results (Farrington 2006). Detailed computer models of the ICAP theory should be developed that allow users to click on the boxes of Fig. 1 to see more underlying detail or to see different theories for onset, continuation, and desistance. It would be better to make quantitative rather than qualitative predictions; criminological theories typically predict that X is related to Y or that X is greater than Y, but not the magnitude of relationships. These could build on the mathematical models of MacLeod et al. (2012), which hypothesize three types of offenders with different rates of offending and different probabilities of desistance. It is particularly important to specify crucial tests, where predictions from the ICAP theory differ from predictions from another DLC theory.

The ICAP theory could be improved in several ways. First, different models could be specified at different ages, based on the relative importance of various long-term risk factors (strain, modeling, socialization, impulsiveness, and life events). It might be expected that parental and peer influences would be differentially important at different ages, and the same is true of life events such as leaving school, getting a job, leaving home, and getting married. Second, risk factors that are not currently in the theory could be incorporated (e.g., biological factors or empathy). Third, the theory could be modified to explain differences in offending by age, gender, race and nationality, or country (Farrington and Loeber 1999). Fourth, different models could be proposed to explain the prevalence and frequency of offending, persistence versus desistance, and the length of criminal careers. Fifth, different models of short-term situational influences could be proposed to explain the commission of different types of crimes. Potential offenders could be asked about their likelihood of committing crimes in different situations to investigate their cognitive processes and motivations (Farrington 1993), and efforts could be made to study the learning processes involved in the development of criminal careers.

In order to advance knowledge about DLC theories and test them, new prospective longitudinal studies are needed with repeated self-report and official record measures of offending. Future longitudinal studies should follow people up to later ages and focus on desistance processes. Past studies have generally focused on onset and on ages up to 30. Future studies should compare risk factors for early onset, continuation after onset (compared with early desistance), frequency, seriousness, later onset, and later persistence versus desistance. DLC theories should make explicit empirical predictions about all these topics. Also, future studies should make more effort to investigate protective factors, and biological and neighborhood risk factors, since most is known about individual and family risk factors. And future research should compare development, risk factors, and life events for males versus females and for different ethnic and racial groups in different countries.

Because most previous analyses of risk factors for offending involve between-individual comparisons, more within-individual analyses of offending are needed in longitudinal studies. These should investigate to what extent within-individual changes in risk and protective factors are followed by within-individual changes in offending and other life outcomes (Farrington et al. 2002). These analyses could provide compelling evidence about causal mechanisms. More information is needed about the predictability of future criminal careers at different ages and stages, in order to know when and how it is best to intervene.

DLC researchers should carry out more research on explaining why crimes are committed, and especially on situational influences. Research should also be conducted on interactions between individual and situational factors in explaining the commission of crimes. Studies are also needed to classify types of people according to their most influential risk factors and most important reasons for committing crimes. Questions about situational influences on offending should be included in longitudinal studies of the development of offenders.

DLC theories have many policy implications for the reduction of crime. First, it is clear that children at risk can be identified with reasonable accuracy at an early age. The worst offenders tend to start early and have long criminal careers. Often, offending is preceded by earlier types of antisocial behavior in a developmental sequence, including cruelty to animals, bullying, truancy, and disruptive school behavior. It is desirable to intervene early to prevent the later escalation into chronic or life-course-persistent offending and to develop risk-needs assessment instruments to identify children at risk of becoming chronic offenders. These instruments could be implemented soon after school entry, at ages 6–8.

It would be desirable to derive implications for intervention from DLC theories and to test these in randomized experiments. In principle, conclusions about causes can be drawn more convincingly in experimental research than in nonexperimental longitudinal studies. The results summarized here have clear implications for intervention. The main idea of risk-focused prevention is to identify key risk factors for antisocial behavior and then implement prevention methods designed to counteract them (Farrington 2007). In addition, attempts should be made to enhance key protective factors.

Because of their emphasis on development through life, DLC theories suggest that it is "never too early, never too late" (Loeber and Farrington 1998) to intervene successfully to reduce offending. In other words, it is highly desirable to focus not only on early intervention to prevent the adolescent onset of offending but also on later programs to prevent adult onset and to intervene with offenders to prevent continuation and encourage early desistance.

The fact that offenders tend to be antisocial in many aspects of their lives means that any measure that succeeds in reducing offending will probably have wide-ranging benefits in reducing, for example, accommodation problems, relationship problems, employment problems, alcohol and drug problems, and aggressive behavior. Consequently, it is very likely that the financial benefits of successful programs will greatly outweigh their financial costs. The time is ripe to mount a new program of research to compare, contrast, and test predictions from the ICAP and other DLC theories, in the interests of developing more valid theories and more effective crime prevention policies.

Integrating Rational Choice and Other Theories

Stephen G. Tibbetts
Department of Criminal Justice, California State University, San Bernardino, San Bernardino, CA, USA

Synonyms

Choice theory; Decision making theory; Rational choice theory; Theoretical integration

Overview

This entry will discuss the integration of rational choice theory with other theoretical perspectives in developing a better understanding of why individuals engage in various criminal activities. Both the strengths and weaknesses of such integration will be examined.

Fundamentals/Historical Context

Rational Choice theory, also known as reasonable action theory or choice theory, is a perspective of human behavior that is based on the assumption that individuals will naturally make decisions of whether or not to act in a specific situation in order to maximize their pleasure or benefits, while minimizing potential pain or punishment. This perspective readily lends itself to integration with other theories of crime, given that it can be applied to virtually every type of activity (including all conventional activities as well). The fact that rational choice theory was originally developed by economists, and then adopted by criminologists to explain criminal behavior, is a strong indication of the versatility and general validity of this perspective. Thus, rational choice theory is inherently an integrated theory, and furthermore is quite accommodating to integration with other theories of crime.

Historical Context

Rational Choice theory was first presented as a framework for explaining and understanding of why individuals choose to engage (or not to engage) in certain behaviors in a variety of economic or social behaviors. Emerging primarily from the economic field, the most notable proponent of this perspective was Gary Becker (1968), who later won a Nobel Prize in 1992 in the area of Economic Sciences. In the last couple of decades, the rational choice framework has become perhaps the dominant perspective in the area of microeconomics, which emphasizes the reasons for why people make the decisions they make regarding many aspects of their life.

This perspective assumes that the primary reasoning of individuals in virtually all decisions they make is based on perceived expectations of the potential benefits versus potential costs that are likely to result in such decisions. Obviously, this relates to economic decisions regarding personal finances, but also applies directly to decisions made regarding whether or not to engage in a variety of criminal acts. After all, illegal activities virtually always involve potential risk of punishment or costs, and also typically involve some kind of potential benefit, whether it be financial profit, peer-respect, etc. Thus, it is not surprising that criminologists readily embraced the rational choice perspective and promoted it as a robust framework in developing models of explaining why individuals choose to commit (or not commit) criminal acts. Regardless of the activity being examined, such as financial, social, criminal, etc., the bottom line of rational choice theory is that when individuals make a decision, they are assumed to balance their perceptions of likely benefits versus likely costs of their decision.

Context in Criminological Literature

The development of rational choice theory in the criminological literature can not be understood without acknowledging the rebirth of classical deterrence theory in the field. In the late 1960s, studies began to highlight and examine the importance of the rates of being apprehended by police (often measured as ratios of arrests per crimes reported to police for given offenses), as well as the severity of being caught (typically measured by the length of jail/prison sentences given if convicted for certain types of crimes). Comparisons were made between jurisdictions based on these certainty ratios and length of sentences, with most studies concluding that the certainty ratios appeared to be consistently and significantly related to lower crime rates, but the length of sentence not having as much influence on crime rates, but still related to lower crime rates in some of the studies.

However, researchers soon realized that such aggregate measures are likely not to be considered by individuals who make decisions to commit criminal offenses. Thus, researchers advanced their models to examine individual perceptions of potential risks, such as the likelihood of being caught and the severity that the formal punishments would be if convicted of such crimes. The acknowledgment of this weakness led to cross-sectional studies (i.e., taken at one point in time) that examined individuals' perceptions of certainty and severity of punishment of being caught and then compared them to their actual offending. Studies showed that such perceptions of higher certainty of punishment were consistently linked to lower reported criminal activity, whereas perceptions of the higher severity of being punished were more inconsistent, but many studies showed that such perceptions were also linked to lower reported criminal offending. But once again, researchers realized that their methodology was flawed in the sense that it was likely that individuals' experience in committing crimes was altering their perceptions of getting caught (i.e., experiences affect perceptions of risk, labeled an "experiential effect"), as opposed to the proposed model of perceptions of risk affecting their decisions to commit crimes (which is the classic deterrence model).

To address this weakness in their methodology, a new wave of research emerged that focused on longitudinal or panel studies that measured individuals' perceptions of potential risks, as well as prior criminal offending, in the first wave. Then, at a later date (such as a year later), the subsequent wave(s) measured their reported offending and analyzed this while taking into account their perceptions and past offending measures collected at the first wave. This approach was largely initiated by Raymond Paternoster and his colleagues in a series of studies published in the early- to mid-1980s (e.g., Paternoster et al. 1983). These seminal studies revealed that previous suspicions were indeed true; specifically, an "experiential effect" existed and had a highly significant effect on persons' perceptions of risk. This was a key finding that highly influenced future research in both deterrence and emerging rational choice models for years to come.

Despite the acknowledgement and accounting of an experiential effect in determining individuals' perceptions of risk, the studies that accounted for this effect still typically showed significant effects for levels of perceived formal sanctions, such as the risk of being caught and the severity of being caught/convicted. Still, these models were limited to a more traditional deterrence model, which emphasized only formal sanctions and past offending. This set the stage for a new theoretical framework that introduced other important factors that go into most individuals' decisions to commit crime, namely the rational choice perspective.

Early Rational Choice Models of Criminal Behavior

According to surveys of empirical research (see Tibbetts and Gibson 2002), prior to 1986 there were approximately a dozen of studies on applying the rational choice framework to criminal behavior. Most of these studies were based largely on more traditional deterrence factors, such as perceptions of the certainty of being caught and the perceived severity of punishment that would likely result from being caught. Virtually all of these pre-1986 studies tend to lack an examination of other factors, such as the benefits or profits from committing crimes, as well as the influence of a variety of other factors, such as moral beliefs, emotions, perceived informal factors, etc., nor did they typically attempt to integrate rational choice theory with other theoretical perspectives in the criminological field. Although they did not necessarily create much attention or inspire a flurry of research on rational choice theory, they certainly built the foundation for what was soon to come.

In 1986, the first notable burst of research regarding rational choice theory in explaining criminal behavior emerged by Derek Cornish and Ronald Clarke, who published their seminal book, *The Reasoning Criminal: Rational Choice Perspectives on Offending*. This anthology included many chapters that explored applying rational choice to a variety of offenses, as well as promoting the expansion of the perspective to include or integrate more factors that would likely be important in an individuals' decision to engage in criminal activity. This book was well-received by scholars and the public alike, and was likely almost entirely responsible for the later surge of rational choice studies that were published in the early- to mid-1990s. The several years gap between their 1986 publication makes sense given a normal time-gap between the publication of a notable work and the research that results from it. This gap is expected due to reading the new work (in this case Cornish & Clarke's book), developing new research agendas, creating new survey instruments and measures, administering such surveys or acquiring new data, analyzing the results, writing up the manuscripts, and then going through the process of getting published in peer-reviewed journals. Regardless, the large attention given to rational choice theory a handful of years later showed that the call for more research was quickly answered.

Integration of Informal Sanctions and Personal Sanctions (Self-Conscious Emotions)

In fact, in only a few years after the publication of *The Reasoning Criminal*, a series of studies were published by Harold Grasmick, Robert Bursik, and their colleagues that examined the rational choice framework on a variety of crimes, such as littering, theft, and drunk driving (e.g., Grasmick and Bursik 1990). Beyond the more traditional deterrence factors of official risks of being caught and severity of such punishments if caught, some of these studies also included more informal factors, such as how the individual would expect their family, friends, employers, etc., to react to them being caught for engaging in such behaviors. These informal sanctions that were integrated into estimated rational choice models were largely derived from social disorganization theory (or Chicago School of criminology), which places a focus on the influence that one's social environment – such as family, peers and neighborhood – has on their likelihood of committing crime and delinquency. These studies consistently found such informal factors to be consistently significant influences on predicting the likelihood of people to decide to commit such offenses, and were often far more important than any formal, legal sanctions that were expected. Specifically, the higher the levels of reported expectations that friends, family, employer, etc., would affect the individual negatively for committing such crimes, the less likely the individual was to engage in such behaviors. This was not too surprising given that it is likely that most people care more about their standing with people they interact with every day than with the official sanctions of going to jail for a few months. The informal sanctions are likely to impact their long-term future, as opposed to the typically short-term consequences of official, legal sanctions. Although this may not seem to be a major breakthrough, it was at the time for models on deterrence and rational choice. Furthermore, although not recognized or stated at that time, the incorporation of such factors as informal sanctions and emotions into models of rational models were a form of integration.

Also notably in these studies, the effects of new factors were introduced and estimated, such as the levels of expected embarrassment or shame a person would feel for being caught for engaging in such activities. These emotional factors, especially shame, not only showed consistently significant inhibitory effects on decisions to commit such illegal acts, but also inspired many subsequent studies on the importance of such self-conscious emotions in rational choice models of offending. As with the influence of informal sanctions described above, the integration of these emotional components added an entirely new dimension in terms of factors that should be included in subsequent rational choice models of offending, if they are to be fully specified. Thus, the published research in early 1990s not only added support to what would become the largest wave of studies on rational choice theory in the criminological literature, but also set the stage for integrating other factors into such models.

Key Issues in Integration of Rational Choice with Other Theories

Peak of Research on Rational Choice and Integration with Social Control, Social Learning, and Social Disorganization Theories

Empirical studies have shown that the first peak of attention given to the rational choice perspective was clearly between the years of 1992–1997, according to the database of Criminal Justice Abstracts (see discussion in Tibbetts and Gibson 2002). This 6-year period experienced a significant increase in studies published in the criminological literature regarding applying rational choice theory to various types of criminal offending. Specifically, in these 6 years the total amount of rational choice studies more than doubled the number that had been done in all years prior to 1992. Many of the studies in this period appropriately took the earlier versions of rational choice theory and made them more fully specified, and thus more complete, models of criminal offending on given types of crimes.

Much of this expansion of the rational choice perspective involved the elaboration of the rational choice framework to include various factors or concepts that had not been traditionally considered deterrence variables, as discussed above and below. Other studies actually merged rational choice theory with other established theoretical perspectives, such as social control/bonding theory, social disorganization, social learning, and others. Therefore, a number of the most cited studies in this period integrated the rational choice perspective with various other types of theories, or at least key concepts taken from other established theories of crime.

The key studies in the period of the early- to mid-1990s attempted to integrate rational choice theory with such concepts from other established theories such as social control/bonding, social learning and social disorganization, by incorporating the concepts of attachments to significant others, commitment/involvement in the local community, and perceptions of the reactions of others in their local neighborhood or community would react to their offending as important factors in decisions to commit crimes. For example, the importance of perceptions of how their family, friends, employers, and others in their community were not only examined, but seemed to have more importance in most cases than the perceptions of formal sanctions (i.e., police, courts, corrections) that had been emphasized in the previous rational choice studies that were based almost exclusively on expectations of official punishments. Specifically, the findings of these studies were consistent in showing that the perceived responses of such informal factors, appeared to have just as much, if not more, of an influence on individuals' decisions to engage in a variety of criminal acts.

Such findings make sense because most people in society desire to please those who are closest to them and to the others they interact with on a daily basis. The formal sanctions, on the other hand, are typically considered somewhat removed from their everyday life, in the sense that the daily lives of most individuals are not typically directly affected by the opinion or reaction of police officers, judges, etc. Thus, it is not surprising that the key studies in the early 1990s that examined subjects' perceptions of informal sanctions were quite influential in their decision-making when it comes to engaging in various crimes.

The introduction of these informal sanctions were largely drawn from other established theories such as social learning, which emphasizes the influence of learned attitudes and behaviors of significant others regarding a specific criminal activity, as well as the social rewards and punishments that come from deciding to engage (or not engage) in certain illegal acts. According to social learning theory, the internalization of such attitudes and behaviors of others by an individual regarding a given act increase the likelihood that individuals will either engage or not engage in such activities. In cases in which a person's significant others actually promote the commission of crime, then the individual will view engaging in the act as a benefit in terms of respect from the friends or others that will respect her or him for doing the act, which are seen as a form of reward. On the other hand, if most of the person's significant others look unfavorably on the commission of such an act, the individual is far less likely to engage in such behavior, because this is seen as a form of punishment. One of the benefits of the rational choice perspective is that any factor that creates a potential benefit or cost to their daily life can easily fit in this framework.

Integration of the Benefits or Thrills of Offending

The early 1990s wave of studies also, for the first time, integrated and placed a large emphasis on individuals' perceptions of benefits, or pay-off, from engaging in various criminal activities. Much of this attention was due to the recent publication of the book in 1988 by Jack Katz, *Seductions of Crime*, in which he emphasized the importance of the perceived benefits of committing crime or delinquency. Specifically, Katz had pointed out that there were many positive reasons for why certain individuals, especially young people, who engage in crime for various benefits, such as getting "sneaky thrills" out of offending. Youth tend to get a thrill from committing some offenses that have no actual pay-off in terms of utility, especially among certain groups of youths (such as graffiti, vandalism, unprovoked assaults, being a member of a street gang, etc.).

A good example is vandalism, such as destroying mail-boxes, breaking windows, or other similar forms. Katz specified that much of these behaviors that seemed to have no actual pay-off really did have a large pay-off other terms, such as peer respect, confidence, and relief of built-up anger/stress. Recent studies have shown that such activity actually increases dopamine and testosterone levels, which adds a physiological aspect to the benefits of crime that were not directly examined by most rational choice studies in the early 1990s period, but would surface later. Ultimately, the integration of Katz' model of benefits or pay-off, either from a financial or social or physiological aspect, was one of the key contributions of this wave of studies in the early 1990s. This element fit well into the rational choice perspective as an element of benefit from engaging in criminal acts.

Integration of Moral Beliefs (Social Bonding Theory)

Another notable integration in this large wave of key studies on rational choice theory in the early 1990s was the emphasis on personal moral beliefs, which was largely derived from the social control/bonding theory of crime (Hirschi 1969). Although social bonding theory specified four elements, some of these key elements – attachments to others, commitment/involvement to society, and conventional activities – had already been indirectly integrated into rational choice studies by prior models via informal factors (see above). But it was the last element of moral beliefs that had previously been unexplored, but became an emphasis on influencing the other variables in estimated models of rational decision-making regarding criminal behavior. Specifically, the integration of the concept of moral beliefs, previously seen as a social bonding concept, was presented in rational choice models of crime as a conditioning factor on the effects of individuals' perceptions of the certainty or severity of getting caught when considering engaging in certain types of crimes.

Some of the first key studies to integrate the concept of moral beliefs as a conditional variable was Ronet Bachman, Raymond Paternoster and their colleagues (e.g., Bachman et al. 1992; Paternoster and Simpson 1996), which revealed that the likelihood of decisions to engage in a variety of crimes such as sexual assault and corporate crimes were significantly influenced by their personal beliefs regarding the morality (or immorality) of committing such acts. Furthermore, these studies also consistently showed that the effects of perceptions of likelihood of getting caught officially or severity of subsequent punishment tend to not as be as important when individuals' have high levels of moral beliefs regarding the inherent immorality to engage given specific criminal acts. The findings of these studies further confirmed that there was much more to personal decisions to engage in a given criminal act than simply balancing the perceived risk of formal and/or informal costs of the act versus the perceived likelihood of benefits or potential pay-off. Ultimately, the incorporation of moral beliefs represented a radical departure from the simple framework presented by the early rational choice theorists, which was limited to expected costs and/or benefits. These studies suggested that long-term, time-stable personal beliefs and perhaps many other personality traits or dispositions should be considered as potential factors that may alter the effects of perceived costs and benefits of committing certain crimes.

Integration of Self-Control Theory

The rational choice studies of the early 1990s were also highly influenced by the publication of the book (and prior studies) by Michael Gottfredson and Travis Hirschi, *A General Theory of Crime* (1990). This book claimed that virtually all criminal offending and deviant behaviors are caused by a single factor – low self-control. The theory proposed by the authors quickly became not only perhaps the most researched theory in the field, but also became in the 1990s the perspective ranked by criminologists as the second most important theory in terms of validity of what explains most criminal behavior (Ellis and Walsh 1999), ranked just after social control/bonding theory which was also integrated with rational choice models around the same time period (as discussed above).

Many of the studies on rational choice integrated the concept of self-control into their models of offending, primarily as a conditional or interaction variable, in terms of determining how individuals perceive the risks of being caught and the severity of punishments of being caught. Specifically, studies in the early 1990s by Daniel Nagin and Raymond Paternoster showed that many of the primary factors of the traditional classical/deterrence framework were conditioned by individuals' levels of self-control (Nagin and Paternoster 1993). These findings were further supported by subsequent studies that showed that not only were such traditional deterrence factors conditioned by self-control, but that other factors – specifically anticipated shame and anticipated benefits – also played a significant conditioning role in terms of decisions to engage in various criminal activities (Piquero and Tibbetts 1996). The findings of these studies created an entirely new area of research that explored the conditional effects of the more traditional deterrence/rational choice factors of perceived certainty and severity in light of many other factors that had not been included in traditional models of rational choice.

The amount of research given to rational choice theory in criminological research experienced a relative decrease in the late 1990s, as well as the early 2000 years (Tibbetts and Gibson 2002). In light of this notable decrease in attention given to rational choice theory, some criminologists specifically advised that in order to rational choice theory to make an attempt to elaborate on the rational choice framework and integrate various concepts from more established theories of crime. Subsequently, in the first decade of the new century, the attention and number of studies began to pick up again in the mid-2000s period; this is evidenced by the large number of studies that are currently referenced in Criminal Justice Abstracts between the years of 2005–2010, which averaged 28 studies for each year between 2005 and 2009 (with a high of 34 studies in 2007), which is far higher than any other 5-year period in the history of rational choice studies in criminological literature. Much of this attention was inspired by the studies that were done before in the early- to mid-1990s, that showed that numerous other factors can and do play a large part in individuals' decision-making beyond the traditional deterrence factors regarding perceived costs and benefits of committing crimes. Such studies began to apply rational choice theory to areas that had not been directly emphasized before, such as white-collar crime (for a review, see Simpson et al. 2002). This led to a burst of research that emphasized the integration of rational choice with other established theories, which was largely based on elaborating the rational choice framework to include other key concepts from such traditional, relatively more established theories that will be discussed below.

Recent Research Integrating Rational Choice with Other Theoretical Models and Concepts

It is notable that rational choice theory did not even make the list of the top 23 "most valid" theories in the 1999 study above that examined responses from over a hundred leading criminologists regarding which theories they thought had the most validity regarding serious crime (Ellis and Walsh 1999). This is one of the reasons that some researchers soon after claimed that in order for the rational choice framework to thrive in the criminological literature, researchers must begin integrating other theoretical concepts and propositions into the rational choice model of criminal decision making. Specifically, after a review of the extant research, Tibbetts and Gibson claimed in 2002, "the survival of rational choice theory largely depends on its integration with frameworks that emphasize individual propensities, which has been shown to complement both perspectives" (p. 18). Fortunately, it appears that this call for research has been taken by many researchers in the field. As mentioned above, the first decade of the new century saw a resurgence in the attention and number of studies on rational choice theory, especially those that integrated various concepts or propositions of other established theories into such estimated models. Notably, most of these studies were indeed related to elaborating the rational choice framework to account for individual propensities or dispositions toward committing criminal activity.

Enduring Individual Differences and Rational Choice Theory

The call for more rational choice studies to account for individual propensities in the early 2000 years appears to have been answered, because the most current research in rational choice theory are studies that integrate various other established theories or concepts from such theories, especially those accounting for individual dispositions toward committing crime. These personal propensities that are typically emphasized in most recent studies tend to relate to personality traits or other time-stable factors that are apparent from an individual's early antisocial behavior to later manifestations of criminality. After all, one of the key findings from empirical studies show that people tend to behave quite differently given the same situation, which is likely due to such personal dispositions and personality traits.

Related to the integration of other theories to rational choice, a recent review by Alex Piquero, Raymond Paternoster, and their colleagues recently explored the evidence related to this "differential deterrability" of that exists across different individuals with respect to the perceived sanctions (i.e., certainty and severity of punishment) of traditional rational choice models of crime (Piquero et al. 2011). This review showed that various traditional theories of crime provided much insight toward why certain individuals are more (or less) likely to engage in criminal activity. Specifically, the theories of social bonding, moral inhibition, self-control, impulsivity, emotional arousal, and pharmacological arousal were all shown to be significant additions to understanding the decision making of individuals in whether they would commit or not commit a given criminal act.

Regarding the factors that had not been discussed above in this entry, emotional and pharmacological arousal was one of the most important aspects that this review presented.

Specifically, the Piquero et al. review noted the pioneering studies of the 1990s and recent years that integrated contemporaneous emotional states into rational choice models of offending by such scholars as George Loewenstein, Daniel Nagin, Raymond Paternoster, and their colleagues. Such studies compared sexually aroused males (such as exposing some subjects to nude photographs) to non-aroused males on responses of their likelihood of committing date rape. Not only did the aroused males score higher in their intentions to commit such acts, but these studies also showed that their decisions to commit date rape were not as influenced by traditional rational choice/deterrence factors (e.g., perceived certainty/severity of punishment). Other studies have shown that the perceived benefits of such a date rape sexual act were only partially mediated by such traditional rational choice/deterrence factors.

Additional studies have explored the pharmacological influence of alcohol on individuals' intentions to commit crimes. Specifically, Assaad and Exum (2002) reviewed the extant literature on the influence of alcohol on individuals' likelihood of engaging in criminal activity, as well as how alcohol influences their perceptions of risks of being caught and punished, as well as their perceptions of potential benefits of committing such acts. This review concluded that (p. 77) "under the influence of alcohol, individuals are more likely to attend to salient, provocative cues in the environment. . .are less likely to recognize the costs associated with their own aggressive behavior. . .and may experience increases in arousal that in turn interferes with the cognitive processes that normally inhibit aggression." Furthermore, there are many other pharmacological influences that involve many other substances (e.g., cocaine, methamphetamine, etc.) that were not examined in this review, but are quite likely to influence to influence individuals' perceptions of risks versus benefits of engaging in illegal behaviors. Far more research is needed in this area of how other illegal substance usage influences the various perceptions of costs and benefits of a given act, and thus creating a better understanding of human behavior according to rational choice theory.

Ultimately, the most important point of this entry is the conclusion that the evolution of rational choice theory has recently become far more integrated with other concepts and propositions of more established theories of crime, as well as factors that have not been included in such traditional theories (e.g., emotional arousal, etc.). Such elaboration of the rational choice framework to incorporate these concepts and propositions has created a more robust theory that explains criminal behavior much better than the earliest forms of the theory presented in the 1970s and 1980s. However, despite this success, such integration of rational choice theory with other theories has seen its fair share of criticism.

Criticisms of the Integration of Other Theories with the Rational Choice Perspective

Criticisms of Rational Choice Theory and Integration with Other Theories

Some researchers would likely call such studies/theories that use rational choice theory as a framework, and then integrate other key concepts or propositions from other more established theories, as more of an elaboration of rational choice as opposed to integration of two or more separate theories. However, theoretical elaboration is generally considered a form of theoretical integration (Messner et al. 1989), so such elaborations or expanded models of the rational choice framework that include such key concepts or propositions from other established theories are generally accepted as theoretical integration. Ultimately, the goal of both elaboration or integration is to create a theory that represents the best explanation or understanding of the phenomenon being examined. Thus, whether it be theoretical elaboration or a more complete form of theoretical integration is somewhat moot, because both seek to develop the best model for predicting and understanding the offense being considered. This is what the many of the key rational choice studies of from the early 1990s to contemporary times has sought to do. Apparently the elaboration or integration of rational choice with concepts and/or propositions of other established theories has been successful and enlightening. This can be observed in the dramatic increase in the number of studies in the last decade on rational choice, as well as the significant increase in the explained variation of offending decisions in estimated statistical models of these expanded and integrated rational choice models of illegal behavior.

Other criticisms of the integration of rational choice with other theories of crime have claimed that the proponents of rational choice are in some ways stealing from the other established theories (such as differential reinforcement/association theory) because many of their concepts can easily fit into either a cost (e.g., peer disapproval) or benefit (e.g., peer approval) in a rational choice framework. However, it is true that one of the most beneficial aspects of rational choice models of offending is that it does indeed allow for the introduction of any aspects or factors that may influence individuals' perceptions of anticipated costs or benefits given a particular opportunity to commit a criminal act. Given that the rational choice framework is more of a general theory of behavior, it *should and must include* all relevant factors in terms of specifying models for engaging in illegal acts, especially factors that significantly influence a person's reasoning when deciding whether or not to engage in such activity. Therefore this criticism of being allowed to include many factors that influence individual decision making regarding various behaviors is also somewhat moot, because the inclusion of such factors that affect a person's perception of expected costs versus benefits is what rational choice models of offending are inherently about.

Ultimately, the major criticisms against the integration or elaboration of rational choice models to include factors from more traditionally established models of crime have been shown to be weak at best. After all, why should any theory have "property claim rights" over any concept, factor, or proposition regarding human behavior. Thus, the introduction of the various concepts to the rational choice theoretical framework over the last decades should be embraced, especially in light of how much better the recent estimated rational choice models of crime have shown success in creating a far better understanding of individuals' perceptions in choosing whether or not to engage in a given criminal act.

Intelligence-Led Policing

Jerry H. Ratcliffe
Temple University, Philadephia, PA, USA

Synonyms

ILP; Information-led policing

Overview

Intelligence-led policing is a policing business model that incorporates data analysis and criminal intelligence into a strategy that coordinates strategic risk management of threats with a focus on serious, recidivist offenders. It originated in the UK but has been increasingly adopted around the world.

Definition

Intelligence-led policing (ILP) is a term now embedded in the lexicon of policing around the world. From its origins in the new public management ethos of 1990s Britain to hurried US recommendations for ILP adoption in the wake of the 9/11 terrorist attacks, law enforcement agencies have looked to ILP as the contemporary model (Carter 2009) to integrate the intelligence function into the operations of the police service. The National Criminal Intelligence Sharing Plan (GIWG 2003), developed for the US Department of Justice by the Global Justice Information Sharing Initiative (Global) Intelligence Working Group (GIWG), advocated heavily for the need for ILP, yet they neither defined it nor explained how it should be implemented (Carter and Carter 2009). Wardlaw and Boughton (writing in 2006) point out that “the concept of intelligence-led policing is now widely espoused by police services as a fundamental part of the way they do business. But for such a widely talked about concept, there is remarkably little clarity about its definition and fundamental concepts” (2006: 134). So while the term has joined the jargon of police departments seeking to establish their credentials as innovative and progressive, the absence of a definition from which to direct and measure implementation hampered initial development (Ratcliffe 2008a).

Various definitions of ILP now exist to fill the void. One stresses the philosophical role of the intelligence function within policing, describing it as “an underlying philosophy of how intelligence fits into the operations of a law enforcement organization. Rather than being simply an information clearinghouse that has been appended to the organization, ILP provides strategic integration of intelligence into the overall mission of the organization” (Carter 2004: 4). The Bureau of Justice Assistance has three definitions of ILP within the same document (BJA 2009): first describing it as “a business process for systematically collecting, organizing, analyzing, and utilizing intelligence to guide law enforcement operational and tactical decisions” (p. 3) and then as “a collaborative law enforcement approach combining problem-solving policing, information sharing, and police accountability, with enhanced intelligence operations” (p. 4). The same page finally settles on, “executive implementation of the intelligence cycle to support proactive decision making for resource allocation and crime prevention. In order to successfully implement this business process, police executives must have clearly defined priorities as part of their policing strategy" (p. 4). Thus, within the space of two pages, ILP is a business model, an operational tactic, and a strategic leadership function.

One definition has been increasingly adopted by a variety of writers (e.g., Burch and Geraci 2011; Gottschalk 2010; Hess and Orthmann 2011; Smith 2009) as the de facto definition:

> Intelligence-led policing is a business model and managerial philosophy where data analysis and crime intelligence are pivotal to an objective, decision-making framework that facilitates crime and problem reduction, disruption and prevention through both strategic management and effective enforcement strategies that target prolific and serious offenders. (Ratcliffe 2008a: 89)

This definition was arrived at after consultation and wordsmithing from a number of influential analysts and intelligence managers involved in the implementation of ILP within Britain's National Intelligence Model and beyond. The definition integrates analysis and intelligence into the decision-making structure of a police department and combines a traditional enforcement approach for serious and prolific offenders with the problem-oriented strategic management of crimes and other policing problems. With the inclusion of problems in the definition, there exists the possibility for the business model component to be applied to a variety of (noncrime) policing issues, such as traffic management and crash prevention (as is the case in New Zealand). As the original architects of the UK National Intelligence Model have pointed out, "we knew that the intelligence model was in fact an ideal model for the whole business of policing that would enable police commanders to understand and anticipate risks and threats across the public safety domain" (Flood and Gaspar 2009: 54).

Origins

Rising crime levels in many countries during the 1980s and 1990s drove some police departments to seek out more cost-effective strategies and greater efficiencies from increasingly limited police budgets (Ratcliffe 2008a). The "demand gap" of greater expectations placed on police not being met with equivalent increases in resources placed a strain across the policing sector and drove some to seek out more strategic approaches to the business of policing (Flood and Gaspar 2009). While the USA was the originator for problem-oriented policing, the UK's different policing structure and "more sophisticated legacy" with criminal intelligence (Carter and Carter 2009) provided other opportunities. Emerging from various criminal intelligence reforms during the 1970s (Flood and Gaspar 2009), two influential British government reports, *Helping With Enquiries: Tackling Crime Effectively* (Audit Commission 1993) and *Policing with Intelligence* (HMIC 1997), laid out the government's interpretation of the problems; existing police roles and accountability lacked integration, police were not making the best use of resources, and targeting criminals would be more effective than focusing on crime. The reports also pointed to a potential solution, with *Policing with Intelligence* stating in the first paragraph:

> Good quality intelligence is the life blood of the modern police service. It allows for a clear understanding of crime and criminality, identifies which criminals are active, which crimes are linked and where problems are likely to occur. It enables valuable resources to be targeted effectively against current challenges and emerging trends ensuring the best opportunities for positive intervention and maximum value for money. (HMIC 1997: 1)

Unencumbered by the damaging domestic intelligence failures and bad practices that plagued the development of criminal intelligence in the USA (Carter 2004; Ratcliffe 2008a), British policing leaders looked to reform the police service with a greater focus on the strategic management of crime risks through a better understanding of the criminal environment.

This period of sustained reform in British policing also saw the development of the UK National Intelligence Model (NIM). Enthusiastically adopted by a number of police leaders, some saw it as an occasion to push back against the prevailing neighborhood reassurance/community policing model popular at the time. In particular Sir David Phillips (then Chief Constable of Kent Constabulary) saw the NIM as an opportunity to restore the status of detectives and the criminal investigation department. However, the NIM, actively promoted by the National Criminal Intelligence Service and the Association of Chief Police Officers, established a business model that situated criminal intelligence and analysis – rather than criminal investigation – at the center of police decision-making and crime fighting (Harfield and Harfield 2008; NCIS 2000).

In the USA, the move toward intelligence-led policing has been hampered by a number of factors, both historical and organizational. The Church Report, which investigated the activities of the FBI's counterintelligence program that ran through the 1950s and 1960s, identified numerous shortcomings of the management of criminal intelligence programs. Furthermore, many police departments in the USA were sued under civil rights legislation for maintaining files on people with no criminal involvement (Carter and Carter 2009; Ratcliffe 2008a). There still exists to this day a distrust of police involvement in any activities labeled as "intelligence" (irrespective of how this is defined) both from some members of the community and, as a result, from within the justice system. For many years, the National Institute of Justice and other federal agencies have preferred to refer to ILP with the more vague and inaccurate term "information-led policing" (intelligence is information that has gone through a process of analysis to determine relevance and context to a crime problem).

Organizationally, the fragmented and disorganized way that law enforcement has evolved in the USA has influenced the development of many policing innovations. If the USA had the same population/police department ratio as the UK, it would have fewer than 300 police departments and not in excess of 18,000. Many of these departments consist of fewer than ten sworn officers, and as such their lack of size hampers the development of an intelligence capacity to support ILP. Furthermore, as Carter and Carter (2009) point out, in the USA there is no legacy of widespread intelligence use, the intelligence function has until recently been poorly defined, and there exists to this day a lack of training and expertise to develop the necessary function.

The plethora of small departments with no intelligence capability and neither a tradition nor expertise in said function has steered American development of ILP to emphasize intelligence sharing rather than strategic crime control. A central report that propelled ILP acceptance across the USA was called the National Criminal Intelligence Sharing Plan. The executive summary did not emphasize the needs of efficiency in the face of rising crime, as had the British reports a decade previously. Rather, it alluded to the perceived intelligence failures that led to the terrorist attacks of 9/11 and how that day "initiated a concerted effort by American law enforcement agencies to correct the inadequacies and barriers that impede *information and intelligence sharing*" (GIWG 2003, emphasis added). Tapping into the Zeitgeist may have enhanced readership, but it led many in US law enforcement to incorrectly assume that intelligence-led policing was predominantly a counterterrorism strategy, one that had little to do with many US policing environments.

A positive development of the concerns about lack of intelligence sharing has been the development of the fusion center concept. Locally in the USA, the initial response to 9/11 was overwhelmingly to invest in infrastructure support for first responders and to provide a protective function at locations perceived to be sensitive: there was no major investment in an offender-focused capacity. But with time, the development of intelligence capabilities has continued, both within individual police departments and regionally. The regional capacity has been enhanced with the development of fusion centers, defined as "a collaborative effort of two or more agencies that provide resources, expertise, and/or information to the center with the goal of maximizing the ability to detect, prevent, apprehend, and respond to criminal and terrorist activity" (DoJ 2005: 3). Within the homeland security context, due to the localized and decentralized nature of American policing, local government is more suited to protective functions of places rather than building a capacity to identify and target specific offenders. However, with at least 72 fusion centers now across the USA, fusion centers have (at least in theory) the capacity to develop intelligence packages focused on serious and recidivist offenders across the region, a capacity often beyond the abilities of local police departments. One of their guidelines is to "provide a multi-tiered awareness and educational program to implement intelligence-led policing and the development and sharing of information" (DoJ 2005: 7).

Distinctive Features

ILP arose as a response to the failure of the standard model of policing (Ratcliffe 2008a). The standard model emphasized random patrol, rapid uniformed response, deployment of officers to crime investigations, and reliance on enforcement and the legal system to reduce crime. The failure of the standard model in the 1960s and 1970s paved the way for a variety of responses, ultimately including ILP. In particular, ILP emphasizes the need to focus on serious and repeat offenders rather than a broad-brush reaction to crime events after they have occurred. In other words, targeting the right offenders will help police proactively address much of the crime these offenders commit. Empirical support for this assertion can be found in the classic studies of criminal careers. The Cambridge Study in Delinquent Development found that frequent offenders had not only a high offense rate but also a relatively low likelihood of desisting their criminal careers after each conviction. From the original group of nearly 10,000 boys studied by Wolfgang et al. (1972) in Philadelphia, only 627 (6.3 %) were identified as chronic offenders, but this group were responsible for 52 % of all offenses recorded against the entire cohort. The largest study, following various UK cohorts, found that by the time British men (born in 1953) reached their 31st birthday, 7 % would have at least six convictions against them, and this group accounted for 65 % of all convictions for their birth year.

A second component of ILP is the need for a business model for policing in order to influence the key resource allocation choices: "Intelligence process in law enforcement cannot be merely a voyage of discovery but demands predictability in the delivery and content of intelligence products for managers' decision-making" (Flood and Gaspar 2009: 60). This then requires knowledge of a further distinctive feature, a cross-jurisdictional strategic focus, as evidenced by the enthusiasm for ILP among many officers deployed to fusion centers.

With regard to Compstat, there are some organizational similarities between ILP and Compstat. For example, in both models leadership at the highest echelons, commitment to crime prevention, and accountability at mid-level command are important. However, Carter and Carter (2009) identify a number of distinguishing features, including ILP being multijurisdictional and threat driven (i.e., proactive and focused on anticipating criminality) whereas Compstat is intra-jurisdictional and crime driven, and ILP being strategic and more focused on criminal enterprises while Compstat is time sensitive and focused on street crime.

ILP is quite distinctive from community policing, and there is some discussion about where complimentary components exist (Carter 2009; Ratcliffe 2008a). Community policing places a high value on, and allocates considerable resources to, developing collaborative relationships with members of the community. Recent developments of ILP in the UK recognize the benefits of these collaborative relationships for holistic crime prevention, but as yet do not necessarily incorporate the development and sustenance of those collaborative relationships into ILP programs. There does appear to be agreement that in the area of counterterrorism, the relationships built up over years of community policing work are invaluable to information gathering. Yet where ILP seems a more centralized and objective method of resource allocation and priority triage, community policing emphasized local initiatives across a wide spectrum of policing areas and other (sometimes non-policing) concerns. ILP and problem-oriented policing share a number of objectives, and the overlap between these strategies is considerable, perhaps with the exclusion of the focus on serious and repeat offenders. It is a key component of ILP but one of an optional suite of solutions from the perspective of problem-oriented policing.

ILP is supported by a number of models, both conceptual and functional. The three-i model is a conceptual model that places the intelligence cycle into the business of policing. The three-i model of *interpret*, *influence*, and *impact* requires analysts and intelligence staff not only to interpret the criminal environment but also to influence the thinking of key decision-makers with their analysis. The final stage involves the decision-maker assigning tasks and allocating resources with the aim of having an impact on the criminal environment (for more information, see Ratcliffe 2008a). This idealized conceptual model is operationalized by the UK National Intelligence Model (NIM) (NCPE 2005). The NIM also has multiple levels to recognize the complexity of the modern criminal world. Level 1 deals with local criminality, level 2 addresses cross-border crime between agencies, and level 3 relates to serious and organized crime at national and international levels. The NIM has particular intelligence products for analysts to complete as well as roles for knowledge, system, source, and people assets. All of this is designed to address key ILP targets of individual criminals and criminal groups, crime and disorder hotspots, identified crime series, and the application of preventative measures (Flood and Gaspar 2009).

Critiques and Responses

As with any initiative, ILP is not without its critics. Writing during the early years of ILP development, James lamented the lack of research on which to base the hopes of improved police efficiency through the new (at least in 2003) intelligence focus and the National Intelligence Model (James 2003). He also raised concerns about the increased use of police informants and civil liberties issues with the potential for ILP to increase intrusion into the lives of citizens, a critique that has been raised by the American Civil Liberties Union (ACLU) (Guidetti and Martinelli 2009). Few doubt that work is always required to improve the management, handling, and operationalization of informants (Maguire and John 1995) and that effective mechanisms to manage intelligence files are essential (Carter 2009), but equally there is considerable sensitivity to this issue within local and state law enforcement in the USA, and a return to the COINTELPRO days of unfettered police surveillance seems unlikely (COINTELPRO is an acronym for the now discredited FBI political surveillance and disruption Counter Intelligence Program of the 1950s and 1960s).

From the perspective of 2003 and given journal publication times, one can estimate that James was writing at a time when the NIM had been unveiled no more than a couple of years before. As such, his measured concerns are largely an apt warning for more oversight of the police development of intelligence-led policing in the future. Indeed he notes at the time that “Forces favour strategies that appear to be rational, intelligence-led, based on empirical analyses and responsive to public need” (James 2003: 55). He continues to question the empirical basis for ILP, as did Ratcliffe a year earlier writing in regard to “the absence of a conceptual framework for intelligence-driven policing that is supported by an evidence-based theory. The dearth of any empirical and contextual research into the effectiveness of intelligence-led policing in either the academic or professional literature leaves the police with little option other than to experiment and do the best they can” (Ratcliffe 2002: 64).

Research on the police intelligence function and on police operations has made considerable progress in the last decade. As a result, the theoretical foundations of ILP have also developed over the last decade. An increased police willingness to allow researchers to evaluate their tactics and operations has dramatically improved knowledge on what works in policing, and numerous examples are relevant. For example, an evaluation of Operation Anchorage in Canberra, Australia, found that when police focused on burglary hotspots and used surveillance teams and investigative resources to target known repeat burglars, they were able to reduce burglaries in the city by 53 per week (from an average of around 150). Moreover, this reduction lasted for 45 weeks after the operation concluded, most likely due to the incarceration of a number of high-volume offenders (Makkai et al. 2004). At least 25 chronic offenders involved with an inner-city drug market in the Brightwood section of Indianapolis were targeted with a covert police interdiction and subsequent arrest swoop. The impact of removing these long-time repeat offenders was substantial, with a statistically significant reduction in calls for service for burglary, guns, violence, and robbery across the neighborhood for 2 years (Nunn et al. 2006).

A development of direct offender targeting is the pulling levers strategy. This approach focuses the attention of the criminal justice system on a few key chronic offenders in an attempt to encourage their deterrence from criminal activity. Evaluations have been generally positive, and this initiative is spreading across the USA and a number of other countries (Kennedy 2006, 2009). Pulling levers is described in depth elsewhere in this encyclopedia.

An additional component of ILP is the identification and targeting of police attention to crime hot spots. This aspect of ILP in enshrined as a key component of the UK National Intelligence Model. The targeting of resources to crime hot spots has a growing evidence base, in a subfield termed hot spot policing (Taylor et al. 2010; Weisburd and Braga 2006). The weight of evidence has some even calling in the USA for a national hot spot policing strategy (Mastrofski et al. 2010). The experimental basis for this claim continues to grow. For example, the Philadelphia Foot Patrol Experiment, a summer-long strategic management program to place foot patrol officers at violent crime hotspots, reduced violence by 23 % compared to equivalent control areas (Ratcliffe et al. 2011). And Operation Nine Connect, an extensive surveillance operation that resulted in over 100 arrests, effectively broke up a gang identified by intelligence analysts as an emerging threat and the most violent in New Jersey (Ratcliffe and Guidetti 2008).

So while at least initially in the development of ILP, some research suggested that police attempts to identify key offenders to target were fairly crude (Ratcliffe 2005; Townsley and Pease 2002), more recent evidence appears more hopeful that more “strategic, future oriented and targeted” (Maguire 2000: 315) tactics are emerging. A fruitful path would appear to blend all of these elements, with police identifying crime hot spots and then paying particular attention to the chronic offenders who commit offenses within that area.

Some analysts have critiqued ILP by comparison to the military arena, lamenting that “intelligence” within the policing environment is not well defined (a problem previously identified some years earlier in Ratcliffe 2008a) and that police intelligence analysts would be overstepping their role by making crime prevention recommendations to police managers. As noted by Mark Evans (Evans 2009: 194), bringing both his military and police experience to bear, “in general such thinking mainly reflects weak analytical product, a relatively unsophisticated decision-making model and a lack of understanding about the purpose and value of recommendations.” The military comparison is not relevant because while intelligence has long been a staple of the military and national security areas, the use of intelligence is a “contemporary phenomenon” in modern law enforcement Christopher and Cope (2009: 236). As a result, law enforcement commanders are less likely to be familiar with the use of intelligence resources to guide decision-making. Moreover, it is highly unlikely that they have received any training in this area, given the near total absence of courses available to police managers on problem-oriented policing, intelligence-led policing, or general crime prevention and reduction (Ratcliffe 2004). There is a distinction between an analyst making recommendations and a police officer making decisions (Cope 2004).

Sklansky (2011) worries that ILP (and predictive policing) represents a move toward a technologically driven new version of the "profession model" of policing and away from the philosophies and tenets of community policing. Like James (2003), the concerns are more abstract and serve as an abject warning to policing not to lose the community legitimacy gains of recent years in a wave of technological wizardry and policing by objectives. The challenge may be getting police commanders to embrace "advanced community policing" (Sklansky 2011: 12) anew, when it has not been shown to reduce crime measurably and when police chiefs are facing budgetary constraints and calls for greater efficiency and demonstrated productivity. The issue may rather be the mechanism by which community policing and ILP are integrated. As one commentator has written, "community policing has developed skills in many law enforcement officers that directly support new ILP responsibilities" (Carter 2009: 86).

Future Directions

The future of ILP rests with police leadership and their enthusiasm to adopt more objective, evidence-driven decision paths rather than value-based decision-making (Guidetti and Martinelli 2009). With an explosion of technology-based platforms to manage ever-greater volumes of information, there is a threat that fusion centers, real time crime centers, and intelligence analysts general fall prey to a "naïve empiricism" where information volume trumps quality resulting in an inability to distinguish between information and intelligence (Gill 2000: 211). In this future a balance has to be struck between new data sources ("new knowledge" such as crime mapping and statistical analysis) that tell us a great deal about *what* is going on in our world and policing's "old knowledge" (such as confidential informants and community intelligence) that can tell us *why* the patterns we see are emerging (Ratcliffe 2008b). In this role of answering *why*, it is increasingly clear to scholars of policing that criminal investigators have a role beyond that of case-by-case delivery of justice. Rather than simply investigating individual cases and arresting suspects, detectives have insight into broader patterns and emerging crime trends that can have wider strategic significance.

At present, while strategic assessments are key to the NIM and ILP, many analysts are not involved in strategic analysis tasks, a problem that exists not just in the UK but across most of the developed world. The same can be said for intelligence officers at fusion centers across the USA. Fusion centers are an indication of a more nodal form of governance of the security problem (Wood and Shearing 2007). Where before the police maintained a hegemonic status, now myriad agencies, both government and nongovernment, public and private, have a role in domestic crime control and security. A risk-based approach to the crime problem, such as intelligence-led policing, has a key role in this future. "The problem is that American law enforcement is neither structurally nor substantively ready to support the ILP infrastructure. Just like a building, the foundation must first be in place" (Carter 2009: 82). There is still therefore a pressing need for greater education of intelligence analysts and staff, and even more so of the police leaders that command them, before ILP can demonstrate its full potential.

Intensive Probation and Parole

Charlotte E. Gill
Center for Evidence-Based Crime Policy, George Mason University, Fairfax, VA, USA

Overview

Intensive supervision probation or parole (ISP) is a supervision approach that has emerged to deal with serious offenders in the community. ISP involves increasing the frequency of contact between probation officers and clients, placing offenders in small caseloads so that probation officers have more time to spend with their clients, and more recently a focus on identifying individual risk and need levels and directing probationers to appropriate services and treatment. ISP in the United States, and to a lesser extent in the United Kingdom, became popular as an intermediate sanction to provide a noncustodial alternative to dealing with high-risk offenders and has therefore traditionally focused on surveillance and control of offenders rather than treatment and service delivery. A substantial body of rigorous research studies has suggested that this approach may be ineffective and even harmful if used with lower-risk offenders. However, programs that emphasize a combination of surveillance and carefully-matched treatment, focused deterrence, and behavioral management approaches have shown more promise. ISP may also have suffered because it is difficult to devote sufficient attention to high risk and need offenders in understaffed and under-resourced probation agencies. Thus, ISP as an area of study and practice is currently in flux, but a number of promising future directions may prevent the approach from being discredited as a failed program. Note that in this entry, the terms “probation” and “parole” interchangeably mean a period of supervision or license in the community imposed post-release from prison or as a community-based sentence in its own right. In practice, there is often little difference in supervision practices for these two populations.

Fundamentals and Historical Development of Intensive Probation

In its most basic form, intensive supervision probation or parole (hereafter ISP) involves “tightening up” the supervision of convicted offenders on probation or supervised release from prison by reducing caseloads. This is usually achieved in one or both of two ways: reducing the size of probation officers’ caseloads so that they can spend more time focused on each client and/or enhancing reporting requirements such as the frequency and duration of contacts or increased drug testing requirements. Electronic monitoring, in the form of transmitting devices that notify authorities when an offender breaks a curfew or leaves a specified area or voice-assisted check-in devices, is also frequently added to ISP schemes. The belief behind most intensive probation programs is that if the most serious offenders are to be released back into the community, the more supervision and control they are subjected to, the better.

ISP programs developed over the past 50 years reflect theoretical notions of specific deterrence, surveillance and formal social control, and to a lesser extent informal social control. Offenders are offered the opportunity to remain in the community on the understanding that they are being constantly monitored, and the consequence of failure is the loss of liberty. While the formal social control and deterrence elements of ISP are most often discussed, ISP – as an alternative to incarceration – can also promote informal social control by allowing offenders to remain in the community. This can minimize the disruption of positive social networks and opportunities, such as access to prosocial role models within an offender's family and community, and conventional activities and treatment.

Indeed, the earliest ISP-like programs, which emerged in the United States in the 1960s, focused heavily on the idea of treatment and rehabilitation. They were guided by the belief that smaller caseloads allowed probation officers more time to help their clients improve their lives (Petersilia and Turner 1990). However, a series of field studies of these programs showed that these initiatives made very little impact on recidivism and in some cases even increased probation failure and technical violation rates. A potential explanation for the lack of effectiveness of these initiatives was that no attention was given in their development to how probation supervision activities best served the rehabilitative goal. Although probation officers had extra time to spend with clients, they did not know how to use that time to improve their clients' outcomes. Experimental testing of the programs focused almost exclusively on identifying the optimal client to probation officer ratio rather than supervision content (Clear and Hardyman 1990).

Although ISP does have some roots in traditional criminological theories, in its best-known form, it was primarily intended as a practical solution to a crisis in US corrections and a punitive alternative to imprisonment, rather than a program developed in accordance with theories of offending and behavior or a desire to better understand effective supervision practices. The lack of success of early ISP programs meant that they had fallen out of favor by the 1970s. At the same time, the rehabilitative ideal gave way to a retributive philosophy across the entire criminal justice arena in the United States and beyond, driven by a sharp rise in crime and the popular belief that "nothing worked" to reduce recidivism. In the United States, this convergence of factors triggered an exponential increase in the incarcerated population and the cost of corrections in general. This put substantial pressure on probation services. The probation population was growing in its own right, with an increasing number of serious and high-need offenders being granted parole or sentenced to probation outright. Probation officers' caseloads were becoming unmanageably large (Petersilia and Turner 1993).

Thus, by the 1980s, ISP had begun to make a comeback as a key strategy among other intermediate sanctions (alternatives to imprisonment) that sought to alleviate prison overcrowding and save money. At the same time, intermediate sanctions needed to maintain the appearance of being tough on offenders who would otherwise have been incarcerated and deter future offending through swift, certain punishment effected by close supervision (Petersilia and Turner 1990). Probation supervision in general has long suffered from image problems, particularly a public perception that it is a "soft" approach to dealing with serious offenders who are highly likely to recidivate. In the United States, for example, it is estimated that over 40 % of probationers and more than half of parolees do not successfully complete a term of supervision and that parole violators account for nearly 35 % of admissions to state prisons (Solomon et al. 2008). The new style of ISP was thus much more geared toward reducing strain on the criminal justice system and reassuring the public that serious offenders were not simply "getting away with it" by being released on probation (Petersilia and Turner 1993).

The "Georgia Model" and Experimental Research on ISP

The new generation of ISP programs that emerged in the 1980s thus focused on surveillance and control of offenders through small caseloads, frequent contacts, increased drug testing, and mandatory employment. Georgia was the first US state to implement a program that followed this model, with positive results. Participants in the ISP program had very low recidivism rates, maintained their employment, and paid probation fees that helped offset the cost of their supervision. As a result, the "Georgia model" was adopted elsewhere, with more mixed results. The interest in developing intermediate sanctions, coupled with uncertainty about the effectiveness of ISP, led the Bureau of Justice Assistance (BJA) of the United States Department of Justice to fund a multisite randomized controlled trial, conducted by the RAND Corporation (Petersilia and Turner 1993). The experiment remains one of the largest randomized controlled trials in criminal justice.

The BJA/RAND experiment was implemented in 14 locations. In 12 sites, ISP was compared to routine probation or parole supervision, which usually involves a brief meeting between the probation officers and client once a month, or existing intensive probation caseloads that were not as intense as the Georgia model. In an additional two sites, ISP was compared to incarceration. The exact nature of the program depended on the study site – each jurisdiction chose which components of the Georgia model to implement. However, there were a number of common features across all the evaluations. All included reducing probation officers' caseloads to around 25–30 clients per officer, usually compared to 100 or more in regular supervision caseloads. The frequency of contact was increased from a general standard of about once per month to at least once a week at first, with the frequency gradually decreasing in phases. All the programs also included drug testing and mandated employment.

Participants in the ISP experiments had to be adults. They were generally high-risk offenders, since the primary goal of the Georgia model ISP was to offer a punitive alternative to incarceration for offenders deemed too serious to be supervised in regular caseloads. However, offenders convicted of homicide, robbery, or sexual offenses were excluded from the experiment. Most participants were males in their late twenties and early thirties with extensive criminal histories, and a substantial proportion were drug dependent. Beyond these initial requirements, the study sites set their own additional eligibility criteria for their programs.

The methodology of the experiment involved random assignment to treatment and control conditions. Several waves of data collection followed, including a baseline assessment of demographic characteristics and criminal history, recording of supervision details and services received at 6–12 months, recording of recidivism at 12 months, and monthly drug test data. The researchers also collected data on cost-effectiveness and time at risk. Recidivism was based on official records of technical violations, arrests, convictions, and incarceration.

As with the ISP programs of the 1960s, the results of the BJA/RAND evaluations were disappointing. In general ISP did nothing to reduce recidivism, and because of the increased scrutiny to which probation clients were subjected, the rate of technical violations increased compared to standard practice. A program that had been intended to reduce the strain on the prison system actually resulted in more incarceration, as the greater level of surveillance and drug testing increased the likelihood of probation failure (Petersilia and Turner 1993). The rigorous research design used by the RAND team may have revealed limitations that were not uncovered by earlier evaluations: Petersilia and Turner (1993) note that comparison group participants in some of the more successful program evaluations of the early and mid 1980s were not well matched to probationers who experienced ISP.

Beyond Georgia: Intensive Probation in the 1990s and 2000s

Around the same time as the research evidence against ISP was growing, the "what works" movement was also gaining momentum. Researchers and practitioners began to move away from the idea that nothing worked and to acknowledge the limitations of existing evidence and program design. This led to a renewed interest in the factors that influence successful programming and outcomes. An early turning point in the "what works" movement was the development of the "principles of effective intervention" or PEI (Andrews et al. 1990) – the idea that correctional programs and treatment should be designed to be responsive to offenders' risk and need levels (also known as “risk-need-responsivity” or RNR). The “risk principle” element of the PEI, which has been empirically validated (Lowenkamp et al. 2006), suggests that the most treatment should be targeted only at the highest-risk individuals.

In probation research, the PEI have helped to refine supervision practices and better understand the factors that influence successful outcomes. Although participants in the BJA/RAND experiments were generally deemed to be high risk according to a range of characteristics including age at first conviction, offending history, current offense, and drug treatment needs, there was some variability across evaluation sites in the average risk level of participants, since sites generally set their own eligibility criteria (Petersilia and Turner 1993). Risk/needs assessment and treatment provision were not priorities of the experimental programs. Despite the increased contact with and control of their clients, probation officers did not in general focus on using that time to establish their clients’ risk and need levels using validated instruments and direct them to appropriate treatment (Latessa et al. 1998). However, the RAND evaluators noted a positive interaction between treatment provision, where it did occur, intensive supervision, and reduced recidivism and called for more research into effective treatment as part of probation supervision (Petersilia and Turner 1993).

Subsequently, and as a result of the general interest in “what works,” a new generation of ISP programs emerged in the 1990s. The programs still involved surveillance and control but increased the emphasis on making use of the extra contact time to establish probationers’ risk and need levels and direct them into appropriate treatment. Recently, several reviews and meta-analyses have supported the hypothesis that more modern ISP programs that adhere to the PEI and balance surveillance and control with a treatment component are more promising for reducing recidivism than purely surveillance-based programs (Aos et al. 2006; Drake 2011; Mackenzie 2006). Additional refinements include “community probation” efforts that draw upon additional law enforcement resources to supervise offenders. In these programs, probation officers work in tandem with police officers who are assigned to check in with ISP clients in their beat areas or develop closer relationships with smaller groups of probationers. Although ISP programs have been moving further away from pure surveillance and control, the purpose of most of these multiagency approaches has been surveillance-based, in particular, increasing contact between probation and law enforcement agencies to help police officers learn who are the most serious offenders in their jurisdictions and where they reside (Giblin 2002; Piquero 2003).

International Perspective

Intensive probation has most often been studied and discussed in the United States context. This is perhaps due to its recent history as a cheaper but still punitive alternative to incarceration during a time of significant increase in the prison population, which has occurred to a far greater extent in the United States than anywhere else in the world. Furthermore, post-release probation supervision and aftercare in general are less common in many other countries, especially in Europe (van Kalmthout and Durnescu 2008). However, several other countries have implemented intensive probation and monitoring schemes along similar lines to those seen in the United States. For example, the United Kingdom, whose prison population is the highest in Western Europe and has grown at a record pace, has a highly developed ISP system.

The earliest experimental ISP program in the United Kingdom was the IMPACT (Intensive Matched Probation and After-Care Treatment) scheme in the early 1970s. Surprisingly, the program recognized many of the factors that modern ISP programs in the United States focus on today: that high-risk offenders on probation have complex needs that contribute to their failure rates and probation officers spend little time dealing with them. Offenders were placed in small caseloads and met more frequently with their probation officers than control group participants. Supervision strategies were to be tailored to the needs and risk factors of individual offenders, combine treatment and support with control, and be delivered in the probation office and the client's own environment. The program showed some success for male participants, but not females (Folkard et al. 1976).

Intensive supervision reemerged in the last decade as a provision for serious juvenile offenders. The Intensive Supervision and Surveillance Programme (ISSP) was introduced in 2001 by the Youth Justice Board specifically to deal with prolific and persistent young offenders. It was not originally intended as an alternative to youth detention but was introduced to target a small proportion of serious juvenile offenders thought to be responsible for a substantial proportion of youth crime and is billed as the most rigorous noncustodial approach in the justice toolkit of England and Wales (a similar scheme, Intensive Monitoring and Supervision, exists in Scotland). The program was described as evidence based and involved a variety of approaches to supervision, including at least two surveillance checks per day, electronic tagging, tracking of movements by probation and police officers, and an intensive program of structured activities including education, training, and correctional treatment. However, the evaluation of the pilot programs showed that although the frequency of new offenses declined in the ISSP samples, it also declined for the comparison groups, and the failure rate for ISSP participants was very high. While it is to be expected that high-risk probationers will remain at high risk of reoffending, the increased intensity of supervision and programming did not appear to affect recidivism relative to standard practice.

Nonetheless, ISSP was rolled out nationally and spurred the development of additional intensive probation and community programs that combine frequent monitoring by probation and police officers with treatment and structured programming, including a similar strategy targeted at young adults, "Intensive Supervision and Monitoring" aimed at persistent offenders of all ages who commit volume property crime, and prolific and other priority offender schemes (Gray et al. 2005). In 2008, ISSP was incorporated into statute through the Criminal Justice and Immigration Act. It can now be attached to a community-based sentence for juvenile offenders called the Youth Rehabilitation Order or imposed as a condition of bail or post-release supervision for juveniles. Intensive supervision conditions can be implemented for 6 or 12 months, with the intensity gradually decreasing over time. Like the earlier version of the scheme, it is intended to offer a mixture of punishment and "positive opportunities," incorporates a set number of hours of supervision per week, and must include elements of education, training, or employment; restorative justice; programming to address offending behavior and increase interpersonal skills; and family support (Youth Justice Board 2009).

New Zealand also provides for a sentence of intensive supervision, which can be imposed along with a fine or community service scheme, under its Sentencing Act 2002. As in other locations, the sentence is intended for high-risk offenders and requires frequent contacts between the client and probation officer for an average of 12 months (up to 24 months). However, the New Zealand program differs from others in its emphasis on the rehabilitative nature of the sentence. The goal is to reintegrate the offender back into society, on the understanding that the level of need is sufficiently great that this could not be achieved through regular supervision or other programming. Probation officers are expected to direct their clients into appropriate treatment and assist them with addressing specific needs related to reintegration, such as employment and housing issues.

Key Issues and Controversies

Finding an ISP Model That "Works"

The key controversy surrounding ISP programs is whether or not they are effective. Both of the main waves of interest in ISP programs have been deemed a failure, especially given that ISP is one of the few aspects of criminal justice that has been subjected to multiple rigorous experimental tests. ISP was categorized as a program that "doesn't work" in the influential 1997 University of Maryland report to the United States Congress, *Preventing Crime: What*

Works, What Doesn't, What's Promising (Sherman et al. 1997). By the mid-1990s, interest in the surveillance/control model of probation supervision was largely dead.

However, as discussed earlier, the emergence of the PEI as the dominant paradigm in correctional treatment also drove the development of new ISP programs that focused more on risk, need, and appropriate services. Some of these more recent programs that attempt to balance surveillance with treatment have shown promise. MacKenzie (2006), in a detailed update to the University of Maryland report, lists intensive probation supervision with a treatment component as a "promising" correctional strategy, meaning that further rigorous research is needed but several studies have produced encouraging results. Most recently, a systematic review and meta-analysis of ISP programs confirmed a lack of positive evidence for surveillance-based ISP (Gill 2010). The meta-analysis did not reveal a clear positive effect of treatment-based programs but noted that the programs studied were highly variable and often did not include enough common components to draw meaningful conclusions about the effects of different program features.

There are a number of challenges in drawing conclusions from the overall body of evaluation research on ISP, several of which have already been noted. ISP programs were designed on the basic assumption that supervision is good for offenders in the community, so more of it must be better. However, there have been very few attempts to develop a theoretical basis for probation supervision or identify the qualities of effective supervision strategies (the latter point is discussed in more detail below). Thus, as several scholars have pointed out, there has been very little guidance on *how* to make supervision more intensive or which strategies work best. This may limit the utility of what the field can learn from ISP research.

It is also clear that much of the ISP research suffered from considerable implementation problems. Although surveillance-based programs were intended to be directed at high-risk offenders, definitions of "high" and "low" risk were not standardized across studies, risk levels varied, and the most serious offenders were often excluded from experiments for safety reasons even though it was not unusual for homicide, robbery, and sexual offenders to appear in probation and parole caseloads. This means that many of the programs studied did not necessarily comply with the PEI. Furthermore, the research studies often involved implementing innovative strategies in agencies that were already using standard probation procedures that had been in place for years and were struggling with limited resources (even when research funding was available). Thus, measurements of effect were sometimes based on an experimental supervision strategy that was not as intensive as intended. The planned ratios of intensity between treatment and control groups in the less successful ISP experiments were often similar because agencies found it difficult to meet their targets for caseload size or contact frequency in both the intensive and regular supervision caseloads. This problem also raises the question of whether ISP is a sustainable strategy in practice.

The uncertainty about the effectiveness of ISP has indicated a clear need for further development of programs to understand the complexities of the relationship between surveillance and treatment, probation officer and client, and the question of which supervision strategies should be employed during more frequent or intensive supervision sessions. In addition to the promising evidence for treatment-based and PEI/RNR-based ISP programs, two recent studies of modern ISP programs that have indicated relatively successful effects on recidivism are the Maryland Proactive Community Supervision (PCS) program (Taxman et al. 2006) and Hawaii's Opportunity Probation with Enforcement (HOPE) approach (Hawken and Kleiman 2009). Although the two programs follow different approaches, they reveal some promising strategies for further refining future programs.

The PCS approach focuses on service brokerage and individual case planning by probation officers in a proactive and "seamless" model of supervision and treatment. While PCS retains some of the characteristic surveillance and control elements of the classic ISP model, it emphasizes the “nature and intent” of the contacts between probation officers and their clients to allow for greater rapport building. This relationship is the foundation for leveraging services and treatments that will address the offender’s criminogenic needs and build prosocial networks and skills, ultimately facilitating behavioral change. A hallmark of the PCS approach is a “behavioral contract” or supervision plan that is responsive to the offender’s specific needs. This approach follows the principles of behavioral management, which include incentive and sanction schemes; a focus on criminogenic factors, which leads to tailored, but not mandated, treatment and services; and offender accountability. The probation officer acts as a behavioral manager, working with the offender to understand his or her criminogenic risk and needs and also encourage the offender to do so, develop the supervision plan, arrange services, and emphasize, incentivize, and encourage desistance from crime and achievement of goals.

HOPE, in contrast, strongly emphasizes enforcement, surveillance, and deterrence. However, while the potential deterrent effect of traditional ISP programs lay in the general threat of a return to prison if further offending or violations were detected through more frequent and intense surveillance, HOPE is highly specific and targeted. The main focus of HOPE is on increased drug testing. Participants in a randomized controlled trial of HOPE (Hawken and Kleiman 2009) were notified on a daily basis whether or not they had been selected for a random drug test. Test failures were met with swift, certain adjudication and shock incarceration. However, violators were not simply removed from probation and re-incarcerated – after spending a brief period (usually a weekend) in jail, they continued their supervision with probation officers trained in therapeutic techniques, and repeat violators were directed to specialized treatment as well as receiving traditional punishment in the form of jail stays of increasing duration. In addition, prior to being sent to jail, violators appeared before a judge who reminded them of their probation responsibilities. This hearing emphasized the desire of the criminal justice system to see offenders ultimately succeed in their probation term rather than fail.

The HOPE approach closely aligns with the emerging idea of “focused deterrence,” rather than the broader, classical specific deterrent qualities of traditional ISP. PCS embodies some of the same principles. Focused deterrence strategies have most commonly been used in policing. The framework involves implementing a menu of highly specific, targeted sanctions aimed at preventing offending through a multiagency approach that leverages community, police, and probation resources to directly communicate the reasons for sanctions to offenders. In the policing setting, this approach shows considerable promise (Braga and Weisburd 2012). Focused deterrence, incentives and sanctions, and the combination of treatment and accountability have also shown promise in other corrections settings, such as drug courts (Mitchell et al. 2012), and are consistent with the PEI and other bodies of research suggesting that interventions should be implemented at a high level of focus – whether at small places or with the small proportion of individuals who are high risk – and incorporate specific risk factors. These approaches also contrast with traditional surveillance-based ISP programs that leverage increased scrutiny and a higher probability of detecting a violation as threats to deter future offending but do not focus on the content of supervision, the role of the probation officer, or the relationship between officers and clients.

Another important difference between the HOPE and PCS approaches and traditional ISP programs is that the newer programs do not focus on specific alterations to probation intensity, such as finding the optimal frequency of contact or caseload size. As the earlier research suggested, a reduction in caseload size is not automatically accompanied by a guarantee that probation officers will actually be able to spend more time with their clients or offer more intensive treatment. As noted earlier, the realities of implementation often made it difficult for probation officers to sustain more frequent contact with ISP clients in the RAND research, and resource limitations meant that caseload sizes often crept back up to pre-evaluation levels. Studies that have focused on improving the content of supervision as well as the levels of surveillance, for offenders who are at greatest need of supervision, appear to show the most promise.

Understanding the Content of Supervision

The question of what probation officers actually do when required to supervise offenders more closely is largely unanswered by current research. It is clear from the previous discussions that a lack of focus on the content of supervision has contributed to the failure of both the earliest treatment-based ISP programs and the traditional surveillance-based programs (Clear and Hardyman 1990). On the other hand, more recent programs that have set out specific guidance for how probation officers should spend their time with clients have shown more promising results.

One of the few qualitative studies that have attempted to look inside this "black box" of supervision was by Bonta and colleagues (2008). They examined recordings of over 60 interviews between officers and probationers. They discovered that the probation officers in their sample spent too much time focusing on enforcement and insufficient time on service delivery. The officers did not appear to account for the PEI or offenders' criminogenic needs and were not equipped with the necessary tools to help clients change their behavior – the elements that the recent research on ISP programs suggests are most crucial to successful outcomes. While this study did not specifically examine ISP programs, the development of ISP research to date has indicated that ISP is not successful when it focuses on enforcement through increased surveillance and control and is most successful when it adheres to the PEI and incorporates behavioral management principles.

Shifting the focus of ISP away from surveillance and enforcement toward directing offenders into appropriate services may also help to reduce the "surveillance artifact" problem. Research on ISP shows that participants tend to be more likely to violate their probation. However, this does not necessarily mean that they are less likely to comply. The increased level of surveillance and drug testing to which they are subjected means that probation officers have more opportunities to detect a violation. This is the "surveillance artifact." It presents a challenge for evaluations of ISP because one of the goals of the program has been to keep offenders out of prison, yet the higher probability of failure does not necessarily mean that ISP makes offenders' behavior worse. Pearson (1988) suggested that in some surveillance-based programs in the 1980s, probation officers would "go out in the field actively looking for violations." This is in contrast to PCS and HOPE, which focus more on the content of supervision and responses to violations. It is clear that the future of efforts to improve intensive probation lie in focusing on how well the programs adhere to the PEI and help to manage clients' behavior, and moving away from the idea that there is an optimal caseload size or ratio of clients to probation officers that allows for more intensive intervention without clarifying what that intervention should involve.

Low-Intensity Supervision

The principles of effective intervention suggest that intensive supervision, as well as treatment, should be reserved for the highest-risk offenders. More recent attempts at developing ISP programs have taken this into account and have included a greater emphasis on treatment and service brokerage by probation officers in addition to smaller caseloads and more frequent contact. However, even when ISP programs are successful, it can be difficult to implement them well in practice. A key challenge is ensuring that probationers actually receive *more intensive* supervision. In reality, many probation agencies are understaffed and lack financial resources to hire more officers, and intensive probation clients often end up receiving no more supervision than their traditional supervision counterparts, especially when trial programs (and the associated money and research support) come to an end or are rolled out across the whole agency as standard practice. Low-intensity supervision – allowing the lowest-risk offenders to receive minimal supervision in large caseloads – is an emerging method for dealing with resource issues and allowing existing staff to be reallocated to concentrate on higher-risk clients who pose a greater public safety risk. However, given the prevailing attitude in ISP research that large caseloads have been portrayed as detrimental to crime prevention, this approach raises the question of whether it is "safe" to reduce the level of supervision given to certain offenders in terms of controlling recidivism.

Probation agencies have recently begun experimenting with reducing the intensity of supervision for those at the lowest risk of recidivism. New York City's probation department initiated these efforts in the mid-2000s by pilot testing an electronic kiosk reporting system for a substantial proportion of its lowest-risk caseload. Probationers checked in regularly using an ATM-style device and could be compelled to see a probation officer if adverse circumstances arose. Although no formal evaluation of the kiosk approach was conducted, an assessment of two-year rearrest rates for probationers assigned to the kiosks showed a slight decline in crime, suggesting that reducing supervision did not affect their outcomes. At the same time, high-risk probationers received more frequent supervision and their rearrest rates also declined (Wilson et al. 2007). Similarly, a study in Oregon found that reducing supervision for low-risk probationers in order to free up resources for intensive supervision of high-risk offenders showed an overall decline in crime for the local probation population compared to the previous "one size fits all" approach.

The most rigorous test of low-intensity probation to date is a randomized controlled trial implemented in the Philadelphia Adult Probation and Parole Department, in which a risk prediction model was used to designate 60 % of the agency's caseload as low risk, with the ultimate goal of increasing resources and supervision for 10 % of the caseload predicted to be highest risk. Low-risk offenders were randomly allocated to low-intensity supervision, involving a face-to-face or telephone check-in every 3 months in a caseload of 400 per officer, or a control group receiving regular supervision, involving one face-to-face meeting with their probation officer per month in a caseload of 150–200. The experiment revealed no significant differences between the treatment and control groups after 1 or 2 years, suggesting that low-intensity probation is a safe strategy that does not lead to increased recidivism for low-risk offenders (Barnes et al. 2010; Gill 2010).

Further development of the low-intensity supervision concept will likely be crucial to the future of intensive probation. Not only does it allow resources to be allocated more efficiently, potentially giving probation officers working with the highest-risk clients more time to focus on risk and need assessment and service delivery, but it could also play a key role in enhancing the effectiveness of ISP by moving it further into line with the PEI. As discussed above, many of the ISP strategies tested in the 1980s were not always targeted at probationers at highest risk of recidivism and in greatest need of treatment. Furthermore, some of those evaluations found that ISP was especially ineffective – and in some cases even backfired – for the lowest-risk offenders (Hanley 2006). This is consistent with broader research on the PEI that suggests recidivism among low-risk offenders tends to increase when they are subjected to more intensive programming and that they can safely be assigned to the least restrictive settings (Lowenkamp and Latessa 2004). Research also suggests that low-level delinquents are more susceptible to the influence of more delinquent peers, suggesting that they may be better served by spending more time away from the probation office where they will mix with other offenders and focusing on building positive social relationships and opportunities away from criminal networks (Barnes et al. 2010; Lowenkamp et al. 2006; Lowenkamp and Latessa 2004). In theory, by reducing the time probation officers spend dealing with low-risk clients who are unlikely to recidivate again regardless of the level of intervention, ISP for the highest-risk offenders can be properly resourced and subsequently approved.

Conclusions and Future Directions

Understanding effective practices in probation supervision is important not just to alleviate concerns about probation as a "soft option" and to efficiently use limited resources. It is crucial to understand what works in probation supervision in its own right, not just as a background to leveraging treatment and other programs. Without a strong supervisory foundation, probation officers may not have the opportunity to learn how best to target programming most effectively. Further, when agencies lack funding and caseloads are large (often 150–200), brief supervision meetings may be the only interaction that occurs between the client and the agency. Outside the ISP context, supervision levels can vary widely, from weekly or twice-weekly meetings for high-risk or delinquent probationers to telephone reporting for those near the end of their sentences. In especially busy agencies, clients sometimes simply mail in a card periodically to confirm their contact details (Petersilia and Turner 1993).

The controversies surrounding ISP and the research on treatment effectiveness strongly indicate that probation is most effective when related to the client's risk and need, rather than the agency's operational capabilities. Of course, operational capabilities cannot be disregarded, but finding a balance between the two is crucial. Programs like HOPE appear to be having some success in that regard by minimizing the time probation officers spend on surveillance and control unless the client's behavior or need warrants it. The probation population in the United States has only recently stabilized after growing by more than half a million between 2000 and 2008 alone. Currently 1 in 48 adults is under probation or parole supervision (Glaze and Bonczar 2011). With nearly five million individuals under community supervision, probation agencies must identify efficient and effective ways to restructure supervision and focus proven strategies where they are needed the most.

The current state of research, knowledge, and practice concerning intensive probation highlights a number of future directions for researchers and practitioners seeking to study and improve ISP programming. There is still a need for increased focus on the content of supervision to understand which supervision strategies are most effective for high-risk offenders. It is clear that when the development of ISP programs has focused on what has been termed the "search for the magic number" – trying to discover the optimal caseload size or ratio of clients to probation officers – outcomes for offenders have not been favorable. While intermediate sanctions like ISP are an important strategy for reducing the financial burdens in other areas of the criminal justice system, the ultimate goal should be to protect public safety and ensure that offenders receive a system response that balances punishment with effective intervention, treatment, and assistance to prevent future recidivism. Thus, the content and goals of supervision strategies should be central to the future development of intensive probation. A number of researchers and practitioners have already recognized this and have developed pilot programs centered around focused deterrence and behavioral management approaches to supervision and treatment that are showing promise. These approaches should be further refined and tested using rigorous evaluation methods including randomized trials (a multisite replication of the HOPE experiment is already under way, funded by the United States National Institute of Justice and Bureau of Justice Assistance).

The discussion of low-intensity supervision suggests that intensive probation programs could be most successful when they are implemented as part of a whole-agency approach to restructuring supervision and resource allocation around offender risk and need, rather than as an add-on to regular probation. As probation agencies continue to grapple with increasing caseloads and dwindling budgets, innovative strategies will be needed to maintain effective supervision. Most probation agencies typically follow a "one size fits all" approach to probation supervision and do not vary resources according to risk, largely because typical caseloads are so large that probation officers cannot devote extra time to the supervision of higher-risk or higher-need offenders.

However, this might be achievable when agencies adhere to the principles of effective intervention and classify their entire caseload according to risk. Research and practice in this context should therefore continue to focus on developing and refining reliable risk prediction instruments at both ends of the spectrum.

Finally, for criminologists interested in intensive probation, there remains a need to clarify the theoretical basis for ISP programs. While a number of theories have been suggested for how ISP should work, programs have typically been developed in purely practical settings. As the principles of effective intervention show, returning to theoretical principles and causal mechanisms can help to identify common features of effective programs and inform the development of future programs, especially when there is uncertainty about the effectiveness of an approach. Future research in this area should focus on identifying and testing the mechanisms that underlie successful ISP programs and differentiate them from those that have been less effective and seek to clarify the role and need for post-offense or post-release intensive supervision. Does ISP serve a purpose in itself over and above regular supervision, or is it simply a foundation for directing offenders to appropriate treatment?

Interactional Theory of Delinquency

Terence P. Thornberry
University of Maryland, College Park, MD, USA

Synonyms

Transactional theory

Overview

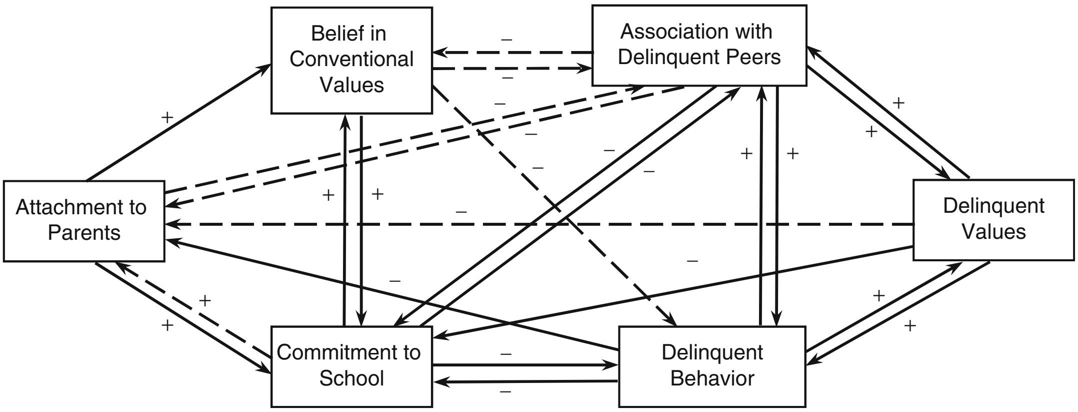
Interactional theory offers a broad explanation for the causes and consequences of involvement in antisocial behavior. When first proposed by Thornberry in 1987, it primarily focused on delinquency and drug use during adolescence and early adulthood. The theory proposed that delinquent behavior was caused by weak social bonds and involvement in delinquent networks but that delinquency also had feedback effects to further weaken prosocial bonds and further embed the individual in deviant networks and belief systems. Prolonged and serious involvement in antisocial behavior gradually evolved over the life course as a function of these reciprocal processes. The theory was subsequently expanded in two major directions. First, Thornberry and Krohn (2001, 2005) added a fuller developmental, life course perspective to account for involvement in antisocial behavior across the life span. The theory offered explanations both for the onset of offending, from childhood through adulthood, as well as for continuity and change in offending as a person ages and develops. Second, Thornberry (2005, 2009) extended the logic of interactional theory to the explanation of intergenerational continuity in antisocial behavior. One of the central premises of this theoretical orientation is that involvement in antisocial behavior has consequences for a person's later development. Those consequences, such as difficulty in the transition from adolescence to adulthood, interfere with patterns of family formation, and with the quality of parenting behaviors, helping to account for why parental involvement in delinquency is a significant risk factor for their children's involvement in delinquency.

The Original Statement

Interactional theory starts with the basic assumptions and premises of a social control theory of delinquency. Youth who are strongly bonded to conventional society are unlikely to have the behavioral freedom to engage in delinquency, drug use, and other problem behaviors. In particular, youth who are strongly attached to their parents and family, who are committed to conventional institutions like school, and who have strong beliefs in conventional values are thereby constrained from engaging in antisocial behaviors. These elements of the bond to society are likely to prevent any prolonged and serious involvement in antisocial behavior. In contrast, youth who have weak social bonds have more behavioral freedom and a higher probability of engaging in antisocial behavior.

Beginning with this basic perspective, Thornberry elaborated upon it to develop a more comprehensive and dynamic explanation for delinquent behavior during adolescence. Theoretical elaboration (Thornberry 1989) is an approach to theory construction that starts with a core theoretical orientation and then elaborates upon it to develop a broader theoretical explanation. There is no specific intent to integrate different theoretical models into a single theory, but insights are taken from other theories and from empirical investigations to develop as comprehensive an explanation as possible. One defining aspect of the theoretical elaboration that is evident in interactional theory is that the causal processes that generate delinquency vary developmentally. For example, the factors that cause offending for a 12-year-old are likely to be different from those that cause offending for an 18-year-old or a 25-year-old. Underlying processes – such as the strength of bonds to conventional society – may be the same, but the way they are manifested and the specific social institutions that are involved vary. Accordingly, Thornberry (1987) presented several developmentally specific causal diagrams of interactional theory. To summarize the logic of the theory, Fig. 1 presents the model for middle adolescence. It should be noted that the general concepts presented in the figure are proxies for more specific causal processes within each of these developmental domains. For example, "attachment to parents includes the affective relationship between parent and child, communication patterns, parenting skills such as monitoring and discipline, parent-child conflict, and the like" (Thornberry 1987, p. 866). Similar extensions can be drawn for the other concepts. In the interest of space, however, we will only discuss the more general concepts here.

Two core aspects of interactional theory are immediately evident in Fig. 1. The first concerns the inadequacy of a basic social control theory to account for delinquent behavior. Weak bonds to conventional society are viewed as creating increased behavioral freedom; that is, they allow individuals to deviate from conventional activities, but they do not necessarily lead



Interactional Theory of Delinquency, Fig. 1 A reciprocal model of delinquent involvement at middle adolescence. Note: Solid lines indicate stronger effects; dashed lines indicate weaker effects

directly to involvement in antisocial behavior. For that to occur, a learning environment is required that channels the behavioral freedom specifically into delinquent behavior, as opposed to other maladaptive responses such as internalizing problems, retreatist behavior, alienation, and withdrawal. This learning environment is represented by two key concepts – association with delinquent peers and delinquent values. Associating with others who engage in delinquent behavior provides role models for imitation and social reinforcements for engaging in delinquent behavior. It also increases the likelihood of spending unstructured and unsupervised time with peers which is also related to delinquent behavior (Osgood and Anderson 2004). In addition, beliefs that it is acceptable to engage in delinquent behavior in certain circumstances, or at least that it is not morally wrong to engage in those behaviors, also increase the likelihood of delinquent behavior.

The second core aspect of interactional theory that is evident in Fig. 1 is its reciprocal and dynamic nature. First, these central causes of delinquency are likely to become reciprocally related over time. For example, youth who are poorly attached to their parents are likely to be less engaged and successful in school, and in turn, youth who fail in school are likely to grow more distant from their parents. Second, delinquent behavior is not viewed as a mere outcome of earlier factors, such as weak commitment to school or associations with delinquent peers, as it is in many traditional theories. In contrast, delinquency is viewed as embedded in a set of mutually reinforcing causal relationships that develop over time and that create trajectories toward or away from prolonged involvement in delinquency. For example, associating with delinquent peers, via learning processes and changes in routine activities, increases the chances of delinquent behavior. But, the more the individual engages in delinquent behavior, the more likely they are to associate with fellow delinquents in part because of social selection processes and in part because delinquent youth are often rejected from prosocial peer groups. Similarly, weak social bonds such as attachment to parents increase the likelihood of delinquent behavior as youth are less constrained to follow the wishes and values of their parents, but involvement in delinquency is likely to further erode the bond to parents since it is typically antithetical to parental wishes and desires.

Thus, delinquent behavior is not merely the outcome of earlier risk factors and causal processes. It is part and parcel of its own development. Weak bonds to conventional society allow for the emergence of delinquent behavior, values, and associations. But as individuals become enmeshed in these delinquent influences, it is likely that their bonds to the conventional world will become further eroded. As a result, alienation from parents and family is likely to increase as does school disengagement. These reciprocal relationships are reflected in the bidirectional arrows presented in Fig. 1. Some are stronger during middle adolescence than others, as reflected in the solid lines, but the orientation of the theory as a state-dependence model (Nagin and Paternoster 1991) is evident. Past delinquent behavior is correlated with future delinquent behavior because of the consequences – the erosion of bonds to conventional society and embeddedness in deviant networks – that it generates.

These reciprocal relationships create behavioral trajectories that lead to different patterns of offending over the life course. At one extreme are youth who are strongly bonded to conventional institutions of family and school and are not embedded in delinquent networks. For them prolonged involvement in delinquency is highly unlikely. At the other extreme are youth from dysfunctional families who have weak bonds with conventional institutions and abundant sources of delinquent peer networks. For these youth chronic, serious offending is much more likely. And, of course, there can be a variety of offending trajectories between these extremes. Moreover, the starting values that give rise to these different trajectories are systematically related to structural variables. Two of the most central are social class and neighborhood composition. Children from impoverished families, especially those living in areas of concentrated disadvantage, suffer from a number of stressors that increase the likelihood of weak bonds and delinquent embeddedness as compared to children from families living in more advantaged neighborhoods with more resources and better schools.

Life Course Extensions

Thornberry and Krohn (2001, 2005) extended interactional theory to account for offending over longer portions of the life course. Antisocial behavior can emerge at virtually any age, from toddlerhood to adulthood. Childhood onset of offending is accounted for by three broad factors – individual characteristics, ineffective parenting, and social disadvantage. Children who exhibit early involvement in antisocial behavior are likely to suffer from a variety of negative developmental traits and neuropsychological deficits, such as impulsivity, risk-taking, and negative emotionality. They are more likely to be born to families experiencing severe structural adversity such as chronic poverty, unemployment, and residence in areas of concentrated poverty. They are also more likely to experience less effective parenting styles such as low affective ties with parents, ineffective monitoring and discipline, and, at the extreme, child maltreatment. More importantly, very early onset of antisocial behavior is likely to be brought about by the intense coupling and interaction of these influences. For example, bidirectional influences between the child's temperament and the parent's child management style have been observed as early as toddlerhood (Shaw and Bell 1993). Also, social disadvantage contributes to both parenting deficits and to negative temperamental qualities in the child.

Antisocial behavior that emerges during late childhood and early adolescence is more likely to be caused by environmental influences. Those influences, which were largely described above and in the original statement of interactional theory (Thornberry 1987), include the weakening of social bonds, associations with delinquent peers, the formation of delinquent beliefs, and the reciprocal influences that develop among them over time.

Thornberry and Krohn (2005) also account for unusually late onset – late bloomers or offenders whose criminal careers do not begin until late adolescence/early adulthood, after the normative peak of onset as described by the age-crime curve. Interactional theory hypothesizes that late bloomers have a number of individual deficits (e.g., internalizing problems like anxiety and depression) as well as reduced human capital (e.g., lower intelligence and lower academic competence). At earlier ages, however, these risk factors for delinquency are offset by compensating factors such as a supportive family, residence in more organized communities, and strong school environments. During emerging adulthood the individual leaves the protective environment of the family and school, begins to seek his or her own identity, and enters adult roles such as employee, partner, and parent. As the prosocial cocoon of adolescence is lost, the individual deficits begin to emerge, creating stress which is likely to be linked to late onset of antisocial behavior such as drug use and criminality.

Continuity and Change

In addition to issues related to onset, life course theories are also interested in the twin topics of continuity and change. Continuity in offending is somewhat more likely for those who start early than for those who start later. Unlike taxonomic theories (e.g., Moffitt 1993), however, interactional theory assumes that continuity is not tightly linked to age of onset. Although there is a positive correlation between onset and persistence, the magnitude of the correlation is moderate (Krohn et al. 2001). Regardless of when one's delinquent career begins, it is possible for that career to continue. Continuity is accounted for by two general processes. The first, which is much more important for those with an early onset of offending, is the stability of factors associated with delinquency. Negative temperamental qualities, ineffective parenting styles, and extreme social disadvantage are all relatively stable over time. Therefore, these factors are likely to continue causing involvement in delinquency at later ages offering a partial explanation for persistence. The second general process, which is important for all offenders regardless of their age of onset, stems from the bidirectional relationships within which delinquency is embedded. As we saw earlier, delinquency has feedback effects that further intensify the factors associated with its causality. Delinquency, especially serious delinquency, erodes social bonds with family, school, and prosocial peers and embeds the individual in deviant social networks and belief systems. As those reciprocal relations intensify, persistent involvement in delinquency becomes more likely.

Although some offenders do indeed persist in antisocial behavior throughout long portions of their lives, most offenders stop or desist from involvement in crime. Involvement in delinquent and criminal behavior peaks during adolescence, and desistance from crime typically unfolds during the transition from adolescence to adulthood. This transition affords new opportunities for social bonds that can reverse previous patterns of behavior. In particular, the major developmental challenges of this developmental stage are to complete the development of autonomy and independence from the family of origin, to establish one's own family of procreation, and to establish stable patterns of work. Successfully doing so is likely to lead to reductions in involvement in antisocial behavior. First, all of these transitions increase bonds to conventional society – especially the roles of partner, parent, and worker. Second, as the individual becomes enmeshed in the conventional roles, they are less likely to associate with deviant peers and to engage in risky time with friends; friendships gradually change to prosocial networks organized around family and work. All of these changes are likely to reduce involvement in antisocial behavior, and at this point, the reciprocal influences begin to work in reverse – increasing social bonds enhances prosocial behavior patterns, and those behavior patterns feed back to increase prosocial bonds. Of course, smooth and successful transitions to adulthood are not available to all. For example, the more extensive an individual's delinquent career, the harder it is to move from antisocial to prosocial behavior patterns. Nevertheless, most youth come through adolescence with enough human and social capital to give them entrée to successful transitions to adulthood. It may be through a "good marriage" or a set of skills that opens employment opportunities, but once those transitions are initiated, the movement away from antisocial behavior is enhanced.

Intergenerational Extensions

Linked lives, a basic premise of the life course perspective, argue that an individual's life course does not unfold independently of that of others. Quite the contrary, the life courses of intimate relations – husbands and wives, best friends, and parents and children – become interwoven over time and mutually influence one another. Consistent with this, there is evidence of intergenerational continuity in delinquency, drug use, and other antisocial behaviors. That is to say, children born to parents who have a history of involvement in delinquent behavior are themselves at significantly increased risk of also becoming involved in delinquent behavior (Farrington 2011; Thornberry 2005, 2009). There are a number of possible explanations for this level of intergenerational continuity ranging from purely genetic influences to shared environmental influences. Interactional theory's explanation for how parental behavior can influence child behavior in this regard is firmly rooted in the life course perspective and is summarized in Fig. 2.

One of the basic premises of interactional theory is that antisocial behavior has important causal influences on subsequent aspects of the person's development. Involvement in delinquency, especially if it is prolonged and serious, is not cost-free – it has negative consequences for the individual and, eventually, for the individual's children. Some of the important consequences that bear on the next generation are represented in Fig. 2. First, there is considerable evidence that delinquent careers are associated with disorderly transitions from adolescence to adulthood. Delinquency interferes with the successful completion of the major developmental tasks of adolescence, and delinquents are significantly more likely to drop out of high school, to become teen parents, to cohabit and exhibit unstable patterns of family formation, and to have higher rates of unemployment or underemployment. Both a history of delinquency and experiencing these disorderly transitions increase the likelihood of experiencing structural adversity as indicated by such factors as poverty, receipt of welfare, and residence in areas of concentrated disadvantage. All of these influences increase stressors such as depression, financial stress, aversive life events, and partner conflict. In other words, delinquent careers can initiate a cascade of negative influences that interfere with adolescent development, disrupt an orderly transition to adult roles, and create

Interactional Theory of Delinquency, Fig. 2 A general conceptual model for understanding the intergenerational transmission of antisocial behavior stress and disadvantage during the period of early or emerging adulthood. These outcomes are not preordained by delinquent careers, but they are significantly more likely to occur for serious delinquents as compared to nondelinquents. Young adults experiencing this constellation of factors are poorly prepared to enter the role of parent and to provide a safe, stable, and nurturing environment for their children. They are more likely to remain involved in antisocial behaviors including substance use and to remain embedded in deviant social networks. In addition, they are less likely to develop strong prosocial bonds to conventional institutions, in particular in the arenas of family and work.

These problematic developmental processes have important intergenerational implications. The most potent pathway by which they influence the child's development and likelihood of delinquency is via their effect on family processes such as family conflict, hostility, and especially the quality of parenting behaviors. Less effective parenting styles include low affective ties and reduced involvement with the child, inconsistent monitoring and standard-setting, explosive and inconsistent disciplinary styles, and, at the extreme, child maltreatment. A robust literature describes the impact of ineffective parenting on the onset and maintenance of delinquent careers (Patterson et al. 1992). Children exposed to this style of parenting are more apt to be involved in delinquency, drug use, and other antisocial behaviors. They are also unfortunately less likely to develop prosocial competencies that may buffer them from these parental risk factors.

In general, the developmental processes depicted in Fig. 2 describe a set of pathways that lead from adolescent antisocial behavior by the parent to an elevated risk for involvement in antisocial behavior by their children. Parental delinquency creates disorder in their life course that enhances the probability of structural disadvantage, stressors, and antisocial behavior during the early-adult years, all of which interferes with the development of competent and effective parenting styles for rearing their children. Those inappropriate parenting styles are the most proximal influences on the child's behavior and the most powerful mediators between parental and child antisocial behavior. These processes certainly do not account for all of the intergenerational continuity in antisocial behavior that has been observed, but they are proposed to account for a substantial share of the variance.

And, at this point, we have come full circle. The children initiate involvement in delinquent behavior in part because they are linked to their parent's history and prior behaviors and to the consequences of those behaviors. But once initiated, their own delinquency begins to have the reciprocal effects described in the original version of interactional theory. Delinquency potentially weakens their bonds to society and enhances their embeddedness in deviant networks thereby increasing the likelihood of an escalating level of involvement in delinquent careers.

Empirical Support

Over the years a considerable amount of empirical support for interactional theory has been demonstrated. The core contention of interactional theory is that delinquency is embedded in a set of mutually reinforcing reciprocal relationships and that delinquency has consequences for the person's later development. In 1996 Thornberry reviewed 17 studies of delinquency and crime that examined bidirectional relationships. Overwhelmingly, they provided empirical data consistent with this core contention. For example, weak social bonds increase delinquent behavior, and involvement in delinquency further attenuates the strength of social bonds. Similarly, association with delinquent peers and delinquent beliefs increase the likelihood of delinquent behavior, and delinquency further cements those associations and beliefs.

In the context of the Rochester Youth Development Study, Thornberry and colleagues conducted a number of empirical assessments of interactional theory (see Thornberry et al. 2003b, for a summary). Jang and Smith (1997) found that delinquency and parental supervision are involved in mutually reinforcing relationships over time. In contrast, the relationship between attachment to parents and delinquency is unidirectional, but interestingly, delinquent behavior was found to attenuate attachment, while attachment was not significantly related to delinquency. Thornberry et al. (1991) and Thornberry and Henry (2009) demonstrated that engagement in school and delinquency are also reciprocally interrelated. Finally, relationships among beliefs, association with deviant peers, and antisocial behavior were investigated in several studies. Thornberry et al. (1994) focused on delinquent behavior, while Krohn et al. (1996) focused on drug use. In both cases support for interactional theory's hypotheses was evident. Reciprocal influences between associations and behavior, between beliefs and behavior, as well as between associations and beliefs were generally evident. Overall, there is little evidence to suggest that the major causal influence is simply from social bonds to delinquency or from peer associations to delinquency. In contrast, there is abundant evidence that these relationships are bidirectional and that delinquent careers develop over time both because of these influences and because of the feedback effects of delinquency on those influences.

Another central contention of interactional theory is that involvement in delinquent behavior has long-term consequences disrupting the normal course of adolescent development and transitions from adolescence to adulthood. Consistent with expectations, involvement in delinquency and drug use was found to be significantly related to early pregnancy, teenage parenthood, high school dropout, and living independently from one's parents during the teenage years (Krohn et al. 1997; Smith et al. 2000). In line with these findings from the Rochester Youth Development Study, many other longitudinal studies also find that involvement in adolescent antisocial behavior leads to later disruption in life course development (see, e.g., Huizinga et al. 2003; Newcomb and Bentler 1988).

Core aspects of the intergenerational theory presented in Fig. 2 have been examined in the context of the Rochester Intergenerational Study. First, there is clear evidence of intergenerational continuity both for general antisocial behavior and for drug use. Parental involvement in these behaviors significantly increases the likelihood of child involvement in these behaviors (Thornberry 2005, 2009; Thornberry et al. 2003a, 2006, 2009). Interestingly, the level of intergenerational continuity is moderated by the level of ongoing parental contact with the child in a manner that is quite consistent with interactional theory's emphasis on environmental influences. In particular, the impact of parental criminality on child criminality is statistically significant for mothers, virtually all of whom are primary caretakers of their children, as it is for supervisory fathers, who have ongoing contact with their children. In contrast, for nonsupervisory fathers – those who have little or no contact with their children – the relationship is not statistically significant and is quite close to zero (Thornberry 2005, 2009; Thornberry et al. 2003a, 2006, 2009). A similar pattern also appears to emerge between the drug-use patterns of grandparents and grandchildren (Thornberry et al. 2006). Overall, the pattern of findings in the Rochester study suggests that ongoing contact between the parent and child is essential for the intergenerational transfer of risk for antisocial behavior to occur (see also Jaffee et al. 2003).

Second, these intergenerational analyses from the Rochester study also offer strong support for the mediational model of intergenerational continuity described above (see Fig. 2). These studies (Thornberry 2005, 2009; Thornberry et al. 2003a, 2009) examined different aspects of parental antisocial behavior; different disorderly transitions; varying types of stressors such as depression, financial stress, exposure to negative life events, and parenting stress; different aspects of parenting styles sometimes based on interview data and sometimes based on direct observational data; and different aspects of the child's antisocial behavior measured by different reporters. Despite these methodological and measurement variations, the results are uniformly supportive of interactional theory's predictions. Adolescent antisocial behavior on the part of the parent leads to later life course disorder that in turn leads to ineffective parenting styles that increase the chances of the child's antisocial behavior.

The findings presented by Thornberry et al. (2009) illustrate this general pattern. For mothers, they found that parental drug use and delinquency during adolescence, as well as being a teenage mother, significantly increased their early-adult depressive symptoms. In turn, depressive symptoms significantly reduced their attachment to the child and that significantly impacted the child's externalizing behavior problems. In addition, maternal depression had a direct impact on the child's behavior. For the supervisory fathers, adolescent involvement in drugs and delinquency increased their early-adult depressive symptoms; depressive symptoms reduced the father's level of attachment to the child and that, in turn, was related to the child's externalizing behavior problems.

A number of other intergenerational studies also report results that confirm interactional theory's basic explanation for intergenerational continuity in antisocial behavior (e.g., Capaldi et al. 2003; Conger et al. 2003). First, these studies find that a history of parental delinquency increases the likelihood of child delinquency. More importantly, they also find that this intergenerational impact is largely indirect, mediated by the types of development processes depicted in Fig. 2. Of particular importance are disorderly transitions to adult roles, continued involvement in antisocial behavior, and, especially, parenting behaviors. As hypothesized by interactional theory, an ineffective parenting style – low attachment, poor monitoring, harsh discipline, etc. – is the strongest and most proximal mediator of the impact of a parent's history of delinquency on the likelihood of delinquent involvement by their offspring.

Conclusion

Interactional theory, first proposed in 1987, offers a broad explanation for involvement in antisocial behavior across the life course as well as for intergenerational continuity in antisocial behavior. It attempts to account both for the major causal processes that are associated with the onset of delinquent careers at different stages of the life course as well as for the consequences of involvement in delinquent behavior. This theoretical approach views delinquency as part of a dynamic developmental process in which factors like individual characteristics, family processes, and peer networks bring about delinquency, but involvement in delinquency also has causal impacts on those factors and, more generally, the person's later development. Those consequences help to account for levels of change and continuity in offending patterns as well as the manner in which the lives of parents and their children are linked with respect to antisocial behavior. There is also a body of empirical support for the basic tenets of the theory and its explanation of offending across the life course and across generations.

International Crime Victimization Survey

Pat Mayhew[1] and Jan Van Dijk[2]
[1]Crime and Justice Research Centre, Victoria University of Wellingon, New Zealand
[2]Human Security and Safety International Victimology Institute, Tilburg University, Tilburg, The Netherlands

Overview

Surveys of people's experience of crime are now well established. They go under various titles – "crime," "victims," or "victimization" surveys. This entry places the International Crime Victimization Survey (ICVS) in the context of the development of other victimization surveys. It discusses the ICVS from the point of view of its main rationale for making international comparisons. It also looks at what has been done on the survey front in terms of international comparisons outside the context of the ICVS and what might be in store for the future.

Victimization surveys have focused on various types of potential victims, although most take a nationally representative sample of people living in private households, as is the case with the ICVS. Those sampled are asked whether they have recently been a victim of crime, regardless of whether the victimization was reported to the police. By including non-reported crimes, victimization surveys provide a different (and larger) count of crime to that from police records – which encompass in large part only crimes reported by victims and which the police choose to record. Several studies have shown that survey-based estimates of commonly committed crimes can give more reliable evidence as to their volume and trends than police figures (see, e.g., Lynch 2006). Victimization surveys also collect social and demographic information to show which groups most often fall victim to crime. Police information offers relatively little on this front.

The Development and Types of Victimization Surveys

The first round of the ICVS took place in 1989 after about a decade and a half of victimization survey development. The most important early national victimization survey took place in the United States in the 1960s. This was followed in 1972 by the first round of what is now called the National Crime Victimization Survey (NCVS), which has been conducted continuously since. Early victimization surveys were also carried out in the late 1970s and early 1980s in Finland, the Netherlands, Switzerland, Canada, Australia, and the UK. These countries still conduct their stand-alone "bespoke" national surveys. By now, so too do many other countries, for example, New Zealand, Belgium, Denmark, Italy, Sweden, and South Africa. The surveys are done on a regular basis, although not necessarily every year. In some countries, victimization questions have been added to other generic household surveys (France, Ireland, Italy, and Romania are examples). In other countries, the ICVS has been adopted as the national survey, using augmented samples (Argentina, Estonia, Poland, and Japan are examples).

In many countries, household victimization surveys have been complemented by surveys focusing on special groups or particular forms of victimization. Violence against women (VAW) surveys are particularly popular, since "general purpose" household surveys are not considered to give good measures of sexual or assaultive victimization, which often involves offenders whom the victim knows. VAW surveys are notable for their differences in approach and have thus produced widely different estimates of harm to women (see, e.g., Percy and Mayhew 1997). Of increasing interest are ethnic minorities as victims of crime, the key issue being whether their different experiences are due to racial prejudice or to broader structural factors which negatively influence victimization risk. Business (or commercial) victimization surveys are also becoming popular. The types of business sectors looked at vary, although retailers and manufacturers have been a common focus. Recently, there has been some activity in terms of measuring cybercrime (or "e-crime") among businesses.

The ICVS

The ICVS has been by far the most serious attempt to obtain a survey-based measure of victimization in a wide range of different countries. It was set up at the end of the 1980s by a small group of academic criminologists (the two authors among them) who were keen to apply survey methodology to explore international comparisons of crime. All the early ICVS academics (along with many others) were clear that using police statistics for international comparisons was fraught because of differences in legal definitions, police recording practices, and the readiness of victims to report to the police. They were also aware that results from bespoke victimization surveys were extremely difficult to compare on account of design differences – in particular, with regard to the questions on victimization and procedures for counting it. The thrust of the ICVS, therefore, was to standardize design and use the same questionnaire and analysis methods to produce equivalent across-country results.

The first ICVS took place in 1989 in 13 industrialized countries (see Van Dijk et al. 1990). It was then repeated in 1992, 1996, 2000, and (with different management procedures) in 2004/2005. Another set of surveys, which have been called ICVS-II, were carried out in 2010 in six countries, and these are returned to. The ICVS was also repeated in 2010 in Estonia, Georgia, and Switzerland.

Some of the initial 1989 survey countries took part again in subsequent rounds, although not all of them. Other new countries joined. To help consistency, much of the data collection in each of the five main rounds of the ICVS was supervised by one polling company. In the first four rounds, survey coordinators were appointed in each country to liaise with the central team to minimize deviations from the central ICVS model (or "template"). From 2000 onwards, efforts were made by the United Nations Interregional Crime and Justice Research Institute (UNICRI) in Italy to execute surveys (usually at city level) in countries in transition and developing countries (see Gruszczyńska (2004) and Alvazzi del Frate (1998) for results). Western industrialized countries have largely paid their own way in the ICVS, whereas others have had financial support. The cost of financing the ICVS has been a major factor in adopting rather modest sample sizes. The template was that national samples should cover at least 2,000 randomly chosen respondents (aged 16 or more), although some countries increased sample size to aid better local measurement. The issue of sample sizes in the ICVS is returned to.

The fifth round of the ICVS in 2004/2005 was organized rather differently. The first was the *European Survey on Crime and Safety* (*EU ICS*) in which all the 15 current member states of the European Union (EU) took part. This was organized by a consortium led by Gallup Europe and financed by the European Commission. Results are in Van Dijk et al. (2007). The second set of surveys was done in countries outside the EU, coordinated by the UN. Van Dijk et al. (2008) report on the results for all countries, in and outside the EU. All told, 30 countries were covered at national level, with another 33 surveys in main or capital cities.

Across all rounds of the ICVS over a period of two decades, more than 140 surveys have been done in over 80 different countries (with national-level surveys in 37). Over 320,000 respondents have been interviewed with a questionnaire that has been translated into 30 or more languages. The full dataset can be consulted at http://rechten.uvt.nl/icvs/ICVS2005_3full.zip (last accessed 11.07.2010).

Other Comparative Surveys

Before the ICVS began, there were a few attempts at cross-national comparisons using victimization surveys. Some studies took results from stand-alone national surveys, but they largely ran into the sand because the victimization count was so heavily influenced by survey design and counting protocols (cf. Lynch 2006). A few studies mounted standardized surveys in a limited number of countries, for instance, in Scandinavia. These exercises have largely sunk into obscurity.

Apart from these early studies and the ICVS, there are some other recent comparative surveys worth documenting.

- In 1996, Eurostat (the statistical arm of the European Commission) piloted a small *Eurobarometer of Crime* (covering the populations of the EU member states). It included questions about victimization experience, with small samples of 1,000 in most countries (Van Dijk and Toornvliet 1996).
- As part of the ICVS program, a comparative International Commercial Crime Survey (ICCS) was mounted in eight countries in 1994, although problems of different sector coverage and small sample sizes meant that little became of it. A similar questionnaire was later used in six other countries. It focused on experiences of business victimization, safety around the business area, pollution issues, and the extent and cost of security. The ICCS questionnaire was modified again by UNICRI in the late 1990s to include more items on fraud, corruption, extortion, and intimidation. Surveys took place in 2000 with small samples of 500 managers in eight capital cities in Central and Eastern European countries (Alvazzi del Frate 2004). There has also been a global, comparative survey of economic crimes against businesses, including cybercrime (PricewaterhouseCoopers 2005; Bussman and Werle 2006). This survey was repeated in 2011 for the sixth time among respondents from 78 countries.
- In terms of violence against women, a World Health Organization survey collected data between 2000 and 2003 from women in 12 countries, although there appears to be some differences in samples and survey administration (Garcia-Moreno et al. 2005). A tighter comparative exercise was the International Violence against Women Survey, which used a fully standardized questionnaire and analysis methods. Between 2004 and the end of 2005, surveys were conducted with women in eleven countries (see Johnson et al. 2008).
- The European Union's Fundamental Rights Agency (FRA) conducted pilots in six EU member states in the late 2006 and early 2007 to test different probability sampling approaches to identify selected ethnic minority and immigrant groups in countries where population data on minorities is often limited. The pilots were the forerunner to the *European Union Minorities and Discrimination Survey* (EU-MIDIS) conducted in 2008 across the EU member states. The victimization questions were taken mainly from the ICVS questionnaire. Risks for ethnic minority residents were considerably higher than for others (EU-MIDIS 2009).

General Methodological Approaches

As said, the ICVS aimed for standardized methodology and questionnaire content. It built upon (and mirrors) some fairly generic features of victimization surveys. These are summarized below, with the ICVS put in context.

- **Samples** – Household victimization surveys generally adopt a stratified random sampling approach to achieve a representative sample in terms of age, gender, and geographical area. (Post-survey weighting is often done to improve representativeness.) Virtually all national surveys are cross-sectional (taking a different sample in each round). The ICVS has not deviated in these respects. Usually one person in each household is interviewed – and this was the case in the ICVS. This is generally someone aged 16 years or over (ICVS) or 18 years or over.
- **Mode of interview** – Interview modes have changed over time. Mail (or postal) surveys were a cheap option early on. These are now largely discounted mainly because of low (and probably unrepresentative) response – although Germany has recently conducted a postal survey in a pilot test for an EU-wide victimization survey that is discussed later. Face-to-face interviewing is still seen as the

"gold standard" – because of higher response rates and the belief that they build more rapport with respondents. Face-to-face interviews now generally use computer-assisted personal interviewing (CAPI) in which the questionnaire is programmed into a laptop which the interviewer uses to enter responses. Telephone interviewing has increased substantially as telephone coverage has grown. It was also boosted by methodological work that showed respondents willing to answer questions of a sensitive nature over the telephone (see Smith (1989) for an early test). Telephone interviews are now nearly always done through computer-assisted telephone interviewing (CATI), with samples typically drawn using some form of random digit dialling. The ICVS design "template" recommends CATI on cost grounds, although in countries where there is insufficient national telephone penetration, face-to-face interviews were conducted, generally with samples of 1,000–1,500 respondents in the main cities.

- **The screening process** – Respondents are screened for experiences of victimization over a given "recall period" (see below). The ICVS screener questions cover ten types of crime. The screener questions use definitions and concepts based on colloquial language rather than the law. In many surveys (the ICVS included), it is common for the selected respondent to answer questions about possible victimizations that can be seen as affecting the household as a whole (in the ICVS case: theft of a car, theft from a car, theft of a motorcycle or moped, theft of a bicycle, burglary, and attempted burglary). The respondent answers only about his/her experience in relation to theft of personal property, robbery, sexual offences and assault, and threats. (This is because it is felt that personal victimizations are not necessarily shared with other household members).

  Screener questions usually aim to elicit a simple "yes" or "no" answer in the first instance, with further questions about the nature of what happened coming later. (This is because a respondent faced with a long list of questions immediately after saying "yes" may soon learn to say "no" to a subsequent screener.) The count of victimization sometimes comes from affirmative answers to screener questions (the ICVS procedure). Sometimes surveyors post hoc count and define the crimes using more detailed information about what happened.

  While the focus of household victimization surveys is on "volume" crime, some surveys have also taken up issues of emerging interest. In later rounds of the ICVS, for instance, additional questions have been added on experiences with street-level corruption, consumer fraud (including Internet-based fraud), credit card theft, drug-related problems, and "hate crime". Counts of these are usually not added to the conventional volume crime count.
- **The recall period** – Victimization surveys aim to estimate victimization over a limited time period. This needs to be short enough that experiences are reliably remembered, but long enough to generate an adequate number of victimization incidents to report upon. Most surveys have a "recall period" of 1 year. Some surveys (the ICVS included) initially ask people about possible victimization over the last 5 years and then focus down – for the main measurement – on the last 12 months, or (as in the ICVS) the last calendar year.
- **Details of victimization** – Many surveys follow up affirmative answers to the victimization "screeners" with detailed questions about what happened. In the case of the ICVS, details of victimization incidents are collected about the "last" incident of a particular type (the most recent incident of assault, for instance). This approach reduces interviewing time, although it may risk bias insofar as respondents choose a "last" incident which is most salient to them or about which they have more to say.
- **Respondent information** – All victimization surveys collect sociodemographic information to assess how risks for different groups vary. This includes age, gender, household income, and personal education level. Some surveys also try to measure "lifestyle" or "routine activities," which the victimological literature

has shown to be important in explaining why some people seem to be in the wrong place at the wrong time or behave in ways that "attract" victimization (e.g., Hindelang et al. 1978). The ICVS has made some small incursions here.

- **Other crime-related information** – Making contact with respondents is the biggest survey cost, so surveyors typically take the opportunity to ask them about crime-related issues, as well as victimization. The questions asked in different surveys have differed but popular topics which the ICVS has also covered include the use of crime prevention measures, attitudes to the police, fear of crime, and (to victims) the police response and the need for victim support.

General Limitations

There have been extensive discussions of the limitations of victimization surveys (e.g., Mayhew 2007). The brief review here applies to the ICVS and virtually all other surveys.

- Sample surveys do not represent the entire population as most sampling frames exclude those in communal establishments, for instance, and the homeless. This makes little difference to national victimization estimates, but it obviously precludes a full picture of victimization patterns.
- Findings are subject to sampling error. Margins of error are obviously greater for surveys with smaller samples. Estimates are most imprecise for crimes that happen relatively infrequently and for answers to questions answered only by part of the sample. The ICVS template, as said, was that national samples should cover at least 2,000 randomly chosen respondents (aged 16 or more). These are sufficient for "top-level" comparisons across different countries for broad categories of prevalent crimes. For very accurate estimates, and estimates for subpopulations, the ICVS struggles.
- Household victimization surveys omit "victimless" crimes (such as drug possession) and crimes against businesses and society at large. There are omissions even for crimes against private individuals. The victimization of children is largely ignored, and it is difficult to cover fraud well, since people will not always know they have been victimized.
- By no means all potential respondents can be contacted, and some who are contacted refuse to take part. Bias from nonresponse needs to be acknowledged, although its extent is somewhat contested. One view is that non-contacts and refusers may have "more to say" in victimization terms. The other view is that people who are available and willing to be interviewed are those who have "something to say." This point is returned to in the context of the ICVS.
- There are other types of response bias too. Serious victimization incidents may be overcounted because of "forward telescoping," whereas more minor incidents may well be undercounted. Incidents of a sexual nature and/or those perpetrated by someone well known to the victim are also likely to be undercounted – because they may not be perceived as "criminal," or because respondents will be reluctant to talk about them. (As said, dedicated surveys are often seen as more suitable here).
- A further challenge is what is known as repeat or "series" victimization (such as domestic violence). It can be hard for respondents to remember series victimization as discrete events located accurately in time. Series victimization also poses a problem for "incidence rates" (the number of victimizations spread across a given number of respondents). Victims of series incidents often cannot count them reliably, and very high values, taken at face value, can distort victimization rate estimates for some groups. Reporting simple "prevalence rates" (the number of respondents victimized once or more in the previous year) is another option and one which the ICVS has generally taken (with the rates published with their margins of error at the 90 % confidence level).

Particular Challenges for the ICVS

Discounting the general limitations of household victimization surveys discussed above, a central question is whether the ICVS has achieved its purpose in terms of standardization and providing culturally relevant measures of crime.

The approach of the ICVS was that all countries should use the same questionnaire, adopt the same fieldwork period, and use telephone interviews. While much has been achieved here, the ICVS has fallen short of full standardization. This was especially so in the surveys in developing countries, where face-to-face interviews were mainly used, and sometimes less experienced interviewers. Marginalized groups living in informal housing were also hard to reach, as were the more affluent living in gated communities living in South America, for instance (Kury et al. 2002). While comparability may not have been seriously undermined, small differences in design and people's response to the survey may have influenced ICVS results to some extent. Some of the main issues are set out below.

- **The questionnaire**. Country coordinators were responsible for ensuring that the initial English language questionnaire was well translated. In the first ICVS, all translations were back-translated and checked by the coordinating group, but back-translation did not always occur subsequently. Particularly demanding was translating the concepts and terms of the screener questions. Other questions and terms were also problematic. For instance, one question asked victims how "serious" they felt their crime had been, but the term "serious" proved difficult to translate. Other problems arose, for instance, with "stranger" (which in some countries is nearer to immigrant) and "bribery" (too serious a term in some countries for the type of low-level bribery the ICVS was trying to capture).

  On other fronts, too, it was inevitable that some countries baulked at the standardized questionnaire, feeling that "they could do better" or that some questions were inappropriate. Some countries were also keen to add additional questions or restructure the ordering of questions, thereby introducing possible "context effects." Some made minor change to the ordering of response categories – causing huge complications in analysis.
- **Response rates** – These have been variable across countries and sometimes rather low. This was so especially in the first 1989 ICVS, when privacy regulations hindered sufficient recontacting of nonrespondents in some countries. Response rates generally improved subsequently, but then fell again in the 2004/2005 ICVS, reflecting a general trend in survey research. It may be that variable and low response affects ICVS results, although the extent of nonresponse bias is contested, as has been said. Analysis of results from the fifth ICVS also showed no statistical relationship in developed countries between the number of attempts needed to reach a respondent and overall victimization rates (Van Dijk et al. 2007). This suggests that reluctance to take part in telephone interviews may not have a serious impact on cross-national comparability. Whether this holds in developing countries is more arguable. The difficulties of contacting marginalized groups, or privileged groups, may mean that victimization rates in developing countries are underestimated.
- **Mode of interview** – An obvious challenge is whether ICVS face-to-face interviews produce similar results to those in CATI mode. Analysis of ICVS results so far has not indicated any systematic bias such that one mode produces higher victimization rates than the other (e.g., Scherpenzeel 2001). The burden of the methodological evidence is that survey productivity is most affected by quality control (e.g., the selection, training and supervision of interviewers).
- **Cultural sensitivity** – It is difficult to know whether people in different countries answer questions about victimization with the same degree of truthfulness. Different cultural thresholds for defining certain behaviors as crime may also apply, especially in relation to violent and sexual victimization. Rates of minor sexual victimization have typically

been higher in Western countries where the social position of women is most advanced, suggesting that subjective thresholds are lower (Kangaspunta 2000). In pilot tests for the proposed *European Security Survey* (discussed later), there were high refusal rates in relation to sexual and intimate partner offences in some Eastern European countries specifically. Thus, there is still a question mark over how well a standardized survey can cope with cultural sensitivity in this domain.

- A rather different issue is whether any one survey can capture experience of and reactions to "crime across the globe." One might suppose that the globalization of markets and mass media information has brought some attitudinal consistency as regards most conventional crime, especially in urban settings. Counter to this, though, is that there are inevitable limitations to the ICVS as a fine-tuned measure of the impact of crime. Despite much common ground in terms of people's usual experience of victimization, some countries may have particular concerns which bespoke surveys could cover better. Questions on bribery and corruption, for instance, are very sensitive to different interpretations as to what they mean and how seriously they are assessed. In some former Soviet countries, street-level extortion in the form of neighbors asking to borrow money is a major concern.

What Has the ICVS Shown?

Space precludes documenting the full extent of ICVS results here. Just four sets of results from the ICVS are singled out. The first is what it has shown as to the level crime in different countries compared to the picture from police figures. The second concerns what ICVS measures of *trends* in crime show relative to trends according to police figures. The third set of results relates to reporting behavior and assessments of police performance and the fourth to victims' assessments of the seriousness of crime across different countries.

ICVS and Police Measures of Crime

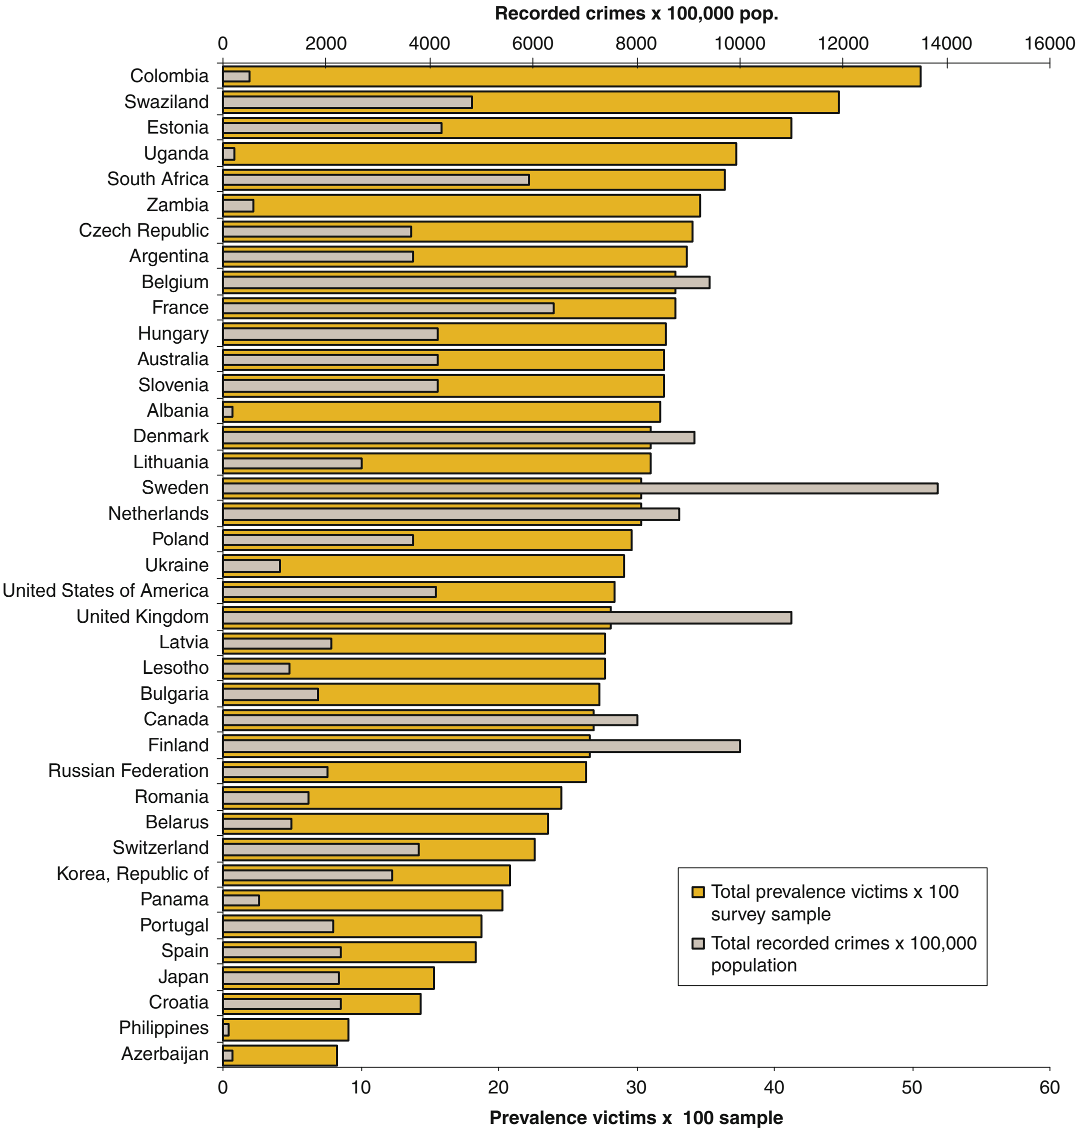
Van Dijk (2009) looked at 39 countries across the world in relation to "total ICVS crime" (as measured mainly in 2000) and "total police-recorded crime" around the same period (drawing mainly on the 2000 UN Crime Survey, which collects a range of criminal justice statistics). Figure 1 shows the results. "Total ICVS crime" is generally more restricted in scope than "total recorded crime," with the result that in some countries (Sweden, the UK, and Finland, for instance), total recorded crime per capita is higher.

Figure 1 shows no correlation between the actual level of victimization and the rates of crime recorded by the police (r = 0.212; n = 39; n.s.). Some countries with exceptionally high recorded crime also show a comparatively high victimization rate (South Africa), but many others do not (e.g., Finland, Canada, and Switzerland). Comparisons between country rankings according to the ICVS and police figures were repeated for different types of crime. The results showed positive correlations for robbery (r = 0.663, n = 37), and theft of cars (r = 0.353; n = 34), but much weaker (and statistically insignificant) correlations for other types of crime.

Trends in Crime

Of the countries which have taken part in the ICVS since 1989, there are 15 developed countries about which information is available from at least four different rounds, enabling an analysis of trends in crime over the last 10–15 years. The average victimization rates for these countries showed them to have peaked halfway the 1990s but declined since. The pattern for individual countries was nearly always the same. The drops are most pronounced in vehicle-related crime and burglary.

In looking at trends in crime, Van Dijk and Tseloni (2012) used results from countries that had taken part in four or five rounds of the ICVS between 1989 and 2004/2005. Rates of overall victimization in North America (Canada and the USA), Australia, and the nine European countries for which ICVS-based trend data are available show distinct downward trends. The drop in



International Crime Victimization Survey, Fig. 1 Total crime by countries (Source: ICVS 2000 and UN Crime Survey 2002 or latest data available (Van Dijk 2009))

crime in the USA was already evident between the 1989 and 1992 ICVS rounds. The turning point came somewhat later in Canada, most European countries, and Australia. Trend data were available from only two middle-income cities in the developing world, but these also point at a downturn in overall victimization since 1996 (Buenos Aires) or 2000 (Johannesburg). In a separate analysis, Van Dijk and Tseloni centered on ten European countries, of which four had data until 2010 from the ICVS-II (see below). In all the countries except Belgium, rates of victimization in 2005 and/or 2010 were significantly lower than those of about 10 years before.

The purpose of Van Dijk and Tseloni's (2012) examination of trends in crime was not simply to focus on the ICVS. They also looked at survey-measured trends from a number of stand-alone national surveys, as well as the police figures in the countries that ran those surveys. Nonetheless, there are points worth noting from an ICVS perspective. First, Van Dijk and Tseloni note the fortuity of the ICVS being initiated in time to register the rise in volume crime, its general "peaking" around the mid-1990s and its subsequent decline since. Second, the ICVS covered a wider range of countries than alternative standalone survey counts did. Third, across this broader range of countries, the ICVS offered a picture of crime trends to compare with police figures. The fact that police figures could have their own momentum in registering changes in crime levels – due to changes in recording procedures or the scale and effectiveness of policing activities – bought the ICVS into play. It would not be fair to say that the ICVS holds credit for the criminological "bombshell" of a fall in crime in many countries in recent years. But in helping to document this, it has greatly added to the case that parochial (national) popular explanations of the fall in crime – such as policing improvements, greater imprisonment, or economic conditions – are not adequate.

Reporting and Police Performance

The ICVS measures levels of reporting to the police to see the extent of differences across countries and whether these help explain variations in police figures at country level. Without going into detail, suffice it to say that fairly marked differences in reporting levels emerge. There are generally higher rates in more affluent countries but still differences nonetheless. Referring back to the data on which Fig. 1 is based, the concordance between police-recorded crime and a measure of ICVS crime *reported to the police* was rather closer than was the case for police-recorded crime and *all* ICVS crime. This is important testimony to the fact that victims' reporting habits are one factor influencing the officially recorded output of police forces.

Although the decision to report a victimization has been shown to be mainly driven by a simple cost-benefit assessment, it also serves to some degree as a measure of confidence in the police. Using data from the ICVS 2000, Goudriaan (2004) found that country-level variations in reporting property crimes were related to confidence in local policing (among victims and non-victims). Van Dijk et al. (2008) also showed an interrelationship between levels of reporting, confidence in local policing and – a third factor – the degree to which victims who did report felt satisfied with the police response. A "police performance" indicator based on the three measures showed that the police performance was perceived to be best in Northwest Europe, Australia, and New Zealand. Scores on the index were lowest for Brazil, Mexico, Argentina, Estonia, Turkey, Cambodia, Greece, and Poland.

The Seriousness of Crime

As said, a challenge for the ICV is how far results might be affected by cultural differences as regards the meaning of victimization and responses to it. One result at least that undermines such concerns relates to victims' assessment of the seriousness of what happened to them – which they were asked to rate on a three-point scale. Van Dijk (1999) looked at results based on the 1992 and 1996 ICVS in relation to 14 types and subtypes of crime in countries grouped into five regions. Because of possible translation differences in the connotation of "serious," mean scores were translated into rank numbers per region. There was a striking similarity in the ranking of the crime types in terms of seriousness. Regression analysis also showed that seriousness ratings were determined much more heavily by crime type than any social characteristic of the victim. That said, there were a few differences. Motorcycle theft, car theft, and joyriding ranked highest in seriousness in developing countries but rather lower elsewhere – no doubt reflecting different economic values of cars and motorcycles. In the Nordic countries where levels of violence are comparatively low, simple assaults and threats are considered as more serious than elsewhere. In terms of victim characteristics, after controlling for crime type, gender was the strongest predictor of how seriously crimes are judged – with women considering crimes somewhat more serious than men.

Conclusions

Victimization surveys are now firmly established in criminological research. Surveys comparing the level and nature of crime internationally are a rather newer enterprise than stand-alone national surveys, although the ICVS started over two decades ago. It came into its own because of growing recognition of the difficulties of comparing police figures. This was something of a kiss of death for traditional comparative criminology, although it is fair to acknowledge improvement of late in exposing the problems of noncomparability. For instance, the *European Sourcebook of Crime and Criminal Justice Statistics* now itemizes the difference in legal definitions, counting protocols, etc. that affect police statistics (Aebi et al. 2006).

While the ICVS has not provided impeccable or comprehensive data by any means, it has arguably improved on what can be gained from police records as regards comparative levels and patterns of victimization in different parts of the world. It has also offered an important addition to the picture from police records on trends in crime.

While the ICVS has shown that it is feasible to conduct standardized surveys in a large number of countries, it nonetheless carries several practical lessons. Conducting surveys in a standardized way, more or less on time, and with sound adherence to the ICVS template posed a considerable logistical challenge. Tight oversight from the central team was needed to ensure that country coordinators engaged with tedious technical detail to maintain consistency. Financial matters were time consuming and challenging, especially with regard to developing countries. Moreover, there were occasional issues as regards ownership of results. When and how these were released was also a minefield – as crime "league tables" are politically sensitive. For countries taking part that had their own national surveys, country coordinators also sometimes needed to be able to explain why the ICVS could give different results as to victimization risks.

Future Developments

Policy interest in international comparisons of crime using victimization surveys has been enhanced by the results to date. Thus, countries are likely to be keen to enter into future comparative survey exercises – especially if fieldwork costs are met. But even where self-funding is necessary, countries that have not taken part in a standardized survey to date may want to sign up, particularly when they have insufficient resources for a bespoke national survey. This makes it attractive for them to take a ride on the back of another survey vehicle, especially when comparisons with other countries are on offer. A striking example of this are the repeats of nationwide surveys based on the ICVS in Georgia in 2010, 2011, and 2012 which have demonstrated a very significant drop in crime (Van Dijk and Chanturia 2011). An abridged version of the ICVS has also been used in 2012 in Moldova and Azerbaijan and is being pilot tested in Tamil Nadu, India. This said, the conduct of victimization surveys in developing countries seems to have stayed somewhat behind. This is unfortunate since in many of these countries, crime remains a major concern and statistics of recorded crimes are of poor quality, if they exist at all.

The logistical challenges of mounting comparative victimization surveys remain. So too do the methodological challenges of improving crime measurement internationally through survey techniques that are hard to standardize in diverse environments. "Survey saturation" in Westernized countries may also become an issue, whatever mode of interviewing is adopted. Over the lifetime of the ICVS, the development of CATI has reduced fieldwork costs and helped consistent questionnaire administration. Now, though, many people (particularly more heavily victimized younger ones) rely only on mobile phones. A key issue is whether viable representative samples can be obtained with the growing diversity of telephone provision – although survey companies will be under strong commercial pressure to achieve a solution. The inclusion of mobile phone users in sampling designs is an obvious priority.

As Internet use grows, computer-assisted web interviewing (CAWI) offers a way forward for surveys in the future, with cost advantages. Pilot testing with CAWI for the national victimization surveys in the Netherlands and Finland has begun, with fairly encouraging results. However, the methodological challenges of CAWI include possible bias due to differential Internet access, a degree of respondent self-selection, and low response rates. In the medium to long term, ways round these problems may be found, particularly by using incentives and representative panels that polling companies are increasingly likely to offer.

What of initiatives currently in place for further international comparative surveys? At present, there are no elaborate plans to repeat the ICVS globally in either of the two forms it has taken in the past – i.e., with a largely academic input or (as in the fifth round) with both an academic and EU input. However, there have been other developments afoot – albeit with a less global focus – which have taken or are taking forward comparative survey-based measures of victimization in different countries.

ICVS-II

The first initiative – the so-called ICVS-II – replicated the ICVS with a reduced questionnaire and across a broader range of interviewing modes. An initial plot was conducted in 2008 by a Dutch agency, NICIS, at the request of the International Government Research Directors (IGRD). NICIS commissioned pilots in Canada, Germany, Sweden, and England/Wales. NICIS subsequently mounted a round of surveys in 2010 with co-funding from the European Commission. Six countries took part: the four who participated in the first pilot, together with Denmark and the Netherlands. The questionnaire used in the first pilot was amended somewhat. Each country was to provide a net sample of 4,000, half of which was to be achieved using CATI and half through CAWI (this split between a register of personal data and addresses' and a "panel"). Results are available on the NICIS website, differentiating between CATI- and CAWI-based results (http://62.50.10.34/icvs/).

European Union Safety Survey (EU-SASU)

A second initiative, led by Eurostat, is a standardized household victimization survey – the *EU Safety Survey*. At the time of writing, this is planned to take place in 2013 or 2014 in all 27 member states. The survey can be seen as an extension of the EU's sponsorship of the 2004/2005 ICVS. It is intended to meet the perceived need for a full EU-wide comparative survey tailored to the current legal and social realities of the EU and its particular policy interests. The results will complement the numbers of crimes recorded by the EU member states annually published by Eurostat.

In 2009, the Universities of Tilburg and Lausanne were contracted by Eurostat to evaluate pilot tests in 17 member states using a draft questionnaire prepared by the European Institute for Crime Prevention and Control, affiliated with the United Nations (HEUNI). The pilot was to assess the questionnaire using different modes of interview, and recommendations were to be made in the light of results as to the best way forward. In the event, the piloted questionnaire proved problematic in the field on several fronts. Moreover, a subsequently revised version (trying to maintain some comparability with a set of core questions from the ICVS) did not entirely meet the approval of the survey agencies in all countries either – testimony to the difficulties of gaining consensus when jurisdictional sensitivities and interests differ. One difficulty has been the degree of stringency that can be imposed as regards interview mode. Although standardization is highly advisable (with CATI currently still the best option), dictating a common mode is unrealistic given different survey capabilities in different countries. There is also pressure from some countries to bypass the *EU Safety Survey* and provide "adjusted" results from their own large-scale national surveys instead – a procedure that may prove tricky to say the least.

European Union Crime Against Businesses Survey

The EU is also testing whether to take forward standardized, comparative surveys to assess the crimes against businesses in the 27 EU member states and the now three candidate countries. Pilot work started at the end of 2011, led by Gallup Europe in collaboration with Transcrime (in the Università Cattolica del Sacro Cuore, Milan). Large pilot surveys are being conducted in 20 of the EU member states, encompassing interviews with 19,000 businesses. A two-stage approach is being tested to minimize nonresponse. The first CATI stage gather information about locality and business activity, and it will screen for the prevalence and incidence of victimization of selected types of crime. In the second stage, CAWI will mostly be used to contact businesses that had reported victimization to collect more details of what happened.

European Union Agency for Fundamental Rights (FRA) Violence Against Women Survey

In 2012, the FRA conducted an EU-wide survey of violence against women. Led by HEUNI and UNICRI, this encompassed interviews with 40,000 women across the 27 EU member states and Croatia (a candidate country). The survey used standardized face-to-face interviews with about 1,500 randomly selected women in each country. (A pretest took place in six EU member states to test the survey questions). The interviews covered women's so-called "everyday" experiences of violence (including physical, sexual, and psychological violence, and harassment and stalking) by current partners, former partners, and non-partners in the past 12 months and since the age of 15. The survey also covered experiences of violence before the age of 15, to give a "lifetime" perspective. The aim is to compare the frequency and severity of violence against women in the different EU countries, including their access to and experience of police, healthcare, and victim support services. First results are expected in 2013.

International Human Rights Standards and Community Sanctions

Christine Morgenstern[1] and Dirk van Zyl Smit[2]
[1]Ernst Moritz Arndt Universität Greifswald, Greifswald, Germany
[2]University of Nottingham, Nottingham, UK

Overview

In criminal justice, the question of the place of human rights often focuses on issues relating to imprisonment. However, imposing and enforcing community sanctions, such as probation, community work, or electronic monitoring, may also pose severe threats to the basic human rights of the offenders and their families. The rights potentially affected differ according to the sanction imposed and the stage of the criminal process – human dignity, privacy, and the presumption of innocence are examples of the rights that may be endangered. These rights are generally protected by binding international human rights law as expressed in the International Covenant on Civil and Political Rights or the European Convention on Human Rights. More specific international standards are set by recommendations and other instruments by international bodies. Questions arise, however, about the extent to which these standards are implemented and their impact monitored. These questions are becoming increasingly important as international cooperation, also with respect to community sanctions, increases and sanctions imposed in one country are implemented in another.

Fundamentals

It is indisputable that general legal standards exist that all sanctions must meet. These standards relate to the substance of the sanctions as such as well as to their appropriate imposition and implementation. They can be found in international human rights law and in national legal systems. The key standard is the absolute prohibition of cruel and unusual or inhumane punishment, although historically it has more often been applied to the death penalty and to the implementation of sentences of imprisonment than to sanctions that are implemented in the community.

It is often thought that human rights violations are less likely in the case of sanctions that are not to be implemented in a prison. Moreover, because community sanctions may serve as alternative to prison sentences, such sanctions are seen as benefits or privileges for offenders – as "doing them good." Therefore, the potential risks that they pose to the rights of offenders are routinely underestimated (Von Hirsch 1990; McNeill 2013) and need to be investigated. Social theorists as diverse as Foucault (1975) and Cohen (1985) have warned that in modern societies, the discipline and control that characterizes prison life may be reproduced within the community when sanctions are enforced there. This is particularly true in countries where a rise in punitiveness (von Hirsch 1990; van Kalmthout and Durnescu 2008; McNeill 2013) has led to many sanctions other than imprisonment becoming harsher, thus transforming measures designed to facilitate the rehabilitation of the offender into measures aimed primarily at supervision and control (van Zyl 1993). In this regard it is noteworthy that more recently scholars have recognized not only the pains of imprisonment but also the "pains of probation" (Durnescu 2011) as posing a potential threat to human rights.

The focus in this entry is on community sanctions and, to a lesser extent, on related community measures. According to the definition of "community sanctions and measures" adopted by the Council of Europe (1992), they refer to penalties that maintain the offender in the community, that is, outside prison, and involve some restrictions of his liberty through the imposition of conditions and obligations which are implemented by designated bodies. The composite term therefore also applies to diversion, compensation, reparation, and even mediation, as long as these forms of intervention are subject to some form of control by law-enforcement agencies in the widest sense. It does not, however, include noncustodial sanctions such as fines, which do not involve a specific "community" element. In most countries, community sanctions in the sense that it is used here far outnumber sanctions or measures that are enforced in prisons.

Safeguarding Human Rights in the Context of Community Sanctions

Rights at Risk

As a general proposition, it must be recognized that the human rights of offenders may be infringed by the nature of any sanction which is incompatible with their human dignity: The near universal prohibition on cruel, unusual, or degrading punishment is a specific application of this human dignity standard. A characteristic of the human dignity test is that it recognizes the ability of all people, including offenders, to reflect, to make choices, and to exercise social responsibilities. The right to human dignity may overlap with other rights. An example is a sanction that forces the offenders to express publicly sentiments that they do not hold. That may be inherently humiliating but it may also infringe a related human right to freedom of expression. Other fundamental rights may be infringed if a court were to order that an offender has to marry the mother of his child (the right to marriage and family life) or has to attend church services regularly (freedom of religion) or has to take birth control measures (the right to privacy). All these are examples of “community sanctions” imposed in various jurisdictions, which have been held to infringe human rights (for details and reported examples, see van Zyl Smit 1993).

Human rights violations also occur, arguably more frequently, when a generally acceptable community sanction is imposed for a disproportionately long period or implemented inappropriately. Particularly if the legal prerequisites for such a sanction are not entirely clear and too much discretion is left to judges and enforcement agencies, the suffering may well go beyond what is acceptable from the human rights point of view, either relative to the offence committed or in absolute terms. Here again, human dignity may be at risk, for example, when a community service order is enforced in a way that exposes the offender to dangerous or unhealthy conditions or otherwise unacceptable risks. Another example is electronic monitoring if it exercises such close control that the offender becomes a mere object of this control. Here, of course, the right to privacy is affected as well, and this also refers to the privacy rights of third parties such as the family of the offender. Further human rights issues that may arise from the ways community sanctions or measures are enforced stem from procedural issues, in particular with regard to due process and complaints procedures.

International Standards

Sources

Against the background of prison population inflation and prison overcrowding, as well as the increasing use of noncustodial alternatives to imprisonment that was emerging without much system, international bodies in the middle of the 1980s started to draft comprehensive instruments that would both encourage the use of community sanctions and other alternatives to imprisonment and protect the human rights of those subject to them. All these instruments build on existing human rights codifications, namely, the Universal Declaration of Human Rights (UDHR), the International Covenant on Civil and Political Rights (ICCPR) on the international level, and, at the regional level, particularly the European Convention on Human Rights (ECHR) but also the American Convention on Human Rights (ACHR) and the African Charter on Human and People’s Rights (ACHPR).

The first international standard minimum rules that dealt with community sanctions were drafted by experts of the United Nations Asia and Far East Institute for the Prevention of Crime and the Treatment of Offenders. Their development was heavily influenced by a set of rules formulated by an international NGO, the International Penal and Penitentiary Foundation (IPPF 1988), which aimed at creating an analogous and complementary human rights instrument to the pioneering 1955 United Nations Standard Minimum Rules for the Treatment of Prisoners, which were widely accepted throughout the world. The final version of this UN instrument, the Tokyo Rules, as they came to be called after their place of birth, or, more formally, the United Nations Standard Minimum Rules for Non-custodial Measures, was adopted by the United Nations’ General Assembly by consensus in December 1990 (United Nations 1990). The development of the Tokyo Rules (TR) was the result of a “careful process of international consensus building” (van Zyl Smit 1993). It is noteworthy that they focused both on encouraging the use of community sanctions and other alternatives to imprisonment and also, albeit to a lesser extent, to the creation of human rights protections against their abuse (United Nations Office on Drugs and Crime 2007).

European standards in this area were also prepared by governmental and independent experts, nongovernmental organizations such as the European Conference on Probation and Aftercare, and the secretariat of the Council of Europe. However, they were focused more clearly on the setting of standards in order to prevent abuses and to a lesser extent on propagating the use of community sanctions. The key standards were adopted in 1992 by the Council of Europe’s Committee of Ministers in the form of the European Rules on Community Sanctions and Measures (ERCSM) (Council of Europe 1992), which remain the primary regional instrument in this area to this day. They were supplemented in 1999 by a recommendation "concerning prison overcrowding and prison population inflation" (Council of Europe 1999). This latter recommendation, when read with the ECRSM, covers the same area as the Tokyo Rules but gives more details on the measures to reduce prison overcrowding as well as offering additional protection for those serving their sentences in the community. Following a critical evaluation of the ERCSM and their implementation, a further supplementary recommendation was adopted at the end of 2000 (Council of Europe 2000). It largely confirmed the existing ERCSM and concentrated on promoting their dissemination.

More was to follow. A further step was taken in 2003 with the adoption of a recommendation dealing with conditional release/parole, which sought to develop safeguards for persons who serve their sentences in prisons but complete them in the community (Council of Europe 2003). The European standard-setting process continues and most recently led to the adoption of the Council of Europe Probation Rules (CEPR) (Council of Europe 2010). Their rules are meant to be a practice-oriented addition to the existing ERCSM and rightly focus on probation agencies as their practices are crucial for the enforcement of community sanctions in conformity with human rights principles.

In contrast to the abovementioned UDHR, which is legally binding as customary international law (Meron 1989; Alston and Simma 1989), or the ICCPR, which is legally binding on all states that have ratified it, the more specific instruments are "soft law" and take the form of nonbinding recommendations. Nevertheless, they derive a degree of authority and legitimacy from the fact that they passed through a long drafting process that involved many governmental and nongovernmental parties and that they were adopted unanimously by the representatives of the states concerned (van Zyl Smit 1993; Morgenstern 2002).

Overriding Principles

Absolute limits for the imposition and enforcement of community sanctions and measures can be found in fundamental principles of international human rights law. As mentioned above, the respect for human dignity (Art. 1 UDHR) as well as the prohibition of cruel, unusual, inhuman, and degrading treatment and punishment (Art. 5 EDHR; Art. 7 ICCPR; Art. 3 ECHR; Art. 5s. 2 ACHR; Art. 5 ACHPR) plays a central role in this regard. Other widely recognized human rights, namely, the prohibition of discrimination (e.g., Art. 2 and 3 ICCPR) or general habeas corpus and due process requirements (e.g., Art. 9, 14 ICCPR), equally have to be respected. Consequently, both the Tokyo Rules (TR) and the ERCSM contain general "hold-all" provisions that refer to "norms accepted by the international community concerning human rights and fundamental freedoms" (ERCSM 21 and 22; TR 4). The precise meaning of these norms in the context of community sanctions needs to be specified, however, a task that the TR and the ERCSM undertake.

Both the TR and ERCSM stipulate the need for legal safeguards for every sanction or measure that has a penal content, while emphasizing that the idea of alternative or community sanctions being soft options or even privileges for the offender in comparison with a custodial sentence is wrong. They therefore call for clear and explicit legal provisions on the introduction, definition, and application of community sanctions and measures (that means sentencing and enforcement, especially regarding conditions and obligations and consequences of noncompliance, ERCSM 3, 4, 7, 9; TR 3.1). One of the fundamental principles spelled out clearly by the ERCSM is the concept of proportionality. Thus ERCSM 6 provides:

> The nature and the duration of community sanctions and measures shall both be in proportion to the seriousness of the offence for which an offender has been sentenced or of which a person is accused and take into account his personal circumstances.

Similar provisions can also be found in the TR (TR 2.6).

To safeguard offenders' rights and thus to implement the "legal citizenship" of the offender, both instruments contain detailed provisions on complaints procedures both against the imposition and the enforcement of community sanctions

(ERCSM 13 and 15; TR 3.5 and 3.6; Morgenstern 2002; van Zyl Smit 2012). Furthermore, particularly the ERCSM highlight that the cooperation of the offender is crucial for the success of the measure. Both instruments also stress the right to privacy of the offender and his family, which is of utmost importance, on the one hand with regard to the use and dissemination of personal data and on the other hand with regard to visits and other personal contacts.

The Pretrial Stage

If a measure is taken before or instead of a criminal prosecution, it is vital that appropriate steps are taken to recognize the human right of being presumed innocent until proven guilty (Art. 11(1) UDHR; Art. 14(2) ICCPR; Art. 6 ECHR; Art. 8(2) ACHR; Art. 7(1b) ACHPR). Although the scope of this principle may differ between jurisdictions, it is widely accepted that when it comes to the decision on whether or not to detain a suspect, it means that during the pretrial phase, generally, the offender should be left at liberty wherever possible, that is, granted unconditional bail. If unrestricted liberty would threaten the proper functioning of the criminal justice process in some way, there is a presumption in favor of conditional bail or its equivalents, that is, keeping the offender in the community but subject to restrictions. It can be observed, however, that this seemingly undisputed principle is particularly at risk when such alternatives to remand custody are set. Bail conditions may serve, whether intentionally or not, coercive, therapeutic, or even punitive purposes, and what should be (pretrial) community measures easily becomes informal sanctions. Moreover, even when they are not punitive, bail conditions are often introduced merely to allow the alleged offender to make a smooth transition from unconvicted to convicted status (Hucklesby 2011), which neglects the crucial principle that the person affected is still presumed to be innocent. It is essential therefore that whenever pretrial measures serve purposes other than to secure the functioning of criminal process – for example, if they are designed as rehabilitative measures or therapy – then the alleged offender must consent to them being implemented at that stage. The presumption of innocence and its consequences are incorporated in the TR and the ERCSM. With regard to the pretrial stage, the TR only mention the need for pretrial dispositions that include the possibility of discharge for minor offences (TR 5.1) and the need to avoid pretrial detention as far as possible (TR 6, United Nations Office on Drugs and Crime 2007). The ERCSM deal extensively with the question of cooperation and consent as one of the core problems of enforcement (ERCSM 31–36) and require it, as do the TR, particularly where any unconvicted person is involved (ERCSM 35, also CEPR 7; TR 3.4).

Sentencing and Enforcement

According to internationally accepted human rights standards, the key guiding principle to be used in sentencing is that of parsimony, particularly if the use of imprisonment is to be reduced. That implies that imprisonment may only be imposed as ultima ratio, both less often and for shorter periods (TR 2.6). The principle of minimum intervention also applies to the nature and duration of community sanctions, in particular with regard to the number and quality of potential conditions and obligations.

According to the preamble of the ERCSM, the application of community sanctions has to balance the need to protect society and the needs of offenders having regard to their social adjustment. The victims' interests are only incorporated indirectly in this preamble in the form that CSM must be implemented in a way that allows for "reparation for the harm caused to victims." It can thus be said that the ERCSM draw mainly on the concept of rehabilitation of offenders: All enforcement activities should gear towards it. The TR contain a similar commitment: They state that the sentencing decision should take into consideration the "rehabilitative needs of the offender, the protection of society, and the interests of the victim." They add, however, that the victim "should be consulted, whenever appropriate" (TR 8.2).

All these sentencing principles derive from respect for human dignity (TR 3.9). A sanction may infringe human dignity, when its penal content is unacceptable. This relates not only to corporal punishment or to humiliating public confessions, discussed above, but also to excessive sentences whose impact on the offender is unpredictable. Where, for example, the law provides for some form of unpaid work as a noncustodial punishment, it should also require the court to determine the total hours to be worked and in which period this has to be done.

A specific question in this regard is whether a sentence of community service requires the offender's formal consent before it can be imposed. Although this requirement is not universal, it exists in several European countries (Morgenstern 2010) and enjoys some recognition as an international standard (United Nations Office on Drugs and Crime 2007). This is partly due to national (constitutional) requirements which outlaw forced labor in general terms. The position in European human rights law is uncertain as Art. 4(3) of the ECHR creates an exception in the penal sphere only for work "done in the course of detention . . . or during conditional release from such detention." On the face of it, it does not extend to community service imposed directly as sanction in its own right (and not a substitute for prison), which should therefore be regarded as forced labor if no prior consent is gained. However, some scholars would extend the exception in the ECHR by analogy and argue that such consensual community service is not forced labor either (Emmerson et al. 2007). Whether the consent requirement may be circumvented when community service is labelled as exclusively rehabilitative is an open question (van Zyl Smit 1993; Morgenstern 2010). The International Labour Organization, rather than entering the debate directly, stresses that the nature of the work must be adequate for the rehabilitative purpose and may not serve a commercial function if it is to avoid being regarded as forced labor (Eradication of forced labour – General Survey concerning the Forced Labour Convention 1930 (No. 29); Abolition of Forced Labour Convention 1957 (No. 105); Morgenstern 2010).

Similar problems arise with regard to the necessity of consent to medical and psychological treatment as part of a community sanction: Does compulsory psychological therapy violate human dignity or other human rights? The instruments explicitly only prohibit "medical and psychological experiments" and "undue risk of physical and mental injury" (TR 3.4, a similar provision can be found in ERCSM 26). In any case, consent has to be informed and voluntary. The argument that the offender always acts under the threat of an otherwise unconditional prison sentence and therefore is never "free" cannot be dismissed immediately. In the end, however, it is not convincing because it leaves the offender at least the choice between two options, and prison is not always the greater evil (Durnescu 2011; Morgenstern 2010).

Both the ERCSM and the TR recognize that the rights of third parties, namely, the family of the offender but also under certain circumstances the victim are at stake. According to ERCSM 23, "the nature, content and methods of implementation of community sanctions and measures shall not jeopardize the privacy or the dignity of the offenders or their families, nor lead to their harassment. Nor shall self-respect, family relationships, links with the community and ability to function in society be jeopardized." Particularly intrusive sanctions or forms of enforcement, such as electronically monitored house arrest or even intrusive home visits and interviews by probation officers, may infringe third persons' rights to privacy and therefore require their informed consent and voluntary cooperation. The same principle applies to victims of crime when they are involved in the enforcement of a sanction as is the case with victim-offender mediation.

Attention must also be paid to the provisions that are made for consequences of an offender's failure to fulfill the conditions of the community sanction. One aspect that has to be considered in the sentencing process is the burden placed on the offender by conditions attached to the sanction. Even if on the face of it, the burden is not excessive, it may become disproportionate and infringe the offender's rights if it is enforced too strictly. In the enforcement process, there should be some flexibility in assessing whether there has been substantive compliance with the terms of the sentence. Most importantly, imprisonment should not be the automatic default sentence for failure to fulfill the requirements of the non-custodial sentence (TR 14.1; ERCSM 86). In deciding what further action is to be taken against the offender, other non-custodial possibilities must be considered, and partial fulfillment must be seen as a proportionately positive aspect. In the breach procedure, all due process requirements must be met (broadly spelled out in ERCSM 76-86).

Post-Sentencing Stage

Most countries have mechanisms that allow prisoners to be released before they have completed their full prison terms. Conditional release (parole) both reduces the burden on the prison system and takes into account the principle of minimum intervention by effectively converting (part of) a term of imprisonment into a community sanction. Early release can have a significant rehabilitative effect when it is accompanied by resettlement measures (Padfield et al. 2010). Nevertheless, early release from prison may raise human rights issues: Particular care must be taken to ensure that power to grant early release is not abused to put prisoners under pressure during the prison sentence. Where early release is conditional on good behavior in prison, it is important that the presence or absence of such behavior is determined fairly. The European Court of Human Rights has recognized that a penalty of loss of remission for a disciplinary infringement may be regarded as the equivalent of an additional sentence of imprisonment (*Ezeh and Connors v United Kingdom* appl. nos. 39665/98 and 40086/98, 19 October 2003). The consideration of early release in general must follow the same principles as stated above: It must be based on clear and explicit legal provisions that allow sufficient discretion to make the system flexible but not unpredictable. Conditions imposed should relate either to assisting the reintegration of prisoners into society or to exercising a measure of control on them while they are subject to such conditions, but must not constitute an additional punishment. Like other post-sentencing dispositions, conditional release and requirements attached to it must be subject to review if the offender so chooses (TR 9.3).

Enforcement and Monitoring of International Standards for Community Sanctions

The impact of international standards depends not only on their formal legal status but on the way in which they are enforced. The TR and the ERCSM are to a great extent the non-custodial equivalents of the respective sets of prison rules developed by the United Nations and the Council of Europe. However, they are less well known, and they do not have the same back up as the prison standards, which at the European level and to a lesser extent at the international level are supported by the monitoring activities of bodies designed to prevent the torture and ill treatment of persons in detention. Even if the ERCSM and the TR are based, in the same way as the prison rules, on the principles of the ECHR and the ICCPR, respectively, almost no jurisprudence by the European Court of Human Rights or of the United Nations Human Rights Committee can be found that deals with the imposition or implementation of community sanctions and measures. This is in stark contrast to the prison rules that are regularly referred to by these bodies when they deal with prison conditions. This lack of wider reference to the rules dealing with community sanctions is regrettable because both sets of rules adopt a highly principled approach towards the human rights-based use of community sanctions and represent what human rights lawyers call “evolving standards of decency” in this field (van Zyl Smit 2006).

It can be argued that the problems of enforcing and monitoring the Tokyo Rules also stem from the fact that they are drafted relatively loosely. For example, TR 1.3 allows implementation of community sanction in a way that “take[s] into account the political, economic, social and cultural conditions of each country and the aims and objectives of its criminal justice system.” This wording reflects the difficulties that are often experienced in arriving at universal understanding and acceptance of one set of human rights (Alston 1994).

More often than not, the inclusion of such very general provisions is the price for unanimity in adopting human rights instruments (Morgenstern 2002) and it is certainly a weakness. On the other hand, the official justification for such a provision in the TR – that they are not meant as one single model because they aim at being considered in very different criminal systems – cannot totally be dismissed if one takes into account that the UN had more than 180 member states at the time of their adoption. The situation, of course, is different at a regional or at least at the European level: Notwithstanding divergent interpretations of specific articles of the ECHR, the question of a universal understanding of human rights is not a source of major controversy within the Council of Europe.

Mechanisms to monitor the implementation of the instruments are limited but vary significantly between the two bodies. The United Nations used to collect data and reports on the implementation of their standards and norms including the TR. However, this material had little value because the information provided by the member states was incomplete. As a result, the systematic collection of such information has largely lapsed. The standards therefore are more often used as tool for technical assistance. The TR, for example, served as basis for the "Handbook of basic principles and promising practices on Alternatives to Imprisonment" (United Nations Office on Drugs and Crime 2007) which is used for training courses or seminars in countries who wish to reform this aspect of their criminal justice systems.

For the ERCSM, too, no formal monitoring mechanism is in place, but the Council of Europe tries to provide a follow-up on their dissemination and implementation by way of expert reports and attempts to collect data on community sanctions through its SPACE II program. Increasingly, also the European Union at least indirectly helps to implement criminal justice standards formulated by the Council of Europe by relying on them when developing its own criminal justice policies and projects (see below and Morgenstern 2009, 2011).

Future Developments

Recently, debates about community sanctions and their human rights implications have returned to the penal policy agenda. The rehabilitative ideal may have had been seriously challenged but in many jurisdictions is (again) acknowledged as the key principle governing community sanctions (Robinson 2008; McNeill 2013). It is also being recognized increasingly that the legitimacy of community sanctions is based on perceptions of how fair and humane they are and that human rights standards provide precisely the necessary and generally available criteria for evaluating them (Sparks and McNeill 2010).

How such standards may impact on criminal policy in the field of community sanctions is revealed by recent developments within the European Union: Historically, the European Union showed little interest in criminal justice and human rights-related questions, which were regarded as matters for the Council of Europe that includes all European states except Belarus. When the European Union became more active in crime and criminal justice-related fields in recent years, the engagement was usually associated with more effective law-enforcement instruments, as these were seen as closely related to its economic and political objectives. One more recently adopted EU instrument, however, aims at facilitating the cross-border enforcement of community sanctions within the European Union. The Framework Decision on Probation (Framework Decision 2008/947/JHA of 27 November 2008) will enable all member states of the EU to enforce a foreign probation sanction or measure according to their national practice; the enforcing state generally has to accept the judgment. Its objectives are "facilitating the social rehabilitation of sentenced persons, improving the protection of victims and the general public, and facilitating the application of suitable probation measures and alternative sanctions in case of offenders who do not live in the State of conviction." Given the very different sanction systems, enforcement modalities, and infrastructures of the 27 member states of the European Union, this is not an easy task, as member states are very reluctant to accept foreign judgments. This particularly refers to an area such as community sanctions where the details of how the punishments should be implemented are still largely shaped by nationally bound cultural norms. A lot of confidence-building measures are necessary, and steps have begun to be taken for EU member states to exchange detailed information about their community sanction systems (Flore et al. 2012). Here the established human rights standards of the Council of Europe come into play because they are already available, have been adopted by an even larger European institution (the Council of Europe to which all EU member states belong), and are based on fundamental common human rights values. They can thus be used as yardsticks or criteria against which national practices can be assessed (Morgenstern 2009, 2011).

Even if we consider that "human rights lawyers are notoriously wishful thinkers" (Humphrey 1973), this can be regarded as a positive development for the rights of those affected who may get to serve their community sentences in their countries of origin. It may be a harbinger of a wider international movement to recognize human rights in the enforcement of community sanctions.

International Policy Transfer

Rob Canton

Synonyms

Exchange; International; Policy exchange; Policy transfer

Overview

There is a long history of the international exchange of ideas, research findings, policies and practices in criminal justice. In recent years, there has been a marked increase in more deliberate and strategic activity to "learn lessons" from the achievements (and sometimes the failures) of other nations and to "import" policies and practices. This has become known as *policy transfer*, which has been defined as "the process by which knowledge of ideas, institutions, policies and programmes in one setting is fed into the policy-making arena in the development and change of policies and programmes in another setting" (Dolowitz et al. 2000, 9). Transfer can take different forms, including copying, emulation, or inspiration. A nexus of factors – economic, political, social, cultural, and organizational – will influence the character and outcome of transfer attempts, and the complexity of these interactions makes the consequences of transfer inherently unpredictable. Different people may have different and changing motivations to transfer and, since neither the intended nor the actual consequences are always easy to identify, evaluation is far from straightforward. Consideration of policy transfer foregrounds the importance of agency and choice in penal policy, redressing theoretical tendencies to explain penal development solely in structural terms. Experiences of policy transfer often expose taken-for-granted features of criminal justice systems and illuminate influences that shape their character and development.

Background

Countries have long exchanged ideas, research findings, and practices in all aspects of criminal justice. As Radzinowicz put it (1999, 357), "Imitations, mutations and cross-fertilization of all kinds of institutions and measures in response to crime can be traced in abundance throughout the world. . .." These have included the study of crime and criminals; the collection, collation, and interpretation of criminal statistics; law; sentencing practice, policing, prisons, probation, working with victims, and crime prevention. Taking place through academic conferences and professional congresses, international publication, correspondence, and study visits, these exchanges have sometimes led to deliberate attempts to "import" institutions or practices from another country. Well-known examples may be found in historical accounts of developments in imprisonment and probation. The character and regime of Pentonville penitentiary in North London, the opening of which was an iconic event in prison history marked by historians as a radical new approach to imprisonment in England, were strongly influenced by American ideas: study visits had been undertaken to explore the relative merits of the silent associated system at Auburn and the solitary confinement regime in Philadelphia and to decide on the better model (Ignatieff 1978). In its turn, Pentonville was influential in shaping prison design in many other parts of Europe.

John Augustus, the Boston shoemaker, whose practice of standing bail for "for an array of convicted adult drunkards, delinquent children and young prostitutes" (Nellis 2007, 28) led many to think of him as the father of probation, inspired the work of probation officers in Massachusetts. These initiatives were later brought to the attention of the British Home Secretary by the Howard Association (*ibid.*) and contributed to the development of probation in England. Anglo-American models of probation were to become widely influential in many other countries. It is to be noted, however, as with the lessons taken into Pentonville, that it seems more accurate to speak of influence and adaptation rather than simple copying.

The case of Mettray, the boys' reformatory, near Tours in central France, affords an instructive early example of both the possibilities and complications of transfer. In the mid-nineteenth century, Mettray was heralded as a model reformatory: many visitors were welcomed from abroad and penal institutions or colonies modelled on Mettray were established in a number of countries. Sydney Turner and Thomas Paynter were sent out from England to find out if the principles of the institution could be replicated in their own country. While they found much to admire, they drew particular attention to differences between French and English culture and tradition so that "... there can be no mere transplanting of it [Mettray] to this country" (Smith 2008, 76). They also noted that the character of Mettray was powerfully influenced by the personal qualities of its charismatic founder, Frédéric-Auguste Demetz, raising questions about the longer-term future of the reformatory as well as precluding any simply imitative "transfer."

The reflections of Turner and Paynter, recognizing that culture, context, setting, and individuals are quite as important as particular techniques or methods in determining the effectiveness of penal practice, should stay in the minds of all involved in modern policy transfer endeavors. Many initiatives are developed regionally or locally and may not be assumed to be readily transferable even to other parts of the same country (Crawford 1998; Edwards and Hughes 2005). In the case of programs to reduce reoffending, for example, even within a single country, initiatives and programs that have had encouraging outcomes in a pilot stage, once "rolled out" nationally, often fail to achieve such impressive results. Plausible explanations include the likelihood that the enthusiasm of the staff who were involved in the first programs, their commitment to and understanding of a new program, may not be replicated when the program is introduced somewhere else (Raynor 2004). Other contextual factors – staff training, committed leadership, targeting (making sure the right people attend), resourcing, and staff supervision – can make a decisive difference. When these programs are taken to another country, with different practices, institutions, and traditions, such challenges increase exponentially.

Thinking About Transfer

David Dolowitz (*ibid.*) framed a series of questions that constitute a framework within which to explore and interpret what can take place when a jurisdiction considers adopting policies, practices, or institutions from elsewhere. These include:

- *Why transfer?* This opens an inquiry into the motivations of those involved. It includes consideration of the reasons why it was felt that policy needed to change at all and why reference to another country was found to be the way to innovate (rather than have recourse to local “indigenous” solutions). It has been suggested that specific transfer initiatives can be placed on a spectrum from voluntary to “coerced” (Newburn and Sparks 2004). Some governments are actively keen to introduce policies from other countries – perhaps because they are believed to be effective and/ or they are thought to be politically advantageous. At the other extreme, conformity with international requirements (e.g., human rights conventions) can require countries to introduce policies even with a degree of reluctance. For example, since no country has ever been admitted to the European Union without first being a member of the Council of Europe (which requires a formal commitment to the European Human Rights Convention), economic ambitions and the aspiration to eventual membership of the EU have been a prominent incentive for some former Soviet countries to enhance human rights by reforming their penal practices and to be seen to be modernizing (Canton 2006). At the same time, many people in these countries hoped to repudiate the Soviet legacy, to find less repressive (and less expensive) responses to crime and to develop criminal justice practices that were consistent with their standing and self-awareness as transitional democracies. It is not clear in such circumstances whether adopting penal policies from other countries should be described as voluntary or coerced. No less significantly, motivations may *change* in the course of the transfer process: as the full implications of transfer become clearer, what was initially sought may now be much less welcome or, on the other hand, what was resisted may now be embraced. Again, a government may adopt a policy voluntarily, while its administration and judiciary may be rather less enthusiastic but find that they have little choice. Many agents are involved, then, and their respective motivations may be different and variable. This leads to our second question.

- *Who is involved?* In the receiving country, very many people may be involved in interpreting new policy or practice and in putting it into effect. Many more may be affected by the transfer and may seek to mediate, mold, or even block the innovation. Transfers typically also involve “exporters” (advisers or consultants), who will support the receiving country in implementation, but who may well have their own interests in the way in which the transfer takes place and develops. A reminder of the many individuals involved, the relationships of power among them, and their various and shifting motivations helps to counter purely structural and potentially deterministic accounts of transfer – for example, the idea of *globalization* – and emphasizes the place of choice and agency in penal policy (Newburn and Sparks 2004).
- *From where?* Commentators have often noted the influence of the USA on penal policy in other countries, as indeed on so many other areas of social policy and on culture: globalization often seems close to Americanization (Newburn and Sparks 2004). Many of the resonant and (too) familiar crime and punishment slogans – *zero tolerance*, *naming and shaming*, *three strikes and you’re out* – are of American provenance, although they have now become part of the discourse of criminal justice debate in any number of countries. In Europe and in many Anglophone countries, the United Kingdom has often been influential – sometimes acting as a conduit for Canadian and American ideas, but also in its own right Dolowitz et al. (1999). Much of the research into *what works* with offenders was led by scholars and researchers in the USA and in Canada; adapted, developed, and applied in the UK; and then spread to other European countries. At the same time, other ideas and practices have a quite different origin: some of the principles of restorative justice and of reintegrative shaming have developed out of studies of premodern, indigenous communities and become well known through academic and practice (rather than political) networks (Braithwaite 1989).

- *What is transferred?* Countries may seek to import institutions, technologies, methods, and techniques. But transfer will also introduce new concepts and meanings, ideas, ways of thinking and talking about crime and punishment, either as part of a new discourse and/or in association with new arrangements and practices. Newburn and Jones (2007) distinguish between the "hard" transfer of particular policies and the "soft" transfer of ideas, principles, and symbols: in their discussion of the spread of the idea of *zero tolerance*, they conclude that there is much clearer evidence for the transfer of the idea and the stance of zero tolerance than of any associated concrete policies and practices. More generally, in the early 1990s, the United Kingdom took note of the way in which the politics of crime and punishment was presented and deployed for electoral advantage in the USA, while other countries too have increasingly recognized the political gains achievable through demonstrably robust responses to matters of crime and punishment. Especially at times of insecurity and enhanced sensitivity to risk, the symbolic weight of being seen to be *tough on crime* has been extensively exploited in this way (Jones and Newburn 2007). This enhanced sensitivity to risk is itself an international phenomenon and has had a wide influence, leading to what has been called a "preventive turn" in the policies of many countries (Crawford 2009). Other examples include ideas about the proper place of "the market" in security or corrections and, reciprocally, the role of the state, which may also be raised when countries look for models from elsewhere.
- *To what degree?* Dolowitz and colleagues (2000) distinguish different degrees of transfer – copying, emulation, a mixture of these, and inspiration (emulation differs from copying in that it implies transfer of the ideas behind, but not the details of, the policy or program). While the conceptual distinctions can be useful, in practice these differences can become conflated, and neither the intentions nor the consequences of transfer can always be confidently assigned to one "degree" rather than another.

Influences on Transfer

Countries differ from one another in many ways and these have their effects upon transfer activities. They include history and culture; the size, geography, and demography of the country; different legal traditions and their relative strength and maturity; the administration of criminal justice and the political management of its institutions; and the training and management of staff. Again, since there will always be differences between "exporting" and "receiving" countries, questions arise about the "tolerance" of these factors – how favorable or antagonistic must they be to support or to spoil transfer? At the least, a provisional identification of the factors which constitute the parameters of transfer, which shape its implementation and its prospects of success, would have to include:

- The criminal law. It is obvious, but easily overlooked, that transferred practices have to be consistent with national law. With political support, the law may be changed, but these processes can be slow and uncertain. Many countries have criminal or penal codes that may have to be supplemented with procedural codes if they are to be put into effect. In one country in the author's experience, the criminal code empowered the court to impose community service orders which were then to be put into effect by the designated competent authority. But no authorities had been so designated, and in the absence of such supporting procedural legislation, no community service orders could be made. Countries also differ markedly in the discretion, both in statute and in case law, that decision makers are accorded. The development of community sanctions, for example, may be thwarted by statutory requirements to impose prison sentences in particular cases.
- Criminal justice institutions and practices. Any innovation will need to find (or, more likely, will need to make) a place for itself within existing arrangements and will inevitably impinge upon the interests of other institutions and professional groups; their response will mediate or even resist implementation.

For example, the introduction of presentence/probation reports for the court makes (is intended to make) a difference to the sentencing process. This disturbs familiar practices and role relationships among the principal agencies, notably in jurisdictions where the prosecutor proposes the sentence to the court. The prosecution and judiciary will react variably to what may be seen as a challenge to their authority.

- Cost. Innovations have to be affordable and criminal justice is always in competition for scarce resources. One example is imprisonment. It is commonly said that prison is more expensive than probation, but where no probation service exists, new money must be found to pay for staff, training, and infrastructure. In comparison, the marginal costs of adding other prisoners to a swollen prison population are relatively small. Meanwhile, to the (very debatable) extent that establishing community sanctions and measures will lead to a reduction in the numbers of people in prison, these gains will only be realized gradually and perhaps no more than notionally.
- Research. Countries vary in the extent to which research is regarded as a foundation for policy or practice. Sometimes the claim is made that policy is *evidence led*, although such claims may be disputed, not least (though not only) because the implications of research findings are typically contested in this area. Broader political considerations and ideology, moreover, inevitably shape the interpretation of research findings so that penal policy is rarely *determined* by research. Even so, research may lend support to (or discourage) policy initiatives. The claim that a practice that has been shown to be effective in one country is now to be adopted can also be politically advantageous. Examples include the introduction in the UK of American strategies – *zero tolerance* or the *broken windows* approach to reducing crime (Jones and Newburn 2007) – and the "modernization" of Eastern European systems by seeking models of effective probation practice from the west of the continent (Canton 2006). On the other hand, most research findings have been made in specific national (or, as we have seen, regional or local) contexts and may not simply be assumed to have the same significance in another country. For instance, actuarial instruments to predict rates of reconviction depend upon statistical correlations established in particular countries that may not be obtained elsewhere. Bauwens and Snacken (2010) have also drawn attention to what may be called *second-hand transfer* where an instrument already modified (and as it may be compromised or even distorted) has been exported again in that revised form. For example, an assessment instrument may be taken from country A, adapted by country B, and then exported in this modified form to country C. The extent to which practices – assessment instruments, offending behavior program – can be modified in this way without prejudice to their integrity is insufficiently understood and may not be taken for granted.
- Political economy. There is a strong association between penal policy and political economy (Cavadino and Dignan 2006), and penal projects will be variably accomplished in societies with different socioeconomic structures. Even within broadly similar socioeconomic systems, there will be political variations that will mediate the transfer and can cause it to take an unexpected direction. Crime and punishment are strongly influenced by broader social policies and trends. Even if politically supported in its own terms, penal change may fail to thrive if it takes a markedly different trajectory from other policies. Desistance research is increasingly drawing attention to the importance of social capital – for example, access to employment and accommodation – in providing viable pathways out of crime; political economy influences the availability of social resources as well as their accessibility by offenders and ex-offenders. Relatedly, there are likely to be differences in the extent to which people regard crime reduction as something that the state should (or even could) achieve. The idea, for example, prominent in many western democracies, that the

police are in the service of the community is not the legacy of many countries where they have been viewed with suspicion as an (often repressive) arm of government.

- Technology and commerce. Technology is increasingly a feature of modern penality in all kinds of ways, from the processing and exchange of information to the electronic monitoring of offenders. The manner in which information is collected and processed can reciprocally influence the way in which the penal subject is understood (Aas 2004). Technological capacity and infrastructure constrain the potential of an innovation and shape its development. This consideration is linked too to commercial markets, as private enterprise becomes increasingly, though variably, involved in penal practices that have traditionally been the prerogative of the state. This has direct implications for transfer. Liberal criminologists, for example, may well be wary about net widening (Cohen 1985) – the idea that penal programs can draw in groups of offenders who had been dealt with before in less intrusive or more informal ways, but commerce in the nature of the case seeks to expand its markets and may give priority to the interests of shareholders over a wider public interest.
- Pressure groups, networks, public opinion. Innovations need their champions and the support or opposition of a pressure group can make a critical difference to the acceptance of a new idea, as can its representation in the mass media. Policy transfer has to engage with these challenges, not least in transitional democracies, where penal developments ought to progress in step with public opinion and with proper regard for their legitimacy. At the same time, where politicians have tried to seek political gain through "talking tough" about crime and punishment, mass media may well oppose and misrepresent any innovation that appears to be liberal.
- The ethical environment. This elusive but significant concept refers to "the surrounding climate of ideas . . . [that] determines what we find acceptable or unacceptable . . . our conception of when things are going well and when they are going badly . . . our conception of what is due to us, and what is due from us, as we relate to others" (Blackburn 2001, 1). The language of human rights, perhaps, as an accepted international ethical discourse, is often the way in which transferred innovations are discussed and interpreted. Even so, there are likely to be decisive differences in conceptions of the rights and duties of offenders and of victims and of the obligations of society towards them. In discussing crime prevention, Crawford comments on variation among countries in the ways in which "crime prevention strategies (seek to) embody a dynamic of social integration or exclusion" (1998, 243). He connects this with wider problems of social and economic cohesion and exclusion. Just the same observations are relevant to penal policies where societies take a variety of positions on whether punishment should be inclusive or exclusive, when (if ever) an offender should be considered an ex-offender, and what obligations (if any) the community has in this regard, as well as putative rights against them (in the name of public protection).

The list is not exhaustive and no doubt other influences could be identified. However that may be, these different factors, acting in different ways and with varying weight, make the development and outcome of transfer activity inherently unpredictable. Bluntly, what works here may not work there.

Culture and Transfer

Culture is increasingly recognized as central to an understanding of crime and punishment (Smith 2008) and is accordingly a critical variable in policy transfer and implementation. The term, however, is contested and used in a number of different ways. Garland (2006) warns that, in appropriating the term from other academic disciplines, criminology risks reproducing some of the confusions and ambiguities that prevail elsewhere. He distinguishes usefully between (1) culture as a collective entity (i.e., *this* culture as opposed to *that*, e.g., African culture contrasted with European) and (2) culture as a distinct influence in shaping penal development – that is, "“cultural” forces (or ideas, or symbols, or values, or meanings, or sentiments . . . {as opposed to} other kinds of entity (such as social, political, economic or criminological factors) . . ." (2006, 422). Culture is important in both senses in considering policy transfer, but the distinction is analytically valuable. A further complication is the use of the word *culture* – as in *legal culture* or *court culture*–where the term seems to mean not much more than tradition, habit, or the familiar way of doing things.

The claim that transfer must be culturally sensitive or culturally appropriate risks losing these distinctions. Transfer, to be sure, must take account of customary ways of doing things, but the purpose of transfer is often precisely to make changes in these respects. Transfer enterprises must assuredly take account of "the cultural" – the ideas, values, and meanings of penality. It could be said penal policies thrive or fail as much or more in the *meanings* they manage to convey than in their effectiveness in reducing crime (Smith 2008), and accordingly, disregard for the meanings of current practice and of the innovations that are intended to vary these meanings can vitiate transfer.

In its other sense – "this culture as opposed to that" (Garland 2006) – culture matters, but should not be seen as either insulated or static. Indeed, transfer typically occurs when a country is already exposed to other kinds of outside social, economic, and cultural influences, and its culture is consequently evolving, often rapidly. Even so, lack of sensitivity to cultural variation could constitute a form of neocolonialism or imperialism (Worrall 2000) – with prosperous countries telling relatively poorer ones how they should respond to crime – and is in any case likely to lead to failure in transfer. In this connection, the attempt to introduce community service/unpaid work into Zimbabwe as an alternative to custody is instructive. The idea that this new penalty of the court might *make amends* was greeted as an affirmation of restorative African traditions that had been suppressed in the first place by a "procedure dominated and prison-happy philosophy" introduced under colonialism (Stern 1999. The quotation, on page 25, is by Elufemi Odekunle). This seems an example of transfer reviving or reaffirming indigenous traditions that had been suppressed in the first place by "transfer" through colonization.

This discussion shows that while the insistence that transfer must respect culture is salutary, it is a claim that can be understood in a number of different ways. Cultural differences can (perhaps too easily) be invoked to account for some of the obstacles to transfer or to reject an initiative that some may find threatening. At one level, it is morally and practically imperative that innovation be culturally sensitive; on the other hand, the whole point of transfer is to bring about change.

Obstacles to Transfer

Among the ways in which transfer may fail is through uninformed or "unknowledgeable" transfer (Dolowitz et al. 2000). This arises from misunderstandings about the context in which innovation is to be made and/or the nature of the challenge that the transfer is intended to meet. Among the most immediate (and often persisting) problems confronting a consultant from another country, then, is trying to understand the criminal justice practices in the country accepting transfer. Difficulties here can be formidable. Most consultants may be presumed to be very knowledgeable about their own national systems, but similarities in institutions and practices can turn out to be superficial and to conceal significant differences. The temptation is to assimilate unfamiliar practices to ones with which the consultant is already familiar. Yet equally there may be "functional equivalence" (an expression, however, to be treated with care) between practices that at first sight seem very different. Consultants must therefore rely heavily upon local experts, although as Nelken warns (2000, 6), "those relied on for descriptions of the aims or results of legal reforms are themselves part of the context they are describing, in the sense of favouring one position rather than another."

Secondly, transfer may be incomplete–although this partly depends on whether copying, emulation, or inspiration is the objective (see above) and remembering too that different actors may have different aspirations here. Thirdly, inappropriate transfers can fail because "insufficient attention may be paid to the differences between the economic, social, political and ideological contexts in the transferring and borrowing systems" (Dolowitz et al. 2000, 34). Transfer seems most likely to be successful where there is social and political affinity and/or ideological proximity between the originating and borrowing systems (Newburn 2002).

There is also the consideration that in many (perhaps most) societies, criminal justice and penal practices are not so much created as *evolve* under the influence of an indeterminate number of interrelated and sometimes antagonistic factors. There should be no assumptions about the internal coherence of the resulting arrangements. As Garland puts it, "Having developed as a means of managing tensions, arbitrating between conflicting forces, and getting certain necessary things done, social institutions typically contain within themselves traces of the contradictions and pluralities of interest which they seek to regulate" (Garland 1990, 282). The introduction of a new institution or practice may disturb the equilibrium. This is part of the reason, no doubt, why penal policy so frequently results in unexpected and indeed perverse outcomes: for example, attempts to provide alternatives to custody can often be associated with *increases* in its use. Contradictory influences, then, can distort transfer and make outcomes inherently unpredictable.

Nor should the challenges of linguistic translation be underestimated. How, for example, is a specialized (and barely even English) term like *responsivity* be presented to an interpreter? Again, the differences among, for example, *deferred*, *conditional*, or *suspended* sentences, are significant, but linguistically subtle. Importantly, too, there is the problem of what translators and interpreters refer to as *faux amis* – false friends – words in different languages whose apparent similarity conceals substantial differences of connotation, resonance, and even sometimes denotation. Crawford (2009) gives the example of the word *community*, whose false friend is *communauté*. When *community* is rendered literally in French (*la communauté*) or German (*Gemeinschaft* is one among a number of possible translations), other and different nuances are imported that could lead to a quite different conception of *community safety*, *community crime prevention*, *community policing*, or *punishment in the community* (see also here the seminal work of Lacey and Zedner 1995). Crawford goes on to emphasize "... the need to excavate and understand the culturally specific essence of key terms and locate them within the context of wider horizons of interpretation" (Crawford 2009, 17).

Evaluating Transfer

If the success of a transfer is to be appraised in terms of the achievement of the intended goals, the first problem in evaluating transfer is in determining the intentions of those involved, which, as we have seen, are often complex, variable and changing over time. Different actors, as we have seen, are likely to have different intentions and consequently may not agree about what would count as success.

With that reservation in mind, one way of investigating the difficulties of evaluating transfer would be to consider a specific initiative and to ask what would count as success here, what as failure. For example, suppose the attempt was being made to introduce community service/unpaid work into a jurisdiction as part of a strategy to provide alternative sanctions to imprisonment (Canton 2006). The attempt would count as unsuccessful, presumably, if no community service orders were made by the courts. But another possibility is that orders are made, but instead of functioning as alternatives to custody (diverting people from imprisonment), they merely widen the net by drawing in offenders who would in the past have been dealt with through other and perhaps less burdensome and intrusive sanctions (this is an altogether likely consequence, as Cohen's (1985) work shows).

Even the size of the prison population would not resolve the question: a decrease could be attributable to other initiatives (reforming administrations, after all, rarely proceed on a single front), while an increase would not necessarily be a sign of failure (perhaps the increase would have been even steeper, but for the introduction of community service). Another possibility is that such community sanctions might be made in respect only of defendants who were powerful or privileged, with custody remaining for the poor. Again, there are other corruptions of transfer that can be envisaged: for instance, a scheme where unpaid work brought personal profit to individuals or commercial interests rather than providing a wider community benefit.

A further challenge is the timescale for evaluation. Some initiatives – the introduction of a new institution or system, of new legislation or changes to the powers of courts – could (at least in principle) be assessed quite quickly. But their longer-term significance, the extent to which they become "owned" and embedded in the criminal justice system, calls for an extended period of inquiry and for sophisticated methods of evaluation. In particular, the "soft transfer" (Newburn and Jones 2007) of new ideas, new ways of thinking about crime and punishment, is likely to have their effects much later on in time.

In summary, the effects of transfer should be evaluated and arguably this has not usually taken place with sufficient rigor. At the same time, evaluation poses formidable challenges–not only of determining effects, which may change over time, but of deciding on the criteria of evaluation in the first place.

Conclusions

Policy transfer is a topic of considerable practical importance. Whether celebrated as the dissemination of good practice and experience or denounced as the imposition of the preferences of (typically) more powerful and affluent countries upon others, transfer activity is common and only likely to increase. A principal stimulus here, which is likely to become still more compelling, is the increasing influence of supranational influences. Respect for international law and a recognition that some level of accountability to the international community is a bulwark against human rights abuses have prompted the promulgation of several treaties and conventions. These have given a mandate for supranational entities – for example, the Council of Europe – to concern themselves with the penal practices of their member states. Penal policy, in short, is no longer the sole concern of the nation state. Such developments are likely to lead to further transfer initiatives as countries wishing and/or required to change look for acceptable and effective models to copy or emulate. Another driver for transfer, as we have seen, is the claim that research can give new insights into effective practice which accordingly should be adopted everywhere – although some of the limitations and caveats to be observed have already been noted here.

Penal policy is also of great theoretical interest. Transfer projects soon expose taken–for-granted characteristics of penal practice in one's own country. Such activities also contribute to contemporary debates in comparative criminology about international convergence and divergence. It is not that convergence should always be seen as an indication of the "success" of transfer activities: it could as well be a function of countries having to confront similar challenges and predicaments (Jones and Newburn 2007). Nor should persistent difference or divergence be taken as a sign of failed transfer, especially if the objective of transfer is taken to be the development of systems and practices that truly belong to the receiving nation and not just the copying of a practice from another place (Canton 2009). But consideration of the processes of transfer and the people involved highlights, as we have seen, the place of choice and agency in penal development to counter explanations that depend on purely structural (and sometimes excessively abstract and deterministic) accounts that invoke concepts like globalization. As Cavadino and Dignan well put it in their discussion of the influences on the character of criminal justice (2006, 452): "... however many factors we incorporate into our theory, it will still not give us the whole story. Individual nations, and their cultures, histories and politics, can be just as quirky and esoteric as individual human beings."

Policy transfer could even be seen as an exercise in *applied comparative criminology*. The determinants of the character of penality and the drivers of change have usually been explored historically (notably Garland 1990). But transfer endeavors put these hypotheses to test and may therefore contribute to fuller and richer understandings of the complex network of influences that shape the institutions and practices of punishment.

Overview

In recent years, victims of crime have moved from the peripheries of both academic and policy discussions concerning criminal justice to become at least rhetorically "central" in modern criminal justice policies in many developed states (Hall 2010). This entry examines some of the newest territory into which victims and victimology are now moving, and, in so doing, it is argued that traditional criticisms espoused by victimologists, namely, that official recognition of victims often fails to account for victims' own perspectives, remain extremely pertinent to this debate. In addition, this entry examines how the scope of "victimization" is expanding, with many commentators now adopting a "social harm" approach to the question of victimization rather than limiting themselves to restrictive, legalistic categories. Nevertheless, it is argued that the classification of such individuals and groups as victims of "social harm" (as opposed to "criminal harm") raises the concern that criminal justice systems may shirk their responsibilities for such victims. It can be argued therefore that notions of social harm represent a challenge to justice processes to better incorporate these "new" victims through the continued development of victims' rights and restorative justice.

Discussion

Expanding Notions of Victimhood

"Criminal Harm" or "Social Harm"?

Over time, the ambit of both *academically* and *politically* recognized "victimhood" has tended to expand. That said, much of victimology (and criminology) continues to be centered on notions of victimization espoused by official sources. Indeed, some go further to argue that society's narrow conception of victimization is brought about by selective definitions of crime, construed for political purposes (Elias 1986). Such arguments have led to the development of "critical victimology" and its expanded notions of victimhood beyond straightforward, criminal classifications to include categories of "real, complex, contradictory and often politically inconvenient victims" (Kearon and Godey 2007, p. 31). This in turn has prompted some authors to approach "victimization" from a cultural perceptive and to focus on "social harms" as experienced by victims and their communities, as opposed to harms necessarily caused by breaches of the criminal law (Hillyard and Toombs 2003).

The conceptualization of victims as those who have suffered harm (as opposed to more technical, legal, or prescriptive definitions) has two key implications. Firstly, it gives scope for a wide cross section of individuals or organizations to be included within the ambit of victimhood. Criminal law, as argued by Hulsman (1986), "fails to capture the more damaging and pervasive forms of harm" (Hillyard and Toombs 2003, p. 12). Focusing on harm thus has the potential to include the often legally ambiguous activities carried out by big corporations or the state, and also activities which the state or its agencies choose not to regulate. This approach also allows for the consideration of "mass harms," whereas traditional criminology has struggled to fully embrace mass victimization, largely remaining focused on the individual. Of course, "harm" similarly is a fuzzy concept, with strong cultural roots, and definitions of it from a state's, a victim's, or a community's point of view are likely to differ. This notwithstanding, a social harm approach also potentially allows victims to be self-defined, something which at present is usually reserved for a small subset of victims (e.g., victims of hate crimes) – though victimization surveys take a victim's eye view. This implies that prosecutors should seek the view of individuals and groups who feel they have been harmed.

The adoption of "harm" as the central element of victimization has been witnessed in many jurisdictions (Hall 2010). In this respect, many jurisdictions have followed the definition set down by the 1985 UN Declaration of Basic Principles of Justice for Victims of Crime and Abuse of Power (hereafter the 1985 UN Declaration):

> 'Victims' means persons who, individually or collectively, have suffered harm, including physical or mental injury, emotional suffering, economic loss or substantial impairment of their fundamental rights, through acts or omissions that are in violation of criminal laws operative within Member States, including those laws proscribing criminal abuse of power. (para.1)

The 2001 EU Framework Decision of the Council of the European Union on the Standing of Victims in Criminal Proceedings [(2001/220/JHA, at http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=CELEX:32001F0220:EN:NOT) follows a similar model (Art.1(a)] as does the South African Victims' Charter and its Dutch equivalent. The US Justice for All Act of 2004 defines a victim as "a person directly and proximately harmed as a result of the commission of a federal offense" (18-USC-3771). This includes victims of white collar and financial crimes.

There are numerous examples of this broadening of victimhood among policy makers and government actors (see Hall 2010). In this entry, two pertinent examples are considered, victims of state actions and victims of environmental crime, to illustrate the complexities inherent in this development and, in particular, the difficulties when such developments occur without direct consultation with victims.

Victims of State Crime and the International Criminal Court

While much of the policy and academic focus on victims has rested on traditional breaches of the criminal law, there has also been growing awareness of victimization at the hands of the *state*. "State crime," itself a markedly underdeveloped concept, is generally used to describe criminal actions carried out by state employees, such as the police, as well as by governments. Academic focus on *victimization* by the state or state employees has been similarly limited, although it was included under the 1985 UN Declaration in the guise of victims of "abuse of power." The inclusion of *omissions* under the definition of "abuse of power" used by the Declaration clarifies that a state is responsible for failure to regulate activities within its borders which lead to transboundary harm. This is particularly significant given the proliferation of cross-border crimes such as human trafficking and international terrorism.

Kauzlarich et al. (2001) characterize victimization by the state as a manifestation of attempts to achieve organizational, bureaucratic, or institutional goals of state agencies. They note that victims of state crime tend to be among the least socially powerful, are often blamed for their suffering, and rely on the victimizer, an associated institution, or civil social movements for redress. Such victims also tend to be easy targets for repeat victimization. From the victimizer's perspective, the nature, extent, and harmfulness of institutional policies tend to be ignored or misunderstood. If suffering and harm are acknowledged, the authors contend that it is often neutralized through a sense of "entitlement," which the authors illustrate by drawing on what they see as "the long history of U.S. abuses in Latin and Central America" (p. 185).

In relation to victims of *crime*, the 1985 UN Declaration has prompted significant criminal justice reform in multiple jurisdictions (Hall 2010). Notwithstanding this, Bottigliero (2004) argues that the victims' movement (at activist, academic, and public policy levels) has focused on what she calls "ordinary" crimes like assault and theft, which can be dealt with in the domestic context, while ignoring the victims of more "severe" crimes such as war crimes, human rights violations, or genocide. At the international level, one significant development is the creation in 2002 of the International Criminal Court (ICC). Constituted by the Rome Statute of 1998, the purpose of the ICC is to try war crimes, genocide, and crimes against humanity which, by their nature, are often perpetrated by those in positions of authority within governments. In most cases such activities will also constitute breaches of domestic criminal laws, but when such crimes are committed within the ambit of wider atrocities by representatives of a state, they are rarely prosecuted. This means that the ICC rarely deals with "abuses of power" as defined by the 1985 UN

Declaration, which only includes activities *not* officially prescribed as crimes, although Wemmers (2009) characterizes the inclusion of "abuse of power" within the Declaration as "a source of inspiration" (p. 124) for the ICC.

Significantly, the Rome Statute legislates for the participation of victims within the ICC process, and the court has adopted a judicial code of ethics which includes judicial obligations to have regard to the interests of victims. The court has also ruled that the definition of "victims" within the Statute is a wide one and "cannot be interpreted as limited to certain categories of individuals" (ICC-01/04-01/06-1119, para.27).

From a victimological perspective, the ICC is a rare example of a discrete judicial system developed *from the outset* with an appreciation for the arguments of the victims' movement. The Court's Rules of Procedure and Evidence contain many safeguards to what are called the rights of victims: including the right to participate in proceedings as a party with legal representation. The rules often bring together an "interests of justice" test with an "interests of victims" test. Perhaps most significantly, the rules provide the general principle that "a Chamber in making any direction or order, and other organs of the Court in performing their functions…shall take into account the needs of all victims and witnesses" (Rule 86). There is however a limitation inherent in the Rome Statute in that the court is not *required* to establish what may be "in the interests of victims" through consultation with the victims themselves but rather, under Rule 93, *may* seek the view of victims or their legal representatives. This leaves the procedure open to the criticism that judges are only taking into account what *they think* the interests of victims may be.

Bottigliero (2004) argues that the infrastructure set up by the ICC begins the process of addressing the needs of victims of state crime, particularly their need for restitution. Of course, the true impact of the ICC on victims will only become clear as the number of cases it deals with increases. On this point, Wemmers (2009) conducted qualitative interviews with court personnel to determine how they felt its engagement if victims would operate. The results indicated serious engagement with the "victim issue" as well as a recognition that the success of the court as a whole to a large extent relied on victims' perceptions, especially at the community level of it as a credible and legitimate institution. A view generally held was that the true test of the ICC was whether it can "effect real changes in the communities, such as restoring the safety of victims and preventing further violence by arresting and punishing offenders" (p. 124). One theme which did not emerge in many of the interviews, but which Wemmers sees as crucial, is victims' relationship with their legal representation at the ICC given the reality that the vast majority will never attend the court.

A further issue raised by Wemmers (2009) and examined in more detail by Bottigliero (2004) concerns the selection of cases for trial by prosecutors working at the ICC. As Wemmers notes:

> The selection of cases by the Prosecutor is a central point in the decision-making process. It is vital that the Court be seen as neutral and fair and that its choice of cases is both a-political and representative of the atrocities committed. (p. 225)

Clearly this reflects a concern that prosecutions at the ICC may be seen as politically motivated. Bottigliero (2004) however has shown that major selection by the prosecutor as to which cases should proceed to the court seems to be based on which cases are most likely to succeed rather than the needs of victims. Prosecutors at the ICC are bound to consider the position of victims, and Article 53(c) of the Rome Statute notes that a prosecutor may decline to pursue a prosecution if it is in "the interests of victims" to do so. The question remains however as to whether prosecutors will approach victims directly for their views or work on their own assumptions as to their needs and the perceived seriousness of the crime.

Environmental Victims

In recent years, progress made in our understanding of the causes of environmental degradations has posed a number of challenges for lawyers, as questions are increasingly raised concerning the responsibility of corporations and states for so-called environmental harms. Indeed, following the previous section, the increasing prevalence of "green" debates among criminologists has rekindled notions of "mass victimizations" and state crime. Lynch et al. (2010), for example, have exposed complex interactions between state and corporate liability following what they call the "politicization of global warming." White (2008) has discussed state crime in relation to the environmental effects of the use of depleted uranium munitions in the Gulf wars. Of course, much environmental crime is committed by corporations *against* governmental regulations or legislation. In such cases the question becomes one of enforcement, and whether the prosecuting agents of the state approach such transgressions in the same manner as they do other crimes. A large body of literature now suggests that the enforcement of regulatory or criminal instruments against corporate offenders is highly variable (Hutter 1997), especially in relation to environmental degradation (Bell and McGillivray 2008).

"Environmental harms" can include direct impacts on human health and economic impacts on a range of industries (fishing, agriculture, tourism, and significant social and cultural damage to traditional ways of life). The implications of environmental harm for issues such as energy security and food security are equally significant. As a consequence, criminal justice systems (at the national and international levels) are increasingly called upon to incorporate "environmental victims" into their procedures. This is a challenging proposition, given the vested economic and political interests inherent to the industrial practices which can foster environmental damage (although it should not be assumed that all industrial or commercially viable practices lead to environmental degradation). As such, environmental victimization encapsulates many of the problematic issues addressed by the critical school and covered by notions of "social harm."

Unfortunately, specific empirical research even on the *human* victims of environmental degradation is scarce, although the first call for the development of "environmental victimology" came as early as 1996. For Williams (1996), victimology represents a solution to what he perceives as an environmental justice movement dominated by activists and relying too heavily on subjective understandings of victimhood. Certainly "environmental justice" is usually acknowledged as a wide concept which emphasizes the involvement of people and communities in decisions (apparently meaning state decisions) which impact upon their environment. "Environment" tends to be defined broadly to include cultural norms, values, rules, regulations, and behaviors (see also Bryant 1995, p. 6). "Intergenerational justice" is often cited as a core component of the environmental justice model, highlighting responsibility to future descendents.

Examples of how criminal justice systems are now being obliged to adapt to meet the challenges of environmental victimization can be drawn from a number of sources. At a national level, for example, the US Crime Victims' Rights Act 2004 has been applied to victims of environmental harm in *Re: Parker; U.S. v U.S. District Court and W.R. Grace & Co.* Nos. 09-70529, 09-70533 (9th Cir). In Europe the EU has adopted Directive 2008/99/EC on the protection of the environment through the criminal law. Though the enforcement of environmental legislation by means of the criminal law is by no means novel, it has often played a secondary role to administrative sanctions and civil penalties. Indeed, Bell and McGillivray (2008) have drawn on the "enforcement pyramid" posited by Ayres and Braithwaite (1992) to describe enforcement tactics of many jurisdictions in relation to environmental "crime." Essentially this pyramid puts "persuasion" at its apex (and, interestingly, does not have criminal recourses there), principally because revocation of a company's license to operate is in fact far more damaging than a relatively small fine. The 2008 Directive is thus indicative of a hardening of attitudes over breaches of environmental law, albeit the response of the EU so far to environmental crime has neglected the impact of such crime on victims. Potential for greater involvement of such victims can be identified within the earlier 1998 Council of Europe Convention on the Protection of Environment through Criminal Law. Though this treaty has not yet entered into force, and indeed has secured little support, Article 11 provides for the participation of environmental groups in relevant criminal proceedings. This has the potential to be a ground-breaking article, raising the possibility of opening up environmental criminal proceedings to wider participation.

At the international level, the most progressive source of legally binding environmental obligations is found in the 1998 UNECE ("Aarhus") Convention on Access to Information, Public Participation in Decision-Making, and Access to Justice in Environmental Matters. The convention requires governments to bring individuals who may be affected into the decision-making process when environmental issues are at stake. What is significant about the convention is that, almost uniquely within international law, members of the public are able to refer possible breaches of their rights under the Convention to its Compliance Committee. Of course, while the Aarhus convention offers something of a "way in" to the international legal order for the individual in practice, this compliance mechanism can be subject to criticisms. There is a lack of real compulsive power on behalf of the Compliance Committee to really address victims' complaints and ensure restitution/apologies from perpetrator states are forthcoming. That said, there is presently a dearth of empirical research on what victims of environmental crime might actually want from a criminal justice (or other) process (Williams 1996). Consequently, moves to increase the attention paid to such victims in many jurisdictions is once again progressing without reference to the victims they are purporting to help.

Addressing the Needs of Victims

To summarize the preceding section, the scope of officially recognized victimhood is expanding. However, it appears to be doing so without asking victims what their perceptions and needs might be. The second section of this entry examines the development of victims' rights and the place of victims in restorative justice processes, both of which provide cogent examples of a more evidence-based process and, as such, shed light on how the above developments might be adapted.

Victims and Criminal Justice: The Perennial Question of Rights or Services

Should victims have legislated rights which they can use to demand better treatment in relation to criminal justice – or should criminal justice agencies be mandated to provide services to improve the victim experience? The question of "rights or services" has been a perennial one since the first empirical research into victims and criminal justice, in both the USA and the UK, showed how they were essential to the system's operation but ignored in terms of their needs and expectations. Subsequent research has continued to reinforce the same needs and expectations of victims, but has also documented the reluctance of criminal justice personnel and policy makers to provide for those needs, partly through a continued focus on professionalism and reducing delay, partly through a misapprehension that meeting victims' expectations disadvantages offenders. In fact, the research on offenders' views shows they would also like to be treated with respect, given information on what is happening and generally feel they were being treated fairly – just like victims.

The slow pace of change has spurred international bodies to promote action to produce a more helpful environment for victims. Following a review of the "patchy" implementation of the 2001 Council Framework Decision, in May 2011 (see Press Release, "Victims" rights: Frequently asked questions,' at http://europa.eu/rapid/pressReleasesAction.do?reference=MEMO/11/310&format=HTML&aged=0&language=), the European Commission is introducing a Directive on minimum standards for victims, the EU's Justice Commissioner, Vice President Reding saying, "Victims of crime need respect, support, protection and to see that justice is served. That is why I am putting victims at the heart of criminal justice in the EU by making sure they can rely on minimum rights and support" (Press release, "European Commission ensures better protection of crime victims," 18 May 2011, IP/11/585, at http://europa.eu/rapid/pressReleasesAction.do?reference=IP/11/585). The EU sums up the needs of victims as being to be recognized, to be treated with respect and dignity, to receive protection and support, and to have access to justice, compensation, and restoration.

It is suggested that the answers to the question of "rights or services?" depend on ideology and on evaluated effectiveness. Criminal justice and legal scholars, seeing criminal justice as primarily a matter for the nation-state and the offender, are loathe to grant any more than service rights to victims, primarily focusing the burden of providing such rights on personnel at the entry to criminal justice: the police, welfare agencies, and volunteers, such as Victim Support. Given that, for victims, most contact with criminal justice is with the police (and Victim Support) – because offenders are rarely apprehended – this is indeed the way to supply most victims with most of what they need. It is underlined by social activists who wish to widen the idea of victim to embrace other harms, including traffic accidents and disasters, as discussed above. For the police or support agencies to help victims, what is key is political (rather than justice) prioritization to victims rather than the multitude of other tasks required of the police and money. Both, however, are currently rather in short supply in this time of recession and fears over public disorder and terrorism.

It is argued that procedural rights (see Edwards (2004) for distinctions between service rights and procedural rights) for victims become more essential further into the criminal justice system. Criminal procedure in all legal systems is shaped and operated through legislated rules. If victims are to receive consideration during prosecution and at court (and in relation to compensation), then the rules need to provide them with those means, and key decision makers within criminal justice must be appointed to ensure they are operationalized. It is notable that the relatively recent provisions for vulnerable witnesses in courts in England and Wales have come into force and been effective for victims in a short time frame (Hamlyn et al. 2004) – with few qualms (other than the technical ones of shortage of court space and learning the technology). The provisions include familiarization visits and giving evidence via video link or from behind screens. They were enacted through legislation (Youth Justice and Criminal Evidence Act 1999), and decisions are made by the presiding judge.

In contrast to the speed of action over vulnerable witnesses – which may be linked to them being for *witnesses*, rather than victims perse – provisions which depend upon individual police officers, prosecutors, or politicians taking action seem to be more tardy and patchy. Victim personal statements (statements made by victims about the effects of the offense on them, also called victim impact statements (in the USA, Australia, etc.) or victim effect statements), for example, though mandated in case law and by government (Shapland and Hall 2010), depend on the police officer giving them to the victim at the right time, and in England and Wales, less than half of victims recalled being offered that opportunity (Roberts and Manikis 2011). Nonetheless, of those offered the opportunity, the majority took it, victims of more serious offenses being particularly likely to participate. Research in Canada, the USA, Australia, and the UK indicates that those who made a statement were generally satisfied (see summary in Roberts and Manikis 2011). Victims, in the studies carried out in Australia, Canada, and the UK, seem to make a statement primarily for expressive reasons (desiring a voice at court), though instrumental reasons, such as affecting sentence, are also important (Roberts and Manikis 2011). Though the introduction of victim personal statements for nonfatal cases seems to have been welcomed by the judiciary (as providing more information), it does not often seem to have affected sentence to a significant extent. However, this would be expected if judges are sentencing primarily on a deserts basis to an "average" range of sentence (only more unusual cases can be affected). In death penalty cases, its use has been far more controversial. Paternoster and Deise (2011), in a randomized controlled simulation experiment with potential jurors in the USA, found that jurors who viewed a victim impact statement were more likely to impose the death penalty, because they sympathized with the victim's family. This has been the fear, but of course most jurisdictions do not have sentence pronounced by juries – and it is highly unlikely professional judges would do the same (Shapland and Hall 2010).

There has always been a dysfunctional tension between criminal justice system personnel's reluctance to provide services (or rights) to victims and their dependence on victims, both for the immediate case and for political support. The public's confidence in the system is mediated through victims' views, with a key determinant of comparative confidence between countries being victims' treatment (van Dijk et al. 2007). This has recently been tested empirically. Bradford (2011), analyzing the national victimization survey for England and Wales, the British Crime Survey, found that victims who did have contact with Victim Support had more favorable views of the fairness of the criminal justice system and higher levels of confidence in its effectiveness. The link between contact with Victim Support and confidence in the criminal justice system was mediated by trust in the fairness of the system; it appears that if victims have someone who listened to their concerns (and may take action in relation to them), they trust the system more and have greater confidence in it. This continues to support Tyler's theory of procedural justice: that those members of the public who have contact with the system view the system through the lens of their perceptions of how fairly it takes decisions and how it treats them (with respect, sensitivity, and dignity scoring highly).

It is interesting that the European Commission, introducing the proposed Directive, mentions the need for both services and rights, though it is clearly moving towards procedural rights. It specifies its reasons for needing a Directive as improving provisions on an equal and nondiscriminatory basis, enhancing trust in the justice system, improving the quality of justice, that minimum standard must apply in all Member States, and that "fundamental rights must be respected" (Communication from the Commission to the European Parliament, the Council, the Economic and Social Committee and the Committee of the Regions, COM(2011) 274, at http://ec.europa.eu/justice/policies/criminal/victims/docs/com_2011_274_en.pdf), in which it links victims' rights to the EU Charter and the European Convention on Human Rights, in terms of victims' human dignity, private and family life, and property.

Victims and Restorative Justice

The European Commission refers to restorative justice, in its Communication (COM(2011)274 final) in its section on compensation and restoration:

> Restorative justice, which is a relatively new concept in criminal proceedings, goes beyond purely financial compensation to focus on the recovery of the victim. As an alternative to, or in combination with formal justice, it aims to restore victims to the position they had before the crime by giving them, if they so wish, an opportunity to confront their offenders face to face and for the offenders to take responsibility for their acts. (p. 6)

Reparation has certainly been one key element behind the growth of restorative justice in many countries, particularly in mainland Europe and Scandinavia. However, restoration of the victim, in the fuller sense of acknowledging the victim has been damaged by the offense, showing how the victim and others have been affected, allowing apology by the offender and determining what best to do next, has been one of the key purposes behind mediation and conferencing as opportunities for interaction between victim and offender.

From a recent survey of key knowledgeable informants, it seems that mediation (victim-offender mediation: in which a mediator meets with victim and offender) is now available in at least 39 countries worldwide, including almost all of Europe (Zinsstag et al. 2011). Conferencing (in which the victim, offender, and mediator are joined by victim and offender supporters, and sometimes community representatives) is now available in at least 48 countries, more frequently outside Europe. Though more commonly used (and legislated for) in relation to young offenders, both mediation and conferencing are growing in relation to adult offenders as well. Mediation is starting to be used widely by the police, more informally, as part of neighborhood or community policing (Gunther-Moor et al. 2009), where police officers either act as mediators themselves or refer cases to community mediators or specialized mediators employed by the police. Mediation can thus be available at many stages of the criminal process (or even outside it altogether): as diversion from prosecution, presentence, post-sentence, or while the offender is in custody. Though widespread, at least in theory, and increasingly backed by both European and national authorities (see the Council of Europe's Recommendation No. R(99)19 on Mediation in penal matters), its implementation has, however, like many initiatives for victims, been patchy, constrained by money and a lack of trained mediators/facilitators.

Restorative justice needs to be voluntary, both for the victim and the offender. What proportion of victims, then, when offered it, decides to take part? Mostly, victims will be offered one "take it or leave it" choice between participating in restorative justice and not participating. It is uncommon for victims to be offered several formats (e.g., conferencing, a direct mediation meeting or "shuttle" mediation, in which the mediator passes questions and answers between victim and offender), though increasingly, schemes are offering several possibilities, depending on the type of offense and the circumstances of the parties. In England and Wales, a recent large-scale evaluation of three schemes found that the percentage of victims offered restorative justice where they agreed to participate was between 30 % and 89 % (Shapland et al. 2011). Victims were more likely to agree where the case involved a young offender (all these sites had agreement rates of 75–89 %), but there was no difference between victims offered mediation and victims offered conferencing. Victims offered indirect mediation were more likely to choose it over a direct meeting with the offender, but the overall rate for conferencing was the same as for indirect and direct mediation combined. Even very serious offenses with adult offenders offered conferencing presentence in the higher courts found a majority of victims prepared to participate. Restorative justice is not, though, suitable for offenses in which there are considerable power imbalances between offender and victim (domestic abuse, some sexual assault cases).

The evaluation results for victim reactions to restorative justice are almost uniformly positive – providing that the offender acknowledges responsibility for the offense and the victim is invited to attend. Processes and the extent of victim participation vary considerably between schemes and countries. In early New Zealand family group conferencing, victims were not always informed or invited at helpful times, but in Northern Ireland youth conferencing, based on the New Zealand model, victims have attended in around 70 % of cases (Shapland et al. 2011). In the Thames Valley diversionary police-run conferencing, victims also tended not to be invited (Hoyle et al. 2002). In family group conferencing, victims may be asked to leave after they have talked about the effects of the offense and before the family and young offender decide with the mediator what should happen thereafter. In contrast, in conferencing based on the Australian RISE model, victims (and their supporters) are active participants in all stages of the conference, discussing what happened, what effects it had, and what should then be done (Shapland et al. 2011). In this model, the conference is intended to end, where possible, with an outcome agreement signed by all present (and 95 % of conferences in the evaluation did so). Despite all these differences between models, victims in all these evaluations were positive about their experiences. However, it is highly likely that these positive results depend upon the process being suitable for the seriousness of the offense. If restorative justice were to be used to replace criminal justice as a diversion measure (as opposed to being offered in addition, as is normal), then particularly for serious offenses, victims would be highly likely to feel offended.

There has been a significant amount of evaluation of restorative justice, most of it concentrating upon whether it reduces re-offending, but including victims' views and the effects on victims. In terms of satisfaction ratings, Latimer et al. (2005) did a meta-analysis of 22 studies which had a control group of 35 schemes and found there was significantly more satisfaction among those who had experienced restorative justice. Sherman and Strang (2007), in a further meta-analysis, concluded that restorative justice with adult offenders reduced crime victims' posttraumatic stress symptoms and related costs, provided both victims and offenders with more satisfaction with justice than did criminal justice alone, and reduced crime victims' desires for violent revenge against their offenders. It is difficult to measure whether restorative justice (or any other initiative taken in conjunction with criminal justice) reduces the harmful effects of crime on victims, because many psychological, social, and financial perceived effects of crime on victims reduce with time (Shapland and Hall 2007), so one would be measuring the "extra" effect of restorative justice beyond that of time and other justice processes. Victim perceptions, however, are that it is helpful in reducing negative effects of the offense as well as enabling victims to have their questions answered about the offense and to communicate with the offender. In the major recent evaluation of conferencing in England and Wales, where conferencing occurred in parallel to the normal criminal justice process and cases were randomly allocated, victims participating in restorative justice said they felt significantly more secure (Shapland et al. 2011). In addition, over half the victims said that it had helped them have closure, with another 20 % saying it had done so to some extent. Victims of more serious offenses were as likely to feel closure and were significantly more likely to feel satisfied with the criminal justice system as a whole.

The extent of satisfaction and the generally positive effects of well-run restorative justice, particularly conferencing, are now so prevalent in evaluations that, in the evaluation authors' view, it would be difficult ethically to justify running further random controlled trials between the presence or absence of restorative justice. It would be difficult to put victims into a control group and so deny them the benefits of restorative justice. That evaluation also found that, at whatever stage of criminal justice the restorative justice was offered, participants were fine about it being done then. However, it is not known exactly which forms of restorative justice are best to offer for which groups. Having a "future-oriented" stage to the restorative justice where participants can discuss what should happen next seems to be important for both serious offenses and neighborhood disputes (Shapland et al. 2011). Supporters bring extra voices and resources to the debate and can help to mitigate any power imbalances (Strang 2002; Shapland et al. 2011). Indirect mediation seems to lead to less satisfaction than a direct meeting, because communication, prized by victims, is circumscribed (Shapland et al. 2011) – but if this is the only kind of contact victims want, should it be withheld?

Conclusion

The development of scholarly interest in victims of crime, as well as policy interest among the world's governments, looks set to continue well into the new century. In the above paragraphs, a number of key areas of development have been set out which will no doubt raise a whole host of questions and challenges for victimologists and criminologists in the coming years. A key concern however is that at least some of these developments are occurring in the absence of detailed research or engagement with victims themselves. Indeed, it is truly fascinating how in both state crime and environmental crime fields, the definition of victims by victims themselves is largely being ignored. In these two fields, detailed victimization studies are absent possibly because they would mean confronting what victims themselves say and think, rather than "using" them as exemplars of damaged people. Of course, in this sense, victims are threats not only to lawyers and the state but also to activist groups wishing to attack states if, for example, it turns out that they desire only respectful treatment, information, understanding, and an apology as opposed to more retributive outcomes. The research into what kind of services or rights victims actually want, as well as their response to restorative justice processes, seems to bear out this hypothesis – although actual answers can only follow detailed empirical work. In sum, while the expansion of victimhood and the development of concepts like "social harm" may benefit those victims still ignored by governments and criminal justice actors, it also places obligations on those actors, and the academy, to find out what these people actually need – and only then consider how best it may be achieved and the extent to which it is valued by victims themselves.

International Sentencing

Barbora Hola
Department of Criminology, VU University
Amsterdam, Amsterdam, The Netherlands

Introduction

International crimes, such as genocide, crimes against humanity, and war crimes, are manifestations of large-scale and serious violations of human rights that have been defined as the most serious crimes of international concern. As noted by *Mettraux* it would be hard to identify crimes more difficult to sentence than international crimes (Mettraux 2005). This is not only due to the atrocious nature of international crimes but also due to their collective, systematic character, often involving state authorities and a huge number of perpetrators. In the last decade a number of international institutions have been established to prosecute and sentence perpetrators of international crimes. Compared to national criminal law systems, there is no "international criminal code" to govern the functioning of these courts. Each tribunal has its own statute outlining in general terms its jurisdiction, and the various tribunals exercise their mandates rather independently with no formal and institutional links to each other. With respect to sentencing, provisions of the statutes, and rules of procedure and evidence, the written law establishing the tribunals and governing their functioning, is usually very sketchy providing judges with only very loosely defined limits to their sentencing discretion. The positive law does not pronounce any sentencing rationales or general principles of sentence determination. It does not contain any penalty structure in the sense of minimum or maximum penalties for individual offences. Usually, no list of relevant aggravating and mitigating factors is provided. As opposed to many domestic jurisdictions, legislation thus plays only a very marginal role at the international level, and one has to examine judicial decisions in order to disentangle the phenomenon of international sentencing.

This contribution will provide an overview of the current practice of sentencing of international crimes. First, it will briefly discuss sentencing practices at various international courts and tribunals that have been set up to prosecute international crimes. Then, the most controversial issues, such as sentencing goals at the international level, hierarchy of different categories of international crimes, and sentencing consistency, will be discussed. The final section will provide suggestions for further research. It will be demonstrated that in the past few decades, sentencing of international crimes at international courts and tribunals has developed rapidly and inspired scholarly discussions and controversies. This attention, however, is still rather marginal. Compared to other aspects of international criminal law, sentencing has been relatively neglected by academics and commentators. There are, therefore, many unexplored areas of sentencing of international crimes that call for further research and inquiry.

Fundamentals of International Sentencing

Plurality of International Criminal Courts and Tribunals

The scholars date the history of international criminal law centuries back, however, the first time an international tribunal held an individual responsible for international crimes came only after World War II. In 1945 the International Military Tribunal in Nuremberg (IMT) and International Military Tribunal for Far East in Tokyo (IMTFE) were established to punish the major Axis war criminals. Due to the stalemate at the international arena during the period of Cold War, there were no similar institutions created. There were, however, some ongoing efforts to set up an international criminal court. After the fall of the Berlin wall ending the period of Cold War, the picture changed significantly. Media coverage of stories of concentration camps in Bosnia, showing pictures which evoked memories of the Holocaust, and of the wholesale slaughter committed in Rwanda in the presence of the UN peacekeepers in the early 1990s caused a public outcry and led to demands that something should be done. The UN Security Council reacted by the establishment of the International Criminal Tribunal for the Former Yugoslavia ("ICTY") and International Criminal Tribunal for Rwanda ("ICTR") – the first ad hoc international criminal tribunals. Shortly thereafter, the permanent International Criminal Court ("ICC") was set up at the Rome Conference in 1998. The increased interest in achieving justice and thus preventing international crimes in the future led to the establishment of many other so-called internationalized courts and tribunals such as for Sierra Leone, Kosovo, East Timor, Cambodia, or Lebanon. As opposed to the ICTY, ICTR, and ICC, all the internationalized courts have a much stronger "national element" (hybrid jurisdiction over international and domestic crimes; mixed composition with international and domestic judges, prosecutors, and defense attorneys; applicability of international and domestic law). In this respect, the ICTY, ICTR, and ICC can be perceived of as the only "purely international criminal tribunals." Furthermore, sentencing of international crimes is exercised not only at the international level by international courts and tribunals but also by many domestic courts in nation states.

International Sentencing Law and Practice

IMT and IMTFE

Traditionally, statutes of international criminal tribunals have paid only very limited attention to sentencing. The Charters of the postwar military tribunals included only one provision regulating sentencing basically authorizing "death or such other punishment as shall be determined [. . .] to be just" (Art 27 IMT Charter; Art 16 IMTFE Charter). Also, the case law of these tribunals and successor trials held by various national courts in the aftermath of World War II left only very few sentencing guidelines (Schabas 2006). The IMT's judges recognized a wide range of mitigating factors for sentencing of international crimes, including superior orders, age, position in the military hierarchy, efforts to reduce victims' suffering, and duress (Schabas 2010). Otherwise, however, sentencing argumentation of the post-World War II judges was not very developed. The IMT in Nuremberg rendered 19 sentences (three defendants were acquitted) while the Tokyo tribunals convicted 25 individuals. Twelve Nuremberg defendants and seven Tokyo defendants were sentenced to death. The IMT convicted three other defendants to life imprisonment while the IMTFE sentenced 16 individuals to life in prison. Otherwise, determinate sentences ranged from 7/10 (Tokyo/Nuremberg) to 20 years imprisonment. More than 100 defendants were sentenced during the 12 succession trials held in Germany by occupying powers; among them, 12 defendants were executed (Heller 2011).

ICTY and ICTR

International sentencing law and practice have become more sophisticated after the Cold War with the jurisprudence of the ad hoc international criminal tribunals. The regulatory framework for sentencing is almost identical for both tribunals. Applicable penalties are limited to imprisonment, and when determining the terms of imprisonment, judges shall have recourse to the local courts' practices regarding prison sentences (Yugoslavian or Rwandese). Articles 24/23 ICTY/ICTR Statutes contain very general instructions as to what factors should be taken into account in imposing sentences: the gravity of the offence and the individual circumstances of the convicted person. What is actually meant by the "gravity of crime" or which "individual circumstances" are relevant is unclear. The judges are left to evaluate the gravity of a crime and relevance of individual circumstances on a case-by-case basis.

The ICTY and ICTR judges consider the gravity of a crime to be the primary consideration in sentencing and the litmus test for the appropriate sentence. In this sense, the ICTY and ICTR judges endorsed the classic "just desert" principle of proportionality and argued that punishment should be proportional to the gravity of the particular offence(s) committed by a defendant. It should reflect the magnitude of harm caused by the defendant and his role and degree of participation in the offence(s) (i.e., the so-called offence gravity proportionality) (D'Ascoli 2011). Given the fact, however, that all international crimes tend to be extremely serious entailing extreme harm, it is unclear how much guidance this metric offers (Sloane 2007a). In many domestic jurisdictions, criminal codes provide for sentencing range for individual offences and thus set limits to judges' discretion. This is not the case at the international tribunals, and judges are free to evaluate proportionality of sentences on a case-by-case basis.

The proportionality assessment in the case of international crimes, however, is complicated not only by the lack of positive law guidance and extreme seriousness of crimes under the tribunals' jurisdiction but also by the fact that the tribunals deal with crimes committed by multiple perpetrators often acting in hierarchically organized groups. In this respect, the so-called defendant-relative proportionality of sentences becomes relevant. The defendant-relative proportionality dictates that a punishment should be proportional relative to the other defendants who committed international crimes within the same conflict, i.e., high-ranking individuals who organized, planned, and ordered the crimes should be punished more severely than low-ranking followers who "just" executed criminal orders. According to Ohlin, the relatively low ICTY sentences are the consequence of the fact that "the Tribunal was implicitly prioritizing defendant-relative proportionality over offence-gravity proportionality" and sentenced many defendants to relatively low sentences "because it was reserving space at the top of the scale for Milosevic, Mladic and Karadzic" (Ohlin 2011). The judges at the ICTY and ICTR implicitly endorsed the defendant-relative proportionality by applying the so-called principle of gradation. The principle of gradation is closely related to the position a defendant occupied and the role he/she played in the overall conflict situation. It stipulates that sentences should be gradated along with increasing authority of a defendant in the state structure and significance of his/her role in crimes. The relative position of the accused, however, has to always be balanced against the seriousness of the committed crimes. It is not the steadfast rule that all low-ranking defendants automatically receive low sentences and all authorities are automatically punished the most. Accordingly, offenders receiving the most severe sentences tend to be senior authority figures, such as ministers or governmental officials. However, very severe sentences can also be imposed on those at lower levels who zealously orchestrated or participated in crimes (Ewald 2010).

The provisions of the Statutes are supplemented by the Rules of Procedure and

Evidence. Only one rule, Rule 101, of the 165/154 ICTY/ICTR rules governing the proceedings before the tribunals is dedicated to factors relevant to sentencing. Rule 101 clarifies the regulation of the sentencing process only to a very limited extent. It limits the range of applicable sentences – the maximum sentence available to the judiciary is life imprisonment. It also instructs judges to take into account any aggravating and/or mitigating circumstances when determining the sentence. However, no list of aggravating and mitigating factors is provided. Only two potential mitigating factors are explicitly mentioned: "superior orders" and "substantial cooperation with the Prosecutor." Effectively, judges are left to determine on a case-by-case basis what factors justify an increase or reduction in sentence length. According to case law, mitigating factors need to be established upon the balance of probabilities and need not directly relate to the charged offences. The standards applicable to aggravating factors are more stringent. Aggravating factors must be proven beyond any reasonable doubt, and only those circumstances directly related to the commission of the offence charged and to the offender himself when he committed the offence may be considered in aggravation. A wide range of factors have been accepted by the tribunals in aggravation/mitigation of a sentence. "Abuse of superior position/authority/influence" is the aggravating factor most frequently used, while "family circumstances of a defendant" or "his/her assistance of victims" is among the mitigating factors cited the most by the ICTY and ICTR judges (Bagaric and Morss 2006).

As of July 2012, the tribunals have convicted more than 120 individuals for their involvement in genocide, crimes against humanity, and war crimes during the conflicts in the former Yugoslavia and Rwanda. The sentences range from 2 years imprisonment to the maximum: life imprisonment. Four ICTY and 21 ICTR defendants have been convicted to life imprisonment. The average length of determinate sentences is 15.9 years at the ICTY and 22.6 years at the ICTR. There are differences in sentence length between the ICTY and ICTR – the ICTR sentences are generally longer compared to the ICTY (Drumbl 2007). This difference is mainly connected to the different case composition at the tribunals: in contrast to the ICTY, the majority of the ICTR defendants are convicted of genocide and also many key figures (members of government and other high-ranking figures) and organizers of violence stood trial in Arusha; furthermore, all ICTR defendants are convicted for killing and/or serious violence against victims (Hola et al. 2011). Other possible reasons for the difference in sentence severity between ICTY and ICTR include the reference to national practice (incorporation of national law and sentencing practice) (Beresford 2001) or the sheer gravity of atrocity in Rwanda (Drumbl 2007).

ICC

The Rome Statute of the ICC establishes a very similar, though a bit more elaborate, sentencing framework compared to the Statutes of the ad hoc tribunals. Article 77 provides two types of custodial sentence: "imprisonment for a specified number of years, which may not exceed a maximum of 30 years" and "life imprisonment when justified by the extreme gravity of the crime and individual circumstances of the convicted person." The possibility of life imprisonment was included in the Rome Statute on the assumption that its imposition would be rare (Schabas 2010). In addition to imprisonment, the court may order a fine or a forfeiture of proceeds and property. Article 78 establishes general sentencing criteria in the same way as the Statutes of the ICTY and ICTR: the court shall take into account the gravity of the crime and the individual circumstances of the convicted person. The ICC Rules of Procedure and Evidence complement this general framework and provide judges with a more detailed sentencing guidance. Rule 145 states that the totality of any sentence must reflect the culpability of a defendant; and judges are asked to balance all the relevant factors, including any mitigating and aggravating factors and consider the circumstance of both: the convicted person and the crime. The Rule 145 further contains a demonstrative list of sentencing factors, including aggravating and mitigating circumstances. The lists resemble factors accepted in mitigation or aggravation in the case law of the ICTY and ICTR. Consequently, similar to the ICTY and ICTR, the ICC judges are vested with broad discretionary powers when it comes to sentencing. How this discretion will materialize in practice and whether the ICC judges will draw upon the rich sentencing jurisprudence of their predecessors at the ICTY and ICTR remain to be seen. Currently, the first ICC defendant Thomas Dyilo Lubanga has been convicted for the war crime of “conscripting and enlisting children under the age of 15 years and using them to participate actively in hostilities” and sentenced to 14 years of imprisonment.

Internationalized Courts and Tribunals

The Special Court for Sierra Leone (SCSL), Special Panels for Serious Crimes in East Timor (SPSC), and Extraordinary Chambers in the Courts of Cambodia (ECCC) constitute examples of the so-called internationalized tribunals combining international elements with much stronger links to domestic systems (in the sense of the applicable law, punishable offences or composition of tribunals). The sentencing practices and case law of these courts have been neglected in the scholarship, and most attention of commentators focused on the ICTY and ICTR. This lack of attention might be the result of the fact that case law and case composition at these tribunals have not been as extensive and/or varied compared to the ad hoc tribunals (SCSL rendered nine sentences; SPSC rendered 84 sentences focusing exclusively on low-ranking defendants; ECCC has so far convicted only one perpetrator). Similar to the other international courts, judges of the SCSL, SPSC, and ECCC have been vested with large discretionary powers when it comes to sentencing, and no detailed sentencing guidelines are provided by the positive law. Especially at the SCSL and the ECCC, judges seem to find inspiration in the case law of the ICTY and ICTR and often refer to the principles endorsed by the ad hoc tribunals’ judges. The sentencing argumentation of the SPSC judges, on the other hand, is very rudimentary and limited to description of factual findings and relevant aggravating and mitigating circumstances. Similar to the ICTY and ICTR, the sentence ranges at these courts are rather broad: (i) SCSL, 15–52 years; (ii) ECCC, handed down just one sentence of life imprisonment; and (iii) SPSC, 11 months–33 years and 4 months imprisonment. The high average sentence at the SCSL – 38.6 years – might be related to the fact that the tribunal is not allowed to render life sentences and instead it has handed out rather long sentences (40–50 years) to a couple of defendants. In contrast, the average sentence at the SPSC is comparably low – 8.6 years. This might be influenced by the fact that all defendants at the SPSC were lower-ranking crime executioners convicted usually of single instances of crime. More research is needed to describe and analyze sentencing practices at the internationalized tribunals and compare them to the sentencing regimes of the ICTY/ICTR/ICC but also domestic sentencing of international crimes.

Current Issues and Controversies

Goals of International Sentencing

The positive law outlined above does not contain any general provision explaining objectives to be pursued in sentencing. The Preamble of the ICC Statute seems to incorporate the purposes of retribution and general deterrence. The ICTY and ICTR Statutes are virtually silent in this respect. Accordingly, ICC, ICTY, and ICTR judges are generally free to switch from one self-chosen rationale to another as they see fit (Bagaric and Morss 2006). Some principles specific to sentencing have emerged in the ICTY and ICTR case law. In this respect, judges clearly found inspiration in classic “domestic” penal theories (Drumbl 2007). Over the years, the following purposes have been listed by international judges as relevant for international sentencing: retribution, justice, deterrence (general and specific), rehabilitation, expressivism, reprobation, stigmatization, affirmative prevention, incapacitation, protection of society, social defense, and finally restoration/maintenance of peace and reconciliation. Different combinations of some of these principles are usually listed at the beginning of the sentencing part of a judgment. There is no uniform approach in the tribunals' case law regarding the objectives of international punishment. In general, deterrence and retribution are emphasized in the majority of the cases. Next to retribution and deterrence, the third most frequently cited sentencing objective by the ICTY and ICTR judges is rehabilitation. Nonetheless, in the majority of cases, it is emphasized that rehabilitation should not be given undue weight given the seriousness of committed crimes. The exact way how the various purposes guide sentence determinations at the tribunals is, however, unclear (Henham 2005). The influence of retribution is apparent from the fact that gravity is consistently emphasized by the judges as the primary consideration in sentence determination and that proportionality between gravity of crime and sentence severity is often underscored. Decisions of judges regarding relevant aggravating and mitigating factors could be linked to retribution, rehabilitation, and reconciliation. While not being decisive during sentence determinations, rehabilitation is conversely emphasized at the sentence enforcement stage, and demonstration of rehabilitation seems to be one of the decisive factors of decisions granting early release to imprisoned convicts.

The relevance of these various sentencing objectives to international crimes has been discussed at length in legal doctrine. The legal scholars, however, also do not seem to agree on the objectives of international sentencing. Bagaric and Morss noted that goals of international sentencing in the form of reconciliation, retribution, and rehabilitation are either highly speculative or misguided. The only justification for the practice is according to these scholars general deterrence. Its relevance is, however, significantly undermined by the selective and infrequent prosecution of international crimes (Bagaric and Morss 2006). In contrast, Ohlin argues that deterrence together with rehabilitation and expressivism are inapposite in case of sentencing international crimes, and international sentencing ought to be based on retributive considerations (Ohlin 2009). Beresford, on the other hand, observes that retributive sentiments should play only a slight role in the development of international sentencing since they may prove counterproductive and disruptive to the restoration and maintenance of peace in the afflicted communities. He also cautions against according undue prominence to deterrence in meting out of sentences, especially taking into account the length of the proceedings at the international level. Rehabilitation should also be approached with caution since the judges cannot predict what rehabilitative programs are available in states enforcing the sentences (Beresford 2001). In contrast, Harmon and Gaynor advocate (general) deterrence as the sentencing objective in the case of international crimes and state that "there is some evidence that the international justice system is forcing western military commanders to listen more closely to their legal advisers when selecting targets and weapons for bombing missions" (Harmon and Gaynor 2007, p. 695). Noting the relative leniency of international sentences compared to domestic jurisdiction, Harmon and Gaynor consider the application of the concept of retribution in cases of large-scale crimes and mass atrocities unsatisfactory. Applying rehabilitation in the context of sentencing military and political leaders is according to these authors also inapposite since usually they are individuals with high social skills and do not clearly pose a criminal threat to society (Harmon and Gaynor 2007) Nemitz argues that retribution should not play the dominant role in the international criminal justice system especially because the heinous nature of the international crimes makes it impossible to state that the perpetrator of various crimes against humanity deserves a sentence of so and so many years. The sentencing purpose of deterrence also has, according to Nemitz, shortcomings especially (i) given the fact that many perpetrators of international crimes actually do not act rationally, do not weigh pros and cons of committing crimes, but act in the heat of a combat situation and (ii) given the slight chances that a perpetrator will indeed be apprehended and tried at one of the tribunals. He however acknowledges that deterrent effect might be greater for high-ranking perpetrators.

Nemitz argues that affirmative general prevention in a sense of educating public that violations of ICL are always prohibited should be the primary aim of sentencing (Nemitz 2001) Drumbl is also very skeptical regarding the ability of international trials to attain retributive, deterrent, and expressive aims due to the selectivity of international prosecutions, pervasive discretion of international judges, and political contingency of the process of international criminal law (Drumbl 2010). Similarly, Sloane argues that the efficacy of justifications for punishment derived from domestic systems is compromised at the international level. International criminal law differs from domestic criminal law in several respects that are relevant to the social institution of punishment, including the nature of (i) the community that authorizes international criminal law, (ii) the crimes addressed by it, and (iii) the perpetrators judged by it. He then argues that the principal value of international punishment lies in its expressive dimensions, which more accurately capture the nature of international sentencing (Sloane 2007b). Consequently, a rather vivid academic debate regarding the purposes of international punishment has developed in international criminal law scholarship. To determine goals for international sentencing that would reflect a specific character of international crimes being a form of collective criminality and of international criminal justice system based on multiplicity of international criminal courts and institutions with limited mandates is a challenging task that would for sure spark off academic discussions also in the future.

Hierarchy of International Crimes

As noted above the statutes of the international tribunals do not contain any sentencing tariff. Similarly, judges in the current case law emphasize that there is no hierarchy among individual categories of international crimes and that all the crimes are very serious violations of international (humanitarian) law. The question of hierarchy among genocide, crimes against humanity, and war crimes, however, was not so clear-cut in the past. In the early ICTY and ICTR case law, judges endorsed the idea of hierarchy among genocide, crimes against humanity, and war crimes. Genocide was labeled as the crime of crimes and considered the most serious category of international crimes (Prosecutor vs. Kambanda, ICTR-97-23, Judgment, 4 September 1998, para. 16). In the first ICTY cases, judges indicated that, all else being equal, an offence committed as a crime against humanity, that is, with awareness of a widespread or systematic attack on a civilian population, is more serious than an ordinary war crime (Prosecutor v. Tadic, IT-94-1-T, Sentencing Judgment, 14 July 1997, para. 73). Later, both tribunals, however, seem to adopt the stance that there is no preestablished hierarchy between individual categories of crimes emphasizing that *all* crimes under their jurisdiction are very serious violations of international humanitarian law.

In contrast, several legal scholars have argued that there should be a hierarchy of individual categories of international crimes based on the assessment of their objective gravity. According to these scholars, when the same act, e.g., murder, is committed as either genocide or a crime against humanity or a war crime, there should be a gradation in punishment reflecting different contextual requirements of individual categories. Each category of crimes requires proof of different *chapeau elements*, i.e., genocide requires special intent to destroy in whole or in part a specific group of people; crimes against humanity must be committed as part of a widespread or systematic attack against a civilian population with knowledge of such an attack; whereas war crimes could be isolated incidents committed within an armed conflict. Due to these inherent differences, it should matter for the purposes of sentencing if an act is classified e.g., as genocide or as a war crime. Scholars have advocated a hierarchy of individual categories of international crimes based on their objective severity (Carcano 2002; Danner 2001; Olusanya 2005). According to these scholars, a genocidal murder should be considered as the most serious entailing the severest punishment, followed by a murder as a crime against humanity and the least severe punishment should be ascribed to a murder as a war crime. Numerous empirical studies have also shown that despite the proclamation of international judges to the contrary, there appears to be differences in the actual sentence length between individual categories of crimes indicating an empirical ordering among genocide, crimes against humanity, and war crimes for the purposes of sentencing (Hola et al. 2011; Meernik 2011).

Consistency of International Sentencing

The requirement of consistency of sentencing could be perceived as one of the fundamental principles of any sentencing practice. It stems from the modern internationally recognized human rights principles and has been explicitly endorsed by the international sentencing case law (Prosecutor v. Mucic et al., IT-96-21-A, Judgment, 20 February 2001, para. 756). Many legal scholars have criticized international sentencing practice, in particular that of the ICTY and ICTR, and labelled it as "irrational" (Henham 2003), "akin to a lottery system" (Olusanya 2005), or "confusing, disparate, inconsistent, and erratic" (Drumbl 2007). These criticisms, however, have never been founded on a comprehensive empirical analysis. Lately, more and more empirical legal studies have emerged and addressed the alleged inconsistencies of international sentencing from an empirical perspective. The majority of these studies focused on the ICTY and ICTR since these international tribunals produced the most extensive sentencing practice. Without any exceptions these empirical studies have identified consistent patterns in the tribunals' sentencing practice. The first to introduce empirical analysis into the research on international sentencing was *Meernik*. Together with his colleagues, he has published several studies analyzing primarily the early sentencing practice of the ICTY and ICTR. In all these studies, they concluded that sentencing at the tribunals seems not to be influenced by political factors and that "there is a fair degree of consistency in the sentences conferred on the guilty and sentences are premised on those critical factors that the judges are asked to apply by the Statutes and Rules of Procedure and Evidence" (Meernik and King 2003; Meernik et al. 2005). Subsequent empirical studies confirmed these findings and identified consistent and predictable patterns in the international sentencing practice (Ewald 2010) Hola in her PhD dissertation identified the following sentencing patterns in the ICTY and ICTR sentencing practice: (i) an empirical ordering/hierarchy among different categories of international crimes with genocide being considered the most serious category of crime, followed by crimes against humanity and war crimes; (ii) a culpability level of a perpetrator is assessed by the ICTY and ICTR judges taking into account primarily a defendant's position in the overall state hierarchy, his role, and the scope of his/her crime with high-ranking organizers convicted on multiple crimes being subjected to the most severe sentences; and (iii) relevance of individualization of sentences with aggravating and mitigating factors cited by the ICTY and ICTR judges accounting for an increase/reduction in sentence length (Hola 2012). All these studies have demonstrated that international sentencing can be statistically predicted to a considerable extent – 70 % of sentence variation can be predicted by legally relevant factors (Hola 2012). It seems that at the international level, despite the lack of sentencing guidelines and large discretionary powers of judges, the sentences appear to be as statistically predictable as sentences in domestic legal systems with more detailed legal regulation of sentence determination such as the USA (Hofer et al. 1999, p. 243). The majority of the empirical studies, however, focused on the two ad hoc international criminal tribunals and examined sentencing consistency within one tribunal at a time. In order to evaluate consistency of international sentencing practice, it is also necessary to not only examine sentences across different international and internationalized tribunals (Meernik 2011) but also evaluate sentencing of international crimes by domestic courts. Some authors have noted undue leniency of international sentences compared to sentences pronounced by domestic courts (Bagaric and Morss 2006; Drumbl 2007).

Specifics and Further Criticism of International Sentencing

Next to the criticism stemming from the alleged inconsistencies of international sentencing, the practices of international courts have been criticized for being disconnected from the reality of victimized communities – as not reflecting the perception of "justice" in states where the crimes were committed. According to some authors, this failure to find a way of relating the outcomes of international sentencing to local perceptions of justice continues to be critical for the future credibility of international criminal justice. There is therefore a need to close this gap between global and local in order to enhance legitimacy of international courts and tribunals (Henham 2007). Drumbl calls for international criminal law interventions to engage with local practices that actually reflect the customs, procedures, and mores of those individuals affected by violence (as perpetrators and victims) (Drumbl 2005). In a similar vein Henham argues that the ultimate challenge for international trial justice is to ensure that the "real" experiences of victims and communities in post-conflict states really do engage with the sentencing outcomes produced by the international courts and tribunals, so that they symbolize legitimacy and justice, rather than rhetoric and partiality (Henham 2005). Damaska warns that realization of this ideal would entail fragmentation of international criminal law and that there should be a uniform legal regime for all international criminals. International judges should, however, always strive to explain the reasons for any deviations in their practice from local norms or practices (Damaska 2008).

International sentencing and focus on individualized guilt and punishment have also been called into question by authors who see fundamental problems with such individualized responses to collective and systematic crimes. International crimes are usually offences entailing a large number of victims, committed as part of a large-scale campaign, and implicating many individuals with very different tasks. These crimes are often state sanctioned and characterized by mass involvement of both military functionaries and civilians. Criminologists have labeled international crimes as "crimes of obedience" and argued that international crimes are a different type of criminality than ordinary crimes (Smeulers 2008). They are crimes of conformism rather than crimes of deviance. In times of collective violence, many otherwise law-abiding citizens get involved and commit extremely cruel acts simply by conforming to their environment. Some authors have argued that this specific character of international crimes calls for a specific reaction. Drumbl maintains that "adequately redressing collective violence requires a discursive shift to other accountability mechanisms, including *collective forms of responsibility*" (Drumbl 2010).

Conclusion and Future Research

International criminal law and international sentencing have come a long way since the World War II when the first international criminal tribunals held individuals legally accountable for international crimes. After the end of the Cold War, there has been a proliferation of various international(ized) courts and tribunals that are called to hold perpetrators of international crimes to account. These developments brought a heightened scholarly attention to various issues of international criminal justice. Relative to the amount of commentary on other aspects of international criminal law, international sentencing still remains to be a rather neglected phenomenon. There are therefore many areas of international sentencing that need to be further explored by scholars.

Above all, there is a paucity of empirical studies on international sentencing. The highest priority for future research is evaluation of effects of international sentencing. Given the panoply of goals international sentencing institutions have ascribed to themselves, it is necessary to assess to what extent these goals are attainable and have been attained by the existing tribunals. Given the specific context within which international criminal justice institutions function and specific character of international crimes, the achievement of these various goals is not self-evident. The effects of international sentencing on perpetrators, victims, and global public (the purported audiences of international criminal justice) shall be operationalized and evaluated. In this respect, further theoretical research should further problematize various goals of international criminal justice and international sentencing and develop sui generis theories that would reflect specifics of international punishment and international crimes.

Given the multiplicity of institutions delivering international sentences, it is also important to examine sentencing practices of other international and internationalized tribunals than ICTY and ICTR in order to assess consistency/fragmentation of "international sentencing system." What are the relationships and influences, in terms of sentencing for international crimes, among all the international criminal courts and tribunals that have emerged in the past decade? In view of the principle of complementarity, one of the governing principles at the ICC, interactions between domestic courts dealing with international crimes and their international counterparts also need to be explored. Researchers should also devote more attention to the context of international sentencing and transitional justice in general. It is necessary to examine how international criminal trials affect and complement various local endeavors to deal with a violent past – not only domestic criminal trials but also other transitional justice mechanisms such as truth and reconciliation commissions or various other local modalities of justice.

Theoretical inquiries should address the questions of linking international prosecutions and sentencing to the etiology of international crimes. The current practice of the international tribunals has been criticized as not sufficiently addressing the peculiarities of international crimes and simply transposing concepts from domestic criminal law. More criminological research is needed in this respect to further promote the understanding of international crimes as collective criminality and its peculiarities with respect to punishment and sentencing individual perpetrators.

Overview

Interrupted time series models compare the levels of a time series before and after the introduction of a discrete intervention. The time series design is often a good match to the questions posed in criminology and criminal justice studies, and many examples of its use appear in the research literature.

The popularity of interrupted time series designs is largely attributable to the strength of the causal inferences that they allow. Shadish, Cook, and Campbell (2002) evaluate a variety of common research designs in terms of their ability to guard against threats to four types of validity: statistical conclusion validity, internal validity, construct validity, and external validity. Within each threat category, they consider a more detailed list of potential problems. Interrupted time series models are vulnerable to comparatively few of the issues that Shadish et al. identify. Several threats are nevertheless plausible in typical applications, and these require attention before making causal assertions.

Researchers can reduce threats to statistical conclusion validity by using long time series and analytical methods that are suited to temporal data. Threats to internal validity, the most important challenges to causal inference, require a combination of design variations and modifications to the statistical analysis. Methods for addressing construct validity threats also rely on statistical adjustments, especially dynamic modeling of possible impact patterns. Ruling out threats to external validity, in contrast, depends on replicating the quasi-experiment in diverse settings.

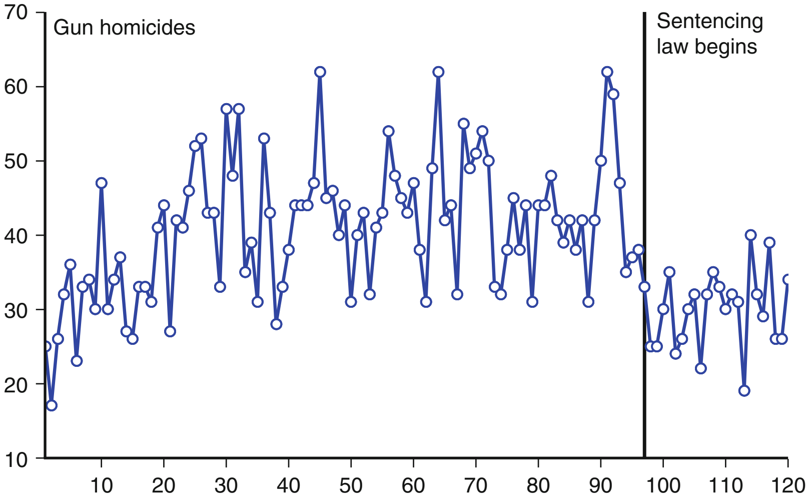
Fundamentals of Interrupted Time Series Models

Interrupted time series models use repeated measurements on an outcome variable to estimate the causal impact of an intervention. The interrupted time series design is among the strongest types of quasi-experiments, and it has many applications in criminology and criminal justice research. Interrupted time series models are especially useful in evaluating the outcomes of legal interventions, because they are well suited to the aggregate archival data that these studies often employ.

The time series design is intuitive in its structure, and variations on it have a long history of use in the natural and social sciences. Careful assessments of the design by Donald T. Campbell and his collaborators (Campbell and Stanley 1963; Cook and Campbell 1979; Shadish et al. 2002) nevertheless did much to increase its popularity among social researchers. The discussions by Campbell and associates are largely responsible for current understandings of the interrupted time series design's structure and also of its strengths and limitations.

In skeletal form, an interrupted time series model breaks a long series of observations into pre-intervention and post-intervention segments, and a data analysis then compares the segment means. A rejection of the null hypothesis of equality between the means supports a conclusion that the intervention produced a change in the outcome variable.

Figure 1 presents a simple example of a time series quasi-experiment. The data are 108 months of gun homicide counts from Detroit, Michigan (Loftin et al. 1983). A law that imposed a mandatory sentence enhancement for persons convicted of firearm crimes became effective



Interrupted Time Series Models, Fig. 1 Monthly Detroit homicide counts, 1971–1979 (Source: Loftin et al. 1983) during the 97th month of the study. A plot of the time series appears to show that gun homicides fell after the law began. Consistent with this appearance, the post-intervention mean represents a 29 % drop from the pre-intervention baseline. Solely from these results, one might conclude that the law reduced gun homicides.

Such a conclusion would be premature, however, because the analysis ignores several major threats to valid inference. The most obvious of these involve statistical questions about whether the series decreased by more than a chance amount during the post-intervention period. Visual inspections of time series are notoriously prone to error, making formal hypothesis tests necessary to establish the existence of a post-intervention change. Yet standard tests assume independent observations, and this is a requirement that time series data usually do not meet. Later observations in a series are almost always predictable from earlier ones, and serial dependence will bias the test results. A satisfactory data analysis therefore requires attention to statistical issues.

Time series quasi-experiments are also subject to design-based challenges to inferences about causal effects. Campbell and his associates systematically examined potential threats to validity that are inherent in a variety of research designs. They concluded that interrupted time series studies guard against most of these threats relatively well, but that several threats are plausible in most applications. The following sections further discuss both analytical and design issues in time series studies, considering threats to validity and ways of reducing their influence.

Four Threats to Valid Causal Inference

Campbell and Stanley (1963; Campbell 1963) divided validity threats into two broad categories, internal validity and external validity. Threats to internal validity considered whether the intervention was the cause of an observed change in the outcome variable. Threats to external validity considered whether any causal effect of the intervention held outside the original research setting.

Interrupted Time Series Models, Table 1 Common threats to validity in interrupted time series quasi-experiments

Type of validity	Threat to validity
Statistical conclusion validity	Low statistical power
	Violated assumptions of the test
Internal validity	History
	Maturation
	Regression artifacts
	Instrumentation
Construct validity	Novelty and disruption
External validity	Interaction over treatment variations
	Interaction with settings

Cook and Campbell (1979) expanded the Campbell and Stanley classification, adding two new threat categories. Threats to statistical conclusion validity arose from problems that Campbell and Stanley had previously considered under the heading of internal validity. Threats to construct validity involved sources of confounding that Campbell and Stanley had regarded as components of external validity. In a further revision of the classification, Shadish et al. (2002) retained Cook and Campbell's four-category scheme but substantially added to the set of specific threats.

Table 1 lists the threats to each type of validity that apply to the interrupted time series design. Shadish et al. (2002) include more threats within each category than appear in the table, and any of these might in theory operate in an interrupted time series analysis. Many of the threats are usually implausible, however, and the table includes only the most common and realistic possibilities.

Threats to Statistical Conclusion Validity

Threats to statistical conclusion validity come from situations in which analysts err in concluding that a correlation exists between a pair of variables. Shadish et al. (2002: 45) identify nine specific ways in which such threats can arise, but all of these fall into two more general categories that involve either Type I or Type II error rates. A Type I error, or α-error, involves rejecting the null hypothesis when it is true. In a time series quasi-experiment, this would occur if the data analysis yielded false evidence that the intervention influenced the outcome variable. A Type II error, or β-error, involves failing to reject the null hypothesis when it is false. Here the intervention did affect the outcome variable, but the statistical analysis was not successful in detecting the impact. Conventionally, analysts fix the Type I error rate at $\alpha \leq .05$ and the Type II error rate at $\beta \leq .2$ (see, e.g., Cohen 1988).

Threats to statistical conclusion validity involve distortions to the values of α and β, and the usual solution is to control the error rates through an appropriate statistical model. Although other reasonable classes of models exist, the most common choice in interrupted time series studies is the *Auto*R*egressive* I*ntegrated* M*oving* A*verage* (ARIMA) models of Box and Jenkins (1970).

Under the null hypothesis of no intervention effect, one can write an ARIMA model as

$$\varphi(B)Z_t = \theta(B)a_t \qquad Zt = Y_t - \mu_Y$$

Here Z_t and a_t are observations from a stationary time series and an *iid* $N(0,\sigma^2)$ error term, and $\varphi(B)$ and $\theta(B)$ are polynomial lag operators. Given appropriate constraints on $\varphi(B)$ and $\theta(B)$, one can solve the ARIMA model for a_t:

$$\theta(B)^{-1}\varphi(B)Z_t = a_t$$

To carry out the null hypothesis test, one first codes the intervention as a binary variable,

$$X_t = 0 \text{ for } t \leq N_{pre};\, X_t = 1 \text{ thereafter}$$

One then adds to the ARIMA model a function of X_t – conventionally called the "transfer function" – to represent the following causal impact:

$$\theta(B)^{-1}\varphi(B)Z_t = a_t + \omega X_t$$

In this model, ω estimates the effect of X_t on Z_t. Since a_t is *iid* $N(0,\sigma^2)$, a test of the null hypothesis that $\omega = 0$ now follows standard procedures.

Interrupted Time Series Models, Table 2 Parameter estimates for dynamic mandatory sentencing intervention model

Response model: $\varphi(B)$ (homicide) – $\theta_0 = a_t + \omega(\text{law}_t)$ $\text{law}_t = 0$ for observations 1–84; = 1 for observations 85–108	
$\theta_0 = 42.25$	$t(\theta_0) = 39.16$
$\omega = -12.04$	$t(\omega) = -3.99$
$\varphi = 0.28$	$t(\varphi) = 3.00$

Methods for building ARIMA models appear in Glass, Willson, and Gottman (1975), McCleary and Hay (1980), and McDowall et al. (1980). The $\varphi(B)$ and $\theta(B)$ operators are themselves of no interest for the hypothesis test, and they are present only to control irrelevant variation. The transfer function measures the impact of the intervention on the series, and estimating it accurately is the major goal of the analysis.

Table 2 presents an ARIMA impact analysis of the Detroit firearm homicide series from Fig. 1. The intercept, θ_0, shows that on average about 42 gun homicides occurred each month before the mandatory sentencing law began. Following the law, the mean number of firearm homicides dropped by 12 per month, a 28 % reduction. The *t*-value for the intervention coefficient allows a rejection of the null hypothesis of no change at $p < .0001$. The φ term in the model controls for serial dependence between the observations that would otherwise inflate the Type I error rate. In the example, the serial dependence is statistically significant, but small enough that only a slight difference exists between the ARIMA impact estimate and the original naive model. Obviously, this type of outcome often does not occur.

Although a satisfactory ARIMA model will control for Type I error threats, it does not fully address Type II errors. Failing to reject the null hypothesis does not mean that it is true, and accepting the null requires showing that the research design had sufficient power to detect an effect if one existed.

Of the factors that determine the power of a time series study, the underlying effect size is the most important consideration. Small effects are difficult to separate from random variation, and they result in tests with low power. Besides the effect size, the power of a time series quasi-experiment also depends on the length of the series, and on the balance between the pre-intervention and post-intervention segments. Authorities often recommend 50 observations as the minimum series length necessary if an analysis is to detect an effect (e.g., McCleary and Hay 1980; McDowall et al. 1980). Statistical power will also increase as the design more closely approximates perfect balance, with equally long pre-intervention and post-intervention segments.

Threats to Internal Validity

Shadish et al. (2002: 55) consider nine threats to internal validity, and any one of these might apply to time series quasi-experiments. Under realistic circumstances, however, only four threats are serious concerns. *History* and *maturation*, which are inherent in the use of time series data, may occur in any application of the design. *Instrumentation* and *regression* are also sometimes problems, but they arise only in designs that evaluate planned interventions. Many interrupted time series studies instead involve *natural experiments* (Campbell 1963), where an intervention occurs without advance planning. In these settings, instrumentation and regression threats are usually implausible.

The most serious threats to the internal validity of a time series quasi-experiment come from the operation of history. Historical threats are changes in a time series that occur along with the intervention but that are due to other causes. Some critics argue that such threats are ubiquitous, and that they will always undermine conclusions from an interrupted time series design (e.g., Piquero 2005; Harcourt and Ludwig 2006). These claims rest on a too simplistic understanding of the time series quasi-experiment, but they are helpful in emphasizing the need to take history seriously. Although interrupted time series studies can never completely rule out lurking historical threats, they can greatly reduce their plausibility through appropriate design adaptations.

A standard design-based approach to historical threats is to analyze one or more comparison series. A nonexperimental comparison will never be fully equivalent to the outcome under study, and this approach will therefore always be open to question. Comparisons can nevertheless take numerous forms, and a careful selection of them can help rule out possible historical artifacts.

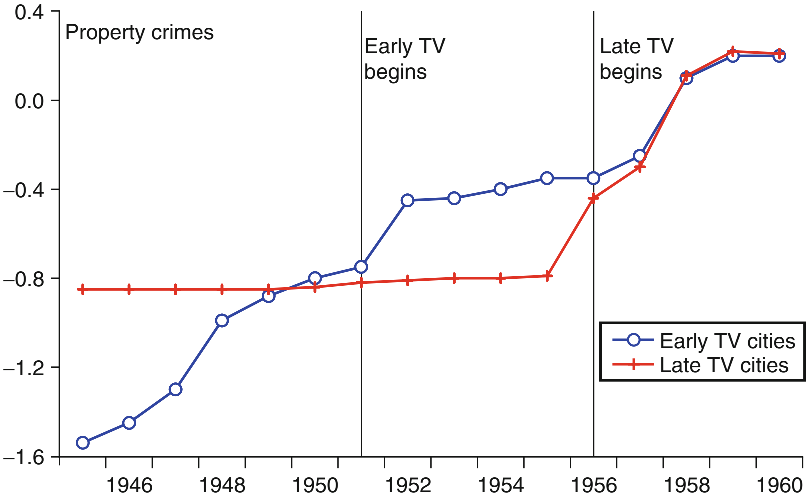
An analysis might consider other treatment series that the intervention should have affected, for example, or control series that it should not have affected. The analysis might also examine the intervention's impact within different subgroups, or consider switching replications in which the intervention shifted from one series to another. A consistent pattern of results across different variables or time periods undermines historical explanations and provides support for an intervention effect. In general, historical explanations become more difficult to justify as the pattern of comparisons becomes increasingly dense (Morgan and Winship 2007).

Hennigan et al. (1982), who examined changes in crime rates following the introduction of commercial television, exemplify the use of comparisons to address historical artifacts. In 34 "early" television cities that Hennnigan et al. studied, TV broadcasting began in 1950. In 34 "late" TV cities, television was not available until 1954. Figure 2 presents annual time series of property crimes for the "early" and "late" city groups.

Historical events are plausible threats to inferences about the impact of television in either the "early" cities alone or the "late" cities alone. Many conditions varied during the period in which each group adopted television, and some of these could explain a change in crime. The Korean War was underway in 1951, for example, and the economy had slid into a recession during 1955. More generally, alternative explanations for a change in either set of cities are easy to construct.

Yet when considering the two time series together, the changes in crime rates are more difficult to dismiss simply as the product of historical events. Plausible historical explanations would have to account for increases that occurred

Interrupted Time Series Models, Fig. 2 Annual property crimes for cities with commercial TV broadcast service in 1951and for cities with TV in 1955 (Source: Hennigan et al. 1982)



at different time points, but at each point affected only one group of cities. A critic might conceivably create such an explanation, of course, but persuasively justifying it could be another matter.

A one-time change in a single time series will usually allow multiple historical explanations. As the number of pertinent comparisons increases, however, historical threats become easier to dismiss. Although a time series quasi-experiment can never completely eliminate history, it can rule out all but the most complex (and therefore unlikely) possibilities.

In contrast to history, methods for addressing the other three threats to internal validity do not rely on extensions of the design. Maturation threats, in particular, require the use of statistical modeling. Maturation is the result of a developmental process that operates independently of the intervention, and it will generate a secular trend in the outcome series. Social science data sometimes display such trends, and trending patterns are especially common in the long series that are most desirable for analysis. Maturational trends can therefore take the appearance of an intervention effect, and this makes them a problem in any application of the design.

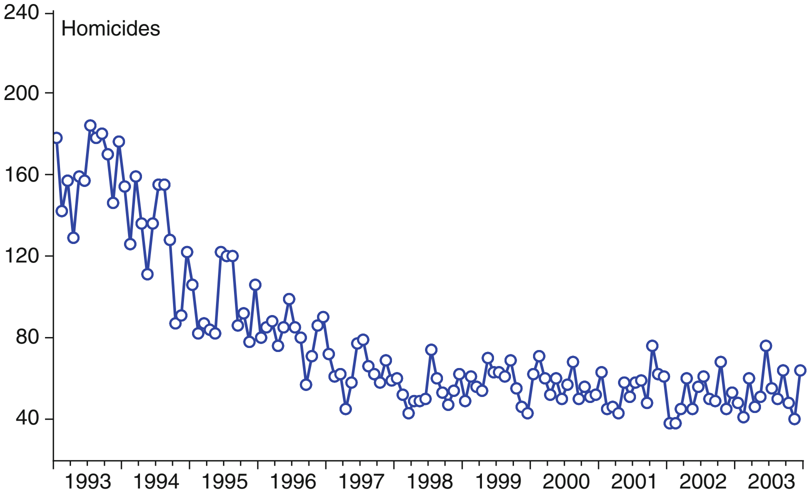
An illustration of a maturation threat appears in Fig. 3, which shows monthly homicide counts from New York City between January 1993 and December 2003. Pridemore, Chamlin, and Trahan (2008) used similar (although not identical) data to study whether the 2001 World Trade Center attack affected the frequency of homicides in the city. The series is generally flat for several years before and after September 2001, inconsistent with the possibility that the terrorist attack was a catalyst to broader changes in violence. Yet the downward trend in the early years dominates Fig. 3, and this suggests that a maturational artifact may account for the apparent lack of impact. Pridemore et al. recognized this threat, and in an analysis that controlled for it also found no evidence that the World Trade Center attack influenced homicides.

Controlling for maturational threats requires modifications to the quasi-experiment's statistical analysis. The usual ARIMA model for an interrupted time series design,

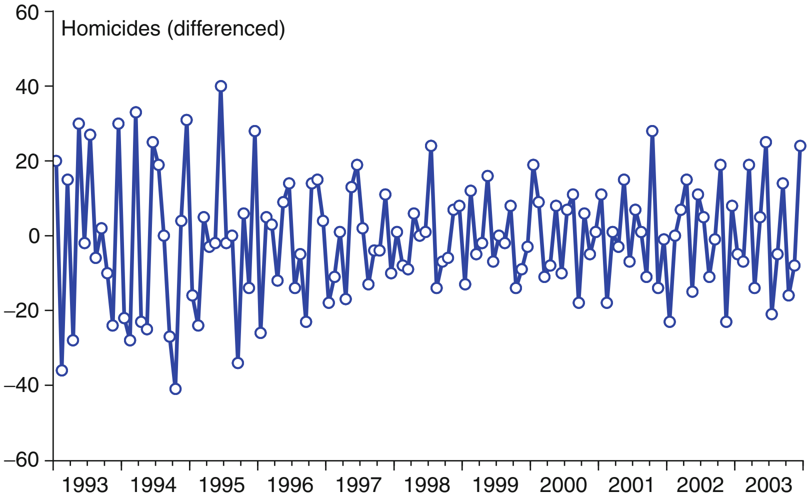
$$\theta(B)^{-1}\varphi(B)Z_t = a_t + \omega X_t$$

assumes that $\varphi(B)$ and $\theta(B)$ fall within the bounds of stationarity and invertibility (Box and Jenkins 1970: 49–51). If this is not so, the series under analysis will be nonstationary, and the model will not have a proper solution.

Nonstationarity can generate a secular trend, but it also manifests itself in other patterns that lack constant means. The New York homicide series does not exhibit a consistent trend over its entire length, for example, and instead displays



Interrupted Time Series Models, Fig. 3 Monthly New York City homicide counts, 1993–2003 (Source: U.S. Department of Health & Human Services (various years))



Interrupted Time Series Models, Fig. 4 New York City homicides from Fig. 3, differenced

the "drifting," up-and-down, appearance that characterizes a trendless random walk.

Although nonstationarity is a common occurrence in social science applications, converting a series to first-differences will almost always resolve the problem. Using "∇" to represent the differencing operation,

$$\nabla Y_t = Y_t - Y_{t-1}$$

a nonstationary series can be modeled as

$$\nabla Y_t = \varphi(B)^{-1}\theta(B)\, a_t$$

$$\text{or} \quad Y_t = \nabla^{-1}\varphi(B)^{-1}\theta(B)\, a_t$$

Figure 4 plots the first-differences of the New York homicide series. The differences fluctuate around a constant and unvarying level, and the differencing operation has removed maturation as a realistic threat. If the mean of the differenced series is zero, the series follows a directionless random walk; otherwise, the mean difference is an estimate of its secular trend.

Besides resolving maturation threats, differencing a series also removes the influence of any and all time-constant causes of the outcome variable. To take only one example, homicide rates are generally higher in large cities like New York than they are in rural areas or suburbs. Suppose that Y_t is New York's homicide rate, and that W represents population size and all other variables that make New York's rate consistently different from those elsewhere. After differencing the series,

$$Y_t - Y_{t-1} = f(a_t) - f(a_{t-1}) + W - W$$

$$\nabla Y_t = f(a_t) - f(a_{t-1})$$

and the influence of W and other time-constant causes disappears from the model. This property establishes a link between the interrupted time series quasi-experiment and the fixed-effects designs that are popular for analyzing panel data (Allison 2009).

As with maturation, regression threats to internal validity distort conclusions from a statistical analysis. Yet, unlike maturation threats, regression is plausible only in a limited range of circumstances. Regression arises mainly when an intervention occurs after a time series reaches a level that observers find so alarming that they take action to change it. In these reactive situations, regression to the mean can produce an increase or decrease that is independent of any intervention effect. When an intervention occurs naturally, without advance planning, threats due to this type of mean reversion are much less plausible.

Reactive interventions are common in criminal justice settings, because new legal initiatives are often the result of unusually high levels of some undesirable phenomenon. In one of the best-known early applications of the time series quasi-experiment, Campbell and Ross (1968) studied the impact of a speeding crackdown on Connecticut highway fatalities. Traffic deaths dropped significantly after the crackdown began, but this was largely due to a regression artifact. Fatalities had soared immediately prior to the intervention, which occurred as a response intended to reduce them. A predictable drop in traffic deaths followed the crackdowns as accidents moved down toward their historically average levels.

Regression becomes a less serious threat as the time series becomes longer. Introducing the intervention when the series is at an unusually high or low point will bias estimates of the pre- and post-intervention means. The bias decreases as the pre- and post-intervention segments grow longer, however, and it will eventually shrink to zero. Use of at least 50 observations for a time series quasi-experiment will generally be sufficient to make regression artifacts implausible, but longer series will obviously be more desirable than this minimum.

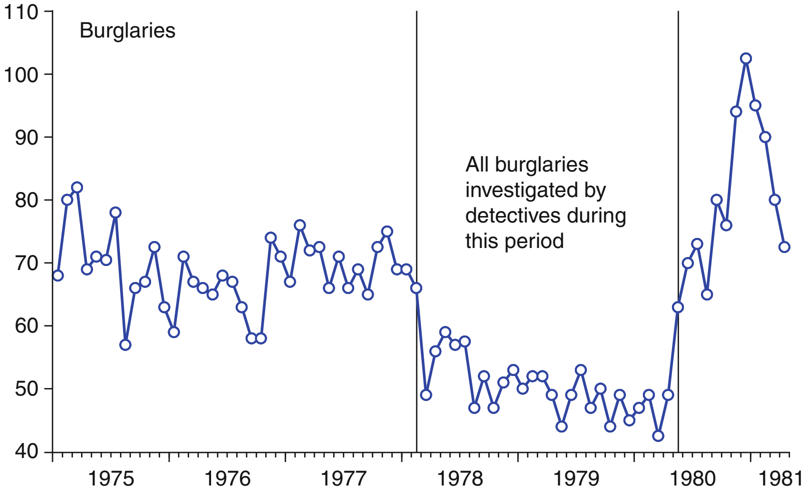
Like regression, instrumentation can be a realistic threat to validity in situations with planned interventions. These interventions often come with a package of other changes, including new ways of measuring the outcome variable. The new measurement methods are then confounded with the intervention, and they will provide an alternative explanation for any post-intervention difference in the series.

Figure 5 is from McCleary, Nienstedt, and Erven (1982), and shows a time series of monthly burglary counts from Tucson, Arizona. Before 1978, uniformed patrol officers investigated all burglary reports within the city. Detectives then assumed the investigative responsibility for a 2-year period between 1978 and 1980, after which investigations passed back to the uniformed officers. Burglary counts dropped when detectives investigated the cases, consistent with the hypothesis that they were more skilled in crime prevention.

The switching interventions help eliminate historical explanations for the lower burglary counts, but instrumentation threats remain plausible. Additional analysis by McCleary et al. showed that in fact the detectives and uniformed officers used different methods of keeping records. This instrumentation artifact explained the lower counts during the period that detectives handled the cases, and after controlling for it, burglaries did not vary with the type of investigating officer.

Unlike cases with planned interventions, the risk of instrumentation threats is typically low when time series quasi-experiments involve natural interventions. Measurement methods could

Interrupted Time Series Models, Fig. 5 Monthly burglaries for Tucson, 1975–1981. During a 24-month period, burglaries are assigned to detectives for investigation (Source: McCleary et al. 1982)



in some cases change if an intervention occurred naturally, but this would require an unusual set of circumstances. Natural experiments are therefore ordinarily not plausible settings for instrumentation threats to exist.

Threats to Construct Validity

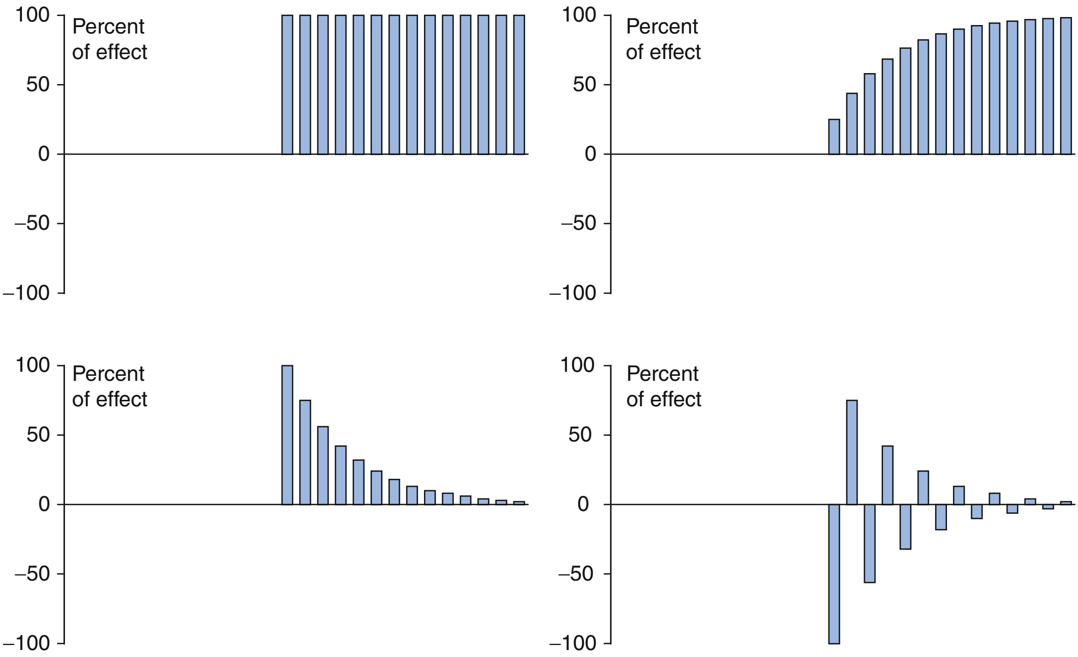
Threats to construct validity involve the adequacy of "the match between study operations and the constructs used to describe those operations" (Shadish et al. 2002: 73). Of the 14 specific threats to construct validity that Shadish et al. list, only one, *novelty and disruption* is relevant to the interrupted time series design. Because interventions seek to alter established patterns of conduct and action, the outcome variable may react to features of an intervention that are independent of its intended causal impact.

As with maturation threats, the data analysis can allow for threats due to novelty and disruption. To accomplish this, however, a researcher must have a general idea about how the construct validity threats should operate.

Figure 6 displays four impact patterns that an intervention might produce, including three patterns that incorporate the effects of novelty and disruption. The models in the first row of the figure illustrate permanent intervention responses. In these cases a series may change instantaneously or gradually after the intervention occurs but, in either case, it changes permanently. The *abrupt, permanent* response model requires the least elaborate theory, and it is the pattern that researchers most often entertain. This model assumes that any influence of the intervention is immediate, and that the impact holds constant throughout the post-intervention period. If these assumptions are true, the analysis faces no threats due to novelty and disruption.

In contrast, the *gradual*, *permanent* response model assumes that the full influence of an intervention is distributed over time. Here the novelty and disruption associated with the intervention act to slow its full impact, and the response follows a damped curve. This pattern is sometimes a reasonable model for the influence of new laws on crime rates. In these cases, organizational inertia and the diffusion of information among potential offenders may work to spread the law's effects over multiple time points. The novelty and disruption threats then help mask the total impact of the law, and an analysis that does not allow for them will produce downwardly biased estimates.

The models in the second row of Fig. 6 depict temporary responses to an intervention. Both the *abrupt*, *temporary* and *gradual*, *temporary* patterns involve cases in which novelty and disruption threats entirely account for an observed change. Here the outcome variable responds to the intervention initially, but this influence



Interrupted Time Series Models, Fig. 6 Model responses to an intervention

eventually wears off. Under ideal conditions, with a long post-intervention time series, an analysis may ignore the threats to validity that these temporary impacts pose. Under less-than-ideal conditions, the researcher must accommodate the effects within the structure of the analytical model.

The structure of the usual linear ARIMA model does not allow the types of dynamic responses that novelty and disruption typically produce. To incorporate these more elaborate patterns, Box and Jenkins (1970; Box and Tiao 1975) proposed a lagged polynomial transfer function,

$$\theta(B)^{-1}\varphi(B)Z_t = a_t + \delta(B)\omega X_t$$

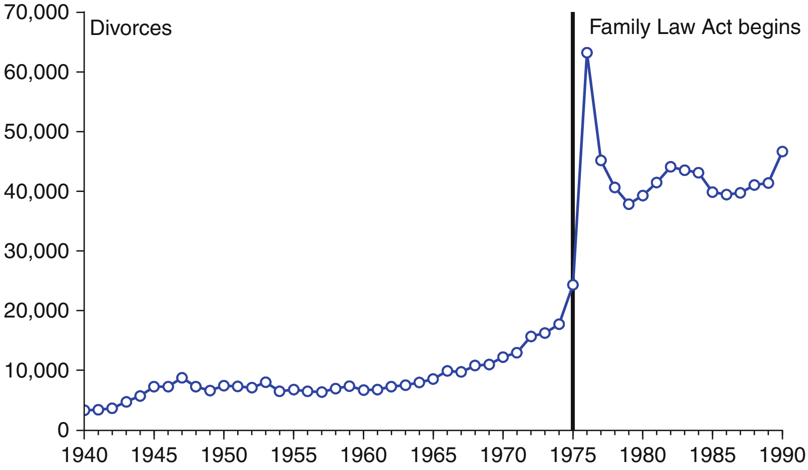
where $\delta(B)$ is a polynomial lag operator and ω is the usual impact estimate of the effect of X_t on Z_t.

The polynomial lags make the ARIMA model nonlinear, and this complicates estimation and interpretations of the results. These inconveniences aside, the lag model directly addresses novelty and disruption, and it is an effective approach to controlling them in practice.

Besides the individual effects, permanent and temporary responses to an intervention may also exist together. Figure 7 shows a time series of divorce rates before and after adoption of the Australian Family Law Act of 1975. The Act allowed no-fault divorce, and its opponents argued that divorce rates would increase as a result. An evaluation conducted by the Australian government concluded that divorces did initially rise, but that over the next 3 years they dropped back to their initial levels. The government evaluation attributed the temporarily higher post-1975 divorce rates to the operation of a trend.

Reanalyzing these data, McCleary and Riggs (1982) modeled the impact of the Act as partly temporary and partly permanent. A temporary increase occurred immediately, but this response then rapidly decayed over the next 3 years. McCleary and Riggs found that divorce rates never fully returned to their earlier values, and that they instead eventually stabilized at a new and higher level.

Whether or not they have permanent effects, legal interventions can sometimes display



Interrupted Time Series Models, Fig. 7 Australian divorces before and after the 1975 Family Law Act (Source: McCleary and Riggs 1982)

temporary impacts that amount to decaying spikes. Failing to allow for such transitory changes can lead to invalid inferences, and this gives researchers an incentive to develop models that closely mimic observed data patterns. Yet a data-dependent modeling strategy raises another serious threat to statistical conclusion validity: *fishing*. Fishing refers to tailoring a statistical model to match the peculiarities of a specific set of data, and it invalidates standard approaches to statistical inference. To avoid fishing threats, researchers must specify the form of intervention models before undertaking the analysis, and this substantially limits the situations in which complex temporary response models are possible.

Threats to External Validity

A time series quasi-experiment usually considers an intervention's influence on only a single series, and this restriction threatens its external validity. External validity considers whether a finding generalizes beyond a particular sample of data to other settings, treatments, and outcome variables (Shadish et al. 2002: 83). If a new law influences crime rates in one area, for example, will the same law – or a slightly modified version of it – also influence crime rates elsewhere?

Threats to external validity are limitations on the generality of an impact, and they come from interactions between the intervention and other components of variation. Two sources of interactions are variations in treatments and variations in settings. In the first case, seemingly irrelevant differences in the intervention, such as small changes in the wording or penalty structure of a law, will alter its impact. In the second case, the effect of the intervention will not be constant across areas, perhaps due to unmeasured differences in environmental conditions. A new law may affect crime rates in some states, for example, but not in others.

Threats to external validity are impossible to evaluate when an analysis considers only one time series. Ruling out these threats necessarily requires replicating the quasi-experiment under a diverse set of circumstances. Concerns about external validity will decrease as the range of variation in the interventions and settings grows.

A complication in using replications is that they can produce results in support of very different conclusions about an intervention's impact. Evaluations of the preventive effects of laws regulating firearms, for example, have yielded an array of positive, negative, and null estimates (Hahn et al. 2005). In these situations, the variance of the impact distributions can be more important than are point estimates of the average effect size.

Given the availability of replications of a time series quasi-experiment, a researcher can evaluate external validity using one of two approaches.

First, the analysis can pool the data from the set of individual time series to form a single overall model. It can then use the diversity in the combined data to estimate both the average effect size and its expected variability (e.g., McGaw and McCleary 1985). Second, the analysis can pool only the impact estimates from each of the time series models, decomposing them into components associated with various types of validity threats.

The first approach uses more of the information contained in the replications than does the second, and this ideally makes it the better choice. The first approach also requires a full set of observations from each of the original series, however, while the second approach only requires information about the impact estimates. The second approach is therefore often more practical to use, and it is also generally easier to apply. Statistical models for the second approach come from meta-analysis, and divide the effect variance into parts due to the setting, intervention, and other potential confounders. McDowall, Loftin, and Wiersema (1992) use a meta-analysis model to estimate the overall impact and variability of mandatory sentencing laws for firearm crimes.

By training and custom, social scientists usually concentrate on the results of individual studies, and this can sometimes make replication strategies controversial. Tonry (1995), and Durlauf and Nagin (2011), for example, both criticize the McDowall et al. study for its use of pooled estimates. Much of their concern apparently reflects a strong ideological opposition to mandatory sentencing laws, but some of it is also likely due to misunderstandings about what replications can accomplish. Although external validity threats can threaten inferences from interrupted time series studies, current practice often gives less weight to these threats than to those from the other three validity types.

Conclusions

Interrupted time series models are important to all of the social science disciplines, including criminology and criminal justice. Of the various ways in which criminologists use time series data to make causal inferences, interrupted time series analysis is among the most popular approaches. The interrupted time series design has applications in a wide range of situations, and it allows stronger causal statements than do most nonexperimental alternatives.

Time series models are of course also vulnerable to multiple validity threats, and one would normally not use them if randomized controlled trials were possible. Still, given the practical constraints imposed by field research, a time series study is in many settings the strongest feasible approach. In criminal justice and criminology, especially, situations often arise in which researchers want to estimate the impact of a well-defined policy change on an aggregate outcome variable. Interrupted time series studies provide a natural fit to the data and research questions in these situations, and this can make them the quasi-experimental design of choice.

Overview

The key elements of the overall approach to prevention and intervention on crime in contemporary China are outlined in Fig. 1. The approach is best understood as state-initiated comprehensive management or governance of social order. Developed in the new era of economic liberalization and reform, the policy of comprehensive governance was first promulgated in 1981 as a key organizational tool for crime control but only legislated for in 1991 (Situ and Liu 1996a). The approach emphasizes prevention, education, and punishment of offenders through coordination and cooperation between political, legal, educational, cultural, economic, and social bodies yet sits in an integrated manner alongside "strike-hard" campaigns by police against more serious and organized crime (Jiang and Dai 1990; Situ and Liu 1996a; Zhong 2008). While the development, nature, and dynamic interplay between these elements can only be fully explicated through detailed sociohistorical analysis, this entry describes and contextualizes the relevant organizational and thematic issues contained within the comprehensive approach to the prevention and intervention on crime, including the complex relationship between public and private agencies in prevention and intervention on crime in China.

Intervention and Prevention in China, Fig. 1 The crime prevention framework in China

restorative justice
community corrections
removal of some death penalty crimes
severe punishment of recidivists and dangerous offenders

Introduction

In 1962, Leifeng, a Chinese People's Liberation Army soldier, died; he was decorated by the state for his exemplary kind deeds. His helpful actions were universally acknowledged, and the month of March was designated as the month of "Learning from Leifeng," when everyone was encouraged to follow the example of Leifeng and undertake helpful and kind actions (Bakken 2000). Fifty years on, modern socialist China is both a very different yet similar place. At the societal level, a depoliticized place; yet in terms of the language of governance, including management of crime, familiar (Dutton 2005: 252–255). In the social control mechanisms of contemporary China, "exhortation through example" and mass participation are still regarded as key tenets by the ruling Chinese Communist Party (Bakken 2000; Chen 2004). Social order in China is supposed to be maintained by the capacity of society's members to understand one another and to act in concert in achieving common goals through common rules of behavior. The most important distinction is the efforts of the Chinese state to control both the behavior and the minds of the people (Wilson et al. 1977). Social conformity in the Chinese vocabulary is not limited to behavioral conformity with the rule of law but always moralistically identifies with the officially endorsed beliefs of social standards and behavioral norms. The Chinese tradition, both before the creation of the People's Republic (in 1949) and since, is that of "greatest unity" of society (Ren 1997). Thus, the current crime prevention framework known as "comprehensive governance (or management) of social order" takes crime as caused by a complex set of psychological, social, and economic factors and to be prevented and "cured" by a similarly rich interplay of state mechanisms.

The policy of comprehensive governance of social order adopted since 1991 is, in essence, traditional strategies with new components: thus, it continues the Maoist ideology of the state as "moral entrepreneur" (Wilson et al. 1977), combined with formal and informal mechanisms; the policy continues with the perceived need to develop citizens' knowledge about laws in the Republic; it revives the Maoist "mass line" – listening to the ideas of the people and the ruling party working with them (Dutton 2005); finally, it continues to promote lenience and recognizes the importance of rehabilitating offenders through correction while adding a bifurcatory "harsh" aspect – namely, that of severely punishing recidivists and organized criminals through long prison sentences and via the death penalty if required (Liang 2008). These key themes are enlarged upon in what follows.

Key Conceptual and Organizational Themes

Along with modernization, crime rates have risen significantly in China's cities over recent decades (Liu 2005). While there has been no national-level victimization survey in China, there is city-level data from the key city of Tianjin, where estimates on risk of major crime types are available to scholars (Zhang et al. 2007a). Surveys of this type in China are not without research challenges and concerns, for example, around gaining access, designing and deriving samples, protecting privacy of respondents, and ensuring data integrity and quality (Zhang et al. 2007b). Crime is now, to use David Garland's term, a "normal social fact" in urban China (Garland 2001). A fellow traveler alongside economic development has been insecurity, built into the fabric of everyday life. Crime has increasingly become a daily consideration for anyone who owns property or uses public spaces in urban China. People have felt the need to establish control over risks and uncertainties, and the desire to assuage feelings of insecurity has become ever more urgent. For the Chinese Communist Party, the increasing crime rate has posed a threat to the legitimacy and stability of its rule, and social order has become a major government concern (Dutton 2005; Muhlhahn 2009). As originally developed in the 1980s, one key organizational theme within the policy of comprehensive governance is to engage in so-called "strike-hard" anticrime campaigns. This prong of the policy focused on attacking crime directly, as opposed to the longer-term goal of prevention and social reintegration of offenders. "Strike hard" has been described as an extreme form of the educative and deterrence function of punishment used as a method of crime prevention and social control. It is essentially a policy of employing severity and swiftness to deal with criminal cases considered to be a major threat to public or social order (Trevaskes 2007a, b). "Strike-hard" anticrime campaigns take two forms. One is the large-scale campaign that runs for up to 3 years, focusing on a variety of crime targets chosen by the state. The other is the "specialized" smaller-scale campaign targeted at one category of crime. Party authorities initiate both the national campaigns and the specialized anticrime drives, which are run under the leadership of Party committees and criminal justice personnel at provincial, municipal, and local levels. Campaigns against organized crime and drug crime are well described in recent literature (Trevaskes 2007a, b, 2008). Police, prosecutors, and courts work together to ensure swift arrests, swift prosecution, and swift and severe punishment for the targeted types of crime that the authorities identify. "Severity" limits judges' discretionary power and requires them to punish relatively harshly. "Speedy" investigation, prosecution, and adjudication of cases to deal efficiently with identified criminals, often within several days of their arrest, distinguish these campaigns from the usual criminal justice process (Muhlhahn 2009). "The People's War on Drugs" is a major specialized campaign that operated as the drug crime counterpart to an existing campaign against organized crime (Trevaskes 2008). It was launched in mid-2005 and exemplifies comprehensive management of social order as an approach to crime fighting through interagency cooperation between the criminal justice agencies. It is the latest in a long succession of antidrug campaigns since the late 1980s and is China's key countermeasure against an alarming rise in heroin use. The core strategy is to block the sources of drugs and stop their circulation. The national modus operandi of the campaign in its first year was to separate tasks across individual agencies rather than to use a multiagency method. Individual agencies included customs, railways, water police, airline security, forestry police, and the postal services.

Criticisms of "strike-hard" campaigns abound in the Chinese literature (see Trevaskes 2007a, b for details). Among senior policy makers and senior administrators, anticrime campaigns are overwhelmingly supported, but among practitioners, there is greater ambivalence and criticism. Problems identified in the Chinese-language literature include the difficulty of control and accountability where criminal justice agencies overstep the mark in campaigns, that like cases are not treated alike in terms of severity across place and time, and the problems of confusion on the ground as different agencies compete to "deliver swift justice." Many Chinese scholars question the overall effectiveness of the strike-hard policy (see Trevaskes 2007a, b). Apart from no significant reduction of crime rates following the campaigns, there are criticisms of the lack of long-term prevention effects (Liang 2005). However, some research argues that the anticrime campaigns have significantly impacted on lowering serious crime (Chen 2012). In this regard, it is interesting to note that the recent fourth "strike-hard" campaign in 2010 targeting two types of criminals – violent criminals (esp. with gun and organized criminals) and so-called "mass-hatred" criminals (including telephone fraudsters, children and women traffickers) – has been remarked upon more favorably by commentators. Unlike previous campaign waves, the police this time were focusing more on prevention – for example, increased patrol, problem-oriented policing, and mediating community conflicts rather than arresting and delivering severe and swift punishment (Yang 2010).

As an element of the comprehensive governance of social order, "strike-hard" campaigns draw from deep cultural wellsprings, and any adequate understanding of why such a practice is continued, despite what appears to be very limited success, needs to recognize how the practice partly reflects the remnants of classic Maoist "mass-line" thinking: the categorization and targeting of specific criminal types and defining social harm according to the socialist social relations violated an important aspect of Mao's early campaigns against "political enemies," the flexible nature of administration of law in practice during campaigns, and finally the educative role performed by state agencies (police, prosecution, and courts). In essence, the "strike-hard" campaign performs a number of noninstrumental, expressive political functions for the ruling Party (see Liang 2005). Thus, short-term severe strike campaigns became an indispensable complement to decreasing traditional mass-line neighborhood-level preventive control. This leads to a second key theme within the comprehensive governance of social order, namely, mobilization of broad preventive forces, particularly at neighborhood (community) level.

The origin of mobilization lies in the working style of the early Chinese Communist guerilla movement of the 1930s, linking popular participation with the guerilla struggle (see Selden 1971). Mao framed it in the following terms, "...take the ideas of the masses and concentrate them, then go to the masses and propagate and explain these ideas until the masses embrace them as their own..." (Mao 1967, vol 3, 119). In the Mao period, the Chinese peasant was mobilized out of any passive role into willing, positive, active participation based not on broad notions but on a single commitment to the total social and economic transformation of society. Campaigns were highly organized mobilizations of mass commitment to push over barriers to proletarian dictatorship and socialism, and mass-line thinking has continued to echo throughout the post-Mao period. Wang (1989) sets out the theory of comprehensive governance and basic rationale for the revival of somewhat moribund mass-line security organs and renewal of community activism under Party committee leadership. In this context, commentators point to the pioneering role of the Fengqiao district in Zhejiang province, where in the early 1960s local mass democracy was put into effect, illuminating how long-term effective crime prevention role relies upon taking wider administrative measures (Dutton 2005).

Under the 1991 law on comprehensive governance, all government organizations at different levels regard taking comprehensive measures to secure prevention as one of the most important duties, with an appropriate responsibility system for management; it is also accepted that it is imperative to mobilize and rely on the broad mass of ordinary people in the community. Within urban environments, the "subdistrict" level typifies how these arrangements are structured. For example, in Shanghai, the subdistrict would have an office of comprehensive management and a community structure would contain members of the residents' committee, community police, property owners, housing management, private security personnel overseen by the police together with social workers responsible for meeting the needs of local offenders, and finally local volunteers who are usually retired and receive small financial subsidies. Financial support and human resources are underpinned by government spending. Emphasizing nonlegal methods to solve neighbor disputes is another key characteristic of the comprehensive approach. People's mediation is a process whereby the parties concerned to a dispute seek to reach a mediation agreement on the basis of equal negotiation and free will and thus solve the dispute between them, and the mediation agreement reached upon mediation is binding to all parties concerned, and the parties concerned are asked to fulfill it as agreed. There is a mediation committee as part of every residents' committee (Hong 2011). Since the 1990s, people's mediation has faced some unprecedented challenges. Along with rapid social changes, China's dispute resolution system has gone through significant transformations. Courts have increasingly been favored by the public as a forum to solve disputes. In 1990, the people's courts handled about 1.8 million civil lawsuits. This number jumped to 3.4 million in 2000, a nearly twofold increase. Meanwhile, the numbers of mediation committees and disputes solved through mediation have declined steadily. In 1990, there were approximately 1 million mediation committees that solved 7.4 million disputes. In 2000, these numbers dropped to 960 thousand mediation committees that solved 5 million disputes (Hong 2011). In the 1980s, people's mediation committees disposed of an average of almost 11 times more disputes than trial courts, but this ratio had decreased to 1:1 in 2001. In response, and as part of the comprehensive approach, the Chinese government has made significant policy reforms to revitalize mediation, during the Fourth National People's Mediation Work Conference held in Beijing in 1999; the Ministry of Justice added an important phrase, "using multiple methods to solve problems," to the original people's guideline of "combining mediation and prevention, with prevention as the main goal" for mediation. The Ministry called for people's mediation committees across the country to gain cooperation and resources from administrative and judicial organizations to expand the range of disputes that can be solved by mediation (Hong 2011).

Details of the practice of the comprehensive approach to prevention can be gleaned from research studies on Guangzhou and Shenzhen (Situ and Liu 1996b; Zhong 2008). In Guangzhou, government aimed for "the establishment of 1,000 security neighborhoods in which criminal events must be substantially reduced, the transient population must be adequately managed, and the public environment must be made safe and clean" (Situ and Liu 1996b: 95). Organizationally this involved establishing the coordinating Office of Comprehensive Management which ensured coordination of crime prevention, monitored the level of transient population, and developed environmental schemes; it is a well-developed contractual responsibility system – contracts not only clearly define responsibility but also make security a responsibility that is legally binding on all people involved. Failure to meet the conditions of the contract can result in administrative penalties, such as resignation or dismissal, or financial punishments, such as a fine or elimination of bonus. Those who are responsible for the occurrence of serious criminal incidents are also subject to criminal charges. By linking the security duties to individual interests, the system of responsibility effectively promotes the motivation of contractees and improves the quality of their performance in carrying out preventive duties. Patrol-based neighborhood teams were also established, with volunteers receiving some training and augmenting police patrol. Linked to this was police-initiated "anticrime" campaigns against specific crimes (as described earlier in this entry). Finally, situational measures were implemented, including "gated" entry and the securing of ground floor apartments with "bars-to-windows".

In Shenzhen, five neighborhoods were studied to examine the practice of comprehensive governance (Zhong 2008). Shenzhen local government sought to develop "little safe and civilized communities" (LSCC). In terms of safety, residents should feel safe, with few serious crimes and general public security cases kept under control. In terms of civilization, active politics, economy, culture, education, hygiene, and so on were required. Thus, in an LSCC in Shenzhen, there must be a strong conformity to law and regulation, good public order, high degree of civilization, upright social morale, beautiful environment, and harmonious neighborhood relationship. Piloting of schemes began in 1992 and took place over a number of years, with full development in 1998. For a little community to be eligible for LSCC, it has to meet these criteria and go through a complicated rating process. The rating categorizes the communities into "exemplary," advanced, pass, or failure, on an annual basis. If a community fails to meet the standards in the second year, it is stripped of the original level. It can also strive to upgrade to a higher level in subsequent years. The important measures in implementing the comprehensive approach to building such communities have four elements: organizational features (ideological underpinning, responsibility system, mass prevention and mass management, and fund raising), safety measures (police, private security, situational measures, and management of the transient population), civilization measures (moral education, promoting harmony, community development, and environment improvement), and of course the rating system itself.

A final significant theme in understanding the changing conceptual basis of contemporary crime prevention and intervention in China is that of the recent promotion of the idea of "balancing leniency and harshness"; this idea has been brought to bear in the areas of alternatives to normal punishment (restorative justice) and the death penalty in particular (Trevaskes 2010). Within the wider policy of comprehensive governance, this development has resulted in a redefinition and use of what are considered "serious crime" and "minor crime." After 2006, a series of criminal justice reforms began to be publicized after President Hu Jintao espoused "building a socialist Harmonious Society" as the touchstone of the Sixteenth Party Congress governance objectives for the coming decade. These reforms were aimed at addressing the crucial political issue of encouraging social harmony by preventing further social conflicts during a period of accelerated economic and social transformation. In 2006/2007, the Chinese Communist Party used this policy as a rationale for momentous changes to the death penalty, thus the change in 2006, requiring the Supreme People's Court to ratify death sentences, in contrast to the previous practice of allowing provincial courts this power. More recently still and in keeping with this shift, recent amendments to the Chinese Criminal Law in 2011 have removed the death sentence from many nonviolent economic crimes. In 2007, criminal justice authorities announced changes at the other end of the spectrum – moves to decriminalize a wide range of minor offenses and to encourage courts to use a greater variety of alternatives to custodial sentencing, such as restorative justice and involving community-based corrections. Restorative justice techniques are intended to provide assistance, guidance, and direction to residents who have committed minor offenses, have been caught by police agencies, or have been released from correctional institutions. Traditionally, these have been organized in the form of help groups that normally consist of the offender's parents or relatives, a member of the neighborhood committee, and an officer from the neighborhood police station. Currently, social workers and volunteers are also likely to participate in such groups. The primary goal is to intervene in the lives of residents, especially young residents, who are at risk of becoming offenders and to reintegrate the ex-offenders back into the community. Nevertheless, restorative justice involving victims is not without its critics in China, where certain scholars have argued that it is immature and confused, incompatible with Chinese constitutional law (Zhao 2005). Application of community corrections, involving management of sentences outside of prison, is itself still "experimental" and is permitted in some 18 Chinese cities. A recent review of the scientific literature on community corrections in China highlighted a number of issues: the small number of recidivism studies following release from prison, a lack of reliable information surrounding recidivism rates in general, and very few studies comparing China's particular circumstances with those of the West (Liang and Wilson 2008).

Conclusions

Research from the USA, Europe, and the UK suggests that community crime prevention transcends both situational and social prevention and indeed transcends the borders between developmental and situational prevention, with its focus on social relationships within and beyond individual communities (Ekblom and Pease 1995). In the West, criminological commentary on the community approach to crime prevention has journeyed backwards and forwards, at times stressing the significance of informal social control on crime and disorder inside individual communities, while at other times orienting around the opportunity reduction model (or situational crime prevention) and emphasizing partnership/interagency working including community and problem-oriented policing. This entry has analyzed the policy and practice of crime prevention and intervention in China, a process conforming to recognizable forms of community crime prevention in the West. However, its "Chinese characteristics," resting upon unique forms of social capital, are also evident (Zhuo 2012). In addition, the state, through all the levels of the Chinese Communist Party, plays a determining role and it could hardly be otherwise. The state-led comprehensive approach both structures and mandates community organizations working with the police and other government agencies, in concerted efforts to achieve reductions in crime. As mentioned in the introduction, traditional strategies with new components underpin the approach: its ideological underpinnings and mass-line tradition reinvented by a responsibility system and incentivized by financial contract arrangements and government investment at all levels of governance make it distinctive from community crime prevention approaches described by Western commentators (Welsh and Hoshi 2002). Neighborhood committees still function as an important part of the grassroots organization but are under financial pressures and under challenge from newly emerging market influences and organizations. The public security bureaus (police) still uphold the mass line and place great emphasis on good relationships with the masses – yet actively try to adapt to the new environment of greater "police professionalization" and mixed markets in security provision. Dutton notes the irony of the revival of Maoist rhetoric and mass-line forms, since the "revival" actually signaled the demise of the significance of transformational politics; instead it was part of the slow process of political and ideological drainage that would change the nature of mass mobilization in China. The new dynamic fueling these developments has been monetary incentives rather than "revolutionary" volition (Dutton 2005: 260–262). The new money-incentivized forms are, in this sense, actually the commodification of mass-line security (Dutton 2005: 298–299).

Contracted services in private security vary appreciably across urban neighborhoods in China. For some newly established, affluent neighborhoods, private security companies provide a variety of services ranging from neighborhood cleaning to guarding services (Trevaskes 2007c). They engage in night patrol and manage security devices (CCTV cameras). Some of the services overlap with the activities traditionally performed by neighborhood police stations and residents' committees. Furthermore, some neighborhoods, especially older ones, do not have any contracted services. Very little research has been conducted on the interconnections between the traditional organizational forms of prevention in neighborhoods (the comprehensive governance model) and contracted services.

Returning to the bifurcatory nature of China's comprehensive approach, one should note that it is not without precedent. It has been argued that in the last three decades, the practice of crime prevention and intervention in both the UK and the USA exhibited two distinct patterns of action (Garland 2001): an adaptive strategy stressing prevention and partnership and a strategy aimed at identifying "dangerous" offenders and expressive punishment. The roots of such bifurcation lie in complex political rationalities – and China is not an exception to the playing out of such governmental processes (Liang 2005: 395). In the end, the nature and dynamics of change in China's comprehensive crime prevention strategy can be understood as an anthem to how financial incentivization came to appear both normal and even natural, despite the fact of it being so alien to the planned economy of the past.

Finally, for those unfamiliar with the literature on policy and practice of crime prevention in the People's Republic of China, this entry has perhaps had a somewhat "strange" quality principally because there has been little comment on policy evaluation. Bowles et al. (2005) point to generic obstacles to evaluation of policy in developing countries, namely:

- A lack of empirical information about the functioning of institutions
- A lack of articulation of policy options and policy objectives
- A lack of articulation of the inputs, of the outputs and outcomes associated with interventions, and thus of the raw material for estimating the costs and benefits associated with interventions.

The lack of research-led evaluation in China merely confirms this litany of obstacles (Liang and Lu 2006).

Overview

The interviewing and interrogation of suspects is important to securing convictions against the guilty and freeing the wrongly accused. There are two general methods of questioning suspects: information gathering and accusatorial. The information-gathering approach, used in the United Kingdom, New Zealand, Australia, and elsewhere, is characterized by rapport building, truth seeking, and listening. The accusatorial approach, used primarily in the United States and Canada, is characterized by accusation, confrontation, psychological manipulation, and the disallowing of denials. Academics and practitioners hotly debate which method is more effective, particularly in light of increased awareness of the problems with false confessions. Two separate but related meta-analyses were conducted to address this question. The first relied upon data from five observational field studies and the second from 12 experimental, laboratory-based studies. The primary outcome measures were true and false confessions. Results revealed that both information-gathering and accusatory methods were associated with the production of confessions in field studies, though the experimental data indicated that the information-gathering method was more diagnostic in that it increased the likelihood of true confessions while reducing the likelihood of false confessions. Although continued research is needed to better understand the methods that produce true and false confessions, the results of these meta-analyses suggest that the information-gathering approach may be more effective in comparison to the accusatorial approach.

Introduction

The elicitation of false confessions is an international problem that has been documented in almost every continent (Kassin et al. 2010; Lassiter and Meissner 2010). Two general factors have been linked to the incidence of false confessions: personal (psychological) vulnerabilities of the individual and the use of accusatorial (psychologically based) interrogative methods. Accusatorial methods are common practice in the United States, Canada, and many Asian nations, and the use of these methods has been linked to false confessions (Kassin et al. 2010; Lassiter and Meissner 2010). In response to the increased awareness of the prevalence of false confession, the United Kingdom, Norway, New Zealand, Australia, and several other countries have amended their interrogation practices to employ information-gathering methods of interrogation (Bull and Soukara 2010). This entry summarizes the research evidence on the relative diagnosticity of the accusatorial interrogation and information-gathering interview approaches. Diagnosticity is the ratio of true to false confessions, with an effective interview/interrogation method maximizing true confessions while minimizing false confessions.

This entry is based on the systematic review conducted for and published by the Campbell Collaboration (http://www.campbellcollaboration.org) (Meissner et al. 2011). As will be shown below, the existing research evidence suggests that although both accusatorial and information-gathering approaches increase the likelihood of obtaining a confession in the field context, experimental laboratory studies demonstrated that the information-gathering approach yielded more diagnostic confessions (by increasing true confessions and reducing false confessions) when compared with the accusatorial method.

Key Issues and Controversies

Generally speaking, two distinct methods of suspect interview and interrogation approaches have emerged: information gathering and accusatorial. The information-gathering approach to interviewing and interrogation is based on establishing rapport between the interviewer and suspect and seeks to elicit information rather than obtain confessions. The interviewer uses positive confrontation and an open-ended questioning approach to elicit information from the suspect; psychological manipulation is anathema to the goals of the interview. This approach is exemplified and codified in Great Britain’s adoption of the Police and Criminal Evidence (PACE) Act of 1984 and later modified as the PEACE model in 1993. The PACE Act explicitly prohibited the use of psychologically manipulative techniques and required the recording of all custodial interrogations. Furthermore, the PEACE model focuses on developing rapport, explaining the allegation and the seriousness of the offense, emphasizing the importance of honesty and truth gathering, and requesting the suspect’s version of events. Suspects are permitted to explain the situation without interruption, and questioners are encouraged to actively listen. Finally, the information-gathering approach relies on cognitive-based strategies to detect deception.

In contrast, the accusatorial method is typified by the United States model and is best illustrated by the “Reid Technique” (Inbau et al. 2001). In this method, the interviewer establishes control over and confronts the suspect, presumes guilt, and ultimately aims to obtain a confession. As distinct from the information-gathering approach, accusatorial methods use closed-ended and confirmatory questions and employ psychological manipulation which generally involve three components: (a) *custody and isolation*, in which the suspect is detained in a small room and left to experience the anxiety, insecurity, and uncertainty associated with police interrogation; (b) *confrontation*, in which the suspect is presumed guilty and told (sometimes falsely) about the evidence against him/her, is warned of the consequences associated with his/her guilt, and is prevented from denying his/her involvement in the crime; and finally (c) *minimization*, in which a now sympathetic interrogator attempts to gain the suspect’s trust, offers the suspect face-saving excuses or justifications for the crime, and implies more lenient consequences should the suspect provide a confession. Lastly, this approach relies on anxiety-based cues (e.g., verbal, nonverbal, and paralinguistic)

Interview and Interrogation Methods Effects on Confession Accuracy, Table 1 Five distinguishing dimensions of information-gathering and accusatorial interrogation approaches

Dimension	Information gathering	Accusatorial
Interpersonal dynamic	Rapport building	Control oriented
Approach	Direct, positive confrontation	Psychological manipulation
Question type	Open-ended, exploratory	Closed-ended confirmatory
Primary goal	Elicit information	Obtain confession
Clues to deception	Cognitive	Anxiety

in order to detect when suspects are being deceptive. Table 1 summarizes the differences between the information-gathering and accusatorial approaches along four dimensions.

Meta-Analysis Methods

Researchers have relied on two primary methods of examining the influence of questioning technique on confessions: field studies of actual interrogations and experimental laboratory studies with mock crimes and transgressions. Whereas the field studies offer greater external validity, it is not possible to determine the "ground truth" or the veracity of confessions obtained in this context. In contrast, experimental studies allow for the manipulation of guilt and innocence but are limited in their ability to precisely model the context of a criminal interrogation. As such, two systematic reviews and meta-analyses of the accusatorial and information-gathering literature were conducted, one examining field studies and the other examining experimental studies.

The first meta-analysis focused on observational field studies; the second, on experimental laboratory-based studies. Although briefly summarized here, readers interested in more details regarding the methods are referred to Meissner et al. (2011). To identify studies that might be included in the analyses, more than a dozen reference databases were searched (using over 20 search terms), the reference sections of several comprehensive sources on interviewing and interrogation (books, articles, and reports) were reviewed, and researchers in the United States and overseas were contacted for any unpublished research. To be eligible for inclusion in the meta-analyses, field and laboratory studies must have met the following criteria:

- *Intervention*: Eligible field studies must have coded or quantified the use of at least one interview or interrogation technique, which was then categorized into information-gathering, accusatorial, or general interrogation approaches. Eligible laboratory studies must have involved the experimental manipulation of information-gathering and/or accusatorial methods with one another or with a control interview method (e.g., a simple request for compliance).
- *Outcomes*: Eligible field studies must have reported the analysis of confessions and have had sufficient quantitative data to calculate effect sizes, specifically including the relationship between the use of the certain interview/interrogation methods and elicitation of a confession. Laboratory studies must have reported the number of true and/or false confessions from "guilty" or "innocent" participants, respectively, in a manner that would permit calculation of an effect size.
- *Population/samples*: The population of interest for both the field and experimental studies was criminal (mock) suspects of any age, nationality, or status who were accused of committing a criminal act, a transgression, or withholding important information.

The initial search identified over 2,000 studies, though the vast majority was screened out. After this preliminary screening, 33 field studies and 22 laboratory studies were coded to determine final eligibility, of which five field studies and 12 laboratory studies were ultimately included in the meta-analyses. All included and excluded field and experimental studies (as well as the reasons for exclusion) can be found in Meissner et al. (2011).

Results of the Meta-analyses

Field Studies

The five field studies were identified through the systematic search, three of which were conducted in the United Kingdom, one in Canada, and one in the United States. These five studies represented data from 608 interrogation sessions. Of these sessions, 39.4 % were coded from audio recordings, 36 % from video recordings, 20 % were live interrogation sessions, and the remaining 4.4 % were from transcriptions of the sessions. The alleged crimes for which the suspects were being interrogated varied from social security benefit fraud to serious violent crime such as murder and robbery. Between 39 % and 64 % of the suspects in the interrogation sessions confessed or offered some admission of guilt. The studies classified the interrogations as accusatory, information-gathering, or combined interrogative method, resulting in eight possible pair-wise comparisons across the five study samples.

The effect size was Hedges' *g* based on dichotomous outcomes (i.e., confess vs. not confess) using the Cox computation method (see Lipsey and Wilson 2001; Sánchez-Meca et al. 2003). The relationship between the use of certain interrogative methods (accusatorial, information-gathering, or general interrogative methods) and elicitation of a confession was the focus of the analysis. All analyses were based on a random-effects model, and the results are presented in Table 2.

Three field studies assessed the relationship between use of accusatorial methods and elicitation of a confession in a real-world context and showed that such a method was associated with a large and significant increase in confession rates. Furthermore, there was no significant degree of variability across the studies suggesting consistency in findings across studies.

The relationship between information-gathering methods and elicitation of a confession was assessed through two field studies. These studies also found that the use of such a method was associated with a large and significant increase in confession rates. The results varied meaningfully between these two studies, however, with a substantially smaller effect in one study (.38 vs. 1.04).

Interview and Interrogation Methods Effects on Confession Accuracy, Table 2 Mean weighted effect sizes for field studies

Interrogative method	*k*	*N*	*g*	95 % CI	*Q*
Accusatorial	3	306	0.090***	(0.38, 1.41)	4.89
Information gathering	2	222	0.86*	(0.04, 1.69)	5.54*
General interrogative methods	3	422	0.19	(−.069, 1.06)	25.35***

$^{*}p < .05$; $^{**}p < .01$; $^{***}p < .001$

A number of tactics observed in these studies could reasonably be coded as a part of accusatorial and information-gathering approaches. Three field studies examined the influence of these combined methods in eliciting confessions in a real-world context as opposed to those methods that might be exclusively linked to either accusatorial or information-gathering approaches, and showed no significant relationship between the use of these general methods and confession statements provided by suspects. However, these results were highly variable across studies, ranging from a low of − .40 to a high of .79.

Based on these field studies, it appears that the use of accusatorial and information-gathering methods of interrogation was significantly associated with the elicitation of confession evidence in a real-world context in contrast to those characterized as not accusatorial or information gathering, or even those techniques characterized as both accusatorial and information gathering. Although these results suggest that such methods are effective tools for elicitation of confession evidence, it is important to note that these findings fail to distinguish the diagnostic value of the interrogative evidence – field studies offer little or no information to distinguish between innocent and guilty suspects, and ground truth in such contexts is nearly impossible to determine. As such, researchers have assessed the diagnostic value of interrogative methods

Interview and Interrogation Methods Effects on Confession Accuracy, Table 3 Mean weighted effect sizes for experimental studies

Interrogative contrast	Outcome	*K*	*N*	*g*	95 % CI	*Q*
Accusatorial versus control	True confession	6	272	0.46*	(0.06, 0.86)	7.52
	False confession	14	892	0.74***	(0.35, 1.12)	32.99**
Information gathering versus control	True confession	2	110	0.67*	(0.02, 1.32)	1.41
	False confession	2	110	−0.23	(−0.98, 0.52)	0.11
Accusatorial versus information gathering	True confession	3	215	0.64*	(0.01, 1.28)	3.62
	False confession	3	215	−0.77*	(−1.46, −0.08)	4.43

$*p < .05$; $**p < .01$; $***p < .001$

by modeling the interrogative process in an experimental, laboratory context.

Experimental Studies

Twelve experimental studies were identified through the systematic search, and these studies provided 30 contrasts between the different interrogation methods. All but one of the studies was conducted in the United States. Nine were published in peer-reviewed journals and three are currently unpublished.

Eleven of the 12 studies used variations of the Kassin and Kiechel (1996) or the Russano et al. (2005) paradigm. The Kassin and Kiechel paradigm is one in which all participants are "innocent" of the mock crime of crashing the computer. The Russano et al. paradigm includes participants randomly assigned to an innocent or guilty condition of a known, intentional act (i.e., cheating in an academic context). Eleven of the studies used undergraduate students as participants, with two studies including participants from other age groups. The results are presented in Table 3.

Accusatorial versus *Control*. The contrast between an accusatorial interrogative method and a control interview condition demonstrated that accusatorial methods yielded a moderate and significant increase in the frequency of true confessions and large and significant increase in false confessions. Typically, the control technique was the absence of a specific technique; for example, if the experimental manipulation was the presentation of false evidence, the control condition did not present false evidence. The findings for false confessions were highly variably across studies.

Information Gathering versus *Control*. Two studies examined the influence of information-gathering interrogative methods versus a control condition in eliciting true confessions and false confessions. These studies demonstrated that information-gathering methods yielded a greater frequency of true confessions, but did not significantly influence the likelihood of eliciting false confessions.

Accusatorial versus *Information Gathering*. Three studies assessed the direct contrast between accusatorial and information-gathering interrogative methods in eliciting true confessions and false confessions. The results demonstrated that information-gathering methods produced a significantly greater frequency of true confessions, while significantly reducing the frequency of false confessions, when compared with accusatorial methods. Neither analysis produced significant variability, suggesting consistency in findings across studies (*Q*s < 4.43, *ns*).

This meta-analysis of the eligible experimental literature demonstrated several key findings that may have implications for policy and practice. First, while accusatorial methods significantly increased the likelihood of obtaining a true confession (when compared with a no-tactic control condition), these methods also significantly increased the likelihood of obtaining a false confession – a finding consistent with many cases of wrongful conviction in the United States (see Kassin et al. 2010; Lassiter and Meissner 2010). In contrast to this, information-gathering approaches significantly increased true confession rates, but showed no significant increase in the rate of false confessions when compared with a no-tactic control condition. In fact, information-gathering approaches appeared to show a numerical decrease in the rate of false confessions obtained. When compared directly against accusatorial methods, information-gathering approaches showed superior diagnosticity by significantly increasing the elicitation of true confessions and significantly reducing the incidence of false confessions.

Future Directions

A number of variables were considered for inclusion in a moderator analysis of the influence of accusatorial methods in eliciting false confessions. Unfortunately, studies varied little in several key factors. For example, only two of the 14 independent samples involved children or adolescents, while the remainder involved college students. In addition, none of the studies manipulated race or ethnicity in participant recruitment or analyses of the data. Similarly, only one study was conducted outside of the United States.

It is important here to note that field studies fail to offer us important information regarding the relative diagnostic value of the confession that is elicited. That is, such studies lack "ground truth" that would enable us to factually determine the veracity of the statement provided by a suspect and thereby preclude the ability to assess the diagnostic value of the information elicited and the effectiveness of such techniques when employed in the field. One method often used to assess veracity in field studies has been to evaluate the "strength" of available evidence against the defendant; however, none of the studies took this approach to evaluating the likely credibility of the confession evidence obtained as a moderator of interrogative efficacy.

Additionally, each of the studies included in the field study meta-analysis examined the bivariate relationship between certain interrogative methods and elicitation of a confession. As indicated in the review, a number of control variables could reasonably be included in such analyses (e.g., factors related to interrogator experience, crime type, interrogator/suspect ethnic backgrounds, geographic characteristics), and more complex modeling approaches (such as multilevel modeling or path analysis) could have been pursued, albeit many (if not all) of these studies may not have had a large enough sample size to consider multiple factors simultaneously. Researchers are strongly encouraged to initiate more systematic, multilevel analyses of the influence of interrogative methods. Further, there is a great need for the use of quasi-experimental methods in the field context as the effects of certain interrogative methods are currently unknown. Quasi-experimental methods could include the examination of the influence of certain factors in real-world interviews and interrogations, such as the use of the cognitive interview, whether suspects are told they are being recorded, and many of the variables under consideration here. Such quasi-experimental methods are effective tools for assessing the policy implications of alternative approaches to police interviewing and interrogation and should be considered in the years ahead.

Conclusions

The meta-analyses summarized above suggest that the information-gathering approach introduced by Great Britain can be effective in eliciting confession evidence but also has the advantage of eliciting more diagnostic information. In the experimental meta-analysis, when the information-gathering and accusatorial approaches were contrasted, the information-gathering approach clearly produced more advantageous outcomes (although caution is warranted given the small number of eligible studies). Specifically, the information-gathering approach produced significantly more true confessions, whereas the accusatorial approach produced significantly more false confessions. As such, the results suggest that law enforcement, military, and intelligence agencies should consider the use of information-gathering approaches to interrogation. In addition, research should be conducted to further refine and solidify the understanding of the effects of various interrogative methods in eliciting true and false confession evidence, therein providing a stronger foundation for evidence-based practice and policy recommendations.

Interviewing Eyewitnesses

Julie Gawrylowicz and Amina Memon
Department of Psychology, Royal Holloway,
University of London, Egham, UK

Overview

Eyewitness researchers have attempted to take what we know about memory and social influence and wrap it into a set of procedures for interviewing eyewitnesses. This has resulted in a number of empirically based investigative interviewing tools. Some of these tools have been successfully implemented into current police practice. The most developed and researched procedural package for gathering detailed reports from cooperative eyewitnesses without compromising overall accuracy is the Cognitive Interview (CI). Since its development 25 years ago, novel and alternative interviewing strategies have been developed, including the Self-Administered Interview© (SAI), a pen-and-paper version of the CI. The SAI can be administered at the crime scene and to multiple witnesses simultaneously, thereby reducing police time and resources.

Although a lot has been achieved during the past two decades with regard to improving and standardizing investigative interviewing of witnesses, victims, and suspects, especially in the UK, there remain controversial policy issues, such as how to best train investigative interviewers and which methods to use for recording interviews. Under researched areas include how to best interview vulnerable suspects and procedures and practices for interviewing traumatized victims and witnesses. It is important to promote the collaboration between practitioners and academics to ensure that investigative interviewing practice continues to evolve and is driven by contemporary theories and research findings.

Fundamentals

Investigative interviewing is an essential information-gathering tool in any context where the interviewer needs to find out what if anything has happened and where the goal is to achieve as accurate recall as possible. The need to obtain credible information in an investigative context has become even more important given the increase in terrorist offences around the world. Köhnken (1995), in a review of the information-processing approach to interviewing, highlights the numerous uses of an interview ranging from an expert witness interviewing children and adults during competency assessments and custody disputes to obtaining information about present moods, attitudes, opinions and to establishing rapport with the interviewee. This entry focuses primarily on the forensic applications of interviewing where the goal is to obtain accurate and complete information from a victim or witness about some action or behavior they experienced in the past.

In order to be able to interview eyewitnesses effectively, police officers and other members of the Criminal Justice System need to understand how memory works. It is crucial to consider which factors may impact memory and how to obtain reliable and accurate information about past events. In a nutshell, the process of remembering information can be subdivided into three different components: encoding, storage, and retrieval (Tulving 1995). Encoding refers to the initial intake of information by our sensory systems. Thus, for an eyewitness to be able to describe the face of a perpetrator during a police interview, he or she would need to have paid attention to the perpetrator's face when the crime occurred. Assuming the information is encoded, it will be stored in our memory system until it needs to be accessed again. Information that has been successfully encoded and stored can then be retrieved.

Why Does Our Memory Fail?

People may fail to remember information due to problems with encoding, storage, or retrieval. For instance, information might not have been encoded in the first place. This might happen due to external factors such as poor visibility or objects obstructing the view or internal factors such as the witness not paying attention to specific details. Several cognitive psychology studies have investigated the change-blindness phenomenon, the failure to observe large changes in a scene which would normally not go unrecognized (Simons and Rensink 2005). A well-known psychology study of change blindness is the gorilla experiment by Simons and Chabris (1999) in which participants were asked to watch a video clip showing a basketball match and to count how many passes the players were making. In the middle of the clip, a gorilla walked through the scene. It was found that more than half of the participants (66 %) failed to notice the gorilla. The change-blindness phenomenon has been replicated numerous times with different paradigms and different stimuli (see Simons and Rensink (2005) for an overview), and the findings have strong practical implications particularly in forensic settings. During the occurrence of a crime, the failure to detect changes in the scene can have dramatic consequences. Investigative officers need to be aware that problems with encoding are not uncommon in humans and might influence what the witness subsequently recalls and how accurate this information is.

Some information we encode may enter our memory but will be forgotten quickly afterwards. Not all information is stored efficiently, and most information is forgotten soon after the incident has happened (Ebbinghaus 1964/1885). Therefore, it is not unusual for an eyewitness to say, "I don't remember what the perpetrator looked like."

During the interview process itself when the witness engages in retrieval, several factors may impact how much will be recalled and how accurate this information is. The way a question is phrased and characteristics of the interviewer can influence how much a witness discloses and/or remembers and how accurate this information is likely to be (Milne and Bull 1999). Generally, open-ended questions and free-recall instructions, such as "Tell me everything," do elicit accurate responses from witnesses, but often the provided information is sparse (Davies et al. 1989). The interviewer might feel the need to ask more specific questions to generate a detailed account or to elaborate on specific details; however, the more specific the questioning style becomes, the less accurate the responses may be. Leading and suggestive questions should be avoided, since they imply the desired answer to the interviewee.

The misinformation studies by Elizabeth Loftus provide a potent illustration of this problem. During a well-known and often-replicated experiment (Loftus et al. 1978), participants were presented with slides depicting an automobile-pedestrian accident at a junction with either a yield or a stop sign. Subsequently, half of the participants were asked whether the car stopped at a stop sign and the other half whether it stopped at a yield sign. Thus, half of the participants received misleading post-event information in the form of a suggestive question. After a delay, participants engaged in a forced-choice recognition test. The two presented choices were slides depicting the car accident with either the yield sign or the stop sign. A significant difference was obtained between the control and the misled group, with the misled group making considerably more errors and reporting considerably more often to have seen the misleading post-event information in the original slide.

Misleading post-event information can manifest itself in many different ways, such as in written format or provided by an individual, for example, a co-witness. The feedback a police officer may give to a witness, for example, during or after an identification task, can be also regarded as post-event information and may influence how confident the witness is about the task at hand, as well as how he or she remembers the original event. Wells and Bradfield (1998) conducted a study during which participants had to identify suspects from photo spread arrays. After identifications had been made, participants received either confirming feedback that they picked the suspect or disconfirming feedback that they selected the wrong person. Feedback manipulation did not only affect participants' reports about how confident they were when they made the identification but also the accounts about the original event, such as memories about the viewing conditions present at the original event. These studies highlight how important it is for an investigative interviewer to be aware of the fragility of memory and how differences in questioning style and content can influence the completeness and accuracy of a witness account.

Current Investigative Interviewing Techniques in the UK

Given the importance of accurate recollection during investigative interviews, researchers have developed techniques to increase the quantity and quality of witness accounts, which are based on theoretical knowledge about how our memory works (Fisher et al. 2011). Some of these techniques are developed for specific witness populations, such as children, whereas others are developed to be used in much broader settings.

The National Institute of Child Health and Human Development (NICHD) developed a structured interview protocol for interviewing child witnesses, specifically focusing on child abuse victims (Lamb et al. 2007). The protocol can be divided into two phases: the pre-substantive and substantive interview phase. During the pre-substantive phase, the interviewer introduces himself or herself and explains the purpose and the ground rules of the interview. The rapport phase creates a comfortable and supportive atmosphere and enhances the interpersonal relationship between interviewer and interviewee. The child will be asked to report an experienced event unrelated to the incident in question, to familiarize himself or herself with the open-ended questioning approach, and to demonstrate the level of detail which is expected during the substantive interview phase. During the transition from pre-substantive to substantive phase, a couple of open-ended prompts are used to identify the target event under investigation. If the child makes an allegation, the interviewer starts the substantive phase with an open invitation ("Tell me what happened") followed by other free-recall prompts ("Tell me more about it" or "What happened then?"). After the initial free narrative, the interviewer prompts the child with cued questions ("When did it happen?" or "Who was there?") to obtain a more complete and detailed account. If necessary, option-posing questions can be used in the end to obtain crucial details not previously disclosed by the child. Interviewers are advised to not use any suggestive questions at any time during the interview (Lamb et al. 2007). The NICHD has been tested empirically in several field studies in different countries, among others, in the UK, France, and Israel. A recurrent finding is that interviewers using the NICHD protocol asked in general more open-ended questions and fewer focused, option-posing, and suggestive questions than interviewers who employed a standard interview. In addition, interviewers using the NICHD technique imposed focused, option-posing, and suggestive questions much later during the progression of the interview. Regardless of age, children interviewed with the NICHD protocol provided more information during the open-ended prompts, and significantly fewer details were revealed with direct, option-posing, and suggestive questions. Importantly, no age differences were found, suggesting that the NICHD protocol can be regarded as a suitable interview technique for children as young as 3 years of age (Cyr and Lamb 2009).

An interview technique focusing more on the general population is the Cognitive Interview (CI). It was developed by Ed Geiselman (University of California, Los Angeles) and Ron Fisher (Florida International University) in the 1980s (Fisher and Geiselman 1992) and since then has been tested and applied in various interviewing settings and with different witness populations, including adults with and without intellectual disabilities, children, and the elderly (see the meta-analysis by Memon et al. (2010) for a comprehensive overview). In its structure, the CI is very similar to the NICHD; however, it is unique in that it comprises several memory-retrieval techniques also known as mnemonics, which are based on fundamental theoretical principles regarding memory organization, storage, and retrieval. One of these principles is Tulving and Thomson's encoding specificity hypothesis (1973), which states that successful retrieval of information is most likely when the context and the cues present at retrieval match those present at the initial encoding. Reinstatement of the initial encoding context should therefore lead to an increase in accessibility of the stored information. Godden and Baddeley (1975) tested this assumption empirically by asking participants to learn word lists either underwater or on land. Subsequently half of the participants who learned the words underwater engaged in retrieval underwater, whereas the other half retrieved the words on land. The same retrieval procedure was applied to participants who encoded the words on land. Intriguingly, participants who encoded the words underwater were better at recalling them underwater compared to on land, whereas participants who learned the word lists on land recalled more items on land than underwater.

In an eyewitness situation, it is unlikely that cues which were present during encoding will be physically present at retrieval, since the investigative interview will probably take place in a police station. However, witnesses can be encouraged to reinstate the context of the original event mentally, thereby inducing cues which may facilitate their recall. The second memory principle is Bower's multiple-component memory trace theory (1967), which proposes that our memory is a network of associations rather than an accumulation of single, unconnected incidents. Consequently, there are multiple ways to access or cue one specific memory.

Initially, the CI consisted of four general retrieval techniques: mental context reinstatement, report-everything instruction, change-perspective, and reverse-order technique. During the mental context reinstatement, the interviewee is instructed to form a mental image of the physical and personal context present at the witnessed event. The interviewer can help the interviewee during this task by encouraging them to imagine what they could see, hear, and smell when the incident occurred and to think about any experienced feelings. The second technique is to ask the interviewee to report everything they have seen, including small, unimportant, and partial information. This technique may encourage witnesses to recall the event from a more detailed memory level. Research by Milne and Bull (2002) suggests that the mental context reinstatement together with the report-everything instruction is the most effective component of the CI. The change-perspective and reverse-order techniques are based on the assumption that information not accessible via one route might be accessible via another route. The change-perspective technique encourages the interviewee to recall the event from different perspectives, for example, from the perspective of another witness or from another angle. The reverse-order technique asks the witness to recall the event from different starting points or from a different chronological order. Both techniques encourage the interviewee to use different retrieval routes to access the information in question.

The CI was revised several times to increase its effectiveness and to make it more suitable to the needs of different witness populations. The revisions focused mostly on the enhancement of social dynamics and communication between interviewer and interviewee (Fisher et al. 2011). The following techniques are part of the revised CI: rapport building, focused retrieval, and interviewee compatible questions. Rapport building refers to the attempt to get to know the witness better and to make him/her feel more at ease. An important part of the rapport building is the transfer of control, during which the interviewer makes clear that it is the witness who has the knowledge of what happened and the interviewer does not know anything. Therefore, the interviewee is the active one doing all the talking, while the interviewer, who is the listener, is passive. During the questioning phase, where the interviewer takes the lead in asking questions based on what the witness has said in free recall, some additional techniques are used. Focused retrieval encourages the interviewee to form mental images of specific details. Interviewee compatible questions are guided by the interviewee's pattern of recall and prevent disruptions during retrieval. Empirical tests as well as field studies have revealed that the CI elicits significantly more correct information than control interviews (25–50 % more), without a significant decrease in accuracy rates (see Fisher et al. (2011) for a review and for a meta-analysis; Memon et al. 2010).

Although the beneficial effects of the CI are well established through laboratory and field studies, research has revealed that police officers often do not follow the whole procedure and/or only use aspects of the CI they consider as useful (Oxburgh and Dando 2011). Moreover, officers tend to find the CI too time consuming, difficult to administer, and sometimes not appropriate for specific cases they are dealing with. In particular, police officers report that they have difficulty applying the mental context reinstatement component of the CI (Dando et al. 2009). On the basis of these practical limitations, Dando and colleagues developed a modified mental context reinstatement technique called Sketch Mental Context Reinstatement (MCR). The sketch procedure appears to be more time efficient and easier to administer especially for frontline police officers.

In a recent laboratory study (Dando et al. 2009), participants received either Sketch MCR, traditional MCR, or no MCR during a structured interview protocol after having watched a criminal event. Participants in the Sketch MCR condition were provided with a pen and paper and were instructed to draw a detailed plan or sketch of the event they had witnessed. Interview protocols including the original MCR and the new Sketch MCR elicited significantly more correct details than the no MCR condition. The accuracy rate was significantly higher for Sketch MCR interviews than for original and no MCR interview protocols. These findings imply that a CI interview protocol including the Sketch MCR technique can be regarded as effective as an original CI. Beyond that, CI protocols comprising the Sketch MCR were significantly shorter in duration than the original MCR CI protocols, which can be regarded as an enormous benefit considering the limited resources available to frontline police officers. In addition to the pragmatic benefits, the Sketch MCR technique may be also particularly suitable for vulnerable witness populations, such as the elderly, since it places fewer cognitive demands on the witness.

Recently, a pen-and-paper version of the CI was developed by Gabbert et al. (2009) to protect witness memory from the negative effects of delay and misleading post-event information. The novel recall tool is called Self-Administered Interview© (SAI) and can be administered to witnesses after the incident has happened. Empirical research has shown that it is crucial to interview witnesses as soon as possible after an incident has occurred to be able to obtain accurate and reliable accounts (Tuckey and Brewer 2003); however, this is often not possible due to demands on police resources and time. In addition, the police frequently have to deal with incidents where there are multiple witnesses at the scene, such as during natural disasters, mass accidents, or terrorist attacks. It is not always possible for the police to interview all witnesses simultaneously, and often witnesses are not interviewed for several days, weeks, or even months after the incident has happened. During these delays, forgetting may occur and memory is also more susceptible to misleading information. The SAI facilitates police practice, since it can be administered promptly at the scene of an incident. It is totally self-explanatory and can be completed by witnesses in their own time (Gabbert et al. 2009).

The most recent version of SAI comes in the form of a booklet comprised of seven sections with information, instructions, and cues that aim to facilitate witness recall and are essentially based on the underlying memory principles of the CI (Hope et al. 2011). Section A includes mental context reinstatement instructions which encourage the witness to place themselves back to the point in time when the incident has taken place and to think about the event in as much detail as possible before writing down the memories. Thereafter, witnesses are asked to “report everything” that they remember. The next section focuses on eliciting a detailed person description by asking the witnesses several questions about the perpetrators appearance (e.g., hair, build, distinguishing features). Section C encourages witnesses to draw a sketch of the crime scene to generate important spatial information, which might be especially important during road traffic incidents, and to get additional information about possible escape routes of the perpetrators. In Section D, witnesses are instructed to describe any other people who were present at the crime scene, also when they were not directly involved to identify other witnesses. Section E requests information about any present vehicles and Section F about general conditions which may have impacted the visibility of the event, such as weather, obstructions, and time of day. The final Section G allows witnesses to report any additional information not previously mentioned or covered in any of the prior sections (Hope et al. 2011).

Early laboratory studies revealed that participants provided considerably more accurate information about a to-be-remembered event when interviewed with the SAI compared to free-recall instructions. The amount of correct information recalled was similar to that elicited with a C-I. Furthermore, participants who received the SAI directly after they witnessed the event remembered more information about it during a 1-week later free-recall test than individuals who had not completed the SAI (Gabbert et al. 2009).

In 2009, field trials of the SAI started in England and Wales initiated by the Association of Chief Police Officers (ACPO) Investigative Interview Committee. The main aims of the field trials were to examine the type of information provided by witnesses and the nature of event, to get end-user evaluations, and to identify situations in which the SAI is most useful (Hope et al. 2011). Trials have also focused on police officers' opinions about the efficiency of the SAI. It was found that the majority of officers experience the SAI as user-friendly and time saving. However, some officers raised concerns such as that it is only suitable for cooperative witnesses, that vital information may be missed, and that officers may use it incorrectly. The Greater Manchester Police in the UK is now providing officers with a SAI training package to inform them about its usage and theoretical underpinnings (Hope et al. 2011).

Policy Issues

Given the extensive research on investigative interviewing, predominantly on the CI technique, and the light it has shed on faulty interviewing practices, the question can be asked whether police interviews have improved in the 20 years since the CI was first introduced. One of the main issues that arises from the in-depth analysis of the research literature on investigative interviewing is that, despite numerous psychological studies, police officers are reluctant to use the complete enhanced version of the CI (Kebbell et al. 1999). In a recent analysis of police interview techniques, Fisher and Schreiber (2007) requested 23 detectives in Miami experienced in investigations of robbery, sexual assault, homicide, and internal affairs to tape-record their witness interviews. Analysis of these interviews revealed interviewing behaviors that were similar to those identified 20 years earlier. This was particularly disappointing in view of the scientific progress made in the field and the efforts to disseminate findings to practitioners and implement training programs. The evidence from the UK suggests that many police officers are inadequately trained in investigative interviewing techniques. In an evaluation of 75 police interviews, for example, Clarke and Milne (2001) found no evidence of the CI procedure having been used at all in the vast majority (83 %) of interviews. As a result of this, there have been changes in the way training is delivered in the UK. Most police officers are subject to a tiered approach with novice police officers receiving basic training in interview skills (the Tier 1 procedure), and as they progress through their career, they can acquire additional interview tiers. Advanced courses build on skills acquired in earlier courses, and there are courses directed at specialist interviewers such as police working in child protection. The tiered model encourages continuous learning about and acquisition of advanced knowledge on the best interviewing practices and recent discoveries in cognitive psychology. Furthermore, it ensures that police officers will only learn about interviewing techniques which are most relevant to their current role and responsibilities in their career. It is essential to continuously monitor and assess police interviewing practice and training to ensure best practice.

Another controversial issue with respect to investigative interviewing is whether interviews should be electronically recorded and be made available to the courts and experts. In some parts of the UK (England and Wales), interviews with witnesses are electronically recorded, whereas in other countries (Scotland), interviews with witnesses are based on hand-written notes taken during the interview. This may be problematic as we know from research that interviewers' recollections regarding the content and structure of interviews are far from being infallible. Lamb et al. (2000) compared 20 audiotaped forensic interviews of sexual abuse cases with the verbatim notes made by interviewers during the course of the interview. It was revealed that interviewers often failed to report in their notes many of the details provided by the children and many of the utterances they used to elicit them. Twenty-five percent of forensically relevant information was not provided in the notes. In addition, interviewers often failed to accurately recall the question format utilized and stated that they used more often open-ended questions than they actually did. The failure to accurately recall when and which questions are asked during an interview can have severe consequences especially in forensic settings, such as undermining the credibility of a child witness during a sexual abuse case. It is crucial to use objective and accurate methods of recording, such as video recordings, which do not affect adversely the credibility of the evidence.

Future Research Directions

It should be noted that the NICHD, the CI, and the SAI all focus on interviewing cooperative witnesses. Few studies have investigated the effectiveness of these protocols with uncooperative witnesses, such as suspects. Suspect interviewing plays an important part during criminal investigations, particularly to gather further information or evidence about additional perpetrators and other related criminal activities. In the USA, suspect interviewing is very confrontational, and the most frequently taught and used interview technique is the so-called Reid technique, which focuses on identifying truth tellers and liars and eliciting a confession (Kassin et al. 2010). In contrast, suspect interviewing in the UK changed dramatically in the early 1990s from "obtaining a confession" to "information gathering" (Bull and Milne 2004). Since then, recommendations on suspect interviewing were published and a new interviewer training program was developed which standardized for the first-time interview practices in England and Wales (Bull and Milne 2004). The aim of the new guidelines and the training program was to make suspect interviewing more transparent and fair. The training constitutes of a five-part model called PEACE, which stands for planning/preparation, engaging and explaining to the suspect, account from the suspect, closure, and evaluation (Bull and Milne 2004). Although the PEACE model has been successfully implemented in current UK police practice, there remain unanswered questions. O'Mahony, Milne, and Grant (2012) raise the issue that there is no guidance available on how to best interview vulnerable suspects, such as suspects with an intellectual disability. This is an important topic, given the high prevalence rate of people with intellectual disabilities in the UK (Emerson et al. 2001) and their increased risk of getting involved in criminal activities, due to living in underprivileged neighborhoods with high crime rates and/or being more likely exploited by criminals to assist in illegal activities because of their low understanding of their actual involvement in a crime and their heightened need to be accepted by other people (Davis 2005). The majority of research in the area of offenders with intellectual disabilities has looked at assessment and treatment of sexual offenders (see the book by Craig et al. (2010)). Empirical research on investigative interviewing has focused merely on interviewing vulnerable victims and witnesses (Milne 1999) and has neglected somewhat the research question of how to best interview vulnerable suspects.

Another area which needs to be researched in more depth is the impact of trauma on witness memory and how the different interview protocols work best with traumatized witnesses. For example, should the SAI be administered at the scene of a crime to a traumatized witness, or should witnesses and victims first be assessed and allowed to recover before they are subjected to an interview? Would a face-to-face CI meet the special needs of these types of witnesses better than the SAI? Until now psychological research has focused predominantly on the impact of emotional events on people's memory, without considering the impact of the applied interview technique (Reisberg and Hertel 2004). Some evidence suggests that highly emotional or distinctive events are remembered well and very vividly. Researchers call these memories flashbulb memories, because of their intense and detailed nature (Brown and Kulik 1977). Many people report, for example, to have remembered the death of Princess Diana (1997) or the 9/11 attacks on the World Trade Center (2001) as if they had happened yesterday. People are also often very confident in the accuracy of such flashbulb memories. However, a detailed and confidently held memory does not necessarily need to be accurate as demonstrated by Neisser and Harsch (1992). They interviewed people after the 1986 Challenger space-shuttle disaster about their whereabouts when the incident had happened and when and where they first heard about it. Three years later, the same people were reinterviewed. People still reported detailed and highly confident memories; however, these memories were often prone to errors and sometimes were even completely different from their first recollections. Findings from laboratory studies suggest that arousal can aid as well as impair memory for an experienced event and that it strongly depends on the type of detail one is trying to recall. Central details, such as details associated with the gist of the event or which are spatially central, are usually remembered very accurately, whereas peripheral details, which are plot irrelevant, are often remembered poorly (Reisberg and Hertel 2004). Thus, witnesses of and victims to traumatic events can provide accurate accounts; however, they may be less complete. The empirical and practical question of which interview technique is best for interviewing traumatized witnesses and victims and the most appropriate time at which to interview them remains as yet unclear.

Conclusions

The knowledge acquired through psychological research has helped to develop interviewing techniques which are based on well-established psychological theories regarding memory, communication, and social interaction. The UK, by basing its national investigative interviewing strategy on psychological theory and research, provides a good model for other jurisdictions to follow; however, this does not mean that enough has been achieved. Enhancing the efficacy of investigative interviews is a continual process, and there is always room for improvement, especially at a time where police forces face major cuts in their resources and need to consider alternative more time-efficient methods to interview eyewitnesses. The SAI provides one way in which police can save time and resources and the available research suggests it might be a practical alternative to the face-to-face interview. Of course, there will be situations where the police will need to assess the suitability of a witness for an investigative interview such as the CI particularly if the witness is traumatized or intellectually challenged. This is an area where further research is needed and specialist interview teams need to consider how best to deal with vulnerable witnesses or those with special needs. Another area where interviewing practices need further consideration is in dealing with offenders, particularly those with intellectual disabilities. It may be that existing protocols can be modified to meet the needs of specific groups. Practitioners working in the Criminal Justice System and academics need to work together to ensure that investigative interviewing follows best practices and that miscarriages of justice based on faulty interviewing practices are minimized.

Overview

Investigative Psychology (IP) is a subdiscipline of psychology developed by David Canter for the integration of a diverse range of aspects of psychology into all areas of criminal and civil investigation and legal processing (Canter 1995b, 2011; Canter and Youngs 2009). It considers all forms of offending action from arson, stalking, and robbery to murder, rape, or terrorism, exploring the psychological processes involved in the detailed actions and the influences on and characteristics of perpetrators. The starting point for such studies is the operational challenges that arise during investigation or in court, but the models and theories that have emerged inform the general psychological understanding of offending action and offenders.

The discipline may be understood in terms of the three key strands of academic activity which it encapsulates: (1) the modelling of criminal action and perpetrator inferences (the focus here is on the differentiation of patterns of criminal action and the determination of the psychological processes underlying these differences that have their origins in individual differences and experiential or lifestyle characteristics of the offender (see Canter and Youngs 2009)), (2) the investigative processes (this includes the study of investigative interviewing techniques as well as the decision-making processes of investigators and juries; although less developed, it extends to considerations of effective legal questioning techniques in court), and (3) the assessment and improvement of investigative information/legal evidence (this includes the study of eyewitness testimony, as well as addressing questions of veracity whether through the study of false allegations, false appeals, false confessions, or forensic psycholinguistic studies of authorship attribution).

Although the discipline is based upon a distinct philosophical approach to human beings and a particular meta-methodological approach to studying them, the discipline may also be readily understood in terms of the specific and concrete operational questions it seeks to answer (See Table 1: Key Concepts and Terms).

Moving Beyond Offender Profiling to Investigative Psychology

A major emergence of IP was the drawing of outline pictures of offenders, which subsequently became known as “offender profiles.” This activity of giving informed advice to criminal investigations can be traced back to biblical times; this advice grew and developed over the centuries, as illustrated by early description of the characteristics of witches and subsequent proposals of the classification of people on the basis of their physical characteristics and the inferring of criminality from certain subsets of those characteristics. Even though these early attempts at identifying the indicators of deviance were fundamentally flawed, they did point in the direction from which an Investigative Psychology could eventually emerge (see Canter and Youngs 2009). The contributions that IP can make to police investigations are most widely known and typically understood in terms of “offender profiles.” Offender profiling is held to be the process by which individuals, drawing on their clinical or

Investigative Psychology, Table 1 Key concepts and terms

Investigators' questions	Informed by psychologists' understanding of:
What type of crime is this?	The differentiation of criminal action
What are the likely characteristics of the sort of individual who might commit a crime such as this?	Investigative inferences
Which of the possible suspects is most likely to have committed the crime?	Investigative inferences
Where is the offender most likely to live in relation to the crime?	Geographical offending profiling
Which other crimes are likely to have been committed by the same perpetrator(s)?	The consistency of criminal action
Are the decisions made during the investigation free from distortion and bias?	Decision-making under stress/cognitive load
Have the lines of enquiry pursued been determined systematically?	Decision support tolls
Can we get the witness to remember more?	How to interview a witness
Can we tell if a suspect is lying?	The detection of deception
Can we tell who wrote something?	Forensic psycholinguistics
Did this crime really happen?	False allegations
Did this person really do the crime they say they did?	False confessions

other professional experience, make judgments about the personality traits or psychodynamics of the perpetrators of crimes. Recently, Canter has pointed out that the idea of a distinct "profiling" process is a fallacy.

Certainly, from the perspective of scientific psychology, any such "process" would be flawed in its reliance on clinical judgment rather than actuarial assessment. The clinically derived theories upon which much "offender profiling" has relied are equally questioned by research psychologists (Canter 1995, 2011). Canter modelled the relationship between the offence (A)ctions and offender (C)haracteristics, as canonical equations between particular sets of A and C variables.

The lack of scientific rigor evident in the profiling process has, for two decades, driven proponents of IP research to map out the scientific discipline that could underpin and systematize contributions to investigations. Interestingly, this more academically grounded approach is opening up the potential applications of psychology beyond those areas in which "profiling" first saw the light of day, rather than moving away from operational concerns. Early "profilers" insisted that their skills were only relevant to bizarre crimes in which some form of psychopathology was evident, notably serial killing and serial rape, but investigative psychologists now study and contribute to investigations across the full spectrum of illegal activities.

Nevertheless, as outlined, through the development of a scientific psychological approach to the study of criminal actions and detection processes, a much more challenging set of questions emerge than is apparent in fictional accounts of "profilers." These require consideration of what is actually consistent for an offender from one situation to another. There is also the challenge of dealing with how a criminal's actions may change over time due to many different processes of maturation and learning, as well as the variations introduced by any particular situation.

Fundamentals of Investigative Psychology

The Modelling of Criminal Action and Perpetrator Inferences

The potential links between the actions associated with a crime and the characteristics of the person who committed that offence are informed by a number of questions that are implicit within the concept of "profiling" and associated activities (Canter 1993; Canter and Youngs 2009).

Salience

In order to generate hypotheses and investigative possibilities and to select from them, detectives and other investigators must draw on some understanding of the actions of the offenders involved in the offence they are investigating. They must have some idea or template of typical ways in which offenders behave that will enable them to make sense of the information obtained. A central research question, then, is to identify the behaviorally important facets of offences – those facets that are of most use in revealing the salient psychological processes inherent in any given crime.

So many different aspects of a crime can be considered when attempting to formulate views about that crime that there is the challenge, before any scientific arguments can be developed, of determining which of those features are behaviorally important, in the sense of carrying information on which reliable empirical findings can be built. Accordingly, determining salience turns out to be a much more complex issue than is often realized with parallels in many areas of information retrieval. It requires the determination of base rates and co-occurrences of behaviors as well as an understanding of the patterns of actions that are typical for any given type of crime.

Consistency

One aspect of these salient features that also needs to be determined as part of scientific development is whether they are consistent enough from one context, or crime, to another, such that they can form the basis for considering and interpreting those crimes and accompany them with other offences. The establishment of consistency is not straightforward. There are weaknesses in the sources of data, particularly "patchiness," whereby in some instances certain features – or their absence – will be recorded and in others not. To deal with these problems with the data, there is an emerging range of methodologies that focus on working with the sort of information that is available from police and other crime-related sources.

In general, there are two rather different aspects of criminal consistency; one is the consistency from the actions in a crime to other aspects of the offender's life. This may thus allow some aspects of a one-off crime, such as the expertise involved, to be used to form views about an offender's previous training. So, the question here is which features of an offence are consistent with which, if any, aspects of an individual's background and personal characteristics.

A quite distinctly different form of consistency is that between one crime and another committed by the same person. This is often, rather loosely, referred to as an offender's modus operandi, or M.O. The question here then will be which features of an individual's offending behavior are consistent across situations, separate offences, and even across different types of offences. There are many aspects of this latter form of consistency that need to be clarified; for the moment we just need to be aware of its relevance at the core of IP.

A more conceptual challenge to determining consistency, as in all human activity, is that some variation and change is a natural aspect of human processes. There therefore will be criminals who are consistently variable or whose behavioral trajectories demonstrate some form of career development, as well as those whose criminal behavior will remain relatively stable over time. Research around all these possibilities of consistency is therefore central to any development of a scientific basis for offender profiling.

Development and Change

Any consideration of consistency will be against a backdrop of likely change in a serial offender's activities. Some variation is a natural aspect of human processes. Accordingly, there will be criminals who are consistently variable or whose behavioral trajectories demonstrate some form of career development, as well as those whose criminal behavior will remain relatively stable over time. The question of what is characteristic of an offender is one aspect of the operational problem of linking crimes to a common offender in circumstances where there is no forensic evidence to link the case. To date there has been remarkably little research on linking crimes. The challenge to police investigations can be seen as the reverse of the personality question. Psychologists usually have a person and want to know what will be consistent about that person from one situation to another. Police investigators have a variety of situations, criminal events, and need to know what consistencies can be drawn out of those events to point to a common offender.

However, if the basis of these changes can be understood then they can be used to enhance the inference process. The following five relevant forms of change are identified and need to be considered when establishing actions to crime scenes and their relationship to offender characteristics.

Responsiveness. A criminal's actions may not be the same on two different occasions because of the different circumstances he/she faces. An understanding of these circumstances and how the offender has responded to them may allow some inferences about his/her interpersonal style or situational responsiveness to be made that have implications for the conduct of the investigation.

Maturation. Maturation is an essentially biological process of change in a person's physiology with age. Knowledge of what is typical of people at certain ages, such as sexual activity or physical agility, can thus be used to estimate the maturity of the person committing the crimes and to explain the possible basis for longer term variations in an individual's criminal activity.

Development. The unfolding psychological mechanisms that come with age provide a basis for change in cognitive and emotional processes. One reflection of this is an increase in expertise in doing a particular task. Evidence of such expertise in a crime can thus be used to help make inferences about the stages in a criminal's development that he/she has reached and indeed to indicate the way their crimes might change in the future.

Learning. Most offenders will learn from their earlier offending in the same way that learning theorists have shown that behavior generally is shaped by experience. So, for example, an offender who struggled to control his first victim may be expected to implement some very definite restraining measures during subsequent offences. Indeed, for offenders, the particularly salient, potentially negative consequences of their actions (e.g., prison) may make this a powerful process for change in the criminal context. An inferential implication of this is that it may be possible to link crimes to a common offender by understanding the logic of how behavior has changed from one offence to the next.

Careers. The most general form of change that may be expected from criminals is one that may be seen as having an analogy to a legitimate career. This would imply stages such as apprenticeship, middle management, leadership, and retirement. Unfortunately, the criminology literature often uses the term "criminal career" simply to mean the sequence of crimes a person has committed. It is also sometimes confused with the idea of a "career criminal," someone who makes a living entirely out of crime. As a consequence, much less is understood about the utility of the career analogy for criminals than might be expected. There are some indications that the more serious crimes are committed by people who have a history of less serious crimes and that as a consequence, the more serious a crime, the older an offender is likely to be. But a commonly held assumption, such that serious sexual offences are presaged by less serious ones, does not have a lot of empirical evidence in its support.

Cultural Shifts. There are also important changes that come about from the developments in society. Increased security precautions will lead offenders to change their behavior.

Differentiation

Although an offender's consistency is one of the starting points for empirically based models of investigative inference, in order to use these models operationally, it is also necessary to have some indication of how offenders can be distinguished from each other (Canter 2000). In part, this reflects a debate within criminology about whether offenders are typically specialist or versatile in their patterns of offending. Research suggests that offenders may share many aspects of their criminal styles with most other criminals, but there will be other aspects that are more characteristic of them. It is these rarer, discriminating features that may provide a productive basis for distinguishing between offences and offenders. Canter also posited a conceptual structure known as the Radex (see Canter 2000; Canter and Youngs 2009), as the basis for modelling these patterns of variation and similarity in offending action. As Canter and Youngs (2009) note then, the Radex of Criminal Differentiation hypothesizes that the patterns within criminal action will be organized according to a combination of quantitative and qualitative themes. Numerous empirical studies have supported the Radex hypothesis, leading to recent explorations of the theoretical and conceptual import of this structure.

The rarer features combine to create that which may be regarded as a "style" or "theme" of offending. Therefore, the production of a framework for classifying these different styles is a cornerstone of IP. The classification frameworks are ways of organizing the themes that distinguish crimes which can then be drawn on in inference models so that, rather than being concerned with particular, individual clues as would be typical of detective fiction, the IP approach recognizes that any one criminal action may be unreliably recorded or may not happen because of situational factors. But a group of actions that together indicate some dominant aspects of the offender's style may be strongly related to some important characteristic.

Recent work has identified a single, generic theoretical framework for understanding the different styles of offending that can be identified across the range of offending forms from burglary or robbery and sexual assault to serial killing or stalking. This is the Narrative Action System model (Canter and Youngs 2009) with its corollary Victim Role Assignments model (Canter 1994; Canter and Youngs 2012). The Narrative Action System identifies four generic styles of offending that reflect the focus and origins of the action (termed an action system mode; see Canter and Youngs 2009) combined with the underpinning criminal narrative : the Hero's Expressive Quest, the Professional's Adaptive Adventure, the Revenger's Conservative Tragedy, and the Victim's Integrative Irony. The Victim Role model emphasizes the interpersonal components of these generic offending styles, distinguishing the offender's interpersonal approach to the victim (or "role assignment") on the basis of different forms of empathy-deficit and control strategies (Canter 1994; Canter and Youngs 2012).

Inferences

As outlined, the heart of these questions is what has become known as the "profiling equations" (Canter 1993, 2011). These are equations that provide the scientific bases for inferring associations between the actions that occur during the offence – including when and where they happen and to whom – and the characteristics of the offender, including the offender's criminal history, background, base location, and relationships to others. They are also referred to as the "A → C equations," where A are the actions related to the crime, and C are the characteristics of typical offenders for such crimes, and → is the argument and evidence for inferring one from the other.

Although this relationship is not an "equation" in strict mathematical sense, it is helpful to keep the looser meaning implied by the simple formulation. Thinking of the relationships as a family of equations simplifies the discussion of what the central questions of IP are. It also helps to clarify the many challenges and complexities that arise in trying to establish empirically any relationships implied by these equations. It is important to emphasize, though, that specifying the problem as a set of equations does not mean that these are a purely mathematical or statistical way of carrying out profiling. Rather, by studying what would be involved in solving these equations, it becomes clear that we have to use more conceptual, theory-driven approaches if we are to have any hope of producing a scientific basis for psychological contributions to investigations.

A starting point for understanding the challenges inherent in the A → C relationships is to recognize that the A → C mapping will rarely take the form of simple one to one relationships, rather there are a range of complexities in the ways that As relate to Cs. These complexities can be thought of as "canonical equations," which are "the relationships between two sets of variables." There is always a mixture of criminal actions that are being related to a mixture of characteristics or other criminal actions. The relationships are between combinations of action variables and combinations of characteristic variables. Therefore, the whole concept of a "canonical equation" shows that small changes in any one variable can influence the overall outcome.

Investigative Psychologists have conducted – and continue to conduct – a wide range of empirical studies of different types of crime, with the purpose of establishing solutions to these equations, in the hope of providing objective bases for investigative inferences. The complexity of the A-C relationship does however require the development of theoretical models to explain the relationships that may be expected for different combinations of variables, in different contexts.

Psychological Processes Underlying Investigative Inferences

Once there is some information to work with, there is the significant challenge of determining what conclusions can be drawn from this information. These conclusions are inferences that claim that certain features are linked. The inferences that detectives make in an investigation about the perpetrator's likely characteristics will be valid to the extent that they are based on appropriate ideas about the processes by which the actions in a crime correlate with the characteristics. Investigative Psychologists have advanced five possible processes that may be drawn upon to develop these inferences: (a) Personality theory, (b) Psychodynamic theory, (c) the career route perspective from criminological theory, (d) social processes, and (e) Interpersonal Narrative theory. Any or all of these theories could provide a valid basis for investigative inferences if the differences in individuals that they possess correspond to real variations in criminal behavior.

One general hypothesis is that offenders will show some consistency between the nature of their crimes and characteristics they exhibit in other situations. This is rather different from psychological models that attempt to explain criminality as a displacement or compensatory activity, resulting from psychological deficiencies. The evidence so far is consistent with this general consistency model, suggesting that processes relating to both the offender's characteristic interpersonal style and his/her routine activities may be particularly useful in linking actions and characteristics. Valid inferences also depend upon an understanding of the way in which a process operates. Conceptually there are a number of different models that can be drawn on to link an offender's actions with his/her characteristics. One is to explain how it is that the offender's characteristics are the cause of the particular criminal actions. For example, if a man is known to be violent when frustrated, this knowledge provides a basis for inferring his characteristics from his actions. A different theoretical perspective would be to look for variables that were characteristic of the offender and that would influence the particular offending actions. A highly intelligent person, for instance, may be expected to commit a fraud rather differently from someone with educational difficulties. The intelligence may be reflected in the style of action even if not in the actual cause of the action. A third possibility is that actions give rise to some consequences from which characteristics may be inferred. An example of this would be when particular types of goods are stolen that imply that the thief must have contact with other offenders who would buy or distribute those goods.

Other approaches to inference are less based on assumptions about the enduring characteristics of the offender and more on their interpersonal and social context. In terms of "criminal career," this is the idea that because criminals develop and learn as they commit more and more crimes, their most recent crimes may tell us more about the crimes they have committed in the past than about their enduring characteristics. The need to take on board consistencies in offenders' characteristics as well as the developments and changes of their lives has been articulated in personal narrative models. This approach also gives more emphasis on the sense the offender makes of his/her life and their agency in acting out their life story as they see it unfolding. This perspective has had particular power in assisting the identification of themes within criminal activities.

From an applied perspective, it is also important that the variables on which the inference models draw are limited to those of utility to police investigations. This implies that the A variables are restricted to those known prior to any suspect being identified, typically crime scene information and/or victim and witness statements. The C variables are limited to those on which the police can act, such as information about where the person might be living, his/her criminal history, age, or domestic circumstances.

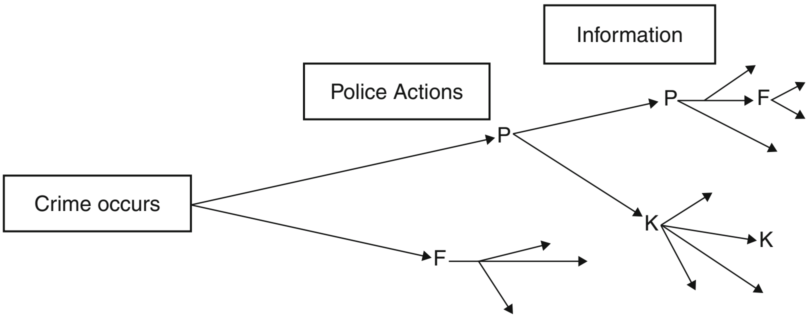
These inference models operate at the thematic level, rather than being concerned with particular, individual clues as would be typical of detective fiction. This approach recognizes that any one criminal action may be unreliably recorded or may not happen because of situational factors. But a group of actions that together indicate some dominant aspect of the offender's style may be strongly related to some important characteristic of the offender.

Investigative Processes: Investigation as Decision-Making

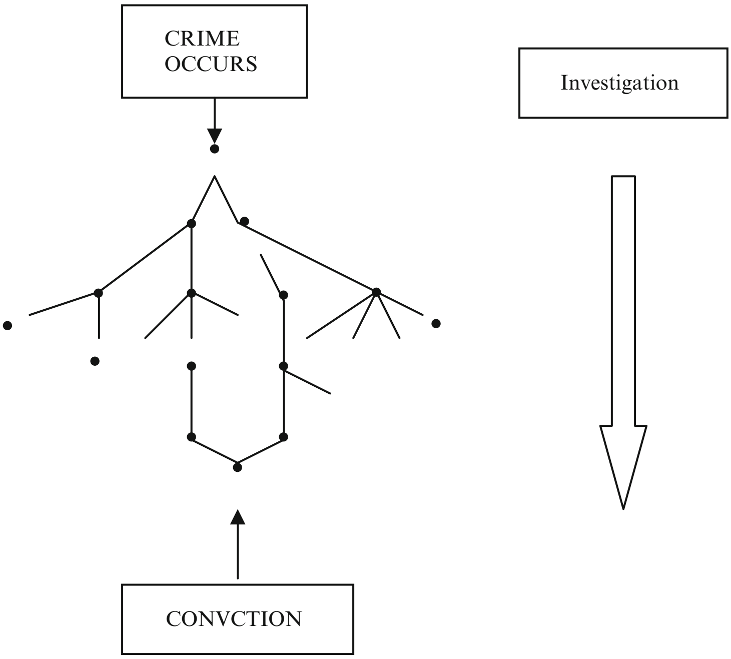
The decision-making phase of the investigative cycle is to select from the various options that are revealed through the earlier stages and act on those options, either to seek further information or to prepare some action that will lead to an arrest or proceedings in court. More specifically, the decision-making tasks that constitute the investigation process can be derived from consideration of the sequence of activities that detectives follow, starting from the point at which a crime is committed through to the bringing of a case to court. As they progress through this sequence of activities, detectives reach choice points, at which they must identify the possibilities for action on the basis of the information they can obtain. For example, when a burglary is committed, they may seek to match fingerprints found at the crime scene with known suspects. This is a relatively straightforward process of making inferences about the likely culprit from the information drawn from the fingerprints. The action of arresting and questioning the suspect follows from this inference.

However, in many cases, the investigative process is not so straightforward. Detectives may not have such clear-cut information, for example, if it is suspected that the style of the burglary is typical of one of a number of people they have arrested in the past. Or, in an even more complex example, they may infer from the disorder at a murder crime scene that the offender was a burglar disturbed in the act. These inferences will either lead them to seek other information or to select from a possible range of actions, including arresting and charging a likely suspect.

Investigative decision-making thus involves the identification and selection of options, such as possible suspects or lines of enquiry that will lead to the eventual narrowing down of the search process. Throughout this process, detectives must gather the appropriate evidence to identify the perpetrator and prove their case in court. A clear understanding of the investigation process as a series of decision-making tasks allows the challenges implicit in this process to be readily and appropriately identified. The main challenge to investigators is to make important decisions under considerable pressure and in circumstances that are often ambiguous. The events surrounding the decisions are likely to carry a great emotional charge, and there may be other political and organizational stresses that also make objective judgements very difficult. A lot of information, much of which may be of unknown reliability, needs to be amassed and



Investigative Psychology, Fig. 1 Schematic indication of the rapidly developing information in a major police investigation



Investigative Psychology, Fig. 2 Police investigation indicating the convergence on a suspect and conviction

digested. In decision-making terms, the investigative process can be represented as in Fig. 1.

In this diagram the lines represent investigative actions by the police, while the nodes are the results of those actions, i.e., new pieces of information or facts. Immediately after a crime occurs, detectives often have few leads to follow up. However, as they begin to investigate, information comes to light opening up lines of enquiry. These produce more information, suggesting further directions for investigative action. The rapid buildup of information in these first few days will often give rise to exponential increases in the cognitive load on detectives, reaching a maximum weight after some short period of time. At this point, investigators will often be under considerable stress.

As the investigation progresses, detectives will eventually be able to start to narrow down their lines of enquiry by establishing facts that close off all but one of them, substantially reducing the general level of demand. The general diamond shape in Fig. 2 represents the typical progression of an investigation. The diagram depicts the initial buildup and then the subsequent narrowing down of the information (the nodes) under consideration and investigative steps related to these (the lines) as the investigation becomes increasingly focused to the point where an arrest occurs.

The Assessment and Improvement of Investigative Information/Legal Evidence

Decisions clearly rely upon information, which is often carved out of real-world events. In a typical police investigation, a mass of information accumulates. The sheer volume of information can reduce the effectiveness of an investigation, as happened in the Yorkshire Ripper enquiry in the UK or more recently in the inquiry into the murder of the English television journalist Jill Dando.

On top of the demands of the amount of information that the police have to deal with is the great variety of material. Each different type of material has to be managed and examined in different ways, requiring different skills and different assessment processes. This information comes from a variety of different sources. There may be photographs or other recordings of the crime scene. There may be records of other transactions such as bills or telephone calls. Increasingly there are records available within computer systems used by witnesses, victims, or suspects. Often there will be witnesses to the crime or results of the crime will be available for examination. Further, there will be information in police and other records that may be drawn upon to provide indications for action. Once suspects are identified, there is further potential information about them, either directly from interviews with them or indirectly through reports from others. In addition, there may be information from various experts that has to be understood and that may lead to specific actions. Apart from being potentially overwhelming in terms of its sheer quantity, the information takes many different forms. It is slanted in many different ways, having been either originally generated for other purposes, or distorted by human perception and memory processes, or, indeed, particular motives. Moreover, while the information available does have certain strengths (such as the fact that it may have been given under oath), it has not been collected with the careful controls of laboratory research. The information on which police rely on in an investigation is therefore often incomplete, ambiguous, and unreliable.

Furthermore, because the information is carved out of real-world events, it must be treated with great respect and considerable caution within IP. A continuum of trustworthiness can be regarded as running from the most trustworthy evidence (the hard evidence at the crime scene) through to the least (the statement of a culprit who denies guilt). The hurdles in the way of trustworthy evidence are present at every stage of an investigation, from initial witness statements, through comments from suspects, to how evidence is presented in court. The challenges this poses for investigations have a different emphasis from those that are posed for research. The biggest problems for research are the biases in the sampling and the gaps and lack of detail in the data. So the researcher always has to work from a record made of the events by some third party.

It is by conceptualizing and treating this information as “data,” and the ways in which it is obtained as research processes, that psychologists can make a further broad class of contribution to investigative activity. Understanding it in this way allows us to use psychological principles and knowledge to evaluate and improve the information detectives need to progress an investigation or to back up a case in court. Two aspects of scientific data assessment are particularly relevant to investigative information: its usefulness and detail and its accuracy and validity.

There are a variety of contributions psychologists can make to the improvement of the accuracy and validity of the information available in an investigation. A number of formal validity assessment techniques have been developed to assess the truthfulness of witness accounts when no objective means of doing this are available. Most of these techniques are based on the assumption that honest accounts have identifiable characteristics that are different from fabricated accounts.

There is much more evidence to indicate that for many people, there are psychophysiological responses that may be indicators of false statements. The procedure for examining these responses is often referred to as a polygraph or "lie detector." In essence, this procedure records changes in the autonomic arousal system, i.e., emotional response. Such responses occur whenever a person perceives an emotionally significant stimulus. The most well-established indicator is when the respondent is asked to consider information that only the perpetrator would be aware of, known as the "guilty knowledge" test. A more controversial procedure is to ask "control questions" that many people would find emotionally significant, in order to determine if they elicit responses that can be distinguished from those questions relating directly to the crime. However, in both these applications of psychophysiological measures, the most important element is the very careful interview procedure before measurements are made and during the process.

In general "lie detection" is more productive in supporting a claim of innocence than in providing proof of guilt. For this reason, many jurisdictions do not allow "lie detector" results to be presented as evidence in court. Its value in eliminating possible suspects is used in a variety of jurisdictions around the world. In some investigations, the suspect may deny that he/she made a statement that has been attributed to him/her. In such cases, techniques based on the quantitative examination of the language used may be drawn upon to evaluate the claim. So, for instance, a forensic linguist may try to establish whether the use of particular nouns is typical of the suspect or not. Interestingly, however, indications are that the psychological components of written or verbal accounts, i.e., what is meant and how it is expressed, may be more useful in attributing authorship than the linguistic features, such as counts of particular words.

Sometimes the concern will be not with the veracity of the suspect's account but with that of an alleged victim. This can be an issue in cases of sexual or other abuse. In such cases, the complainant is not a suspect, and the more intrusive processes of lie detection are rarely used. However, investigators can draw on studies of the circumstances under which such false allegations are made and use those as guidelines for more intensive examination of the circumstances. Whether or not this is a valid way of identifying false allegations is a topic awaiting further research.

Investigative Psychology in Action

There has been a long journey from trying to profile the characteristics of a witch through the attempts to fathom the criminal mind of the late nineteenth and twentieth centuries. The experienced detectives, notably at the FBI training academy in Quantico, who drew attention to the possibility of working directly with what occurred in a crime to draw systematic inferences about offenders, pointed the way to a more empirical, scientific basis for psychological and related behavioral science contributions to police investigations. The blossoming of applied psychology into many areas of professional activity laid the foundations for an Investigative Psychology that goes far beyond the initial speculations about serial killers of 50 years ago.

It has been demonstrated throughout this entry that IP is relevant to the full range of offence activity. Psychology and related disciplines need no longer be assigned to the "hit-and-run" offering of an "offender profile," which is only relevant to bizarre, extreme crimes. It is now taking its place as of central importance to many aspects of police training and beyond. The groundbreaking work of IP has continuously emphasized the value of systematizing and presenting visualizations of investigative information and the development of decision support systems than can be an integrated aspect of police activities. Two areas in particular are proving fruitful for such decision support: geographical offender profiling and the linking of cases to a common offender. Both of these will benefit from an increasing amalgamation of spatiotemporal and behavioral information as has been attempted in recent investigative decision support systems.

Italian Mafia

Giulia Berlusconi
Università Cattolica del Sacro Cuore and
Transcrime, Milan, Italy

Synonyms

Italian organized crime

Overview

Different ways of conceptualizing the mafia have been proposed over the time, emphasizing either the cultural or the organizational factors. The former describes the mafia as a subculture typical of certain areas of Southern Italy, whereas the latter focuses on its internal configuration. The mafia has also been conceptualized as a business enterprise, although its political dimension has also been emphasized by delineating it as an industry of private protection. Indeed, Italian mafias differ from other criminal organizations for their will to political dominion in the areas of their traditional presence. Another peculiarity of mafia groups in Italy is their internal configuration and the resort to symbols and rituals that promote the creation of strong ties among the affiliates.

Italian mafia organizations include Cosa Nostra (Our Thing) in Sicily, the 'Ndrangheta (Society of the Men of Honor) in Calabria, and the Camorra in Campania. Although these criminal organizations share common elements, they differ in terms of history, internal organization, illegal market activities, and infiltration in the legitimate and informal economy, and cannot thus be considered as a single phenomenon. The historical and cultural background, the internal organization, and the expertise provide an explanation for the differences that emerge with regard to the presence of mafia groups in illegal markets and the way they conduct their criminal activities. Extortion is instead common to all Italian mafia organizations, and it constitutes the core business of Italian mafias, since it allows them to gain control over a specific territory and thus exercise political power in that area.

The large profits coming from illegal activities are invested both in the illegal markets and in the legitimate economy. Investments in the legitimate economy allow mafia organizations to extend their political dominion by infiltrating into and controlling legitimate economic sectors. Among the economic sectors, mafia groups seem to favor the public construction industry, as well as other "protected" sectors where the public administration regulates the participation by requiring a specific license or permission and thus reduces the competition.

To this day, most research on Italian mafias focused on areas of their traditional presence and explored the reasons they emerged in those territories, whereas little is known about the colonization and transplantation processes. In the future, the adoption of more complex interpretations of the mobility of criminal groups might help identify the factors that foster transplantation and that make it successful.

Mafia and Organized Crime

For a long time, the term "mafia" has been used as a synonym for organized crime (Blok 2008), and Italian mafia has been considered a paradigm of organized crime (Paoli 2003). Nonetheless, the term "mafia" refers to a specific form of organized crime (Finckenauer 2005), and the illegal organizations that have been presented as its archetype include large-scale criminal groups other than Italian mafias, such as the Chinese Triads and the Japanese Yakuza (Paoli 2002).

The main trait that distinguishes mafia groups from other criminal organizations is their political dimension. Although actively involved in illegal market activities, mafia groups cannot be reduced to these activities (Paoli 2002) nor is their internal configuration the consequence of their participation in illegal businesses (van Duyne 1997). Besides the provision of illegal goods and services and the maximization of profits, mafia groups aim at exercising political dominion over the areas where their members live and where most of their illegal activities are conducted. The control over the territory is guaranteed by a generalized system of extortion, which also allows mafia organizations to increase their income (Paoli 2003).

Another peculiarity of mafia groups is their internal configuration. Despite variations, mafia organizations are characterized by the presence of government bodies that coordinate the activities and regulate the relationships among their member. Symbols and rituals, including a ceremony of affiliation, promote the creation of ties of brotherhood among the members of the organization, who become "men of honor" and are subject to the duty of silence (Paoli 2003).

Italian Mafias

The first comprehensive study of the mafia was published in 1876 by Leopoldo Franchetti (1974), who described it as an extralegal social system, namely, a specific and socially accepted way of exercising violence to solve conflicts. After Franchetti's work, different ways of conceptualizing the mafia have been proposed over the time, emphasizing either the cultural or the organizational factors (Sciarrone 2009). The cultural approach describes the mafia as an attitude, a subculture typical of certain areas of Southern Italy, rather than a formal organization (Hess 1973), although organizational factors have also been considered by analyzing the network of family, friendship, and business relations of mafia members (Blok 1988; Schneider and Schneider 1976). The organizational approach instead emphasizes the internal configuration of mafia groups and describes them as formal organizations with articulated structures and a set of symbols and rituals. The depiction of mafia organizations as criminal associations can also be found in the Italian penal code, where Article 416bis describes the mafia as a specific type of criminal organization and lists the main features of mafia groups.

In the mid-1980s, the focus shifted from cultural and organizational aspects to the illegal activities carried out by criminal organizations, and the mafia was conceptualized as an enterprise. According to Pino Arlacchi (1988), between the 1950s and the 1960s, the Italian mafia had experienced an entrepreneurial transformation and had focused on the accumulation of capital. Other scholars refused the identification of mafia groups with business enterprises and the sharp distinction between a modern and an old mafia. They instead emphasized either the importance of the threat or use of violence to regulate economic transactions (Catanzaro 1992) or the political dimension, describing the mafia as "a specific economic enterprise, an industry which produces, promotes and sells private protection" (Gambetta 1993, 1). More recently, the complexity of the phenomenon has been recognized (Santino 2006), and Italian mafias have been described as "multifunctional organizations" involved in a plurality of illegal activities and aiming at pursuing a plurality of goals, including the exercise of political power over a specific territory (Paoli 2004, p. 274). Mafia groups cannot thus be reduced to their economic dimension, both because they originated before the illegal markets they operate in and because their activities include noneconomic ones, such as the exercise of political dominion (Paoli 2002).

Most of these conceptualizations of the mafia have been proposed with particular reference to the Sicilian mafia, also known as "Cosa Nostra." However, mafia organizations which originated from and mainly operate in Italy include Cosa Nostra (Our Thing) in Sicily, the 'Ndrangheta (Society of the Men of Honor) in Calabria, and the Camorra in Campania.

Although these criminal organizations share common elements, the history of the mafia "cannot be reduced to a single scheme or interpretation, valid in every situation and time" (Lupo 1996, p. 26). Italian mafias differ in terms of history, internal organization, illegal market activities, and infiltration in the legitimate and informal economy (Sciarrone 2009), and they thus need to be discussed separately.

Cosa Nostra

The term "mafia" first appeared in 1865 in a report by the then-prefect of Palermo Filippo Gualterio, who used it to refer to Sicilian criminal groups. Only 20 years later, the same term was adopted in the United States to refer to a criminal organization of Italian origins. The same organization was also referred to as "La Cosa Nostra," as Joseph Valachi testified in 1963 before the Permanent Subcommittee on Investigations of the US Senate Committee on Government Operations. The same term has also been adopted by Sicilian mafiosi, together with other names, such as "Onorata Società" (Honored Society) (Lupo 1996).

Evidence of antecedents of Cosa Nostra in Sicily can be found starting from the second half of the nineteenth century, although only in the 1920s, the Italian government ordered a systematic repression of Sicilian mafia groups. After World War II, Cosa Nostra extended its power, mainly by expanding from the countryside into the largest cities and infiltrating into the public construction industry. In the mid-1970s, the Sicilian mafia entered the illicit drug market further increasing its power and profits, until the beginning of the 1990s. In 1992–1993, the killing of the state prosecutors Giovanni Falcone and Paolo Borsellino was followed by an intensification of law enforcement repression.

As a consequence, Cosa Nostra adopted the so-called "strategia dell'inabissamento" (sinking strategy), aimed at reducing its visibility and thus the attention from law enforcement agencies by minimizing violence. However, this strategy also led mafia groups to concentrate their illegal activities in Sicily, mainly focusing on extortion and infiltration in the legitimate economy (Lupo 1996; Savona 2012).

The internal structure of Cosa Nostra has not changed since the 1950s. It is composed of a number of *cosche* or families. Each *cosca* controls a specific territory, and a boss, who is elected by the affiliates, is in charge of its management. His counselors are also elected by the affiliates and assist the boss in his decisions. The hierarchical structure of the *cosche*, the direct election of the high-ranking positions, and the frequent turnover guarantee the cohesion of the group and help strengthen the ties of brotherhood among mafia members. In 1957 a Commission was also created to regulate the relationships among the different families. The meetings were attended by representatives of the *mandamenti*, namely, groups of three or four families. The Commission had the aim of settling disputes, sanctioning violations and taking any decision related to the use of violence, whereas each *cosca* was still autonomous in doing business (Paoli 2003).

The intensification of the law enforcement repression since the early 1990s and the arrest of Bernardo Provenzano, the latest chief of Cosa Nostra, in 2006 have considerably weakened the Sicilian mafia, which has experienced a strong reorganization process. However, despite the undergoing crisis, the organization can still rely on a widespread network of entrepreneurs and politicians that ensure Cosa Nostra the ability to commit extortion and infiltrate into the Sicilian legitimate economy (DIA 2010).

The 'Ndrangheta

Evidence of the presence of the 'Ndrangheta in Calabria dates back to the end of the nineteenth century, although the term "'ndrangheta" has been consistently used only since the 1960s. Different names instead appear in the first judicial documents, such as "mafia" or "camorra" – which were used to refer to Sicilian and Neapolitan mafia organizations – or "onorata società" (honored society) and "picciotteria" (Paoli 2003). The limited violence and the fact that it was considered outdated in comparison to Cosa Nostra and the Camorra made law enforcement agencies and scholars not to pay too much attention to the 'Ndrangheta (Ciconte 2011). Today the Calabrian mafia is instead considered the most powerful among Italian criminal organizations and the most involved in drug trafficking, and in June 2008, it was included into the US Treasury Department Office of Foreign Asset Control (OFAC) Foreign Drug Kingpin list (U.S. Department of State 2011).

The 'Ndrangheta is organized in *cosche* or *'ndrine* which are usually formed by the members of the same family and exercise their influence over a specific territory according to the arrangements made with the other families. The fact that members of the *'ndrine* are bonded by kin ties guarantees secrecy and trust (Paoli 2003). Within each *'ndrina*, specific tasks are also assigned to the affiliates, according to their formal rank in the organization. A two-level hierarchical structure is present; low-level affiliates are referred to as members of the *società minore* (lower society), whereas bosses are part of the *società maggiore* (higher society). Within both the *società*, a long series of different roles and tasks can then be identified.

The familistic structure of the Calabrian mafia has been considered for a long time a sign of backwardness, compared with the Sicilian mafia and the Neapolitan Camorra. Rather than being old fashioned, this type of structure guarantees a high degree of cohesion among its members and minimizes the risk of defections. The number of defectors has indeed always been lower than that of other Italian mafia groups (CPA 2008; Ciconte 2011). The internal cohesion is also guaranteed by a set of formal rules, an extensive use of rituals and symbols, and strong barriers to entry. As in Cosa Nostra, an affiliation ceremony or *battesimo* is indeed required for a new affiliate to be appointed and become a "man of honor" (Paoli 2004).

For a long time, the ‘Ndrangheta was conceived as a confederation of families without a coordinating body which establishes common rules in order to avoid conflicts among the *cosche*. This idea of the ‘Ndrangheta as an horizontal organization started to be reexamined in the 1990s and has been abandoned when the existence of a collective body (*Crimine* or *Provincia*) entitled to establish common rules and settle disputes emerged from recent criminal investigations (TrMi 2010). However, despite the presence of a collective body, each family enjoys a monopoly on its territory and the autonomous running of illegal activities, even though a collaboration among different *cosche* is frequent, especially for the trafficking of drugs (Ciconte 2011).

The power of the Calabrian mafia also comes from its ramifications, both in other Italian regions and abroad. In the last decades, the ‘Ndrangheta has indeed created outposts both in Central and Northern Italy and in foreign countries, where it has developed an extensive network of contacts to facilitate its involvement in illegal market activities. Kin ties maintain their importance in the internal organization of the *‘ndrine* also outside Calabria, since they allow for a quick replacement of affiliates in case of arrests by law enforcement agencies. However, in addition to mafia associates, ‘Ndrangheta groups resort to other individuals outside the organization and can rely on an extended network of contacts with both common criminals and legal entrepreneurs and politicians (CPA 2008; Ciconte 2011).

The Camorra

The Camorra refers to a variety of independent criminal groups and gangs which conduct their illegal activities in Campania. These criminal groups – unlike Sicilian and Calabrian ones – vary considerably from long-lasting family businesses to gangs developed around charismatic leaders, often in competition among each other (Paoli 2004).

First mentions of the Camorra as a criminal organization can be found in police records which date back to the early nineteenth century, when written statutes describing symbols and rituals, as well as signs of the presence of stable coordination mechanisms, were found (Behan 1996). Although most symbols and rituals have been maintained, the Campanian underworld has changed, and the contemporary Camorra has turned into a different criminal organization. In the 1960s, the Camorra groups entered the tobacco and later the drug market, making large profits which were then invested both in the same illegal markets and in the legitimate economy, dealing mainly with public sector contracts (Paoli 2004). With the development of the contraband industry, competition among rival groups increased, as well as their dynamism and the territorial control (Behan 1996).

The presence of a stable mechanism that coordinates the activities of the different groups and settles disputes among them no longer exists, making wars against rival gangs more likely to occur than in Sicily and Calabria (Paoli 2004; DIA 2010). The Camorra is indeed horizontally organized, with criminal groups forming temporary alliances and maintaining their autonomy (Barbagallo 2010). As for Cosa Nostra and the ‘Ndrangheta, the direct physical control over a territory is fundamental for Camorra groups. “Once this control is won, criminal gangs can not only extend their protection rackets, illegal gambling, usury, cigarette, and drug trading; they can begin to become power brokers, mediating between ordinary people and ruling politicians” (Behan 1996, p. 110).

The heterogeneity of criminal groups and gangs which populate the Campanian underworld is reflected upon the illegal activities they conduct. Smaller groups are mostly involved in the supply of illegal goods and services, such as extortion, loan sharking, drug trafficking, counterfeiting, exploitation of prostitution, and illegal gambling; the most powerful and long-lasting groups combine these illegal activities with infiltration into the legitimate economy and the public administration sector (Paoli 2004; DIA 2010).

Illegal Activities

Extortion and protection constitute the core business of Italian mafias. Although extortion is not as profitable as other illegal activities, such as usury, drug trafficking, or infiltration in the public sector contracts, it does not require any initial investment, and it can be carried out without high risks or high managing costs. Besides being a source of profit, it allows mafia groups to gain control over a specific territory and thus exercise political power in that area, as well as it enables them to establish contacts with legal entrepreneurs and penetrate into the legitimate economy. The sum that legal entrepreneurs are forced to pay is usually calculated on the basis of their legal profits, so to encourage their compliance and minimize the risk of reporting to law enforcement agencies. In some cases, however, extortion is also exploited by mafia groups to take possession of profitable businesses by forcing entrepreneurs to undersell their company when they are no longer able to handle mafia organization's request of money (Paoli 2003; Savona 2012).

Extortion can take shape in different ways. The most common one involves the request of money in exchange for protection. However, mafia groups also resort to "indirect extortion" (Sciarrone 2009, p. 76). In this case, the mafiosi establish special relationships with a selected number of legal entrepreneurs, and they ask for materials or services normally provided by the entrepreneurs' businesses in exchange for protection. Another form of indirect extortion involves the request to hire affiliates or other people related to mafia members. By giving suggestions for hiring, mafia groups create new jobs for those who accept their presence and collaborate with them, and thus increase the collusive behavior within their communities (Sciarrone 2009).

Whereas extortion is common to all Italian mafia organizations, some differences emerge with regard to their presence in illegal markets and the way they conduct their criminal activities. These differences depend on the history and culture of the three mafia groups, as well as their internal organization and their expertise. These three factors – historical and cultural background, organization, and expertise – provide an explanation for the involvement of the 'Ndrangheta and the Camorra in drug trafficking, an illegal business formerly run by Cosa Nostra. The same factors also explain the involvement of the Camorra in counterfeiting and in the illegal traffic in waste. The Neapolitan mafia has indeed exploited the need for new places for waste disposal and the inefficiency of the public administration and corrupt politicians to enter the market, whereas the lack of the same combination of criminal opportunities in Sicily and Calabria have prevented Cosa Nostra and the 'Ndrangheta to do the same (Savona 2012).

Together with extortion, drug trafficking is among the most profitable illegal activities conducted by mafia organizations, and it is carried out in coexistence with other criminal groups. Indeed, in the 1980s and 1990s, mafia groups tried do gain the monopoly of the drug market both in their traditional communities and in some Italian cities, enforcing retailers to buy solely from them, but they never succeeded in controlling the whole exchange of drugs in an entire city or even in one neighborhood, except for a few mafia strongholds in southern Italy (Paoli 2004; DIA 2010).

The 'Ndrangheta is particularly active in the illegal drug market since 1980s, when the Calabrian mafia has succeeded in entering this profitable market partly at the expense of Cosa Nostra, whose members were no longer considered trustworthy interlocutors, especially by South American drug producers. Among drug trafficking activities, the 'Ndrangheta is mainly involved in the importation and wholesale distribution of drugs, especially cocaine and heroin. The position of strength of 'Ndrangheta families in the illegal drug market is guaranteed by their extensive network of contacts in Center and Northern Italy, both with their affiliates and with external drug dealers. In the last decades, the Calabrian mafia has also created outposts in foreign countries which serve as transit countries for the smuggling of drugs (CPA 2008; DIA 2010; Ciconte 2011).

The illegal activities mafias are involved in are not limited to the trafficking of drugs. Other illegal goods are provided by the Italian criminal organizations, such as firearms and counterfeited products. Mafia groups are also involved in the illicit traffic in waste, illicit gambling, loan sharking, frauds, as well as robberies and homicides (DIA 2010). The large profits are then invested both in the illegal markets and in the legitimate economy.

Infiltration of the Legitimate Economy

The infiltration of mafia organizations in the legitimate economy "has to do with the very nature of Italian mafia groups and their claim to exercise a political dominion within their communities" (Paoli 2004, p. 284). Extortion allows mafia groups to achieve an indirect control of companies, by forcing them to pay for protection services, hire specific people, or supply materials or services. Investments in the legitimate economy allow mafia organizations to extend their political dominion by infiltrating into and controlling legitimate economic sectors. The management of legal companies is indeed a way mafias can create new job opportunities and extend their power within their communities, as well as establish relationships with legal entrepreneurs and politicians. Also, the large illegal profits generated from illegal activities cannot be completely reinvested in the same illegal markets. The management of legal companies thus enables the mafiosi to launder part of their money and make even more profits from investments in the legal markets (Arlacchi 1988; Ruggiero 1996; Fantò 1999).

Among the economic sectors, mafia groups seem to favor the public construction industry, as well as other "protected" sectors, i.e., those where the public administration regulates the participation by requiring a specific license or permission and thus reduces the competition. These economic sectors are generally characterized by a low productivity, but they do not require specific skills nor technological innovations (Sciarrone 2009). Also, they allow mafia groups to capitalize on their competitive advantages, namely, the constant availability of floating assets and the possibility to discourage the competitors by resorting to violence (Arlacchi 1988).

Future Directions

Most research on Italian mafias focused on areas of their traditional presence, namely, Western Sicily (Palermo, Agrigento, and Trapani provinces), Southern Calabria (Reggio Calabria province), and Naples and its surroundings. Only recently the interest in the mobility of criminal groups has generated a small but significant number of studies on mafia transplantation into new territories (Sciarrone 2009; Varese 2011; Campana 2011). Different interpretations have been proposed on whether, why, and how mafia groups expand to new and distant territories. Peter Reuter (1985) and Diego Gambetta (1993) have argued that mafia organizations tend to be local in scope and are not likely to migrate. However, examples of successful mafia transplantation do exist (Varese 2011). The possibility that generalized migration of the population or of convicted mafiosi relocated outside their areas of origin might foster the mobility of criminal groups has also been discussed, as well as the hypothesis that involves specific mafia expansion strategies (Sciarrone 2009). To this day, little is known about the colonization and transplantation processes, whereas a significant body of research has explored the reasons Italian mafias emerged in their territories of origin. The adoption of more complex interpretations of the mobility of criminal groups might help identify the factors that foster transplantation and that make it successful.

Judicial Leadership and Performance

Ingo Keilitz
CourtMetrics, Williamsburg, VA, USA

Synonyms

Governance; Organizational performance measurement; Performance management

Overview

Judicial leadership is what leaders of court systems do to translate values, visions, and goals into exceptional organizational performance. It means mobilizing and inspiring employees and other stakeholders to get extraordinary things done for their organizations. This entry explores the relationship between leadership – widely considered the most important element of effective justice system administration – and self-governed, well-managed, and operationally efficient courts. It focuses on organizational performance measurement, a precondition of effective self-governance of courts.

The theme of this entry is that the relationship between leadership and effective organizational self-governance of courts, especially the role of performance measurement, is uniquely important for courts. Buttressed by the doctrine of separation of powers doctrine and the principle of judicial independence, courts enjoy, at least theoretically, a greater level of freedom from scrutiny and interference than other components of the executive and legislative branches of government. This freedom and institutional independence cannot maintain legitimacy in practice without effective self-governance; and effective self-governance is dependent on judicial leadership. In practical terms, effective self-governance of courts is the manifestation of the separation of powers doctrine and the principle of judicial independence.

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

To achieve a truly independent (and, practically speaking, a self-governing) judiciary requires judicial system leadership to overcome resistance from various entrenched interests that view courts as not deserving or not capable of self-governance, or both. To be effective, self-governance should drive a judicial system leadership committed to transparency and accountability and to rigorous performance measurement and performance management that ensures adherence to the highest standards of organizational performance.

The organization of this entry is as follows. It begins with a brief definition of court performance measurement and performance management. The next section makes the case for the unique importance of transparency and accountability to the self-governance of courts. Stated simply, without transparency and accountability for performance, it is unlikely that judicial systems can be institutionally independent. Judicial leaders must ensure that a transparent and accountable self-governed framework exists not just in the "law and the books" but also in the "law in practice." Described in the next section is the imperative of value-oriented performance measurement and how this imperative folds into a broad vision of self-governed, well-managed, effective, and operationally efficient courts.

The difficulties of thinking in terms of organizational performance measurement and its relationship to effective self-governance contribute to the theme of the next section of this entry under the heading "How Are We Performing?" It describes two related impediments that have stood in the way of the advance of performance measurement, transparency, and accountability, and the self-governance of courts. The first is the reliance of courts and justice systems throughout the world on third-party monitoring and evaluations, which are quite different from performance measurement on various dimensions, to assess their performance. The second is a related tendency to think in terms of a research or program evaluation paradigm when addressing the question of *How Are We Performing*? – a paradigm ill suited to answer the question except in a very narrow sense. The theoretical foundations and methodology of the disciplines of performance measurement and research overlap, of course, but they are very different in important aspects – purposes, sponsorship, organization, audience, functions, timing, and data interpretation rules – that are critical for self-governance of courts.

The final section of this entry concludes with the proposition that judicial system leaders should focus on ensuring an effective self-governance of courts that is transparent and accountable and to committing to the primacy of performance measurement to drive success.

Court Performance Measurement Defined

Court performance measurement is the process of monitoring, analyzing, and using performance data on a regular and continuous basis for the purposes of transparency and accountability and for improvements in efficiency and effectiveness. This definition encompasses both performance measurement per se and the use of performance data in management (sometimes referred to as performance management). Measures of court performance include, for example, those promulgated by the National Center for State Courts (National Center for State Courts 2005, 2009):

- Court user/citizen assessment and satisfaction with court services including access to the courts, fairness and integrity, timeliness and expedition, and their general trust and confidence in the court
- Clearance rates, that is, the number of outgoing cases as a percentage of the number of incoming cases
- Case finalization time (also referred to "time to disposition," "on-time case processing," and other terms)
- Time in custody prior to trial (median number of days in pretrial detention)
- Reliability and accuracy of court files
- Backlog, that is, percentage of cases in the system longer ("older") than established timeframes
- Trial date certainty expressed the proportion of all trials that are held when first scheduled

- Court employee engagement (a proxy for court success)
- Recovery of criminal and civil court fees as a proportion of fees imposed
- Money expenditure per case (net costs per finalization)

These measures used by United States courts and, on a more limited basis, by courts in other parts of the world are linked to success factors and core values; they form a set of balanced measures of a court's or court systems' performance; they focus on outcomes, that is, how well the courts are making things better as a result of their efforts instead of how much effort has been expended or by how many resources are used; they represent strategic planning in action; and, finally, they provide clarity and strategic focus to guide judicial leadership.

With the rapid advance of data analytics and business intelligence into judicial systems around the world, the capacity of courts to measure and manage their own performance has grown exponentially (Keilitz 2010). Court leaders and managers today can access and analyze performance data in seconds, what in the traditional world of courts would take weeks or months. It is not yet clear, however, to what extent courts have actually used performance data on a regular basis to guide planning, budgeting, strategy, and management decisions, a state of affairs that is probably true of governments in general, at least in the United States (Hatry 2010).

Judicial Independence, Transparency, and Accountability: The Law in Practice

In the United States, an independent judiciary is taken for granted as a matter of principle. Central to United States constitutional law is the doctrine of the separation of powers and the dynamic of checks and balances of three separate and independent functions of what we today see as the legislative, executive, and judicial branches of government. Article III of the United States Constitution vests judicial power in the third branch of government. The constitutions of 39 other States also *expressly* require that governmental power is divisible among three coequal separate branches. The function of checks and balances renders the judiciary dependent on the other two branches for resources. The purpose of this separation of powers is to prevent the concentration of governmental power and to provide for checks and balances.

Unfortunately, this constitutional framework and related legislative and policy mandates are not self-executing in practice, not in the United States or elsewhere throughout the world. There are few constitutions and laws, if any, that require judicial systems to be self-governing or specifically authorize the means to ensure that they are. Institutionally independent does not necessarily mean self-governing. As argued by some scholars, the difference between the United States, where self-governance is arguably more in evidence, and other judiciaries has less to do with prevailing theories of how popular sovereignty relates to jurisprudence and political theory but with the institutional capacities of courts to act independently in practice.

Three critical elements of modern democracies – and, arguably, the preconditions of a market-based economy – are a capable state, the state's subordination to the rule of law, and government accountability to its citizen. There can be little doubt that the ideas and principles underlying these elements that are enshrined in law are fundamental causes of why some states fail and others prosper. Yet, the "law on the books" is not sufficient (Dakolias 2005). It is, of course, important to know what the law established as formal practices, but this will not be enough to understand the reality on the ground. Creating remedies for case processing delay and court congestion, for example, requires examining causes beyond the law to organizational structure and practice including the size of demand for dispute resolution and the points in the processing of cases where perverse incentives might exist that are contrary to efficiency.

Rule of law reform, which has been underway throughout the world for quite some time, began with a focus on drafting and enacting laws, codes, and rules. These initiatives, however, soon gave way to attention paid to the "law in practice" as opposed to the "law on the books," as it became clear that laws are quite literally of little use if no efforts are devoted to establishing the means of their implementation and enforcement.

In a 2002 study of 75 countries, Lars Feld and Stefan Voigt looked into the effects of an independent judiciary (Feld and Voigt 2003). They distinguished between de jure independence (that expressed in formal law) and de facto independence (that which is implemented and enforced). Their de jure indicator was based on 12 variables made up of 23 characteristics concerning the legal basis for judicial independence (including institutional arrangements, appointments, tenure, salaries, and transparency). The de facto indicator based on eight variables measured over time in 75 countries shows the degree of judicial independence in practice (effective average term length, changes in number of judges, income, and court budgets). Not surprisingly, the main finding of the study is that judicial independence "on the books" is insufficient. They found that de jure independence was not correlated with economic growth, whereas de facto independence was conducive to economic growth. Indeed, de jure and de facto independence appeared to be almost completely unrelated, as there was no overlap whatsoever between rankings of the top ten countries examined.

Because courts traditionally have a greater degree of freedom from scrutiny compared to other public institutions, courts need to balance this independence with transparency and accountability for performance. As noted by the former president of the International Association for Court Management, Marcus Zimmer, judicial leaders often "fail to fathom that attaining such independence is conditioned upon their willingness to accept the commensurate levels of individual and institutional accountability." Institutional independence, he writes, means "having in place an accountable self-governance framework built on effective internal control and enforcement mechanisms to ensure the confidence of the other branches and the trust of the people in its capacity to independently administer justice" (Zimmer 2011, p. 138). Regular and continuous performance measurement addresses this need. Performance measurement promotes an independent judiciary by providing transparency and accountability.

The Performance Measurement Imperative

An imperative of value-oriented performance measurement and performance management folds well into a broad vision of judicial leadership of self-governed, well-managed, effective, and operationally efficient courts. This imperative rests on five basic assumptions that speak to the relationship between judicial leadership and performance measurement.

Performance matters. Successful leaders show a strong preference for outcome measurement that gauges the desired results of program of services instead of measures of inputs (such as the number of staff, costs, or hours worked by judges and staff). Nothing else really matters as much as results defined in terms of quality, that is, the achievement of good results as efficiently as possible. The quality of courts' success should not be measured by how many hearings are held or even by the number of cases that are resolved or by the number of programs and processes they call for. What matters are outcomes that matter to the people served by courts. Self-governance of courts should be organized for performance.

Effective performance measures focus on ends, not the means to achieve them. They emphasize the condition or status of the recipients of services or the participants in court programs (outcomes) rather than the internal aspects of processes, programs, and activities (inputs and outputs). They focus on results rather than quantification of resources or level of effort. Traditionally, court managers have relied on measures of volume or frequency in three categories: (a) amount of work demand (such as the number of cases filed), (b) number of products or services delivered (such as the number of cases filed), and (c) the number of people served. Increasingly, there is the recognition that while such measures show demand and how much effort has been expended to meet that demand, they reveal nothing about whether the effort has made any difference – that is, whether anyone is better off as a result.

Second, performance is not about the numbers. Performance measurement uses numbers, but it is not about the numbers. It is about the perception, the understanding, and the insight required of effective leadership. Ultimately, it is not the measure itself that is important, but rather the questions that it compels judicial leaders to confront (Spitzer 2007) questions such as:

- How well is the court, court system, or justice system performing?
- Where is the court now (performance level, baseline)? What is the current performance level compared to established upper and lower "controls" (e.g., performance targets, objectives, benchmarks, or tolerance levels)?
- How well is the court performing over time? Is performance better, worse, or flat? How much variability is there? (trend analysis)
- Why is this particular performance happening (analysis and problem diagnosis)? What happened to make performance decline, improve, or stay the same. What are some credible explanations?
- What is the court doing to improve or maintain performance levels? (planning future outcomes)
- What actions should be started, continued, or stopped altogether as a result of what the measure reveals? What should be done to improve poor performance, reverse a declining trend, or recognize good performance? (strategy formulation)
- What performance targets and goals should we set for future performance (goals)?

Third, courts must count what counts and measure what matters. Figuratively and literally, performance does not count unless it is related to the things that really matter and are critical to the success of a court. Key success factors have been referred to in the literature of organizational performance measurement as major performance areas, standards of success, perspectives, domains, performance criteria, key results factors, and key outcomes. Whatever they are called, they form the framework of a court's accountability and transparency to the public and other stakeholders.

Alignment of performance measurement with purpose and fundamental responsibilities is vital. Well-conceived performance measures serve to align an organization's efforts with the achievement of its mission. The requirement of linkage of performance measures to a court system's mission and strategic goals is vital.

Fourth, performance measurement is a powerful antidote for too much information. Information overload is one of the biggest irritations of modern life. And it seems to be getting worse. It can make justice system executives and managers feel anxious and powerless, reduce their creativity, and render them less productive. A profusion of phrases describe the anxiety and anomie caused by too much information: data asphyxiation, data smog, information fatigue syndrome, and cognitive overload. Surveys have found that most managers believe that the data deluge has made their jobs less satisfying or hurt their relationships. Some think that it has damaged their health. Many managers think most of the information they receive is useless. The explosion of information hitting the courts is going off within systems too fragmented and disorganized to absorb it. Performance measurement, supported by business intelligence tools like performance dashboards, is an antidote and a remedy to data fog. It focuses on what counts and filters out the rest.

Finally, measuring and managing court performance is an essential survival skill for court leaders and managers. The right performance measures effectively delivered are clear, unambiguous, and actionable. Focus and clarity are factors of effective leadership. Above all, leaders need to be clear. Performance measures such as clearance rates or court user/citizen satisfaction focus on a limited number of success factors like access, fairness, and timeliness of case processing. They count only what counts and measure only what matters.

The discipline of performance measurement provides a conceptual shortcut to a host of organizational competencies like strategic planning, resource management, and communication with stakeholders. The benefits of an effective court performance measurement and management system are the same, for example, as those of strategic planning – that is, accountability, consensus building, focus, coordination, control, learning, communication, hope, and inspiration.

To identify the right performance measures, a court system must address the same fundamental questions about guiding ideals, values, mission, goals, and broad strategies as it must address in strategic planning. When it identifies a core performance measure such as court user/citizen satisfaction with court services, for example, it communicates a clear, simple, and penetrating theory of its "business" – its ideals and purpose – that informs decisions and actions.

How Are We Performing?

The question *How Are We Performing*? lies at the heart of self-governance and effective leadership of courts. The capacity and political will to address this self-directed question regularly and continuously using the tools of performance measurement is the hallmark of a successful court organization. More and more court leaders and managers are turning to performance measurement to drive success. However, the trend is on a slow march impeded by two entrenched ways the judicial sector has tended to measure its success: (1) reliance on third-party monitoring and evaluations of court performance and (2) an adherence to a research paradigm for assessing court performance.

Self-governance, transparency, and accountability of courts will depend on the degree to which these two impediments are attenuated. Court leaders will need to champion and support the self-assessment of performance by courts, instead of relying on third-party evaluations. They will need to seek the replacement of the methodologies of the disciplines of *research* or *program evaluation* (or evaluation research), which have dominated justice sector assessment in the past, with that of *performance measurement and management*. These suggestions are consistent with the values, principles, and tools of the National Center for State Courts' High Performing Courts Framework (Ostrom and Hanson 2010), which is oriented toward United States courts, and the International Framework for Court Excellence (International Consortium for Court Excellence 2010).

Self-Assessment of Court Performance

As with most changes in life, self-directed change is the most meaningful and long lasting. Self-assessment, and not third-party monitoring and program evaluation (or evaluation research), is the hallmark of successful courts. It is integral to effective self-governance. A successful court has the capacity and the political will for self-directed rigorous performance measurement and management that addresses the question *How Are We Doing*? The "we" in the question suggests the critical differences between court performance measurement and third-party evaluations of courts.

Monitoring and Evaluation

Performance measurement is not yet the norm in the United States and around the world, though it has a strong foothold in the United States and large parts of the developed and developing world. Most assessments of programs, processes, and reform initiatives in courts are accomplished instead by monitoring and evaluations instigated and conducted by third parties, including funding agencies, donors, aid providers, and their agents (researchers, analysts, and consultants). The abiding concern of these third parties is return on their investments, and this concern does not necessarily align with the expressed purposes and fundamental responsibilities of courts, at least as these might be conceived by court leaders and managers, and in seminal authorities like the *Trial Court Performance Standards* (Keilitz 2000). For the most part, the focus of these third-party assessments is a specific initiative, program, or process (e.g., juvenile drug courts, small claims mediation, and summary jury trials).

Performance data produced by monitoring and evaluation efforts are used primarily in service of decisions to increase, decrease, or redirect funding or other support. While some performance data may be shared with courts and justice system, as a practical matter, most are collected, analyzed, interpreted, and used, first and foremost, by third parties, that is, funders, donors, aid providers, and their agents. The measures of success are defined and results interpreted by these third parties with little or no shared responsibility or accountability (ownership) by the courts or justice systems implementing the programs, processes, and reform initiatives.

Because of their time requirements and costs, these evaluation efforts are, at best, limited and generally unsatisfactory responses to the question *How Are We doing*? The research paradigm within which these third-party monitoring and evaluation operate makes the results less than responsive to the question. Large-scale studies can take 2–3 years before data reports become available. Therefore, the result of regular and continuous performance measurement by courts themselves is likely to be the major source of information for addressing the question.

Indexing Performance

Another type of third-party monitoring and evaluation of performance of courts takes the form of indexing of justice sector performance. Indexes are useful tools. The idea that complex things can be pinned down and quantified on a simple scale seems universally appealing. Indexes that reduce justice sector performance to a single number for purposes of comparing, ranking, and rating countries are being used throughout the world to understand everything from governance, corruption, economic vitality, health, and education to the quality of life. Governments and reformers are taking such indexes seriously. They are closely watched. “There is nothing,” wrote the *economist* in an October 9, 2010, report of the results of the Mo Ibrahim Foundation’s Index of African Governance, “like a bit of naming, shaming, and praising.”

The crowded field of performance indexes includes comprehensive indicators and indexes that encompass entire countries but include aspects of justice, like the Mo Ibrahim Foundation’s Index, and others more narrowly focused on rule of law like the World Justice Project’s *WJP Rule of Law Index*™ and the American Bar Association’s Judicial Reform Index. The World Justice Project’s *WJP Rule of Law Index*™ incorporates ten elements of the rule of law – such as limited government powers, fundamental rights, and clear, publicized laws – and 49 associated sub-factors that make general reference to various justice “systems” but reference to courts is conspicuous by its absence.

While the indexes are successful in getting people’s attention by “naming, shaming, and praising” the jurisdictions rated and ranked, buy-in of the leaders and managers of courts and court systems may be limited. Well-known indexes like the World Justice Project’s *WJP Rule of Law Index*™ and the American Bar Association’s (ABA) Rule of Law Initiative’s Judicial Reform Index might be seen to reflect the ethos of the sponsoring organizations, and not necessarily the values, purposes, and fundamental responsibilities of courts. Both of these well-known indexes rely heavily on polls of commissioned experts who assess the factors the third parties deem important to judicial reform.

Many court leaders and managers and most elected officials are interested in comparing courts. However, they are not enthusiastic about having such comparisons reported externally unless they stack up well against others (Keilitz 2005). Perhaps stemming in part by a broad interpretation of judicial independence that does not embrace transparency and accountability, many judges have a viscerally negative reaction to public reporting on the quality of judicial services, and some may be appalled that their judicial systems are ranked numerically by outside “experts” on the basis of what they perceive as misinformation.

Third-party assessment of performance, whether it takes the form of indexing or monitoring and evaluation, is the antithesis of self-governance. Because it is not self-directed by courts, it is not as likely to be embraced by its leaders and managers and lead to reform. As might be expected, when performance assessment is, or perceived to be, wholly initiated and executed by external organizations, more energy and resources may be expended by the leaders of courts and court systems on refuting poor evaluation results or low rankings than on developing strategies for sustained reform.

Performance Measurement

Both the disciplines of performance measurement and research adhere to the scientific method and use statistical thinking to draw conclusions. But, as already suggested above, performance measurement and research, or evaluation research, are vastly different in their purposes, functions, sponsorship, uses, and the way they are funded and structured. Sorting out the differences between them, and choosing to employ one over the other, is not just academic hairsplitting.

First, the *purposes* of the two disciplines are quite different. At a very fundamental level, the purpose of performance measurement is to answer the question *How Are We Doing*? in response to the demands for transparency and accountability from stakeholders and to provide a basis for improvement. Performance measurement can give clues to why outcomes are as bad or good as they are, but it cannot go the full distance of determining why things are as they are. Performance measurement can help to identify variations in performance and to isolate where and when those variations occur (e.g., an upward trend in the public's rating of the courts is largely due to attorneys' increased satisfaction with case processing timeliness after the court initiated electronic filing) so that decisions and actions can target improvements. It does not determine causes. Causal inference is the domain of research that helps us to understand why something has occurred. (Of course, an important value of performance data is to trigger in-depth evaluation research.) As noted above, the purpose of evaluation research in the justice sector, for the most part, is to answer the question "What has worked and what has not, and why?" in order to justify donors' or funders' investments various initiatives, programs, and processes.

Second, performance measurement and research differ in their *sponsorship and audience* – that is, who is doing it and for (or "to") whom. Performance measurement is done by the courts, for the courts. Results are made known to court leaders and managers. Distribution of performance data to the public and other stakeholders is done at the discretion and direction of the court, preferable in real (or near real time) in a wholly transparent manner. Evaluation research, on the other hand, is more often than not sponsored or instigated by third parties (e.g., administrative offices of the courts or funding outside agencies). At the extreme circumstances, courts and other justice sector institutions are mere "subjects" of the research. Those conducting the research have no compunction to share the research results with court leaders or managers except as a courtesy or as a quid pro quo for the courts' participation in the research.

Third, the *functions* of performance measurement are specific and targeted, that is, establishing a baseline for current performance, setting organizational goals and assessing whether performance is within determined boundaries or tolerances (controls), identifying and diagnosing problems, determining trends, and planning. Performance measurement is done for the utilitarian and practical purposes of making improvements in court programs, services, and policies. Court leaders and managers use performance information to make improvements in programs and services. Specifically, they might use performance measurement for a number of management purposes such as translating vision, mission, and broad goals into clear performance targets; communicating progress and success succinctly to the public and other stakeholders; responding to legislative and executive branch representatives' and the public's demand for accountability; formulating and justifying budget requests; responding quickly to performance downturns (corrections) and upturns (celebrations) with day-to-day resource allocation; motivating employees to make improvements in programs and services; setting future performance expectations based on past and current performance levels; and insulating the court from inappropriate performance audits and appraisals imposed by external agencies or groups. Evaluation research, on the other hand, seeks truth about the worth and merit of an initiative, program, or processes and is intended to add to our general knowledge and understanding, especially regarding future investments in those initiatives, programs, or processes.

Fourth, performance measurement and evaluation research adhere to different *design and data interpretation* protocols. Consistent with self-governance, performance measurement is focused on the performance of individual courts with the aim of individual accountability. Research, on the other hand, is interested in the generalizability of findings to all courts.

Of course, both performance measurement and evaluation research must adhere to the requirements of the scientific method. Both use quantitative and qualitative methods including surveys and questionnaires, interviews, direct observation, recording, descriptive methods, tests and assessments, and statistical analysis. But these requirements and methods are applied differently in performance measurement and evaluation research. For example, sample sizes may be smaller and levels of confidence lower in performance measurement primarily because replication of results is done on a regular and continuous basis as a critical matter of design. Evaluation research, on the other hand, is episodic. It is done when time and funds permit.

The matter of replication of results highlights a critical design difference between performance measurement and evaluation research. Basically, replication means repeating the performance measurement or evaluation research to corroborate the results and to safeguard against overgeneralizations and other false claims. Repeated measurements – that is, replication – on a regular and continuous basis are part of the required methodology of performance measurement. Analyzing trends beyond initial baseline measurement requires replication of the same data collection and analysis on a monthly, weekly, daily, or, in the case of automated systems, on a near real-time basis. In contrast, replication in research is a methodological safeguard that is universally lauded by scientists, but seldom done in practice.

Conclusion

Judicial leadership is the essential ingredient of the effective and efficient administration of courts. Effective judicial leaders fold the imperative of value-oriented performance measurement into a broad vision of self-governed, well-managed, effective, and operationally efficient courts. They are committed to transparency and accountability. They recognize that institutional independence and self-governance requires courts to be open and accountable. Effective judicial leaders focus on outcomes and use performance measurement as a tool to mobilize and inspire employees and other stakeholders and to drive improvements.

Consider how this relationship between leadership and self-governed, well-managed, and operationally efficient courts plays out in the minds of two successful judicial leaders, Christine M. Durham and Daniel Becker, the chief justice and the state court administrator of Utah, respectively:

> We in the courts should know exactly how productive we are, how well we are serving public need, and what parts of our system and services need attention and improvement. This includes measuring the accessibility and fairness of justice provided by the courts as measured by litigants' perceptions and other performance indices. And we should make that knowledge a matter of public record. (Durham and Becker 2011)

There is no doubt that to achieve a truly independent and self-governing judiciary requires vigorous judicial leadership to overcome resistance from various entrenched interests that view courts as not deserving or capable of self-governance. Most states in the United States today have some form of legislation requiring performance measurement of government institutions and agencies (see Lu et al. 2009). Who does it, how it is done, and whether it will lead to successful self-governance of courts will be determined by its leadership.

Juries, Lay Judges, and Trials

Toby S. Goldbach and Valerie P. Hans
Cornell University Law School, Ithaca, NY, USA

Overview

"Juries, Lay Judges, and Trials" describes the widespread practice of including ordinary citizens as legal decision makers in the criminal trial. In some countries, lay persons serve as jurors and determine the guilt and occasionally the punishment of the accused. In others, citizens decide cases together with professional judges in mixed decision-making bodies. What is more, a number of countries have introduced or reintroduced systems employing juries or lay judges, often as part of comprehensive reform in emerging democracies. Becoming familiar with the job of the juror or lay citizen in a criminal trial is thus essential for understanding contemporary criminal justice systems in many countries. This entry reviews procedures for selecting jurors and lay judges and outlines lay participation in fact finding and in sentencing phases of the criminal trial. It also assesses the promises and challenges of lay participation in law. Reviewing and evaluating the effects of the different approaches that countries have taken to incorporating lay citizens, it reflects on whether the goals of democratic deliberation are being met in both jury and lay judge systems. It concludes with suggestions for future directions for research.

Doing the Job of Democracy

The custom of employing ordinary citizens as legal decision makers in criminal trials is widespread. Originating in early legal systems, this practice has continued in modern times as a vehicle for including a democratic element in law. In approximately 50 countries, ranging from Australia to Kazakhstan to Spain and Sri Lanka, citizens serve as jurors, deciding cases in independent bodies separate from professional judges. In many other countries, such as Italy, Poland, and Japan, citizens participate as lay judges (alternately called lay assessors), deciding cases together with professional judges in mixed decision-making bodies. Whether citizens serve as jurors or lay judges often depends on whether the legal system derives from a common or a civil law tradition. Juries are more likely to act as independent decision makers in common law adversarial trials, whereas lay judges appear more often in civil law inquisitorial trials and tribunals (Thaman 2011).

Delegating the task of adjudicating a criminal trial to ordinary citizens promotes democracy in both legal and political institutions. Laypersons bring the voice of the people to the law. They draw on their own life experiences, allowing trial decisions to more accurately reflect the society that the legal system serves. This is a form of representative democracy in legal institutions (Malsch 2009). When the trial is finished, lay citizens return to the community, sharing the lessons they learned about the law, ensuring an accountable and transparent legal system.

Employing juries and lay judges supports and enhances democratic political institutions. Laypersons act as a check on authority. They balance the power imbued in state officials such as prosecutors or professional judges. And by contributing to decisions that directly affect the people, juries and lay judges engage in an act of self-governance, reestablishing the people's sovereignty. This act of self-governance in the legal realm affects political participation. As individuals perform the duties of a juror or lay judge, they become more connected to the world around them. The French political thinker Alexis de Tocqueville believed that jurors internalized the duties they owed to society and the role they ought to play in government. Writing in admiration of the US jury system, he observed that the jury communicates "the spirit of the judges to the minds of all the citizens" and that "this spirit, with the habits which attend it, is the soundest preparation for free institutions" (Tocqueville 1835/1945, p. 289).

Jurors and lay judges also act as conflict resolvers. They attend to the conflict between the state (as representative of the victim and the community) and the defendant by reaching a verdict in cases that may feature difficult and often complex competing narratives. And, depending on the jurisdiction or type of crime, lay judges and juries may participate in punishment decisions for convicted defendants.

Despite the important role that they play in the criminal trial, juries and lay judges face challenges on several fronts. First, critics argue that the evidence and legal arguments now being introduced in contemporary trials are too complex for untrained eyes. These critics question the lay participant's ability to understand new technologies and scientific methods such as DNA or mtDNA and accuse juries in particular of relying on expert credentials rather than evaluating the substance of expert testimony. A broad trend toward professionalization in the nineteenth and twentieth centuries deepened a mistrust of lay participation in the law and other expert domains. Professionals were thought to be superior to ordinary citizens because of their theoretically rich education, instruction in the practical skills of decision making, and greater adherence to rational scientific principles. Now, in a contemporary twist, modern technology invites new concerns about the soundness of lay decision making, with some worrying about jurors' use of cell phones or Internet to obtain information about cases and parties that would otherwise not be available in the courtroom proceedings (Waters and Hannaford-Agor, in press).

Moving from courtroom proceedings to posttrial coverage, a second concern about lay participation is evident in the way the public scrutinizes criminal trial verdicts. Media and members of the public often disparage jury decision making following controversial judgments, especially in cases where a notorious defendant is found not guilty. The popular press in the United States conveyed public outrage following verdicts of not guilty for O.J. Simpson and Casey B. Anthony, trials that were decades apart. Similarly, support for Spain's recently introduced jury system dropped precipitously following a jury's acquittal of a defendant who was on trial for killing two police officers (Hans 2008).

Remarkably, one of the greatest challenges to lay participation in legal decision making is the sharp decline in criminal trials. Despite a constitutional right to trial by jury, in the United States, plea bargaining and other settlements resolve almost all criminal cases. As a result, the number of jury trials has declined in both state and federal courts. Today, US juries decide just 5–10 % of all criminal cases. In the United Kingdom, the number is even lower, at 1 % of cases. In a surprising contrast, a number of countries outside the United States and the United Kingdom have recently introduced new lay participation systems, often as part of broad efforts to support emerging democratic systems (Hans 2008; Kovalev 2010; Marder 2011).

Historically, European countries transplanted all or part of their legal systems to their colonies. Thus, juries were found in legal systems in the United States and in British colonies in Africa, parts of India, Australia, New Zealand, and some Caribbean and South American countries (Hans 2008; Vidmar 2000). Several countries dismantled the institution postindependence, particularly where native populations saw jury verdicts as furthering the interests of colonizers or where the right to a jury trial was not extended to indigenous peoples. But now, citizen participation is seeing a rebirth, particularly in countries that are democratizing following periods of authoritarian rule (Lempert 2007). Notable examples include Spain, which began conducting jury trials in the mid-1990s, as well as Russia (Thaman 2011). In fact several post-Soviet countries, including Armenia, Kazakhstan, Ukraine, and Azerbaijan, enshrined a right to trial by jury in their constitutions (Kovalev 2010). The newly independent country of Georgia modeled its jury system on US juries and held its first criminal jury trial in the fall of 2011. In the last decade, East Asian countries enacted court reforms which created new and innovative methods of lay participation: Japan adopted a mixed court with lay judges, whereas South Korea introduced a jury system. Other countries, while not adopting the independent jury model, have altered their trial processes away from dossier-based inquisitorial approaches toward more adversarial oral evidence presentation to facilitate eventual citizen participation.

Becoming familiar with the job expected of jury and lay citizens is therefore essential for understanding contemporary criminal justice systems in many countries. This entry first describes the independent fact finding of jury systems and then turns to a consideration of mixed courts of lay and professional judges. It summarizes research evidence about how well lay decision makers function and reflects on whether the goals of democratic deliberation are being met. The entry concludes by considering contemporary challenges and future directions for research.

Juries at Trial

The trial by a jury of one's peers dates back to thirteenth-century England. These early juries were composed of land-owning white men, who testified about their personal knowledge of local disputes. Over time the institution changed so that jurors functioned less like witnesses and more like fact finders. In England, distinct roles for judge and jury developed in the 1700s. A similar evolution took place in the United States toward the end of the nineteenth century (Vidmar and Hans 2007). Formally, the judge determines the law and the jury applies that law to the facts as it finds them. However, in practice, the distinction between applying the law and finding facts is not always so clear.

A sketch of the jury trial reveals a handful of basic steps, starting with selecting individuals from a pool of persons summoned to serve on the jury (National Center for State Courts Jury

Topic Page). Once the trial is underway, the jury listens to the evidence presented and will alone make the decision about whether there is enough evidence to support a finding of guilt. If the defendant is found guilty, in some jurisdictions and some types of trials, the jury may be involved in sentencing the defendant.

Jury Selection

> A large government-funded organization is seeking 12 thoughtful people for group decision-making. Applicants must be willing to put their regular lives on hold for a year or more in return for low pay and zero benefits. Out-of-pocket expenses will not be covered (Butler 2007 p. B1).

This imaginary job advertisement for jury duty captures the challenges that confront judges and other tenured members of the court in their search for citizens to serve as jurors, particularly in lengthy trials. Selecting members of the jury, however, may be the most important stage of the trial because the jury's ability to inject a democratic perspective into the legal system depends on its composition. A jury drawn from a representative cross-section of the population is in a better position to express the full range of the community's views. Yet, for much of its history, juries have reflected the more privileged and elite segments of their communities. Men, whites, and those with more education, higher occupational status, and higher incomes were overrepresented on juries compared to their numbers in the population.

In the last several decades, jury commissioners have taken advantage of technological advances to reform the summoning process in order to achieve more representative groups of prospective jurors. Commissioners combine lists of potentially eligible residents and send out summonses for jury duty to residents living in geographically diverse areas. Some jurisdictions even use targeted replacement mailings to ensure representation from parts of the community that tend to have lower return rates. Governments have raised the compensation for jury service, especially for long trials when jurors may be away from their employment for a substantial period of time. While in many countries these methods still fall short of producing fully representative groups, they are a decided improvement over the past when jurors served based on personal recommendations or were handpicked by jury commissioners.

The process of summoning a large group of eligible jurors begins the trial. While the specifics vary across jurisdictions, typically both the judge and the attorneys are able to remove individuals before finalizing the jury that will ultimately decide the case. In the United States, the judge has the ability to decide "for cause" challenges to eliminate clearly biased jurors, whereas attorneys have a limited number of "peremptory" challenges that they may exercise without providing reasons. Other countries such as England and Wales do not permit peremptory challenges. The Korean system allows each side five peremptory challenges and an unlimited number of challenges for cause (Park 2010). In Canada, subgroups of jurors determine whether other jurors are impartial or should be removed for cause.

Providing a mechanism for removing apparently biased individuals from the jury helps to ensure the integrity and quality of the jury's decision. Nevertheless, opponents criticize the jury selection process, with some pointing to evidence that race and other impermissible factors infect it, and others doubting the ability of judges and lawyers to identify and remove biased jurors. In the United States, a robust field of jury consulting has developed to assist lawyers in selecting jurors; it is employed predominantly in high-profile criminal trials and with wealthy defendants (Tanovich et al. 1997; Vidmar and Hans 2007).

Juries as Fact Finders

During the trial, the jury acts as a fact finder, working through witness testimony, exhibits and the lawyers' arguments in order to uncover the facts of the case. Researchers interested in how juries process truncated and conflicting sketches of events use several theories to explain the jury's fact finding role. The most common theory is the "story model," in which jurors arrange the evidence into a narrative account. Other theoretical explanations focus on the psychological processes of anchoring and adjustment. Jurors anchor on their initial perception but adjust their opinion about the probability of the event having occurred as new evidence is presented at trial. A final theory is that jurors integrate information by weighing relevant information and combining discrete pieces of evidence. Ideally, jurors would evaluate the strength and weakness of evidence using relevant and impartial criteria. However, research indicates that factors unrelated to the strength of the evidence influence some juries. In the aggregate, jurors are more likely to attribute accuracy to eyewitness identification when a witness displays confidence, even though this is not an indication of reliability. As well, juries tend to give more weight to identifications made by police officers.

At its best, jury decision making embraces many of the features of deliberative democracy. Members of the jury hold a diverse set of viewpoints which can be brought forward and evaluated through reason-based discussion. Open discussion helps ensure that trial evidence is thoroughly evaluated, that rival explanations are examined, and that mistaken recollections are corrected. Through this process of deliberation and discussion, the jury reaches binding conclusions on the defendant's guilt or innocence. Empirical studies on group decision making confirm some but not all of the predictions of deliberative democracy theory. Studies show that groups outperform individuals in recalling facts, in correcting errors, and in pooling information. However, studies also show that during the deliberative process, once jurors are made aware of the majority view, they will tend to move in that direction, regardless of whether the view is to convict or acquit. Other studies indicate a leniency bias, where jurors in a numerical minority arguing for acquittal have more impact than a minority arguing for conviction. Either way, as the majority increases, so does the pressure on the minority to conform to the majority view.

Several studies reveal that judges and juries agree on the verdict in a substantial majority of cases, and that when judges and juries disagree, it is for reasons other than the difficulty of the evidence. A recent study of the first 3 years since the introduction of jury trials in South Korea confirms these findings (Kim et al. 2013). While in most cases judges and juries agree on the verdict – 91.4 % of the time in South Korea – when they do disagree, juries tend to be more lenient than judges, perhaps because they have a more generous interpretation of reasonable doubt, because they sympathize with the defendant, or because they disagree with the law. Judges' professional training and prior experience deciding criminal cases are also factors. The sizeable overlap between professional judges and juries should assuage concerns about jury incompetence. On the other hand, the research lends some support to beliefs that juries are more generous to criminal defendants than judges sitting alone.

Juries instantiate civic duty and their work strengthens legal and political institutions. Jurors report higher regard for the institution following their trial experiences (Diamond 1993). In a national survey of over 8,000 former jurors in the United States, 63 % reported that they were more favorable about jury duty after serving. Other studies similarly show enhanced regard for the courts and for judges after jury service. Surveys of jurors in South Korea's new advisory jury system show positive views of the experience (Park 2010).

Moreover, there may be a direct link between jury decision making and interest in politics (The Jury and Democracy Project website). A multidisciplinary team conducted research on the salutary effects of jury service on civic participation (Gastil et al. 2010). An initial study of Thurston County, Washington, residents found that jurors who took part in deciding the verdict at trial voted more frequently in subsequent elections than people who were called for jury duty but were dismissed, were alternates, or were on hung juries that could not reach a verdict. A follow-up study conducted nationwide included a sample of more than 13,000 jurors. This latter study found that jurors who had been infrequent voters were more likely to vote after serving jury duty. In this case, it didn't matter whether the jury had reached a verdict or not.

The job of serving as a juror in a criminal trial does, however, come with a cost. Jurors experience stress, especially following lengthy trials or in trials where the offense and potential punishment is severe (Anand and Manweiller 2005). In a 1998 study, jurors identified several sources of stress, including deciding on the verdict, jury deliberations, disruption to daily routine and dealing with lurid evidence (National Center for State Courts, 1998). A 2001 Canadian study revealed similar sources of stress, including reaching a verdict and the deliberation process. Canadian juries present a particular challenge for researchers, as they are prohibited by law from disclosing any information about jury proceedings. The closed nature of jury proceedings in Canada acts as an additional source of stress for these jurors, who are not able to process potentially emotional or difficult information with others (Chopra 2002). The responsibility placed on juries is particularly acute in murder trials. Jurors play a critical role in bringing legitimacy to punishments that take life or deprive liberty for life. However, murder trials can be lengthy and the evidence presented can be disturbing. For example, the multiple-victim murder trial of Robert "Willie" Pickton, who was suspected in the deaths of 26 women in British Columbia, Canada, lasted just over 9 months (Butler 2007). In order to address these issues, some courts provide psychological, psychiatric, or social work services to jurors following trial (Anand and Manweiller 2005; Chopra 2002).

Juries at the Sentencing Phase

Even if a jury decides the verdict, it is not necessarily involved in sentencing. For most types of crimes in most US jurisdictions, professional judges have the sole responsibility for sentencing criminal offenders. In six US states, jury sentencing is an option in felony trials and defendants may choose either judge or jury sentencing. However, in capital cases, most US states give the decision on whether or not the defendant should be sentenced to death to the jury. In Canada, juries do not participate in sentencing offenders. Murder convictions carry automatic life sentences, and for other convictions, judges determine the sentence bearing in mind sentencing ranges in the Criminal Code, the codified principles of sentencing, and previous similar cases. However, when a defendant is convicted of first- or second-degree murder charges, the jury can make a nonbinding recommendation of how long the defendant should remain ineligible for parole. In South Korea, juries decide on a sentencing recommendation and submit it to the judges. Similar to Canadian parole recommendations, Korean jury recommendations on sentencing are not binding (Park 2010).

Judges and juries will experience the task of sentencing offenders differently in the United States. In many jurisdictions, judges consider statutory ranges, sentencing guidelines, and typical sentences in similar cases as they determine an individual defendant's sentence. In contrast, states often limit the information jurors receive about the offense, the offender, and sentencing guidelines. In Virginia, juries but not judges must impose the statutory minimum sentence. Ironically, jury sentencing may reduce the use of juries at trial, as prosecutors use the prospect of unfettered jury sentencing to encourage defendants to enter a plea before trial (King and Noble 2004).

Lay Judges and Mixed Courts

In countries that follow the civil law tradition, lay judges (alternatively, lay assessors) sit in mixed courts and tribunals with professional legally trained judges. Lay judges serve jointly with professional judges in many European countries, including Germany, Austria, Denmark, France, Finland, Hungary, Italy, Norway, Poland, and Sweden, and in post-Soviet countries including the former Czechoslovakia and in countries of the former Yugoslavia (Hans 2008; Kutnjak Ivković 2007). Several new systems of lay participation use the mixed court model: for example, Japan's mixed court of lay citizens and professional judges, *Saiban-in Seido*, and Argentina's mixed court in Córdoba (Corey and Hans 2010).

Selection of Lay Judges

Similar to the way that jurors are selected, lay judges are ordinary citizens selected from a list of potential candidates who fulfill age, citizenship, literacy, or education requirements. For example, in Italy, lay judges must be Italian citizens of "good moral conduct," between the ages of 30 and 65 years, with at least a high school diploma (Catellani and Milesi 2006). Citizens with specialized skills may be sought for certain cases, such as offenses involving juvenile offenders. In those cases, lay judges may be expected to have parenting experience or a degree in education, psychiatry, social work, or sociology (Kutnjak Ivković 2007; Catellani and Milesi 2006). Some countries explicitly prohibit selection from among occupations with legal education or experience, such as professional judges, prosecutors, attorneys, or police officers; whereas in South Korea, soldiers, police officers, and firefighters are exempted from serving as lay judges because of the essential nature of their jobs.

Typically, a presiding judge or a commission of the court reviews lists of randomly selected candidates. Candidates who meet the legal requirements are appointed or elected and will serve for a period of time (Malsch 2009). The process of selecting lay judges may be more or less democratic and transparent. Citizens may elect lay judges to serve and sit on trials intermittently throughout a period of several years (Kutnjak Ivković 2007). On the other hand, in some countries, important members of the community such as mayors or municipal commissioners appoint potential candidates (Kaplan et al. 2006). To address transparency concerns, the president of the court in Italy posts lists of prospective lay judges in public places for members of the public to review.

In reality, the selection process can be political and can preference certain segments of the population. In Norway, a nomination committee picks candidates from among registered political party members. Some procedures or qualifications will favor middle-class citizens, leading to a disproportionate number of middle-class lay judges. And in countries with a large immigrant population, citizenship requirements may create tribunals that do not represent the population.

Lay Judges at Trial

The numbers of lay and professional judges who sit at trial differs across the various jurisdictions and often corresponds to the severity of the case, with larger tribunals sitting for more serious cases. In Japan, six lay judges and three professional judges decide guilt and sentencing in serious felony cases (Fukurai 2011), whereas in Poland, only three panel members try less serious criminal cases. Other countries have different combinations of lay and professional judges depending on whether the crime is a lesser crime or a more serious felony offense. For example, in Germany, two lay assessors and one professional judge sit for most criminal cases, whereas two lay and three professional judges try the more serious crimes. In South Korea, five to nine lay judges sit in mixed courts, with nine lay judges participating in cases where the defendant could receive the death sentence or life imprisonment. And in Italy, six lay judges and two professional judges hear cases where the defendant could be incarcerated for at least 24 years or life or where the crime is against the state (Catellani and Milesi 2006), whereas a law graduate appointed as an honorary judge for a term of 4 years can decide misdemeanor criminal cases. As in some of the panels noted above, lay judges may outnumber professional judges.

In many mixed court systems, lay judges decide all of the factual and legal issues in conjunction with the professional judges. This is not the case, however, in Japan. There, only the professional judge has the authority to determine questions of law and procedure. It is typical for a professional judge to control the trial. For example, a presiding professional judge may determine the trial date and summons the defendant and witnesses. In certain courts, the presiding judge will examine the witness before other members are allowed to speak. Lay judges can usually take an active role in the trial if they are so inclined. They may examine the evidence and question the witnesses including the defendant, either directly or indirectly through the professional judge.

The mixed court trial will work best when lay judges actively participate. Research indicates that professional judges, the presiding judge in particular, have a role to play in facilitating active lay participation. Lay judges are more likely to ask questions and participate in deliberations when encouraged to do so by professional judges. Lay judges are also more likely to be active during the trial and deliberations when they have special expert or technical knowledge that relates to the issues at trial. These were the findings of observers of mixed courts in Croatia, who noted that while expert lay judges were active at trial, regular lay judges asked questions only infrequently (Kutnjak Ivković 2007). This research also found that the legal professionals, the lawyers and judges, had more respect for the expert lay judges.

Access to the case file or dossier affects the extent to which lay judges are able to do the work of assessing the evidence at trial. Germany prohibits lay judges from reviewing the case dossier and in France, only the presiding judge has access to the dossier (Hans and Germain 2011). Studies of mixed courts in Poland found that even though lay judges were allowed access to the dossier, most did not read the file. Access to the case dossier, laudable if one seeks equality of information between lay and professional judges, is nonetheless controversial in that it is prepared by the prosecution and often contains potentially biasing information such as a defendant's criminal record. Moving from a dossier-based trial to oral presentations, as was done in Japan, tends to equalize the information available to lay and professional judges.

Several jurisdictions have formal rules about the deliberation and decision-making processes to ensure full and fair contributions by citizen participants. In Japan, the judgment must be agreed upon by a majority of the panel, with at least one citizen and one professional in the majority. Norwegian lay judges must consent to the decision written by the professional judge (Malsch 2009). Other jurisdictions may provide for lay judges to vote on guilt or innocence before the professional judges give their verdicts. Research has shown, though, that even with formal requirements, lay judges often agree with professional judges, and rarely use their larger numbers to outvote them. A study in Sweden found that lay judges outvoted the professional judges in only 1–3 % of all criminal cases. In cases where lay judges disagree with professional judges, it is the lay judges who are likely to modify their opinion to resolve the disagreement (Kutnjak Ivković 2007).

Nevertheless, lay participants tend to be positive about their experiences, just as jurors usually are. More than 85 % of Croatian lay judges had positive opinions about their participation. And in a study of Japanese citizen participation, 94 % of the lay judge respondents reported having a positive experience. Lay judges believe they have a substantial and beneficial impact on verdicts. A study of German lay judges indicates that most respondents felt that the court would have decided differently "in a few cases" and only 20 % responded that the court's decision would have been the same without the participation of lay judges.

Even though lay judges serve at the trial level, in most countries, appeals are decided by panels of professional judges only. Some exceptions include Sweden, which uses lay judges at the appellate level, but with a greater number of professional judges sitting on the panel, and France and Italy, which allow lay judges to serve in appeal courts. Lay judges can also sit on certain post-conviction reviews in Germany.

Sentencing Circles

Another way that laypersons participate in the criminal trial is through sentencing circles (Goldbach 2010). In Canada, sentencing circles modeled on Aboriginal healing circles are being used at the sentencing phase of a criminal trial for adult offenders and in juvenile diversion programs, as a way to encourage Aboriginal participation in the criminal justice system. Sentencing circles allow for a more restorative justice approach to sentencing, one that focuses on moral growth, constructive resolution of differences, and empowerment of individuals and the community to take responsibility for harm done.

The Canadian Department of Justice funds approximately 275 community-based justice committees which provide all levels of criminal justice support. In these communities, the justice committee works with the court to decide who will participate in sentencing circles and to identify a local community leader to act as keeper of the circle. In most cases, criminal justice participants, including the judge, the Crown prosecutor, defense counsel, the court reporter, the offender, the victim, and their respective families, form an inner circle. This inner circle can also include probation officers, court workers, youth workers, or police officers. Surrounding that circle is an outer circle of friends, relatives, and interested members of the community. Participants develop recommendations for sentencing and present those to the judge. The procedure can be lengthy and demands substantial commitment from victims, defendants, and the community.

Aboriginal communities participate in sentencing circles to construct sentences for such crimes as aggravated assault, assault causing bodily harm, robbery with violence, criminal harassment, breaking and entering, and arson. Judges are less likely to allow a request for a sentencing circle following conviction of murder or manslaughter. The use of sentencing circles is controversial, particularly in cases of domestic or sexual assault (Dickson-Gilmore and La Prairie 2005). However, this turn to community sentencing reflects a trend in Canada and in other jurisdictions encouraging greater victim and community involvement in all parts of the criminal justice process, as well as a move away from incarceration and retributive justice toward more restorative sentencing approaches. For example, in Canada, the form that the punishment takes following a sentencing circle may involve a conditional sentence, where the offender serves the sentence in the community and undertakes to fulfill certain conditions such as doing community service or enrolling in drug or alcohol treatment programs.

Controversies

Sentencing circles, mixed courts, and juries share similar problems and are confronted by overlapping critiques, which are in large part due to apprehension over lay persons participating in criminal trials. Concerns about lay competency to grasp complicated legal and factual issues are common to both jury and mixed trial systems. Similarly, both juries and lay judges face obstacles in accessing the full array of information that is available to professional judges. Lay judges in mixed courts confront the additional challenge of having to overcome professional judges' control of the hearing and deliberation processes. On the other hand, independent juries are under pressure to make decisions about guilt or innocence on their own, and both jurors and sentencing circle participants must determine punishment without the benefit of the germane experiences or expert knowledge that professional judges possess.

Research offers some reassurance. Studies indicate that lay participants are able to understand complex issues and often match judges in the accuracy of their decisions. In addition, studies show that reforms of the trial system, such as allowing note taking, asking questions, mid-trial deliberations, and the use of notebooks to organize the evidence, can increase the quality of lay citizen fact finding. Other controversies, however, are less easily resolved. Even when procedures are enacted to ensure active participation, lay judges arguably play a minor role in mixed courts. And research confirms that juries are influenced by pretrial publicity about a case, by defendant characteristics such as criminal record, and by preexisting biases about particular types of crimes. It should be noted that professional judges are not immune to some of the same influences. However, judges are generally required to produce written reasons which are thought to protect against biased or arbitrary decisions. Following this line of thinking, in 2009, the European Court of Human Rights (ECtHR) overturned a jury conviction in Belgium, finding that the jury's failure to provide reasons violated the defendant's right to a fair trial under the European Convention of Human Rights (ECHR). To meet human rights requirements, jury verdicts must be justifiable in some fashion (Thaman 2011). Although the Grand Chamber of the European Court observed that the decision was not a general indictment of jury systems, merely an objection to the jury trial procedure in the specific case, it remains to be seen whether this will trigger a widespread call for juries to produce written reasons in Europe.

Two additional controversies that have not yet been discussed are worth reviewing. The first is the problem of wrongful or erroneous convictions that become apparent when exculpatory DNA or other evidence comes to light. Juries in particular are at risk of being portrayed as error-prone and overly eager to convict when it comes to attributing blame for the conviction of an innocent defendant (Vidmar and Hans 2007). Thaman (2011) suggests that requiring juries to give reasons for their decisions would protect against convicting innocent defendants. Yet research shows that the most frequent cause of wrongful conviction, found in roughly 75 % of the cases, is mistaken eyewitness identification. A second important cause is false confessions. Thus, in the overwhelming majority of cases where a defendant is cleared by DNA evidence, the contributing factors relate to the evidence presented, not the jury's decision-making ability. Research through the Innocence Project in Toronto, Canada, illustrates systemic pressures at the trial and investigation stage, either because a particular case has a high profile or because of other institutional pressures (Martin 2002). This research suggests that a pressure to convict creates a bias in favor of building a case as opposed to solving the crime, which in turn shapes how police gather evidence and may even lead officials to disregard or suppress exculpatory evidence.

A second troubling controversy relates to capital punishment cases. Yet here too the problems are largely located in trial and court procedures as opposed to the fact of lay participation. In the early 1970s, the US Supreme Court struck down all state death penalty statutes because of evidence of arbitrariness, inconsistency, and racial bias in capital punishment decisions. Unfortunately, at that time, juries were given little guidance as to how to arrive at the decision to order a death sentence. Presently, state statutes require that juries consider or find certain aggravating circumstances before a death sentence can be ordered, reducing the impact of discretionary decision making.

Jury selection in death penalty cases, however, continues to be a problem for fair and equal decision making. Where the prosecution intends to seek the death penalty, only those jurors who are willing to impose a death sentence are considered to be fair and impartial. Yet research indicates that these individuals are more prone to convict. So-called "death-qualified" juries are more likely to believe the prosecution and have a general crime-control orientation which shapes their evaluation of the evidence. Analysis of capital case outcomes in the USA reveals that the sentence is related to the race of the victim, with black defendants who kill white victims more likely to be sentenced to death than other race of defendant-race of victim combinations. Nonetheless, the political, legal, and ethical justifications for including citizen input in a decision to sentence a defendant to death continue to be compelling. The US Supreme Court confirmed the importance of jury determinations in *Ring v Arizona* (2002). That decision held that in a capital jury trial, at a minimum, the jury and not the judge must decide the elements that make a case eligible for the death penalty, whether they are components of the criminal offense or additional aggravating factors.

Conclusion: Future Research

In the early decades of the twenty-first century, the role of citizen decision making in legal systems worldwide is at an interesting juncture. In many countries like the United Kingdom, the United States, and Canada, where juries have been a prime fact finder for centuries, the jury lives on as a potent symbol of democracy even as the number of jury trials declines. Jurors are largely positive about their experiences and studies indicate that participation on juries increases civic activity. Similarly, lay judges in mixed courts report being positive about their contributions, even though they tend to play secondary roles compared to the professional judges. Systematic research, from surveys of judges and juries in the United States in the 1950s to data collected on juries in South Korea between 2008 and 2010, supports the basic soundness of lay decision making in that it corresponds considerably to professional decision making. On the other hand, research also reveals that sources of bias continue to influence both lay and professional decision making in law.

More recent experiments with juries and mixed courts of professional and lay judges present new opportunities for democratic decision making in a host of countries. These new systems also offer potential for greater theoretical understanding and systematic scientific study. Research already underway in these countries will tell us much about what difference it makes to include laypersons in legal decision making. Because lay participation systems are introduced at particular points in time, researchers may be able to pinpoint their effects more precisely than has been possible in countries with long-standing jury and mixed court systems.

Although there is now research on how jurors and lay judges react to their experiences, how the presence of lay citizens affects criminal defendants is largely unexplored. Advocates of sentencing circles propose the use of restorative justice approaches based on the assumption that the community's active participation in sentencing assists in rehabilitating the criminal defendant. This reasoned connection between democratic, accessible legal institutions and defendants' experiences is theoretically robust and suggests several research questions. Are defendants more willing to accept the verdict or punishment when recommendations or decisions are made by lay members of the community rather than by professional judges? Does the inclusion of lay perspectives increase or otherwise affect perceptions of procedural justice? These questions connect the conduct of trials with justifications for criminal punishment and therefore deserve further investigation.

Jury Decision Making and Eyewitness Testimony

Amanda S. Nicholson, Angela M. Yarbrough and Steven D. Penrod
Department of Psychology, John Jay College of Criminal Justice, The City University of New York, New York, NY, USA

Overview

Jurors are assigned the arduous task of examining and processing copious amounts of evidence – in light of their legal instructions – to determine an appropriate verdict. While jurors do a relatively good job at sorting through the evidence and the law, the complex nature of evidence may lie outside jurors' "common knowledge," and additional education may aid jurors as they process such information. This is especially true in the domain of eyewitness testimony. Eyewitness testimony is extremely influential despite its potential to be unreliable. Eyewitnesses may appear very confident in their identification of the perpetrator, yet be completely mistaken. Indeed, over 75 % of wrongful convictions overturned due to DNA testing have been linked to faulty eyewitness identifications. Unfortunately, traditional safeguards, such as cross-examination of eyewitnesses, result in little improvement in jurors' ability to discriminate between accurate and inaccurate eyewitness identifications. This has led the courts to establish additional safeguards against wrongful convictions based on faulty eyewitness identifications including the use of expert testimony and detailed instructions on how to evaluate eyewitness testimony.

Jury Decision-Making Research

Understanding how jurors make decisions has been a topic that has interested social scientists for the better part of a century. Legal decision making has been studied by examining both group-level deliberations and individual juror decisions. At the group level, deliberation styles have been characterized as either evidence or verdict driven. Evidence-driven deliberations typically entail reconstructing the chain of events and focusing on the evidence presented before determining a verdict. On the other hand, deliberations that are verdict driven tend to be shorter and involve an immediate vote followed by discussion that is centered on how the evidence supports the verdict options. Unfortunately, deliberations in general do little to remedy mistakes or improve evidence and instruction comprehension. However, 12 member juries (as opposed to six) appear to result in more diverse jury composition, more accurate recall of trial testimony, and increased satisfaction among jury members (Saks and Marti 1997).

Because of the cost and time required to conduct research involving juries, the bulk of legal decision-making research focuses on individual jurors. One of the most popular cognitive theories is the Story Model, which takes into account individual jurors' attitudes and beliefs. Jurors proceed through three stages during the course of a trial. First, jurors develop one or more stories based on evidence presented during the trial that are supplemented by personal knowledge of similar events and individual beliefs and attitudes. Second, jurors are provided with judge's instructions that explain the verdict options available to them and the required elements for a finding of each verdict. Finally, a categorical decision is made based on the best match between a chosen story and verdict options available. Story construction is the focal point of this theory and is what will determine one's verdict choice.

Broader cognitive theories have also been applied to juror decision making. For example, dual process theories propose that people process information more or less thoroughly depending upon an individual's motivation and ability to understand such information. Jurors may be overwhelmed by large amounts of information. For example, expert testimony often entails complex information that is difficult to understand. When jurors defer to heuristic cues when evaluating the testimony. Heuristic cues, such as source attractiveness or length of testimony, do not directly contribute to the overall quality of the argument. Jurors should be relying on the clarity and strength of the experts' argument, but if they are unable to assess these features, they may rely on more superficial factors. An eyewitness expert, for example, may present scientific research to the jury outlining what factors may increase or decrease the reliability of eyewitness identifications. If this research is too difficult for jurors to understand, or so lengthy that they lose motivation to process the information, they may not absorb the message the expert is trying to present. However, if the expert presents information in a way that is understandable and interesting to the jurors, they will be more likely to systematically process the information and use it to assist with their evaluation of the eyewitness testimony presented at trial.

Eyewitness Research

Eyewitness testimony can be powerfully persuasive evidence. To the detriment of innocent defendants, such testimony is often damning. Extensive research has determined a variety of factors that may explain how misidentifications can occur.

Research on factors influencing the accuracy of eyewitness identifications has examined two types of variables: *estimator variables* and *system variables*. *Estimator variables* are situational variables associated with the crime, eyewitnesses, and perpetrators that can only be considered after the fact to evaluate the quality of the identification. *System variables* are variables related to police procedures dealing with lineup administration. Both system and estimator variables can impact the reliability and quality of eyewitness identifications and their accuracy.

Estimator variables are outside the control of the criminal justice system. For example, the viewing conditions experienced by the witness when they saw the perpetrator can influence the ability of the witness to later make an accurate identification. Conditions include lighting at the time of the witness' viewing, the witness' distance from the culprit, and the length of time the witness had to view the culprit.

A number of witness characteristics can impact the reliability of eyewitness testimony aside from any situational factors. For example, young children and the elderly appear more likely to make a mistaken identification compared to young adults. In addition, cross-race identifications are less accurate than identifications of culprits who are members of the same race as the witness (Meissner and Brigham 2001). People who witness crimes under high stress are less likely to make accurate identifications than witnesses who are not under stress (Deffenbacher et al. 2004). Furthermore, memory for an event may be limited when a weapon is present as attention is focused on the weapon and shifted away from the perpetrator (Steblay 1992). Lastly, the amount of time between witnessing the event and identifying the individuals is another important consideration in the accuracy of eyewitness testimony as memory deteriorates quickly for details of the event and perpetrator.

During the identification procedure, there are several important factors that can act as indicators of accuracy. For example, the speed at which a witness makes an identification is associated with witness reliability. Quicker identifications tend to be more accurate (Wells and Olson 2003). Perhaps the most important research regarding estimator variables is on eyewitness confidence. Although people commonly use the confidence level of an eyewitness to evaluate the reliability of eyewitness testimony, confidence is not highly correlated with accuracy (Sporer et al. 1995). In some situations the confidence of a witness can be a better predictor of accuracy, as when the confidence rating is taken directly after an identification. However, the most important manner in which the confidence-accuracy relationship is of concern is in relation to how confidence can be impacted by confirmatory feedback (Bradfield et al. 2002) or by a biased lineup (Charman et al. 2011). Confidence is malleable and susceptible to suggestive procedures used by lineup administrators. For instance, witnesses express higher levels of confidence when they receive feedback that they have correctly identified the suspect than when they do not receive this feedback (Bradfield et al. 2002). This occurs regardless of whether the witnesses' identification was accurate or not. Thus, if an identification is inaccurate and the witness receives positive feedback, they will appear more confident to a jury, but actually be mistaken about the identification.

System variables are typically under the control of the criminal justice system. Most often, these variables refer to procedures employed by the police when administering a lineup. There are a variety of biases related to lineup administration, specifically lineup composition, instructions, and presentation method in addition to the behavioral influence of the administrator that has the potential to cause suggestive lineups.

Foil bias occurs when the "foils" or the members of the lineup that are not the suspect (also known as "fillers") do not match the original description provided by the eyewitness (Charman et al. 2011). A distinction must be made between choosing foils that are similar to the suspect and those that are similar to the description provided by the eyewitness. In order to create a fair lineup, the police will often choose foils that look similar to the suspect. While this seems like a reasonable way to make sure that witnesses do not disproportionately identify suspects because they "stand out" in an array, there are several reasons why this matching strategy may be a problem. If foils are chosen based on their similarity to the suspect, the question arises about how similar the foils should be. If a witness is presented with a lineup consisting of almost identical individuals, the lineup task will be too hard, and there is the potential for a large number of false rejections or errors. When a witness provides the police with a description, they are not providing the police with an exact picture of the suspect. The witness may mention the suspects' hair color, eye color, height, weight, or distinctive tattoos or scars. If foils are chosen based on this short list of characteristics, the members of the lineup will differ from each other on a variety of characteristics the witness did not describe to the police. This raises the chances that the eyewitness can correctly identify the perpetrator – but not as a result of suggestiveness created by the police. According to a survey of experts in eyewitness research, 71 % felt that research on foil bias was consistent enough to present in court (Kassin et al. 2001).

Instruction bias is another type of bias that can occur with lineup administration. When using *biased instructions*, the lineup administrator does not explicitly instruct the witness that the suspect may or may not be in the lineup. Failing to provide this information implies that the suspect is present in the lineup, which has the potential to put pressure on the witness to make a choice from the lineup. *Unbiased instructions*, on the other hand, inform the witness that the suspect may or may not be present in the lineup. They also inform the witness explicitly that if they are uncertain about the identity of the suspect, they have the ability to reject the lineup. These instructions have been demonstrated to result in more accurate identifications (and particularly reduce mistaken identifications) as compared to biased instructions (Steblay 1997).

Presentation bias in lineup administration deals with how the various photographs in a lineup are displayed to the witness. In *simultaneous lineups*, all the photographs are displayed to the witness at the same time. The witness may be inclined to compare the photographs and choose the person who most closely resembles their memory of the culprit. However, this "relative judgment" procedure increases the likelihood of a false identification when the perpetrator is not in the lineup. *Sequential lineups* involve showing the witness one photograph at a time. This forces the witness to compare each face to their memory and use an "absolute judgment" when deciding each time whether the photograph is the culprit they remember or not. The sequential lineup presentation procedure results in fewer false identifications with only a modest reduction in the number of suspect identifications – and those lost identifications are likely the result of reduced guessing by witnesses (Wells et al. 2011).

Double-blind administration of lineups is another important method for reducing inaccurate eyewitness identifications. A number of researchers have recommended this method for improving the accuracy and eliminating biases associated with lineup administration (Greathouse and Kovera 2009). *Double-blind administration* of a lineup means that the person administering the lineup to the witness does not know who the suspect is. If the administrator is aware of the identity of the suspect, they may communicate this information unconsciously to the witness through subtle means (i.e., hesitations, pauses, smiles). They also may provide biased feedback to the witness that can affect confidence judgments of that witness going forward. If they are aware of the suspects' identity, they may inform the witness they were correct in their identification, which has the potential to increase future confidence assessments of that witness. Double-blind procedures can eliminate these biases and prevent the possibility that the lineup administrator intentionally or unintentionally communicated their belief in the suspects' guilt during the identification procedure.

How familiar are jurors with the factors that influence eyewitness performance? In order to answer questions about how much lay jurors know and understand about factors that affect the reliability of eyewitness identifications, Desmarais and Read (2011) performed a meta-analysis of various surveys concerning lay knowledge of eyewitness issues. Although laypeople understood more about factors affecting the accuracy of identifications than expected, the authors still concluded that "75 % of the eyewitness factors reviewed herein are 'beyond the ken' of potential jurors" (Desmarais and Read 2011, p. 209). They then concluded that jurors would be assisted in their decision making by expert testimony on these factors. These findings suggest that one way to improve the evaluation of eyewitness testimony by jurors should be to educate them about factors affecting the reliability of eyewitness testimony.

The Efficacy of Traditional Safeguards

Given the various issues with eyewitness identifications, there are obvious concerns about the impact eyewitness testimony will have on jurors in court. To help jurors make sound verdict decisions when eyewitness testimony is involved, the courts have devised a number of methods for sensitizing jurors to factors affecting eyewitness identification accuracy. There has been some debate about the respective efficacy of these various safeguards, but overall it appears these safeguards are not as effective as the courts intended.

Some potential safeguards that occur before a trial begins are *jury selection* and *voir dire*. Before a trial, both the defense and the prosecution have the opportunity to remove jurors from the courtroom that may be hostile to their case or biased on some issue relevant to the trial. This procedure typically involves the judge, prosecutor, and defense attorney interviewing potential jurors to determine whether they are biased. If a potential juror is biased on an issue relevant to the trial, the defense or prosecutor may bring this to the attention of the judge. It is then up to the judge to determine whether they will remove the juror from participating in the jury by exercising a *for-cause challenge* or whether they will attempt to *rehabilitate* that juror and remove their biases. The judge in the case may then ask the juror if they can make a decision about the outcome of the case putting aside their particular biases. The judge will then determine, based on that juror's response, whether they believe that a juror can be rehabilitated. If the judge thinks that juror cannot put aside their biases and decide the case in an unbiased manner, the juror will be dismissed. If the judge does not dismiss a juror, the defense or prosecution may excuse the juror using one of their limited number of *peremptory challenges*.

Another potential safeguard against erroneous convictions is cross-examination of witnesses. Cross-examination is considered the traditional method to prevent unreliable evidence from impacting jurors. It is expected that whatever weaknesses exist in the prosecutor's case will be exposed by the defense attorney through cross-examination (and vice versa). Eyewitnesses are like other witnesses in that they can be questioned by the opposing counsel. In order for cross-examination to be effective, both attorneys and jurors need to possess some degree of knowledge about eyewitness issues. An attorney must know what factors impact the reliability of eyewitness identifications in order to identify such weaknesses in the witness' testimony. Yet describing eyewitness problems for the jury is fruitless if jurors are not sensitive to these issues. Jurors may have difficulty believing information that is contrary to beliefs they have already developed about eyewitnesses, especially if that information is provided to them by a potentially biased defense attorney.

The adversarial nature of cross-examination renders it ineffective as an educational tool for jurors, thus creating a need for some other way to disseminate information about eyewitness issues to jurors. The final two safeguards – *judicial instruction* and *expert testimony* – involve expert advice. *Judicial instruction* is typically used to inform jurors about what evidence they should and should not use when making a decision. Often, a judge will issue an instruction informing jurors to ignore any media coverage of the trial and to avoid using information from media sources when making a decision. Judicial instruction may also be used to instruct jurors to ignore any inadmissible evidence from entering verdict decisions. Judicial instructions are largely ineffective in persuading jurors to disregard inadmissible evidence (Steblay et al. 2006). However, one study found that jurors were more likely to disregard inadmissible evidence if told that the evidence was inadmissible because it was unreliable, rather than if its inadmissibility was due to the fact that it was obtained illegally (Kassin and Sommers 1997). The results of this study suggest that judicial instructions informing jurors about reliability issues with eyewitness identifications could cause them to question the reliability of identifications.

Although standard pattern judicial instructions are regularly used in all cases, recently courts have been supporting the use of case-specific instructions on eyewitness testimony. These instructions would be in place to educate jurors on factors affecting the reliability of eyewitness identifications in a specific case. General eyewitness instructions have existed for

40 years – *US v. Telfaire* (1979). The *Telfaire* instruction was created by the courts to address the problems with eyewitness identifications, but this instruction has not been particularly effective in sensitizing jurors to factors affecting the reliability of eyewitness identifications. Revised instructions may be more effective in educating jurors. Whether such instructions will work is an open question – most research has found judicial instruction to have little to no effect on jurors' verdict responses. Furthermore, it is reasonable to predict judicial instructions may, for the most part, have a skepticism effect on potential jurors. If jurors are informed by the judge about the unreliability of eyewitness evidence, they may assume that the judge believes the identification to be unreliable. Despite these caveats, some courts (e.g., *New Jersey v. Henderson* 2011) are advocating for case-specific instructions that will focus on reliability issues at play in a given identification. It is possible that the proposed judicial instructions will assist jurors in evaluating the reliability of eyewitness evidence, but as yet, none have demonstrated success in sensitizing jurors to the differences between reliable and unreliable identifications.

The most strongly supported safeguard against eyewitness misidentifications affecting jury verdicts is expert testimony. Expert testimony can increase jurors' sensitivity to eyewitness issues. Experts on eyewitness research and human memory are most often hired by the defense to speak to the court and jury about the factors that impact the accuracy of eyewitness identifications. Expert testimony typically focuses on specific system and estimator variables relevant to the case at hand. Support for juror sensitivity has been mixed. However, given the low level of lay knowledge about eyewitness issues, as outlined in Desmarais and Read (2011), expert testimony may serve as a useful educational tool to help jurors understand eyewitness issues. Those authors recommend expert testimony as the most effective safeguard, highlighting that the educational component may make up for the relative lack of knowledge jurors have about eyewitness issues.

Current Controversies and Issues with Eyewitness Research

Research on juror decision making, particularly experimental jury simulations, has been criticized for a variety of reasons. These reasons include the low stakes involved in mock jurors' decisions, the lack of ecological validity, use of college samples, and the lack of deliberating groups. Of course, it is simply unethical and impractical to manipulate variables in actual court cases that could impact the outcome for research purposes. However, the quality and verisimilitude of trial materials used when conducting stimulation studies has continued to improve. Additionally, in a review of the existing literature, Bornstein (1999) found few differences between college student and community samples serving as mock jurors. Overall, the results of posttrial surveys of actual jurors tend to corroborate the findings of stimulation studies, thereby increasing its validity. Still, the courts have been slow to embrace the research despite much consensus among experts regarding the findings.

While most courts have been slow to rely on psychological findings, the New Jersey Supreme Court in *New Jersey v. Henderson* goes as far as any court ever has in embracing psychological research regarding eyewitness identification. The court in *Henderson* appointed a Special Master to hear testimony from experts on human memory and eyewitness identification. Drawing on the Special Master Report, the court exhaustively reviewed eyewitness identification research and the general acceptance of this research among experts.

The *Henderson* court decided to modify the existing criteria used to determine eyewitness identification admissibility in pretrial hearings. These criteria were based on *Manson v. Brathwaite* (1977) which resulted in a two-pronged test. First, courts determine whether suggestive police procedures were used to secure an identification. If suggestive action was taken, the reliability of the identification must be assessed by reviewing the opportunity of the witness to view the criminal at the time of the crime, the witness' degree of attention, the accuracy of his prior description of the criminal, the witness' certainty, and the time between the crime and the identification – criteria initially outlined in *Neil v. Biggers* (1972). *Manson* made it clear that identifications can still be admissible despite the presence of suggestive procedures when the identification is deemed reliable according to the five criteria. The defendant has the burden of demonstrating the identification was made under suggestive circumstances that the police improperly created *and* is unreliable based on the totality of the circumstances.

Extensive research conducted since 1977 has demonstrated that the criteria are incomplete and inadequate measures of reliability. In addition, three of the five reliability criteria in *Manson* are, themselves, influenced by the presence of suggestion (i.e., the witness' certainty, witness reports about opportunity to view, and witness reports about degree of attention). Recognizing these deficiencies, the New Jersey Supreme Court ruled that when an identification is challenged by a defendant, all relevant system and estimator variables should be reviewed, including suggestive factors that may not involve police action, such as lightning and distance. If the defendant is unable to demonstrate a strong likelihood of misidentification, the jury will be charged with the task of determining whether the identification was reliable based on the evidence presented in court. Because juries tend to overestimate the accuracy of eyewitnesses and are unfamiliar with the literature establishing the influence of multiple factors on identification accuracy, the court directed a committee to develop new jury instructions addressing case-specific eyewitness identification factors. Unfortunately, as noted above, the effectiveness of these instructions has not been empirically demonstrated.

Relative to New Jersey, the US Supreme Court in its review of *Perry v. New Hampshire* (2011) was not as receptive to eyewitness research. This was the first case involving eyewitness identification before the US Supreme Court since *Manson v. Brathwaite* in 1977. The Supreme Court affirmed the state court's decision that due process protection against unreliable identification evidence applies only to identifications made under suggestive circumstances that are caused by the police. In this instance, the suggestive circumstances were happenstance, involving a woman looking out of her window into a dark parking lot and identifying a single black male among a group of police officers from 100 ft away. Despite research that demonstrates jurors are unable to determine the reliability of eyewitness testimony, the Court ruled that eyewitness evidence is like any other evidence and is therefore at the discretion of the jury to determine its reliability.

Future Directions

As demonstrated by the large number of people who have been wrongfully convicted, the traditional safeguards used by the courts to prevent wrongful convictions based on eyewitness misidentifications have not fully sensitized jurors to factors affecting eyewitness identification accuracy. The recommendation of the court in *Henderson* to develop case-specific instructions regarding eyewitness factors is a step in the right direction, but it may not be enough.

The Innocence Project has made recommendations focused on improving system variables, including double-blind administration, improving lineup composition, recording confidence statements immediately after an identification, videotaping the entire lineup and identification procedure, and using sequential lineups. Law enforcement agencies across the countries are heeding these recommendations. In addition, the *Henderson* Special Master made several recommendations not accepted by the New Jersey Supreme Court, but worthy of future attention by the courts. First, the Special Master recommended mandatory pretrial hearings for all cases involving eyewitness identifications. Second, it was recommended that the initial burden be shifted from the defendant, who now needs to establish that suggestive procedures were present during an identification, to the prosecution – the party seeking to introduce identifications into evidence. The prosecution would then have the initial burden to prove an identification was reliable. This in essence treats eyewitness evidence like physical trace evidence.

Focusing the majority of recommendations on improving system as opposed to improving the decision-making ability of jurors leaves open the possibility that a confident eyewitness may outweigh any efforts to understand the circumstances that led to the identification. Yet, some jury reforms have been proposed. For example, researchers have called for a return to 12 member juries and requiring unanimity of verdicts to ensure more thorough decision making. In addition, expert testimony may be the best option in court for sensitizing jurors to factors affecting eyewitness identification accuracy. Future research should focus on how these experts can improve the decision-making ability of jurors.

Overview

The strength of the jury system in an adversarial system of justice depends on the impartiality of the jurors. Yet the rapid evolution of Internet-based communication technologies poses serious challenges to the traditional concept of juror impartiality. It is now possible for jurors to access virtually any piece of published information about pending cases in minutes, and the volume of potentially case-relevant information is growing exponentially. Many jurors have become accustomed to using these technologies to conduct research and communicate with friends and family. For some jurors, reliance on these technologies has become so ingrained that it would require conscious effort to refrain from doing so for the duration of a trial.

This entry discusses the notion of what it means for a juror to be and to remain impartial in the digital age. First, it focuses on the impact of new media on how jurors acquire and process information. Then it discusses the impact of new media on public perceptions of the justice system, especially in high-profile trials. Finally, it examines the viability of traditional judicial responses to the newly wired and media-saturated jury pool. It concludes with some sobering reflections about the ability of the justice system to keep up with these technological changes.

The Traditional Concept of Juror Impartiality

The strength of the jury in an adversarial system of justice is the impartiality of the jurors. Impartial jurors are those who are willing and able to consider the evidence presented at trial without preconceived opinions about the defendant's guilt or innocence, to apply the governing law as instructed by the trial judge, and to deliberate in good faith to render a legally and factually justifiable verdict. Traditionally, the process of identifying impartial jurors focused on voir dire during which judges and lawyers questioned jurors about their knowledge of the facts of the case, opinions about issues that might arise during trial, or life experiences that might affect how jurors perceive the evidence they would hear during the course of the trial. Once the judge and lawyers had removed biased jurors, the trial would begin. Except under very unusual circumstances, there was little risk that the selected jurors might lose their impartiality during the remainder of the trial.

The rapid evolution of various types of new media over the past two decades poses serious challenges to this concept of juror impartiality. Internet-based technologies now make it possible for jurors to access virtually any piece of published information about pending cases in minutes, regardless of when or where published. Many jurors have become accustomed to using these technologies to conduct research and to communicate with friends and family. For some jurors, reliance on these technologies for everyday tasks has become so ingrained that it would require conscious effort to refrain from doing so for the duration of a trial. As a result, judges and lawyers can no longer be confident either that a sufficient number of prospective jurors on any given panel will meet the traditional definition of impartiality or that the jurors selected for trial will remain so for the entire trial.

The volume of potentially case-relevant information that might jeopardize juror impartially is also growing exponentially with the proliferation of various types of news media including traditional media outlets as well as cable news organizations, online print media, and specialty blogs. The traditional news cycle involved at most daily updates, but some trials now receive continual, minute-by-minute, 24/7 news coverage as well as ongoing commentary and background information based on interviews with trial attorneys, litigants, witnesses, and even less central players such as coworkers, neighbors, and childhood friends. This level of media saturation exposes a larger number of prospective jurors to potentially prejudicial information about more upcoming trials than ever before in history, making it more difficult to select impartial jurors for trial and to maintain their impartiality throughout the trial.

Traditional approaches to minimizing these effects seem to be losing their effectiveness given the volume and intensity of trial information available to prospective jurors. Some of the most pressing concerns in contemporary jury system management are the impact of these technologies on juror decision-making and on public perceptions of the justice system.

The Impact of New Media on Juror Decision-Making

In a provocative essay published in the July/August 2008 issue of *Atlantic Monthly*, Nicholas Carr described how his use of the Internet seemed to be changing how his brain operates, especially his memory and his capacity for sustained concentration. The article provided an overview of how the development of various technologies – written language, the mechanical clock, the printing press, radio and television – all affected the brain's neural circuitry. For the most part, those changes had a positive impact on civilization, both increasing the scope of human knowledge and distributing it more widely. He then posited that the Internet, which he describes as an immeasurably powerful computing system, might be affecting a similar shift in human cognitive ability. Preliminary neurological studies suggest that Carr's insights may be quite accurate. If so, that prospect will have a profound impact on juror decision-making, especially how trial jurors receive and interpret information during the course of a trial.

Much of the existing scientific literature on juror decision-making is grounded in theories derived from cognitive psychology that individuals engage in schematic processing to interpret their environment efficiently and effectively. "Schemas" act as cognitive filters through which individuals identify people and situations quickly, according to familiar paradigms. For jurors, these schemas take the form of preconceptions and knowledge of the world that they use to construct narratives or stories from trial evidence and fill in missing details to increase the story's internal consistency and convergence with their world knowledge. This cognitive processing helps jurors assess the trial evidence for credibility, consistency, and relative importance. Contemporary researchers refer to this theory as the "story model" of juror decision-making. In more colloquial terms, jurors bring their common sense and community values to inform judgments about a criminal defendant's guilt or a civil defendant's liability for damages. During deliberations, jurors compare these individual narratives and, except in very rare exceptions, arrive at a consensus about the "correct" interpretation of the evidence and application of the governing law to produce a legally valid decision.

Historically, this process took place during trial as the lawyers presented each new piece of evidence to the jury through direct and cross-examination of witnesses. The question-and-answer format through which attorneys elicit oral testimony to support their respective theory of the case was originally intended to provide jurors with an unvarnished and neutral presentation of trial evidence. The format is exceedingly archaic and is almost never employed in other settings in which information is communicated to a lay audience. The jurors' task can be tremendously complicated insofar that it involves taking the individual bits of trial evidence and piecing them together into a coherent picture. In most trials, however, the relatively slow and methodical nature of the trial process, often interrupted by trial recesses and sidebar conferences between the judge and trial attorneys, provided ample time for jurors to reflect carefully on the evidence and make sense of the disparate pieces.

There are two significant implications of the changes wrought in neurological processing by increased use of new media. First, contemporary jurors are increasingly accustomed to the fast-paced and constant mode of transmission that one expects from handheld devices and Internet surfing in which readers jump from hyperlink to hyperlink, skimming materials for key nuggets of critical information without stopping to digest the entire webpage. In addition to reflexively seeking out information online with which to better understand the world, contemporary jurors are also accustomed to receiving constant updates in the form of e-mail and text messages, tweets, and notices from social networking sites that do not require active intent to acquire new information. They just arrive, unsolicited, on one's computer screen or smart phone with information formatted in the highly abbreviated style of headlines, sound bites, and bullet points. Communication in the Internet Age must conform to the "140 characters or less" requirement or risk losing the intended audience in the confusion or boredom of excessive detail and nuance. The traditional style of trial procedure is more and more likely to perplex and antagonize jurors who will have greater difficulty making sense of how its organizational framework presents disparate and detailed pieces of trial evidence.

Second, there is the possibility that contemporary jurors are cognitively either less reliant on or less confident in their collective common sense and community values and thus find it necessary to verify initial impressions about the evidence or to supplement it with external sources found online. Their cognitive schemas are no longer purely internal psychological constructions, but rather exist as an externalized collective schema in "the cloud" where they can be accessed with the click of a mouse. As the urge to use these technologies becomes stronger and the ability to do so becomes easier, judges and trial lawyers will find it increasingly difficult to block juror access to these potentially prejudicial sources of extraneous information so that jurors might maintain some semblance of impartiality until the evidentiary portion of the trial is complete.

At this time, it is uncertain how often jurors already access the Internet on a routine basis. In a preliminary study of the frequency of juror and jury use of new media, the National Center for State Courts (NCSC) found that sizeable portions of trial jurors reported interest in using new media to conduct research on case-related topics and to communicate with friends and family about their jury service experience. Although the vast majority of jurors in that study had daily, if not immediate, access to new media, none of them admitted to acting on that desire. That study involved a very small sample of trials; however, it is clear from court opinions and news stories discussing the problem of the "Googling juror" that the risk is not purely hypothetical. In a review of court opinions published between 1998 and 2010, Thompson-Reuters reported that at least 90 verdicts were challenged based on claims of Internet-related juror misconduct. One-half of those challenges occurred between 2008 and 2010. In 28 cases, civil and criminal, new trials were granted or verdicts overturned. Even where judges declined to declare a mistrial, in three-quarters of the cases, the courts held that Internet-related misconduct had occurred. Indeed, it is likely that the frequency of juror use of new media is much greater than written court opinions reflect as many such instances would not result in a written opinion. In fact, most would likely go undetected.

The crux of the dilemma for the justice system is the impending collision between the traditional view of juror impartiality and contemporary jurors' increasing reliance on new media to inform their decision-making. The traditional strength of the jury system rests on the assumption that the jury considers only evidence properly admitted at trial. Jurors take an oath at the beginning of the trial to render a "true verdict ... according to the evidence, without fear, favor, or affection, and ... governed by the instructions of the court." Intentionally seeking extraneous information about case-related topics is a clear violation of the juror's oath and can result in a mistrial or overturned verdict. As individuals increasingly rely on the Internet to access information to help navigate their environment and interpret the world, it will likely become ever more difficult to prevent them from doing so when serving as trial jurors. After all, jurors understand that jury service is a serious task that requires the greatest degree of attention and competence. It will become increasingly counterintuitive to jurors that they would violate a solemn oath by using the very tools on which they normally rely to inform their judgments in serious matters.

To a certain extent, trial courts have already accepted, and even embraced, a seismic shift in jurors' role in the trial process by adopting trial techniques (e.g., juror note taking, juror submission of written questions to witnesses, juror discussion of evidence before final deliberations) that facilitate active learning styles. Traditionally, it was assumed that juror passivity helped to maintain their impartiality. Contemporary empirical research confirms that enforced passivity does not significantly enhance impartiality and, in fact, can seriously undermine juror performance and satisfaction. The transition to the "active juror" model mirrors many trends in contemporary life in which individuals are encouraged to assume a more active role. In health care, financial management, and continuing education, for example, responsible and competent behavior is defined by a person's willingness and ability to undertake an active partnership with professionals to accomplish both personal and collective tasks. The key question in the context of contemporary jury service is whether Internet use is a legitimate tool to aid juror decision-making (as appears to be the case for increasing numbers of jurors) or a serious breach of juror impartiality that threatens the legitimacy of the jury's verdict.

The latter viewpoint predominates among contemporary trial judges and lawyers. Responses to this type of "juror misconduct" run the gamut from education and outreach to persuade prospective jurors not to engage in Internet use during trial and deliberations, to preventive measures intended to block juror access to the Internet, to punitive measures imposed on jurors who disobey direct orders to forego the Internet for the duration of the trial. Increasingly, informational booklets and orientation programs for prospective jurors emphasize the importance of not accessing the Internet during trial. Many judges and lawyers now question prospective jurors about their Internet use during voir dire to screen out jurors who indicate reluctance to adhering to prohibitions on juror use of new media. Jury instructions have become increasingly specific about prohibitions on various types of the online activities. Judges repeat these instructions more frequently throughout the trial to remind jurors of these prohibitions and to emphasize their importance. Hoping that jurors who understand the underlying rationale for the prohibition on Internet use will be more likely to comply, some judges also explain that extraneous information encountered online is not evidence and deserves no weight in the jurors' deliberations. Finally, some courts ban all forms of electronic devices from the courthouse or confiscate such devices from jurors during trial and deliberations. Ironically, some courts have proposed using technology to combat problems associated with juror use of technology including blocking electronic transmissions in courtrooms and jury deliberation rooms to prevent juror misconduct. When prevention is insufficient, judges are also becoming more willing to punish jurors for violating the admonition and to consider posttrial challenges to verdicts based on juror misconduct.

Impact of New Media on Public Perceptions of the Jury System

Because jurors are drawn from the community at large, they reflect the general social outlook and values of their communities. Indeed, one of the primary roles of the jury is to inject community values into judicial decision-making. Although, as designed, the voir dire process identifies and removes jurors who hold such strong opinions about case-specific issues that they could not serve fairly and impartially, those opinions will still be present in the public at large. This is particularly the case in high-profile trials that generate considerable media attention. One of the great ironies of contemporary society is the apparent disconnect between the jurors' trial and the public trial. Trial jurors will largely be isolated from ongoing media coverage of the trial. All the while, public sentiment may become even more inflamed over the course of the trial in reaction to evidence admitted at trial as well as media commentary on that evidence and non-trial information disclosed by the litigants, lawyers, and witnesses. In essence, a high-profile trial is actually two very different trials – one that the sworn trial jurors experience and one that the public observes as quasi-jurors, which can sometimes lead to very different conclusions about the appropriate verdict. Recent examples include O.J. Simpson's acquittal of murder charges, Michael Jackson's acquittal of child molestation charges, life sentences rather than the death penalty for Terry Nichols (coconspirator in the Oklahoma City bombing) and Zaccarias Moussoui (the alleged 20th hijacker in the September 11th terrorist attacks), and the acquittal of Casey Anthony on charges of murdering her 2-year-old daughter.

Different degrees of information presented to the public also result in a blurring of the line between news reporting, education, and entertainment, between fiction and reality. Much of what the public knows about what actually occurs in the courtroom is what the ever-merging news and entertainment outlets portray. While reports on trial events provide a glimpse into how the justice system works or does not work, most people do not have a realistic sense of what it is like to serve as a juror in an actual trial. People routinely report that their primary source of courtroom knowledge comes from television trial shows such as the *People's Court* and crime dramas such as *Law and Order*.

The various iterations of entertainment shows and news outlets affect the public's expectation about the justice system and jury verdicts. The number of law enforcement and forensic-based crime dramas on television (e.g., *CSI* and its numerous iterations) outnumbers the number of actual trial drama shows. Yet an underlying theme across all of them portrays a fast-paced trial that is resolved in an hour or less with justice unequivocally done. Cable television's 24-hours news coverage and shows such as *Court TV* provide what appears to the public as the inside story with all of the facts revealed including commentaries by so-called experts. Inherent in most jury trials, however, is the reality that trial evidence is often ambiguous, conflicting, and incomplete; the law articulated in jury instructions sometimes borders on incoherence; jury deliberations can be quite contentious; and jurors may nevertheless harbor some doubts (albeit not reasonable doubts) about a defendant's guilt even after returning a guilty verdict.

The public forum for hearing jury trials, as guaranteed by the Sixth Amendment, was seen by the founders as a safeguard for the defendant against abuses by the government. Freedom of the press under the First Amendment was intended to protect the people, to be the voice of the community. The tension between the two, spurred along by new media in the Information Age, contributes to a decline in the public's trust and confidence in the jury system. The courts depend on the jurors as representatives of their respective communities to provide legitimacy to the justice system. As such, central to the mission of the courts is a way to maintain the public's trust and confidence in trial by jury as an effective way to resolve disputes. When there is public outrage over a perceived injustice, especially in a notorious trial, the courts must work quickly and effectively to counter the public's doubt.

Courts now use many contemporary communications tools and techniques to make the justice system appear more accessible and more transparent. Some provide online access to court documents including filings and decisions. Others offer real-time video feeds of court proceedings. Many courts, especially in urban areas, now employ public information officers who are specifically tasked with communicating information about the court's mission and role in contemporary society to the public. Inherent in that task, however, is the paradoxical challenge that the culture of the court is fundamentally at odds with the societal culture that has developed with and in response to these new communication technologies. A recent study entitled "New Media and the Courts: Current Status and a Look at the Future," undertaken by the Conference of Court Public Information Officers, observed that courts rely almost exclusively on textual communication – written opinions and court orders – to speak publicly. This mode of public communication, detailing the proven facts and logic on which court decisions were made, underscored the message that the court's legitimacy rested firmly on the rule of law. Moreover, court communication is primarily hierarchical and unidirectional; opinions and court orders are intended as the final word to be obeyed. They are not intended as an invitation for further discussion except within the highly stylized procedures of a legal challenge to those orders.

In contrast, the Internet is a multimedia environment offering visual and audio formats to communicate in addition to traditional text. These technologies also are intended to be interactive and to encourage collective decision-making on the largest scale possible. While many court public information officers have made tremendous progress in incorporating some new media tools and strategies, at least to communicate non-case-specific information to the public, it is not clear that they will ever fully harmonize these two incongruous cultures without a radical reconceptualization of many of the fundamental principles of judicial independence and legitimacy.

The Continued Viability of Judicial Responses to Counter the Effects of Pretrial and Trial Publicity

High-profile trials cause the most difficulty by far for judges and lawyers in terms of how to mitigate the impact of pretrial publicity on prospective jurors. Trials can become the focus of intense media attention for a variety of reasons. Sometimes the litigants, witnesses, or victims are celebrities, such as in the O.J. Simpson and Michael Jackson trials. Sometimes the case involves particularly violent or heinous crimes that shock the community, including the Oklahoma City bombing trials, the Unabomber trial, and the Moussaoui terrorism trial. Sometimes the case raises controversial social or political issues, including the California Proposition 8 trial involving the constitutionality of same-sex marriage or the prosecution of financial fraud charges against key executives at Enron and WorldCom. The media themselves sometimes highlight particular cases, such as when Headline News (HLN) anchor Nancy Grace took on the Casey Anthony trial as a personal cause célèbre to see justice done for a murdered child. And sometimes there is no apparent reason other than a slow news day for a case to suddenly attract great media attention.

The key issue for courts concerning both the scope and tone of media treatment of pending cases is the impact that it will have on jurors' judgments of defendant guilt, the conditions under which those effects will most likely occur, and the remedial efforts, if any, that are most likely to minimize those effects. Over the past 40 years, numerous empirical studies have attempted to examine these questions, sometimes with inconclusive or even contradictory results, using a variety of methodological and analytical approaches. A meta-analysis (Steblay et al.) of 23 such studies published between 1966 and 1997 offers some well-documented findings on this question. First and foremost, it is clear from the studies that jurors exposed to negative pretrial publicity are more likely to judge defendants guilty compared to jurors exposed to less pretrial publicity or at least more neutral pretrial publicity. The effect was documented most acutely in those studies that employed jury-eligible citizens as study participants compared to those that employed students. The amount of detail communicated in media accounts (e.g., crime details, arrest information, confessions, prior criminal record, and other incriminating evidence) as well as accounts that employed both video and print media produced greater effects than studies that focused on just one type of pretrial publicity. Crimes involving violence, especially homicide and sexual abuse, also produced greater effects on juror judgments of defendant guilt than other types of crimes. Even general publicity, not specifically related to the case at hand, which included a discussion of similar legal concepts (e.g., eyewitness identification) or case facts (e.g., acquaintance rape) had an indelible impact on juror decision-making.

Of critical importance, these studies collectively confirm that the impact of pretrial publicity on individual juror judgments about defendant culpability carries through to the collective verdicts rendered by juries. Remedial efforts employed by courts (e.g., brief trial continuances, expanded voir dire, judicial instruction, trial evidence, and jury deliberation) do not effectively counter the biasing effects of pretrial publicity. Instead, pretrial publicity exerts a disproportionate imprint on juror memory compared to the evidence actually presented at trial. Most of these studies predate the advent of the Internet Age, or at least its apparent effects on human neural circuitry, so it remains to be seen whether these effects are accentuated or attenuated by frequent Internet use.

Traditional mechanisms for mitigating the impact of pretrial publicity include trial delay, a change of venue or impaneling an out-of-county jury, and extensive voir dire including the use of written juror questionnaires. Unfortunately, the approaches to addressing publicity concerns may not be as viable as they once were given the geographic reach and intensity of 24-hours news coverage. Multiple news media, along with the varied reliability of the information source, simply reach more people, often delivered as an unfiltered or even politicized message. Finally, court use of anonymous juries to prevent communication affecting jury decision-making, such as that of external jury tampering or intimidation, is also explored as a valid response.

Change of Venue

One response to pretrial publicity is to delay a trial date as news often migrates “off the front page.” Ironically, that phrase was derived from the traditional print newspaper of the past. In our technology-saturated culture, such a topic is no longer the most popular tweet or the post no longer appears in the current news feed section. As a result, people forget the details they read initially. While Internet postings are virtually eternal, they migrate to the less-visible archive sections. There is no guarantee, however, that an interested juror would be unable to access the old information quickly, if he or she desired. This is in stark contrast to the era of newspapers in which the juror would be required to spend significantly more time to be able to uncover the details of a past news event and would most likely need to physically leave the courtroom to accomplish this task. The loss of control over the flow of information into and out of the courtroom has indeed left some courts unprepared.

Although a change of venue is an option for courts, numerous notorious trials have been successfully tried in the original venue (e.g., the Nanny trial and a series of well-known Mafia cases), and legitimate concerns about the logistical and financial burdens arise when moving the trial. The proposed venue must also resemble the original community in terms of both demographic and attitudinal characteristics due to the historical importance of public access. The US Supreme Court in *Murphy v. Florida*, 421 US 794 (1975), addressed the level of pretrial publicity that deems one incapable of being impartial. The decision did not require jurors to be completely unaware of publicity, but to be able to set aside the information and judge the defendant solely on the information provided in the courtroom. Courts have developed a fairly consistent analytical framework for determining whether the extent and tone of pretrial publicity have so "poisoned" the local jurisdiction that a change of venue is necessary. In *Irvin v. Dowd*, 366 US 723 (1961), the US Supreme Court wrote that if "an appellant can demonstrate that prejudicial, inflammatory publicity about his case so saturated the community from which his jury was drawn as to render it virtually impossible to obtain an impartial jury, then proof of such poisonous publicity raises a presumption that appellant's jury was prejudiced, relieving him of the obligation to establish actual prejudice by a juror in his case." The presumption is rebuttable, however; if the government demonstrates that an impartial jury was actually impaneled in the appellant's case, the conviction will stand despite appellant's showing of adverse pretrial publicity.

The question for contemporary courts trying the most high-profile cases is whether *any* venue can satisfy these requirements. Timothy McVeigh's trial moved from Oklahoma City to Denver, but that was only possible because the trial was held in federal court. State court, by definition, would be required to maintain jurisdiction and hold the trial within the same state. The Washington DC Sniper trial moved from Fairfax, Virginia (a suburb of Washington, DC), to the southern tidewater area of Chesapeake/Virginia Beach. Complicating the matter, some news accounts indicated the sniper had been in the tidewater area of Virginia, possibly seeking additional victims, before capture, raising the possibility that prospective jurors in that venue would be similarly biased. The saturation of national news undermines the widespread effectiveness of granting a change of venue to overcome the challenge of impaneling a fair and impartial jury for it will be increasingly difficult to locate an alternative venue not equally affected.

The Supreme Court recently revisited this framework in *US v. Jeffrey Skilling*, in which the Enron CEO was convicted of multiple counts of securities and wire fraud involving the collapse of the Enron Corporation. The court ultimately held that the amount and tone of pretrial publicity about the Enron collapse was insufficient to establish a presumption that the jury pool was prejudiced, and in any case, the fact that Skilling only challenged one juror for cause and the jury returned acquittals on nine counts of insider trading demonstrated that the impaneled jury was, in fact, impartial.

Intensive Voir Dire

Another traditional mechanism for addressing pretrial publicity is to conduct intensive voir dire. A written juror questionnaire is often given to potential jurors to identify potential bias. Although case law varies in state courts concerning the scope of permissible questions, the strength of using such a questionnaire is its ability to elicit truthful information from the potential jurors about bias, including attitudes about the specific case as well as underlying attitudes about relevant case issues (e.g., personal experience with substance abuse). Conducting voir dire through written questionnaires in addition to oral questioning in the courtroom is more likely to uncover sensitive or personal information that may affect the juror's ability to be fair and impartial. Courts have identified a number of factors relevant to whether the voir dire in a case involving extensive and prejudicial pretrial publicity would be adequate to impanel an impartial jury including (1) the percentage of the entire pool of veniremembers who evidenced bias; (2) whether the court questioned the veniremembers individually; (3) whether the court questioned the veniremembers thoroughly concerning their knowledge of the circumstances surrounding the alleged crime; (4) whether the court asked each veniremember specifically about the nature and extent of any preconceived notions*;* (5) whether the court asked each veniremember about his or her capability to render an impartial verdict; (6) the length of time the process took; (7) whether the court examined the veniremembers outside the presence of other veniremembers; (8) whether the attorneys had the opportunity to recommend further inquiries, and (9) whether the judge . . . inquired into the prospective jurors' exposure to publicity and ability to render a fair and impartial verdict.

If these remedies are no longer viable, at least in the most notorious trials, what else can be done? Or do courts simply acknowledge that the traditional view of juror impartiality cannot be achieved under these circumstances? If impartiality is an elusive goal, the courts would have to accept a compromised version of justice, mitigating to the greatest extent possible the problems while hoping for the best outcome.

Anonymous Juries and Jury Sequestration

In recent times, judges have become more likely to use anonymity measures (protecting the juror's identities). In the trial of Illinois governor Rod Blagojevich on public corruption charges, Judge James B. Zagel ordered that jurors' names not be disclosed publicly until after the trial ended. He noted that he had personally received dozens of letters, telephone calls, and e-mails from the public concerning the trial and was concerned that jurors would also be targeted for harassment or intimidation if their names became public. He noted that prohibiting jurors from using e-mail or other Internet technologies to communicate with friends and family about non-trial matters for the duration of the 4-month trial would impose an extraordinary burden on them, and other means of screening jurors' personal correspondence, e-mail, and telephone calls would be similarly intrusive. Jury sequestration, which can also be used to insulate jurors from outside influence, is expensive to the court and onerous on the jurors, their families, and the courts. Consequently, it is rarely employed except in the most extreme circumstances. Local and national media outlets challenged the order on First Amendment right to access government proceedings in an interlocutory appeal to the federal Seventh Circuit of Appeal. Historically, anonymous juries were rarely permitted in the federal courts unless the trial judge made specific factual findings concerning the immediate risk of jury tampering or intimidation. The fact that Judge Zabel's order ultimately prevailed illustrates the point that many courts have come to appreciate that contemporary communications technologies pose as great a risk or more to juror impartiality as traditional in-person approaches, in part due to the substantially larger pool of Internet-savvy people who might be inclined to contact jurors in high-profile cases.

Conclusions

The introduction and evolution of Internet technologies that has taken place over the past two decades has introduced a number of challenges to the concept of juror impartiality. In many instances, these challenges are simply extensions of the types of challenges that courts have faced in the past – and for which highly effective strategies exist. A thorough voir dire can identify jurors who cannot serve fairly and impartially due to personal knowledge about the case, exposure to pretrial publicity, or preconceived opinions or bias about case-related factors. Effective pretrial instructions about independent research and communications with family and friends can inform jurors about necessary restrictions on their activities during trial to prevent them from being exposed to potentially prejudicial information. Very high-profile trials may require additional measures including anonymous or sequestered juries to prevent jury tampering or intimidation by electronic means.

Although these are all tried and true techniques that require only a little tweaking to be equally useful for maintaining juror impartiality in the Internet Age, some aspects of modern telecommunications technologies appear to affect jurors and jury trials in a qualitatively different way. Perhaps the most troublesome is the apparent impact that frequent juror use of Internet technologies is having on cognitive behavior, especially the ability to retain and interpret information. Future jurors may not be as effective as decision-makers unless they are permitted to access the Internet to supplement and interpret the evidence they are given at trial. That access, however, is currently prohibited on grounds that doing so would undermine juror impartiality. It is hard to imagine a more direct confrontation of traditional trial procedure and modern technological innovation. It is not clear how new media will ultimately change how we think about courts, about jurors and their role in the justice system, and about how jurors should fulfill that role, but it is clear that some change will ultimately occur.

Similarly, the overwhelming volume of news, its iterative manifestations, and its expanding geographical distribution to all parts of the globe pose an immense challenge for courts. Even if the tone of media coverage of an upcoming trial is relatively neutral, the sheer level of detail may so saturate the potential jury pool that it becomes increasingly difficult to impanel a fair and impartial jury in that jurisdiction. But it may be equally difficult to locate an alternative jurisdiction where the level of pretrial publicity and community impact is sufficiently less. Even after a fair and impartial jury is impaneled and the trial has commenced, the court faces the ongoing possibility that the public audience watching both the trial proceedings, often in real time, and corresponding news and commentary will draw very different conclusions about the appropriate outcome of the trial than the impaneled jury would based solely on the evidence and law.

Courts can no longer blandly assume that the public understands their mission and the underlying rationale for trial procedures and that trial outcomes will be inevitably accepted as valid judgments in the court of public opinion. Ultimately, courts will have to devise more persuasive arguments, and more effective strategies to promulgate those arguments, of the continued importance and validity of its core function in the justice system. Courts are institutionally reactive organizations that have been slow to adapt to the implications of new media on court operations generally and in the context of jury trials specifically. But just as new media is affecting changes in human cognitive processing, it is similarly affecting – in a dynamic and interactive way spurred by the use of new media – both public perceptions about the courts and courts' own perceptions about themselves and their role in contemporary society.

As a final note, it is important to recognize that contemporary technologies are changing very rapidly. Courts have been taken entirely by surprise by many of the communications technologies in widespread use in contemporary society. They are even less aware of and prepared for newer technologies that likely have already been developed and deployed; they have not begun to imagine the future implications that these technologies will have on court operations. There is a distinct possibility that the issues discussed in this entry will already have become moot by the time this encyclopedia is published by the introduction of newer technologies. At the very least, however, this entry will provide a historical glimpse of the issues and problems that courts once confronted. Future researchers will have to assess whether their reactions and adaptations were ultimately adequate and satisfactory, or insufficient, in the long run.

Justice Reinvestment

Rob Allen
Justice and Prisons

Overview

While the idea of justice reinvestment (JR) has its origins in the USA, politicians, policy makers, and academics in the UK have shown a growing interest in its applicability over the last 8 years. The level of public spending on prisons in the UK does not yet approach that of the USA whose 2.5 million prisoners represent an imprisonment rate four times higher than in Britain. Yet the UK prison population, particularly in England and Wales, which is by far the largest jurisdiction, has more than doubled in the 20 years since 1991 to reach more than 87,500 in the autumn of 2011. Concerns about the cost and effectiveness of this vastly increased use of imprisonment have led to a widespread desire to find ways of curbing the spending involved or at least diverting it into more productive community-based measures.

The formation of a new coalition government in May 2010 led to a marked change of criminal justice policy with the new Conservative and Liberal Democrat administration aiming to halt the seemingly inevitable rise in prison numbers. The coalition's program for government promised to introduce a "'rehabilitation revolution' that will pay independent providers to reduce re-offending, paid for by the savings this new approach will generate within the criminal justice system" (Cabinet Office 2011). The government has described this as "a radical and decentralizing reform which will deliver a fundamental shift in the way rehabilitation is delivered. It will make the concept of justice reinvestment real by allowing providers to invest money in the activity that will prevent offending rather than spending money on dealing with the consequences" (Ministry of Justice 2010).

It is too early to say what impact this form of justice reinvestment might have. Before it was under way, serious disturbances on the streets of English cities in the summer of 2011 led to demands for a tougher approach to law and order in some quarters but the need to cut public-spending acts as a restraint on those who would reverse policy and return to a the more expansionist prison-building program that the Conservative party favored in advance of the 2010 general election.

A new Justice Secretary appointed in 2012 has announced me acceleration of the introduction of "Payment by returns" with plans to open most probation services to competition. Savings will be used to expand community supervision of offenders released from short prison sentences. But reduced spending on prisons will be sought not by cutting prison numbers but through reductions in the unit costs of prison management.

Some Important Differences between the USA and the UK

At the outset, it is important to recognize some important differences between the USA and the UK which make the idea of justice reinvestment more compelling to Americans than in Britain. The still vastly differing scale of imprisonment in the USA has created a large pool of prisoners who, on any reasonable assessment, could safely be released from prison. As a result of the comparative harshness of sentencing and sentence execution policies, there is inevitably considerable scope for prison-reduction measures. For example, mandatory and truth in sentencing policies have led to the long-term incarceration of large numbers of nonviolent prisoners. Reducing prison capacity potentially frees up sums for reinvestment (or indeed to translate into tax cuts) which are thus substantially higher across the Atlantic than in the UK. There are unlikely to be many "million dollar blocks" in England and Wales – residential neighborhoods where that amount is spent on imprisonment each year – although analysis in the northeast of England found that in 2005 magistrates in Gateshead incurred over half a million pounds worth of costs in sending just over a hundred individuals to prison, on average for a few weeks. Crown court decisions generated substantially greater costs (Allen et al. 2007). A more recent study found that it cost the taxpayer £2.5 million in 2009/2010 to send nonviolent and nonsexual offenders from the London borough of Lewisham to prison for periods of less than a year. The authors concluded that funds that could be made available to local agencies to prevent reoffending through a process of justice reinvestment are therefore considerable (Lanning et al. 2011). But they are substantially lower than in the USA.

It is true too that America's lack of welfare structures and the highly concentrated zones of urban deprivation mean that resources to strengthen housing, employment, substance misuse, and other services are likely to yield quicker and more visible positive impact on the resettlement of released prisoners than might be the case in the UK.

Nonetheless, there is considerable scope for enhancing measures to rehabilitate offenders in the UK. In England and Wales, prisoners sentenced to less than 12 months do not receive any supervision or support from the probation service on release. There are gaps in services even for those offenders who are being supervised in the community. The National Audit Office found in 2008 that "some community order requirements, for example alcohol treatment... are not available or rarely used" – this despite strong links between alcohol and offending. They also found long waiting lists for some order requirements, in particular group programmes on domestic violence" (NAO 2008).

It is also the case that the aspects of the structure of American governance lend themselves to JR approaches. The shared responsibilities exercised by counties, states, and the federal government in running and financing imprisonment provide opportunities to introduce financial incentives to control or, as well as (as has been the case), to expand prison numbers. A variety of fiscal arrangements have been introduced which reward counties which develop measures that reduce demand for custodial places at state level. A virtuous circle is created in which state savings on incarceration are reinvested in local alternatives which in turn further reduce demand for expensive state placements. This process has been seen, for example, in New York State where four closed facilities for juveniles have been closed with resources invested in family therapy and other alternative programs in New York City (Solomon and Allen 2009), but the approach has a history going back to the California probation subsidy scheme in the 1970s. Federal grants have also been used to encourage reductions in custody particularly in respect to disproportionate minority confinement.

In England and Wales, the costs of custody are met almost entirely by central government through the National Offender Management Service, an agency of the Ministry of Justice. There is a modest exception in the case of juvenile custody. Local authorities are currently required to pay a third of the costs when a court orders a child under the age of 17 to be placed in secure care during a remand period in criminal proceedings. This local liability applies in a relatively small number of cases – most juveniles who are remanded into custody are not placed in secure care institutions but in prison establishments which are paid for centrally. However, as part of their program of criminal justice reform, the government is seeking to make local authorities financially responsible for the costs of all secure remands of young people under the age of 18 wherever they are placed. Although responsibility for commissioning and placements will be retained by central government, the aim is to "simplify current arrangements and provide a powerful incentive for local authorities to invest in alternative strategies for this group of young people" (Ministry of Justice 2011). The legislation to introduce this change is currently being debated in Parliament.

The system of American governance also gives the executive a somewhat greater say over the size of custodial populations than in the UK where the courts play a more decisive role. In juvenile justice, it is the executive which decides whether custodial placements are made in some states. In others such placements are in large part made following recommendations by probation officers. This provides a straightforward lever to change rates of committal to custody. In the adult system, executives have often retained the right to adjust the proportion to time served and of course can determine the level of flexibility applied in cases of parole violations. Reintroducing or making more generous schemes for good time credits and introducing a little more discretion in responses to parole violations can have substantial impacts. Legislative change is not always needed to reduce the actual lengths of sentences served or the rate of recalls to prison. In England and Wales, these are the two key factors which lie behind the sharp rise in prison numbers in England and Wales since the early 1990s.

In short, in the USA, the extraordinary rise in mass incarceration has made JR a highly attractive proposition for cash-strapped states and provides numerous opportunities to scale back the use and cost of prison. In the UK, because the rate of imprisonment is lower, the opportunities are somewhat more modest.

Recent Policy Developments in England and Wales

Although the overall rate of imprisonment in the UK is much lower than in the USA – 155 per 100,000 population compared to 743, between 1992 and 2011 – the prison population in England and Wales more than doubled in size. About three quarters of the rise is accounted for by increase in the numbers sentenced to immediate imprisonment and about 16 % by an increase in those recalled to prison for breaching the terms of their release on parole or license. A recent Ministry of Justice analysis suggests that the reasons lie in tougher sentencing and enforcement outcomes (which is not in question) and a more serious mix of offenders coming before the courts (for which the evidence is more contested) (Ministry of Justice 2009). Rising prison numbers represent the costliest tip of a criminalization iceberg which has seen a large extension of the reach of the criminal justice system, during a period of falling crime. The creation of 3,000 new criminal offenses, the development of hybrid forms of social control such as Anti-Social Behavior Orders, and the introduction of indeterminate sentences form a pattern in which social problems are increasingly treated by way of punishment and control. Overseas observers express surprise that this trend should have occurred under a Labor government. Indeed as recently as 2002, in the White Paper "Justice for All," the Labor government listed the record prison population, with its costs and poor outcomes as something that "is not working" (Home Office 2002).

Since then, record prison numbers have like numbers of police officers become something to be trumpeted. Until 2010, the then Labor government relied on the analysis contained in a report they had commissioned from Lord Carter called "Securing the Future" (Carter 2007). In large measure, this offered a "predict and provide" approach to the supply of prison places. The report did contain one or two proposals to reduce or stabilize demand for imprisonment, but its scope was narrowly confined and was dismissed as "deeply unimpressive" by the House of Commons Justice Committee (Parliamentary Select Committee on Justice 2008). It ignored entirely the case for a comprehensive and wide-ranging strategy to reduce the resort to imprisonment and to develop alternative ways of dealing with offenders. Carter's report stood in sharp contrast to the work of the Scottish Prisons Commission which was established in 2007. Its report "Scotland's Choice" set out a vision of reducing Scotland's prison population over time from 8,000 to 5,000 (McLeish 2008). Among its recommendations, the Scottish report called for progress "in developing services that are available nationwide to address the social and health related needs of many offenders" and called on the devolved government "to promote recognition across all departments, all public services, all sectors and all communities of a duty to reintegrate both those who have paid back in the community and those who have served their time in prison" (McLeish 2008).

Lord Carter's report about England and Wales had by contrast nothing to say about social, educational, and health-care policies which are needed to prevent crime, rehabilitate offenders, and reintegrate those leaving prison. There is evidence that despite substantial investment in public services in recent years, major shortfalls in the availability of social provision remain particularly in the most deprived areas and among the most excluded populations in England and Wales. A separate government review of people with mental health problems and learning disabilities in the criminal justice system, for example, concluded in 2009 that for diversion into the health-care system to be introduced effectively, there needed to be sufficient capacity in mainstream services, as well as confidence in those services for those making decisions about offenders (Bradley 2009). While the review did not make a detailed assessment of the adequacy of services, it tellingly noted that in 2006, courts made use of their powers to add a mental health treatment condition to a community sentence on only 725 occasions. Such conditions represented less than 0.4 % of the 203,323 requirements imposed during the course of the year. Similarly, despite considerable investment in drug treatment, the number of residential rehabilitation places is still low compared to other countries. There are about 2,500 beds in England with about 16,000 individuals accessing residential services for substance misuse each year. Given that half of male prisoners and two thirds of women have used class A drugs in the 6 months prior to imprisonment, there is a strong prima facie case for increasing capacity significantly. Despite some progress in establishing community-based services for women offenders following a major review of women in prison, women are still receiving short prison sentences for want of constructive alternatives.

It is arguable too that the distorted priority given to increasing imprisonment has been encouraged by a costly centrally driven system of offender management, the child of an earlier review of correctional services undertaken by Lord Carter. The creation of the National Offender Management Service (NOMS), a central government agency responsible for prison and probation services (and to a lesser extent the Youth Justice Board) has produced a situation in which local health, education, employment, and social services can slough off their responsibilities for people in the criminal justice system, safe in the knowledge that their needs will be addressed by a central government agency. This is most starkly illustrated in the juvenile system where local authorities can shunt the costs of meeting the needs of demanding teenagers onto central government, but it is more generally the case that local mainstream agencies have little incentive to address and absorb crime and delinquency problems in the way that they might.

The formation of the coalition government in May 2010 brought an important change of emphasis in criminal justice policy. The Programme for Government which set out the key policy commitments included a commitment to more effective sentencing policies, an overhaul of rehabilitation, and an exploration of alternative forms of secure treatment-based accommodation for mentally ill and drugs offenders (Cabinet Office 2010).

Specific proposals for criminal justice reform were published 6 months later in the consultation paper "Breaking the Cycle." This proposed a series of measures which aimed to result in "fewer crimes being committed overall, stemming the unsustainable rise in the prison population and ultimately achieving a reduction in the amount of money spent on the criminal justice system. There will be more payback to victims and communities and the public will be better served" (Ministry of Justice 2010).

During the period of consultation, some of the measures proved controversial – particularly a proposed increase in the sentencing discount offered to offenders who plead guilty at an early stage in proceedings. When it became clear that increased discounts would apply to serious crimes such as rape, there was something of a backlash. As a result of pressure from the Labor opposition and from harder line members of the Conservative party, policy on criminal justice assumed a markedly harder line in the weeks leading up to the publication in June 2011 of the government's response to the Green Paper consultation and of the Legal Aid Sentencing and Punishment of Offenders Bill which gave legislative expression to the policy.

The post-consultation policy shows signs that the government has watered down its prison reform proposals on both the supply and the demand side. The response to the consultation makes it clear that the government is "not aiming to cut the prison population – and we are clear that there must always be places for those that judges sentence – but we will manage a stable, effective system rather than undermining it by endlessly and irresponsibly inflating prison numbers for their own sake" (Ministry of Justice 2011). This disappointed many reformers looking for reductions in the use of prison which was but not surprising given that one of the main mechanisms for reducing prison numbers – the increased sentence discounts for early guilty pleas – was to all intents and purposes abandoned.

Disappointing too for reformers was the decision that the government would not push for community sentences to be used instead of prison. Instead, the government has decided to try to "transform community orders into more credible punishments that stop offenders getting to the point where custody is the only option. Non-custodial sentences need to be tough and demanding. For too long, they have fallen short of what is required" (Ministry of Justice 2011). Simultaneously making community sentences more demanding while moving them lower down the tariff of sentencing options no longer looks like a strategy for prison reduction. It rather spells the danger of escalating offenders towards custody by increasing the risk of failure to comply rather than diverting them from it.

The government's commitment towards rehabilitation and a more measured use of prison has also been put at risk by the public disturbances in English cities in August 2011.

Although the government has sought to use the fact that large numbers of rioters appear to be heavily convicted to remake the case for better rehabilitation, courts have adopted a harsh line on the remanding and sentencing of riot-related offenders. The prison population reached record levels in five consecutive weeks in September and October 2011.

2012 saw a new Justice Secretary appointed who published radical proposals to reform the delivery of offender services (Ministry of Justice 2013). The aim is clearly reduce spending by cutting the unit costs both of prison and probation and not by reducing the number of prisoners.

Justice Reinvestment in the UK Developments and Proposals

Policy

Notwithstanding the important differences between the USA and UK, a range of specific policy proposals drawing on JR have been produced in Britain in recent years. Attention was first drawn to the possible application of the concept in the UK in 2004 (Allen 2004), and since then, there has been a range of ideas put forward by academics, think tanks, and charities which look to apply various of the key elements of justice reinvestment. These include suggestions for:

(a) A much more locally driven system of so-called primary justice which would involve shifting control of prisons and key supporting services away from Whitehall to a local level and the creation of a local "safety and justice" budget to fund local prisons and neighborhood policing. This pot of money would be used to commission local services, either from existing providers or by setting up new local services. A local budget could include approximately 35 % of the prison budget, the administration budget for magistrates' courts, local policing, and probation (LGIU 2009).

(b) An extension to the remit of locally based Youth Offending Teams (multiagency professional teams which deal with juvenile offenders) to the adult age group (LGA 2005; Allen and Stern 2007).

(c) More locally based management of the prison system by abolishing the National Offender Management Service (NOMS) which is the central government agency responsible for prison and probation services and replacing it with a network of Community Prison and Rehabilitation Trusts (CSJ 2009).

(d) Using funds earmarked by the government for prison expansion to strengthen measures in the community such as restorative justice which could reduce demand for imprisonment (RCP 2008).

The most thorough-going proposals have come in the House of Commons Justice Committee's substantial report "Cutting Crime – The Case for Justice Reinvestment" (Justice Committee 2010). The report focused attention on not only how much is being spent on imprisonment but what alternative which uses the public money consumed by prison could be put if demand for prison places could be reduced. It also drew attention to how people going to and returning from prison are disproportionately drawn from the poorest neighborhoods and how targeted investment in these areas could help develop more initiatives both to prevent crime and improve reintegration of ex-prisoners. The report argued that the prison population in England and Wales should be capped with an objective of reducing it to two thirds of its then level. It coined the term "pre-habilitation" to argue that resources should be invested in the most deprived communities which produced the greatest numbers of candidates for custody and suggested that mainstream local agencies responsible for providing health, education, social care, and employment should be incentivized to do more to assist offenders subject to community sentences and returning from prison.

Building on the interest in places as well as cases, in 2011, a more detailed strategy plan was proposed by the influential think tank the Institute for Public Policy Research (IPPR) for the funds spent on imprisoning adult offenders for periods of less than 12 months to be devolved from central government to local councils so that they can put in place measures to deal with the causes of offending behavior. Councils would be charged back by the prison service every time someone from their local area was sent to prison for a period of less than 12 months. The IPPR also recommended that probation services should be decentralized and fully integrated into crime-reduction work locally, by placing it under local authority control (Lanning et al. 2011).

These proposals have so far had limited specific impact on policy makers, although the general thrust of the thinking that lies behind them – reduced use of prison and greater localism – resonates strongly with aspects of the rehabilitation revolution. There is however one specific current that underpins government policy on the provision of a whole range of public services which shares some features with JR – that is, payment by results or PBR. A number of government departments are moving towards an outcome-based system of payment for services. Funding for private or not-for-profit organizations involved in getting the long-term unemployed into work, for example, is paid exclusively or heavily based on delivering results – not just placing people in work but keeping them there, with payment made after results have been delivered. Similar initiatives are being piloted in respect to drug and alcohol treatment and have been proposed as a way of funding early intervention programs with children at risk.

In the justice area, the government has pledged to "pioneer a world first – a system where we only pay for results, delivered by a diverse range of providers from all sectors. This principle will underpin all our work on reoffending. This is a radical shift" (Ministry of Justice 2011). One aspect if this relates to diversification of the market – the government says they will no longer provide rehabilitation services directly without testing where the private, voluntary, or community sectors can provide them more effectively and efficiently. An Offender Services Competition Strategy was published in July 2011 which signals a series of competitions for contracts to run nine prisons and a range of community-based programs (Ministry of Justice 2011b).

A second aspect of this relates to the way contracts for the provision of services are framed. A key element of the approach to competition is to "continue to develop and expand a range of models where providers are paid based on the results they achieve. This will allow providers both to innovate and to ensure that value for money is achieved. Providers will be encouraged to put forward innovative models to focus more effectively on rehabilitation..." (Ministry of Justice 2011b). For example, a recently agreed contract to run Doncaster prison (which in fact predates the competition strategy) includes a 4-year payment-by-results pilot starting in October 2011. This contract, apparently the first of its type in the world, will mean that private provider Serco are held to account both for running a safe, decent, and secure prison and the reoffending of their offenders on release. For each year of the pilot, 10 % of the contract value will be placed at risk and will only be retained by Serco if they reduce reoffending by 5 percentage points. If they fail to achieve this target, then money will be paid back to the government. If they deliver more, then they will be paid more than the original contract price (Ministry of Justice 2011). Serco claims that the Doncaster prison scheme could see more than 15,000 fewer offenses a year if it hits its targets.

Practice

Alongside these developments and proposals for policy change, a number of practical pilot initiatives have drawn inspiration from aspects of JR. One of the first which claimed to be based on JR was the Diamond District initiative which operated in six London boroughs in 2009–2010. Multiagency teams including police and probation officers and local authority workers were located in neighborhoods with high numbers of people returning from short spells in prison. (The term diamond was coined to communicate the disproportionate value which would attach to reducing reoffending in these areas.) The teams offered enhanced resettlement support to prisoners returning to the neighborhoods. Although there was no obvious mechanism by which any savings to the prison system would be recouped into the communities concerned, the question has not been pursued since the £11million initiative did not find that the experimental group was reconvicted any less than a carefully matched control group – although interestingly the rates of reoffending for both experimental and control groups were well below the national rate. The evaluation of the project argued that "whilst the headline finding of the report is that there was no evidence of reduced reoffending as a result of the Diamond Initiative within the original cohort-this does not demonstrate that Diamond has failed as an approach: such a conclusion would be erroneous" (LCJP 2011).

Thus, despite the disappointing results, interest in justice-reinvestment-inspired schemes has not waned. Three pilot programs involving JR are under way at the time of writing each of which aims to reduce the demand for custody.

The first relates to juvenile offenders, for whom a Youth Justice Reinvestment Pathfinder Initiative was set up in early 2011. The Green Paper Breaking the Cycle proposed that local authorities should share both the financial risk of young people entering custody and the financial rewards if fewer young people require a custodial sentence. The pilots aim to test how this might be achieved.

Under the scheme, central government will be investing a proportion of the budget used to fund custodial places into grants for consortia of local authorities to commission alternatives to custody in four pathfinder areas. The aim is that as a result the use of incarceration for both sentenced and remanded young people in the pathfinder areas will be reduced by an agreed amount over a 2-year period. If the authorities fail to reduce their use of custody by the agreed amount, they will have to pay back the funding – or a proportion of it – to the Ministry of Justice. Pathfinders will be free to commission and deliver schemes in a way that best addresses their local needs and circumstances.

The second initiative known as the Financial Incentive Model has also been developed by the Ministry of Justice to test the extent to which local partners can work together more effectively to reduce crime and reoffending. This approach is being tested in six local areas: Greater Manchester and five separate London boroughs (Croydon, Hackney, Lewisham, Lambeth, and Southwark). The project covers both adult and youth aspects of the criminal justice system. The basic idea is that the Ministry of Justice would pay local authorities and service providers if they were successful in reducing court convictions and court disposals for adult and youth offenders in the local areas. Sharing the savings that accrued to the Ministry of Justice from the reductions would enable the local authority to reinvest further in crime prevention activity at the local level in line with their priorities.

The rationale for the project is based on the hypothesis that giving local partners more financial accountability for the demand placed on criminal justice services, such as courts, prison places, and probation services, will provide them with an incentive to work more effectively to reduce crime and reoffending locally and thereby to reduce that demand. Under the model, the local partners are free to implement plans to reduce crime and reoffending, targeting their resources on specific groups of offenders in line with the local priorities and crime patterns. Demand on criminal justice services will be measured using a series of metrics focused on offending that results in short custodial sentences and less severe sentences. Demand will be measured across two consecutive 1-year periods, with the measurement period starting on 1 July 2011 and closing on 30 June 2013.

The third initiative, which has attracted significant attention in the UK and internationally, is a novel form of financing services to resettle prisoners leaving Peterborough prison after a short custodial sentence – the so-called Social Impact Bond ("SIB").

A Social Impact Bond is a contract with the public sector in which investment is raised from socially motivated investors and used to pay for a range of interventions to improve social outcomes. As improved social outcomes result in savings to government and wider benefits to society, the government agrees to pay a proportion of any savings back to the investors if the interventions succeed. The payments from government cover the initial investment plus a financial return which depends on the extent to which outcomes are improved. If the outcomes do not improve, investors lose their investment. The term "bond" is a misnomer because all of the capital is theoretically at risk should the project fail to make any impact.

In the Peterborough project, which was officially launched in September 2010, £5 million has been raised from 17 investors – mainly charitable foundations interested in a "mission-aligned" investment opportunity – to fund the provision of services to 3,000 prisoners returning to the community having served a sentence of less than 12 months. Investors stand to make a return if the three cohorts of offenders eligible for the service are reconvicted 7.5 % less frequently than a matched control group of prisoners from other prisons. Nationally about 60 % of short-term prisoners are reconvicted within a year of release, and few of these prisoners have access to support which might help them find a stable home, a job, and assistance with other problems which left unaddressed can rapidly lead back to crime. The funds are being used to commission not-for-profit organizations to provide intensive help before and after release – so-called "through-the-gate" services.

The attractiveness of the SIB to a range of stakeholders is clear. For government a SIB removes the financial risk that they pay for services that prove to be ineffective at addressing social needs and improving outcomes. For investors a SIB offers a potential return on investment – if reconviction events are reduced by 10 % across all cohorts, investors are expecting an annual internal rate of return of around 7.5 % up to a maximum of around 13 %, depending on the scale of the reduction in reconviction events (Disley et al. 2011). The SIB also offers the chance to use capital in a socially useful way. For service providers a SIB provides up-front funding for the delivery of services (so they do not carry the risk of not being paid). For the public and service users, funding raised through a SIB may pay for services that fill a gap in existing provision.

The first evaluation report on lessons learned from the planning and early implementation of the SIB at Peterborough did not find it possible to draw conclusions about or comment on any outcomes from the scheme. It raised a number of questions about its complexity of and the costs of establishing it – the intermediary who arranged the SIB, Social Finance, estimated that it has invested approximately 2.5 person – years of its resources, and more than 300 h of legal advice (provided pro bono), as well as specialist tax advice, in developing the SIB. The report also pointed out that the scheme *is* too small to deliver substantial "cashable" savings – "The ability of the SIB model to lead to identifiable savings for government is yet to be tested, if the SIB model is implemented on a larger scale" (Disley et al. 2011).

If this model were rolled out nationally, the report suggests that there could be incentives to "cherry pick" by prison or area – that is, for funders to choose sites for investment or indeed particular types of beneficiaries for the service who are likeliest to achieve improved outcomes – by implication leaving or "parking" as it is sometimes called more hard to reach people or places. More technical difficulties were also identified – for example, that future SIBs may face the challenge of sharing outcome payments across central and local government departments or other agencies who may stand to benefit from savings brought about by the intervention. Also SIBs in areas of work that currently receive statutory provision will need to devise outcome metrics that enable the government to isolate the effect of SIB-funded interventions from existing statutory services. Short-term prisoners do not usually receive any statutory help so the issue does not arise at Peterborough. The evaluation report also points out that using a Social Impact Bond to fund a new service in a field where no existing interventions are in place also "avoids the many difficult issues raised by the possible need to decommission statutory services in such circumstances – another possible challenge for future SIBs" (Disley et al. 2011).

Supporters of SIBs point to the fact that they provide a vehicle which could attract new money into underfunded activities like resettlement and community support for offenders. Over half the investment (by value) and half the investors (by number) in the Peterborough SIB are either using their endowment or investing in the UK criminal justice area for the first time.

Others are less convinced. The head of the Howard League, a leading penal reform charity reportedly described the system of payment by results for justice services as "nonsense." "Using the example of a prolific burglar who has recently been released from prison, Frances Crook was quoted as saying: "You come out of jail, you're sofa-surfing and you're on drugs, but you clean yourself up, get a job and get a girlfriend. Who should be able to make money out of you? Public service is something which does great good and which we should value. If you introduce profit into public service it changes everything" (Civil Society Finance 2011).

Others have attacked the use of investment bonds more generally as "fairy dust, disguising short-sighted cuts that will do much social damage in future years. We get the social services we are willing pay for with our taxes: this is fool's gold" (Toynbee 2011).

It will of course be some time before data is available to make an empirical judgment about the impact in criminal justice of the payment-by-results approach in general and the Social Impact Bond in particular. That has not prevented the government committing to applying the principles of payment by results across all services which reduce reoffending by 2015.

Conclusion

Justice reinvestment has come to have a range of meanings in England and Wales, and it is possible to identify three types of policy and programs. First, there are relatively pure examples of initiatives that are true to what are generally taken to be the key tenets of the concept, aiming to transfer resources way from imprisonment and into community-based crime-reduction measures of one sort or another (Allen 2011). The Youth Justice Reinvestment Pathfinders and Financial Incentive Model fall into this category. Each is based at the local government level (albeit through consortia of local authorities in the case of the youth scheme), but it is not yet clear how much of a focus they will have in the particular neighborhoods whose residents are disproportionately imprisoned. These programs are all publicly funded with local agencies given incentives to reduce the use of custody through the opportunity to spend resulting savings but facing a concomitant risk of meeting additional custodial costs which might be incurred.

There is a second form of JR which involves the investment of funds from outside government into activities designed to produce positive social outcomes such as reduced reoffending. The Social Impact Bond is an example of a model which offers incentives and risks for investors; if the program succeeds, they will receive outcome payments from the government's savings in prison spending produced by reduced reoffending. If the program fails, government pays for the prison places but not the unsuccessful attempt to reduce reoffending. The scale of likely investment in financial instruments such as this is not yet known. Nor is it clear whether Social Impact Bonds could practicably be used to replace existing activities rather than fund new pieces of work.

Some uncertainty also surrounds the third type of JR which is the approach to contracting based on payment by results. The hope is that attaching financial rewards to successful rehabilitation will promote innovation and that reduced reoffending will bring down demand for prison. But unlike the first type of JR, there is no commitment to reinvest any savings in communities. Unlike the second type, there is no outside funding brought into the system. Given the substantial budget reductions being faced by the Ministry of Justice, it is all too likely that PBR could prove a form of justice disinvestment rather than reinvestment.

Despite the range of JR-related initiatives in place in 2011, there are still possibilities for more extensive and deeper application of the approach. This is certainly the conclusion reached by the parliamentary committee which championed JR in 2010. In an inquiry into the role of the probation service the following year, the Justice Committee concluded that "the model of justice reinvestment explored by our predecessor Committee – of greater investment in a package of reforms to reduce the use of custody, including increased spending on probation services, allowing significant resources to be freed by halting the prison-building programme and enabling current inefficient prisons to close – has not been fully exploited; this will undoubtedly impede the pace at which capital can be transferred from prisons to community-based interventions and will therefore continue to leave probation services and local communities deprived of desperately needed resource" (Parliamentary Select Committee on Justice 2011).

Overview

Juvenile diversion refers to dispositional options that attempt to avoid the stigma of an official delinquent or criminal label (Lemert 1981). It is an overly general term because it can apply to virtually any programmed response that avoids the formality of the justice system. Historically, the exact shape of juvenile diversion has depended on the availability of various treatment and punishment options in a particular time and place. In earlier times, juvenile diversion meant the *reformatory* as opposed to the *penitentiary* and then later the *juvenile* court as opposed to the *criminal* court (Schlossman 1977). More recently, juvenile diversion refers to the avoidance of juvenile court; it has become a court from which youths are to be diverted *from* rather than a court to which youths are to be diverted *to* (Miller 1979). Moreover, the types of youths eligible for juvenile diversion tend to be those who are considered most likely to succeed through its various dispositional options (Cicourel 1968; Cohen 1985). These options include a range of programmatic and non-programmatic responses to common acts of delinquency by adolescents (Mears 2012). The effectiveness of these various diversionary options is an important area of policy-relevant juvenile and criminal justice research (Shelden 2008; Patrick 2005; Cocozza et al. 2005; Chapin and Griffin 2005).

This entry begins with a brief historical review. It then proceeds in section "Definitions of Juvenile Diversion" with a definition of juvenile diversion. Section "Who is Likely to be Diverted" discusses the most likely candidates for juvenile diversion. Sections "Evaluating Successful Forms of Diversion" and "An Example of Diversion" provide an example of juvenile diversion and figures on diversion based on police arrest and juvenile court intake statistics. The concluding section presents future directions for the evaluation of juvenile diversion.

In the Beginning

The idea of diverting juveniles from the justice system appears to be as old as juvenile justice itself. Children were always considered as a category of their own. Early nineteenth-century industrialization and urbanization extended childhood into an older-age category that would be known as adolescence (Empey and Stafford 1999). This shift necessitated the need for juvenile justice. The beginnings of juvenile justice can also be considered the basis for diversionary justice. Under the common law doctrine of *parens patriae*, the state could act as a parent in deciding the best interests of the child even if the child turned out to be an older adolescent (Schlossman 1977). Constitutional requirements for a fair hearing were avoided merely through a judge ordering a juvenile to be placed in the care of the state. As the age of compulsory school education began to extend into older-age categories, officials required a backup diversionary system of governmental control, for example, youths who refused to attend school.

During the 1820s, houses of refuge thus appeared in large cities like New York City as a way of enforcing various status-offending categories, such as not going to school or hanging out aimlessly on the city streets. The house of refuge was the place to divert such youths not only for status-offending acts but also for common acts of theft (Pickett 1969: 20). It was framed as a residential school for the treatment of unruly youths. Most importantly, however, houses of refuge exemplified the beginnings of juvenile diversion because they were considered a more reasonable alternative to the city jails and emerging state penitentiaries (Schlossman 1977). As such, they represented a profound shift in the way that the public and its officials thought about punishment; it was no longer to be based on exclusionary punishment but inclusionary control. Juvenile diversion from criminal justice was to foster the normal return of an adolescent once he had experienced the redemptive and formative assistance of a residential school in the shape of a house of refuge, reformatory, or training school.

But by the end of the nineteenth century, diversion in the shape of out-of-home placement was no longer viewed as desirable. Instead, reformatories became known as ordinary places of imprisonment that could turn an adolescent into a serious adult criminal offender. Reports surfaced about how the house of refuge moved from just being a residential school to a brutal place of punishment (Pickett 1969). A new face to juvenile diversion was needed; this would take the form of a juvenile court. Zimring (2002) in relating the early juvenile court to juvenile diversion notes Judge Tuthill's 1904 explanation of why the juvenile court could save juveniles from a life of crime. Tuthill explained that prior to the juvenile court, delinquents were "educated in crime and when discharged were well fitted to become the expert criminals and outlaws who have crowded our penitentiaries and jails. The state had educated innocent children in crime, and the harvest was great" (145). The juvenile court could divert juveniles from this life of crime by providing a more inclusionary form of control.

The preferred means for avoiding a life of crime was through a system of inclusionary control that avoided the isolation, criminalization, and stigma of incarceration. This kind of diversion from punishment could be organized through a juvenile court. The main method for doing so was in the shape of probation. The history of the juvenile court as a diversionary court is the history of probation as a community-based supervisory form of diversion. The advantage was not only to treat the adolescent in the community but also to save the offending juvenile from a criminal identity; that identity was conceived as ongoing, to be shaped through the malleability of childhood as extended into adolescence. The best place to create a respectable, law-abiding adolescent was to be maintained through the treatment-oriented juvenile court and its emphasis on prevention and control within the community and family.

By the beginning of the twentieth century, officials had made the case for a more all-encompassing system of juvenile diversion from criminal justice. The juvenile court would have a multitude of options as its disposal. In large cities, there would be a clinic in which to diagnose troubled youths. There would also be a separate probation department. The emerging social science of adolescence provided the justification for confirming various techniques for treating troubled youths. The stories of juvenile court reformers told of how best to divert adolescents from a life of crime (Levine and Levine 1992).

As a diversionary court of jurisdiction, the main technique of treatment emphasized inclusion over exclusion; it emphasized probation as a first resort for a wide range of offense. Through a system of probation, parents could be guided to be better parents. But the power of probation would extend far beyond supervision. The probation officer became a key official, critical to both intake and outtake processes. As an intake official, probation officers could appear at various stages in the juvenile justice process. Police officers were often assigned the task of acting as intake probation officers (Wolcott 2001). They could easily dismiss cases, bring a child to the child's home and warn the child and the parent that the offending act could lead to an official arrest. As outtake officials, probation officers had the authority to incarcerate adolescents who repeated their offensive behavior.

The diversionary techniques of the juvenile court at various stages could proceed because it was an insulated, nonpublic legal setting (Miller 1979). The rationale for confidentiality was to protect the identity of adolescents from a public criminal label. This veil of confidentiality worked not only to keep the name of delinquents away from newspaper reporters but also to protect officials from public scrutiny over their decisions to treat and to punish juveniles. The informal nature of the traditional juvenile court became less tolerable as the court appeared to ignore the justice component of juvenile justice. A new wave of reforms would shift the purpose of the juvenile court and the shape of juvenile diversion.

By the 1960s, when critics of the juvenile court were writing about its informal procedures, officials were ready for a new set of diversionary reforms. The US Supreme Court, in a series of decisions, would decide that the juvenile court was much too informal in the way that it adjudicated adolescents (Feld 2000). Constitutional rights needed to be applied to juveniles in a juvenile court, including the right to legal representation. The juvenile court could no longer proceed informally as it had in the past. Several years after the 1964 Gault decision, the President's Crime Commission in 1968 explicitly recommended the diversion of status offenders from a less informal diversionary juvenile court.

In one of the first evaluations to appear on juvenile diversion, Cressey and McDermott (1973) predicted the contemporary shape of juvenile diversion by observing that "there will be a polarization of attitudes and programs: Lawbreaking juveniles are likely to be processed along the lines of the adult model and hence will receive more due process and less humanistic consideration—after all, are they not merely small criminals? Juveniles who have been called 'predelinquents,' because they can't get along at home or in school, will be diverted (61)." Cressey and McDermott's prediction would become true at both ends of the justice system. In less than a decade, waiver legislation expanded the eligible population of juveniles who could be brought into criminal court. Singer (1996) has referred to this hard-end of the juvenile and criminal justice system as *recriminalization*. A segment of juveniles viewed as ineligible for the treatment-oriented mission of the juvenile court are now seen as criminally responsible and deserving of criminal sentencing in criminal court. But this kind of diversion would be at one extreme end of the juvenile justice system, while at another softer end, inclusion would persist through the proliferation of programs that avoided the more formal juvenile court. The informal system of juvenile justice expanded beyond the juvenile court's ability to adjudicate delinquent status (Mears 2012).

Definitions of Juvenile Diversion

Most definitions of juvenile diversion focus on its inclusionary technique of invoking control. As noted, the term diversion has over time encompassed a variety of agencies, institutions, and programs. Diverting juveniles from the juvenile court to the criminal court through waiver legislation is an aberration of terms since it avoids the inclusionary, non-labeling function of juvenile justice (Singer 1996). For juveniles that are deemed criminally responsible for their offenses based on the seriousness of the crime and prior history, diversion is the juvenile court (Feld 2000).

A definition of diversion suggests the following possibilities. First, there is *true* diversion. Edwin Schur (1973) defined true diversion as a form of "radical non-intervention." But any offense that invokes a response may be viewed along a scale of first and last resorts of dispositional options (Emerson 1969). The most frequent source of juvenile diversion is the police (Wolcott 2001). For common acts of delinquency, the police are the first to respond, and they frequently respond by warning adolescents not to repeat the offense. This kind of diversion may be considered non-programmatic. It avoids mandating an intervention that might disrupt the life of the adolescent. Non-programmatic diversion operates on the theory that a warning is sufficient to avert the repetition of an offense.

Juvenile diversion may also be referred to as programmatic. The police, intake officials, and even prosecutors as well as judges may refer juveniles to a variety of treatment options. They may be directly related to the operation of the juvenile court but without any formal adjudication or official penetration into the juvenile justice system. They include a range of options – including drug, youth, and family relation courts (Chapin and Griffin 2005). These newly established centers for diversion provide an alternative way of confronting adolescent offending while allowing the juvenile court to focus on serious acts of delinquency.

Thus, juvenile diversion as typically defined is inclusionary and cost-effective. Juvenile courts when first created as an informal diversionary court were cheaper to operate than the criminal court. Probation is less expensive than incarceration. Today, the informal system of juvenile justice is less expensive than the post-Gault formality of the juvenile court. Juvenile diversion is also defined by its more inclusionary form of control. The house of refuge was more inclusionary than the city penitentiary. Similarly, probation is more inclusionary, less stigmatizing than out-of-home placement. Last but not least, juvenile diversions into drug rehab, stop-shoplifting programs, or any number of treatment-oriented nonformal juvenile justice proceedings are less stigmatizing than adjudication in juvenile court. The most inclusionary form of juvenile diversion is the type that is referred to as non-programmatic in producing a warning rather than a programmed intervention.

Who Is Likely to Be Diverted

Advocates of juvenile diversion would indicate through their mission statements that their programs are for those adolescents who deserve a particular form of treatment. Criminologists who have evaluated diversion see more than just the objective need of the adolescent for treatment. Juvenile diversion tends to be defined by a set of local administrative rules and procedures as well as by the availability of various treatment options (Hasenfeld and Cheung 1985). Criminologists also recognize that these options are not evenly distributed. They depend on the resources of a community and the ability of parents to afford various diversionary options. More affluent communities are in a better position to provide their youths with a range of diversionary options. Similarly, affluent families have at their disposal a range of options in a private system of treatment for their troubled youths. The police may be attuned to the possibilities of true, non-programmatic diversion because they see affluent parents as competent to control their youths. Petty acts of shoplifting and property destruction may be settled civilly, because affluent parents are in a better position to pay the cost of their child's offending.

Closely associated with class indicators of diversion is race. Disproportionate minority confinement in juvenile institutions may be viewed as a function of a lack of suitable alternative diversionary programs. In a report sponsored by the US government's Office of Juvenile Justice and Delinquency Prevention on racial disparities within New York State, the authors concluded that the differences in the race of youths locked in juvenile facilities can be largely attributed to "the greater availability of diversion programs in suburban areas, coupled with the greater affluence of suburban families and their ability to access services for their children and compensate victims, leads to over-representation [of minorities] in the juvenile justice system" (Nelson and Lansing 1997). A variation of the above quote can be found in nearly all federally mandated, state studies of the disproportionate confinement of minority juveniles and numerous scholarly articles and books (Feld 2000, Leiber and Stairs 1999; Ward 2013).

In Stanley Cohen's 1985 book, *Visions of Social Control*, he relates a theory of diversion on who is most likely to receive the more inclusionary justice system's controls. He illustrates soft-end diversionary justice as targeting those who are believed to most likely to succeed. He refers to the acronym YARVIS (Young, Attractive, Rich, Verbal, Intelligent, and Successful) to describe the most likely candidates for diversion. *Younger* adolescents are more likely to be diverted because they are viewed as too naïve to be held fully responsible for their behavior. The *Attractive* may be viewed as those who look more like the children of officials, who would reflect majority class and race characteristics. This distinction is invoked by Jerome Miller (1979) when he suggests that there is a basic split between how some youths are perceived as more or less deserving of treatment. Juvenile diversion reproduces this basic bifurcation in decision-making. Similarly, the *Rich* as noted have options that are simply unavailable to the impoverished. Therapeutic schools can easily exceed the cost of the most expensive private colleges, and only the wealthy can afford this kind of juvenile diversion. Moreover, professional therapy is generally a luxury for those who have insurance to cover its cost or who can pay for the out-of-pocket expense of a therapist. The *Intelligent* have always maintained an advantage in that they can articulate their troubles and the reasons for their delinquency. Their prognosis for success is generally considered better than those who suffer from a range of intellectual and learning disabilities.

Evaluating Successful Forms of Diversion

Determining the rate of success of juvenile diversion is a difficult task. The criteria for selecting youths can confound any evaluation of the true effectiveness of a treatment program. The ability to assign youths to programmatic and non-programmatic treatments requires an experimental design that cannot easily be implemented. Programmatic and non-programmatic efforts at diversion may be viewed as desirable independent of any proof of recidivism. Judgments about who is eligible for a diversion are often based on judgments about the probability of success; creating selection effects can easily confound experimental and quasi-experimental research designs. Moreover, there may be long-term effects to juvenile diversion that cannot easily be detected through short-term studies.

The success of programmatic efforts at juvenile diversion most often rests on the sense that officials have of a particular policy. A diversionary program may make sense because it is cost efficient when compared to alternatives and when it reflects the desire of officials and the public to see a minimum sanction applied. A litany of sensemaking approaches to understanding organizational structure (Weick 1995) and how juvenile diversion makes sense in contrast to a range of alternatives is the reason for programmatic and non-programmatic responses. So houses of refuge made sense as a residential school for troubled youths in contrast to the city penitentiary. Similarly, probation made sense as supervised care within the community in contrast to the reformatory. Last but not least, the informal system of juvenile justice today makes sense when contrasted to the more formal procedures of the juvenile court. The litany of juvenile diversionary responses is generally considered appropriate for more deserving youths as subjectively defined by officials in their case processing decisions. Juvenile diversion will continue to proliferate in a multitude of forms independent of any proof of success in terms of recidivism. Instead, success is defined in relation to a range of possible alternatives.

An Example of Diversion

As stated in the previously cited government report, juvenile diversion is more likely to take place among youths in affluent communities and affluent families. The following unedited letter from an affluent youth in an affluent suburb illustrates the point of diversion:

> Dear Chief Probation Officer Riley:
>
> I would like to point out how thankful I am for being granted the opportunity to make right of what I have done wrong. The pre-trial diversion program gave me a chance to realize how serious and real breaking the law is. Along with being granted the pre-trial program I was obligated to pay all fees to the court, finish the JDP [Juvenile Diversion Program] program, visit a personal counselor, finish twenty hours community service, and take random drug tests. Because my record was so important to a successful future for me, I completed all the tasks I was allotted to accomplish within six months. In doing so I learned not to get in trouble. I do not plan on ever having to show up to court for anything again. I think every kid with a first offense deserves the pre-trial diversion program. Because ones record is so important, a clean one is important for their future. I am very grateful for the opportunity I was given.
>
> Sincerely, an arrested affluent youth in an affluent suburb

Success is deemed possible because this particular adolescent's family was able to hire a private attorney, and in this affluent suburban town, a juvenile diversion program created the opportunity to avoid adjudication as a delinquent. Community service, drug testing, and therapy enabled this particular youth to meet the conditions of his pretrial diversion. By meeting those conditions, the youth escaped a possible conviction not only in juvenile court but also in criminal court. He could have been charged with a felony and faced prison time for a large quantity of marijuana that was found in his possession along with other drug-related paraphernalia. The fact that he was able to avoid formal adjudication as a delinquent is related not only to his youth but to his affluence, intelligence, and attractiveness as a good candidate for diversion. His diversion might not have been possible if his parents were unable to afford the cost of a private attorney, the time spent in court, and the insurance money for private counseling and professional therapy. The empathetic response of officials in this affluent suburb recognized the youth's adolescence and identified with his parents' desires.

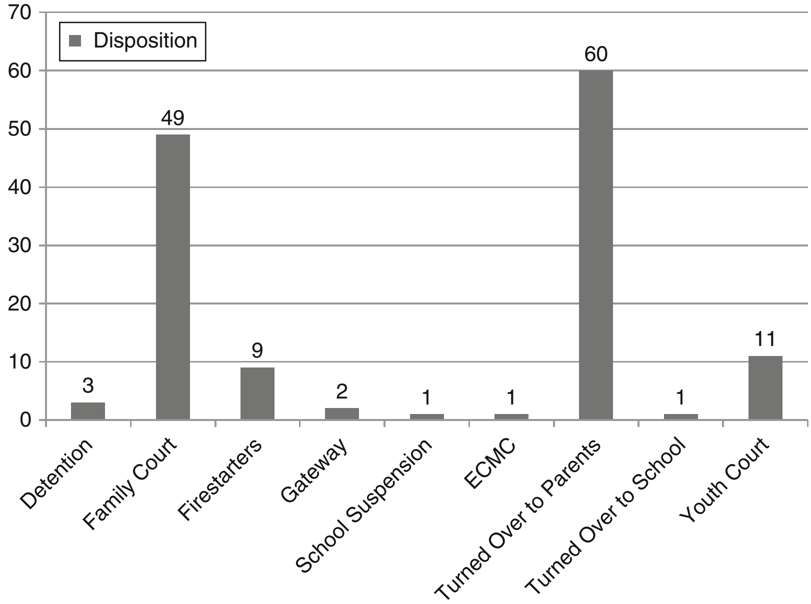
Data on Juvenile Diversion

A large part of the business of understanding diversion involves evaluating various programmatic designs. Various diversionary programs are considered panaceas when first implemented. The reliability and validity of these evaluations are beyond the scope of this entry and are discussed elsewhere. For now, it is important to bear in mind that a range of diversionary programs exists, independent of any proof of effectiveness. They exist because they make sense to officials and the public who support them as alternatives to the expense and stigma of incarceration. Rather than a non-programmatic form of diversion (true diversion), programs like youth and drug courts, restorative justice, first offender programs, and a wide range of other programs are thriving under the banner of diversion.

It is important to bear in mind that the traditional role of the police has been to act as a gateway to juvenile justice. This point has been emphasized by David Wolcott (2001: 363) who concluded that "the police made the juvenile justice system run." This conclusion is based on the filtering function of the police to decide which adolescents would be brought into juvenile court. He examined statistic for Chicago, Detroit, and Los Angeles during three distinct periods of time. The story that he tells is one of juvenile diversion that reflected the organizational practices of the times. It is not an even story given that the availability of options created the possibilities for juvenile justice to take on a variety of diversionary tracks.

In one affluent suburban town which is similar to where the previously mentioned diverted youth resided, data on the disposition of police arrests reveal a familiar story. First, it is important to bear in mind that the police can act as the first source of diversion. They can decide if an offending youth should just be warned or referred to the juvenile court. Figure 1 shows the arrests of juveniles younger than 16 in an affluent suburb. Of the 137 recorded official arrests for acts of delinquency (non-status offenses), only 36 % were referred to the juvenile court (New York's

Juvenile Diversion, Fig. 1 Officially recorded police recorded dispositions of juvenile arrests for 2001, Amherst, New York (Source: Singer 2014)



Family Court). The remaining arrests were diverted either to their parents or a variety of treatment-oriented programs. The most common of these was the town's youth court. This type of diversion avoids any kind of juvenile court record, and its most severe sanction is of the community service type.

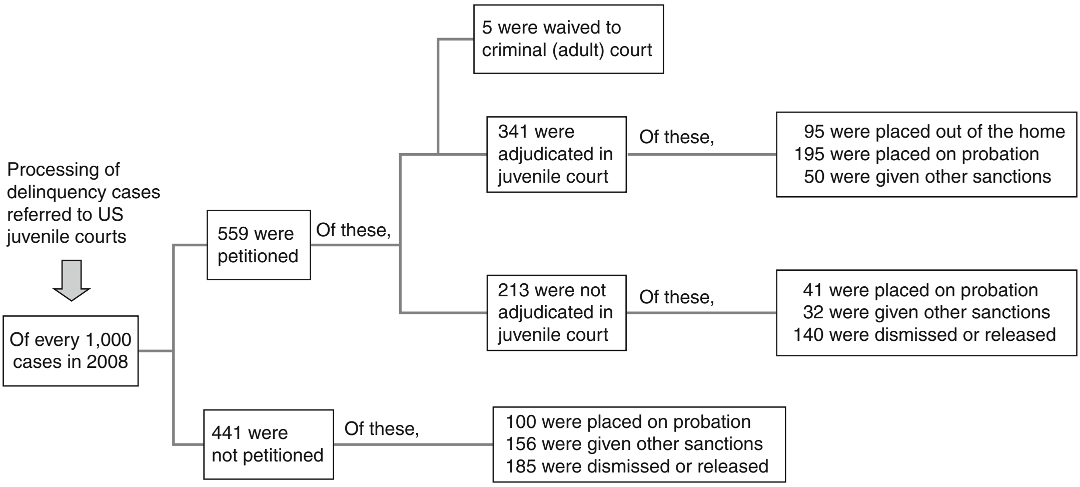
But what happens if a juvenile is referred to the juvenile court? Once juveniles are referred to juvenile court, they may receive diversion into any number of programs through intake independent of the formal hearing. Figure 2 presented national court statistics for case processing decisions in 2008 based on nationwide juvenile court statistics as compiled by the National Center for Juvenile Justice. Of those who were not formally processed in the juvenile court, most were given a range of sanctions including probation. About 42 % were dismissed or released. This non-programmatic form of diversion as exemplified by true diversion is after the fact that in some jurisdictions the police have already acted as filtering agents in only bringing a small proportion of youths with whom they make a recorded contact into the juvenile court.

Figure 2 is for the entire USA; it does not include the wide array of programs to which adolescents can be placed as a condition of their diversion in affluent suburbs such as the one represented by the graph of arrests in Fig. 1. Informal dispositions should be higher in more affluent counties and towns. In this particular affluent suburb, youths may be eligible for its Drop-Out and Early School Intervention, First Offender Youth Board program, Serving at Risk Adolescent Homes program, Responsible Adolescent Parenting program, and the nationally recognized Tough Love program. Many of these programs are family based and require family therapy as a way of confronting an adolescent's offensive behavior.

The impact of these programs is difficult to assess except in its most general form. There are advantages and disadvantages to non-programmatic forms of juvenile diversion. For Lemert and other theorists of labeling, these programmatic forms of diversion had the risk of isolating youths with other youths who were equally delinquent.

Future Directions

Programmatic efforts to deal with offending youth exist to respond to trouble. Thus, qualitative research by Robert Emerson (1969) has defined trouble along a continuum of first resort and last



Processing of delinquency cases referred to US juvenile courts
Of every 1,000 cases in 2008
559 were petitioned
Of these,
5 were waived to criminal (adult) court
341 were adjudicated in juvenile court
Of these,
95 were placed out of the home
195 were placed on probation
50 were given other sanctions
213 were not adjudicated in juvenile court
Of these,
41 were placed on probation
32 were given other sanctions
140 were dismissed or released
441 were not petitioned
Of these,
100 were placed on probation
156 were given other sanctions
185 were dismissed or released

Juvenile Diversion, Fig. 2 Juvenile court case processing decisions (2008) (Source: Puzzanchera et al. 2011)

responses. These first and last responses are historically place specific. The house of refuge, as noted, was initially conceived as a first resort, an alternative to the city penitentiary. It became a last resort as new ways of seeing how to respond to adolescents evolved in the shape of probation and its juvenile court. The emerging social science of adolescence has created new opportunities for considering how best to respond to the reasons for adolescent offending. For those jurisdictions that could afford the luxury of a mental health clinic and a professional staff of probation and social workers, there was little need to divert from the juvenile court.

However, a more formal juvenile court brought a more expensive juvenile court – one where lawyers would have to be paid and rules followed similar to criminal court. This was to reduce the risk of injustice that might be caused by sentencing a juvenile as delinquent for a crime that they did not commit. The Gault decision was to safeguard the risks of a too informally driven juvenile court. But this informality would be extended in an expanding front-end of juvenile justice where most adolescents would receive some sort of sanction based on the assumption that diversion was more just for its treatment protocol and less stigmatizing than formal handling in juvenile court.

This assumption of the justice of juvenile diversion needs to be examined in its organizational and legal sense of justice. The decentering of the contemporary juvenile court became so blatant that Jerome Miller would refer to the juvenile court as a setting from which juveniles were to be diverted. This was not always the case as previously noted. But the reasons for diversion need to be examined based on (1) the sense of justice that juvenile diversion produces in an informal system of juvenile justice, (2) the risks that the treatment will be just as stigmatizing as formal processing, and (3) the meaning of the treatment for officials and the public, that is, how success and effectiveness are to be defined.

Edwin Lemert's (1972) theory of secondary and primary deviance is often cited in textbooks as the reason for diversion. But this can be disputed based on Lemert's writings that avoided the simplistic notion of a labeling theory. Trouble was identifiable in the shape of an offense. The method of reacting to that offense defined the type of control that would be deemed as most effective. The courts can make a bad situation worse, leading to secondary deviance by separating the adolescent from the mainstream of society. This process of social attenuation could occur through an adolescent's repeated identification with delinquents. It is them against us as exemplified by the concept of social attenuation that Lemert warned against. The problem for many programmatic efforts to divert juveniles is they risk further isolating youths by not dealing with their troubling behavior. Moreover, the best place for treatment may not be in the home when the source of trouble is the home, such as in instances of child abuse. How to maintain the social status of troubled youths may require an individualistic and not programmatic response, such as individual therapy.

The social organization of juvenile justice in each community also needs to be revisited to assess the extent to which juvenile diversion matters in the lives of adolescents. This entry has referred to research on programs in one affluent community and a government report that points to disparities in diversion based on the availability of services. Affluence matters both on community and familial levels. Cicourel (1968) made this point in his study of the social organization of juvenile justice when he compared two cities that varied in their policing and official responses to delinquency. The less affluent city was less professional, and officials were more inclined to make arrests rather than to negotiate diversion. The status of parents was considered equally important as well as the possibilities that parents were willing to negotiate a disposition.

To look deep inside of juvenile justice systems is to examine the reasons for a veil of confidentiality that is there not so much to protect the status of adolescents but to protect officials from public scrutiny of their decisions. Juvenile justice in general may be considered a black box of decision-making, and this makes decisions regarding juvenile diversion difficult to trace. Officials must be convinced about the importance of transparency in their decision-making along with the rights of adolescents to have their identities protected.

Criminologists can provide that independent evaluation. But it requires the hard work of gathering the intimate details of administrative decision-making. Criminologists should also look at the extent to which diversion is supported independent of concerns about offender recidivism.

Conclusion

Juvenile diversion is an integral aspect of our justice system. It was the basis for houses of refuge, reformatories, juvenile courts, drug courts, and youth courts. Juvenile diversion will remain with us as an integral part of our juvenile justice systems. The principle of juvenile justice is rooted in the concept of diversion. But it is a principle that revolves around doing nothing (radical nonintervention) or doing something (programmed treatment). This difference too often neglects the fact that doing nothing often involves at a minimum a warning and announcement that a rule has been violated. Similarly, doing something often turns into doing nothing if the juvenile is inappropriately placed in a program that has little effect on their troubling behavior.

Diversion is not only to be found everywhere in a complex system of juvenile justice, but its basic characteristics are closely identified with the notion that adolescents are deserving of another chance. Yet eligibility for diversion is not evenly distributed based on the resources of the community where an adolescent lives and the status of their parents to afford a number of possible options.

The most simplistic approach is to consider diversion as a first resort in a system of justice where individuals are given a multitude of chances. Yet not only are these chances dictated by a prior history of offending but also by the seriousness of the offense. Generally, the more serious the offense, the less likely the offending adolescent will be eligible for diversion.

Future research needs to examine the mix between place, characteristics of adolescents, and the availability of diversionary programs if they are to be able to fully assess the meaning of juvenile diversion in a complex modern-day system of juvenile justice.

Overview

During the last quarter of the twentieth century, a conservative reform movement took hold that quickly came to dominate the national debate over juvenile justice policy. Legislators in virtually every state enacted punitive legislation that challenged foundational principles of the juvenile justice system and, for a time, appeared to threaten its continuation. This entry considers this "Get Tough Era" in juvenile justice – the factors that brought it about, the changes it introduced, and its legacy for the future.

In order to appreciate just how radical a departure the contemporary Get Tough movement represents, it is helpful to recount a bit of history.

Juvenile Court and the Progressive Era: A separate justice system for juveniles took shape over the course of the nineteenth century and came to fruition in 1899 with the founding of the juvenile court in Cook County (Chicago), Illinois. Beginning in about 1820, industrialization, urbanization, and immigration transformed what was then a largely rural America: Factories sprang up from the Eastern seaboard to the Midwest, drawing internal migrants from rural areas and massive waves of immigrants from Western and Eastern Europe. In a single generation, small towns like New York and Chicago grew into densely inhabited and chaotic cities characterized by a host of social problems: slums, infectious disease, alcoholism, mental illness, homelessness, civil unrest, and burgeoning levels of crime and delinquency. In impoverished urban neighborhoods, children living in crowded ghetto tenements took to the streets to play, to scavenge, and to work – as newsboys, shoe shiners, peddlers, beggars, and thieves. The presence of destitute children in the streets, unsupervised and exposed to the perceived evils of urban life, disturbed more affluent residents. By the 1880s, groups of educated, middle-class women (the "Child Savers") came together to address the plight of these endangered (and potentially dangerous) children. They advocated successfully for many reforms, including child labor laws, compulsory school attendance laws, mothers' pensions (the precursor to Aid to Families of Dependent Children), and a specialized court to handle delinquents and children at risk for delinquency (Feld 1999).

Up to this time, children who violated the law were prosecuted in criminal courts and received the same punishments as applied to adults. In urging the removal of children from the purview of the criminal justice system, the Child Savers argued that there are important differences between youth and adults that ought to inform societal responses to youth misbehavior. Drawing from the emerging discipline of child psychology, they portrayed juvenile offenders as immature, dependent, and vulnerable children who require special protection. In contrast to adults, they argued, children are immature not just physically, but mentally: They lack adult capacities for reasoning, moral understanding, and judgment. Because these capacities are the grounds on which attributions of criminal culpability rest, it is unjust to subject youth to adult criminal punishments. Moreover, they contended, whereas adults are relatively fixed as to personality and disposition, children are malleable and especially vulnerable to external influences. Consequently, they ought to be shielded from exposure to unwholesome elements in their neighborhood and home environments and – should they commit crime – from the corrupting influence of adult offenders in jails and prisons. At the same time, young people's malleability makes them especially good candidates for intervention to prevent them from becoming adult offenders. Finally, unlike adults, children are dependent on others to meet their basic needs and to provide guidance and supervision. They argued that when the natural parents are not equal to this task, the state has an obligation to step in and assume this responsibility.

On these grounds, the Progressives urged the creation of a juvenile court that would replace the punitive model of criminal justice with a civil-therapeutic one: The new court would function as a benign, nonpunitive institution with a mission to act "in the best interest of children" to safeguard their welfare and promote their positive development. Based on this optimistic vision, the first juvenile court was established, supported by the common law doctrine of *parens patriae* – the state as parent and arbiter of child rearing. Because the court's mission was benevolent, its framers did not hesitate to draw its jurisdiction broadly to include not only children accused of crime but also those merely "at risk" for delinquency (Tanenhaus 2004). Further, its jurisdiction over children brought under its care extended to the age of majority: A child found within the purview of the juvenile court law might remain under state care and supervision for a brief period or an extremely lengthy one, depending on the nature and extent of his problems and needs.

To protect children, the court closed its proceedings to the public and created euphemisms for the stigmatizing terminology used in criminal courts. ("Petition," "adjudication," and "disposition" replaced "charge," "conviction," and "sentence.") In court, a judge met with the child and his parents, urged the child to admit wrongdoing, gathered information – less about what the child had done than about why he had done it – and developed a treatment plan to address the youth's problems and needs. The treatment most often involved probation or commitment to a correctional "school" for the purpose not of punishment but rehabilitation. Although the court's unregulated procedures had enormous potential for abuse, supporters trusted that the judge would "put himself in the position of a wise, affectionate, and careful parent" (Cardozo 1925) and exercise only benevolent despotism.

Setting the Stage for the Get Tough Era: For about 70 years, the juvenile justice system functioned in relative obscurity without challenge to the lawlessness of its court proceedings or the punitive realities of its correctional institutions. This came to an end in the late 1960s and early 1970s when, in a series of decisions, the Supreme Court compared the juvenile court's lofty rhetoric with the reality of the juvenile justice system in practice and, drawing parallels between the juvenile court and the Star Chamber, concluded that youth were entitled to constitutional procedural safeguards to protect them from erroneous findings of delinquency. Most importantly, the Court afforded juveniles the right to counsel, the right to confront and present witnesses, and the privilege against compelled self-incrimination, and required that offenses be proven beyond a reasonable doubt.

The Court did not endorse punishment by the juvenile courts, nor did it abandon the idea of rehabilitation. Indeed, it encouraged states to continue to pursue the "noble experiment" with which it began. However, by providing youth with procedural protections, the Court shifted the focus of juvenile proceedings from identifying and addressing the causes of a youth's misbehavior to proof that she or he had committed a crime. In so doing, the Court made explicit a relationship between law violations and juvenile court dispositions that had previously been implicit and unacknowledged (Bishop and Feld 2012). Notwithstanding the Court's continued endorsement of the juvenile court's therapeutic mission, its decisions had the effect of creating a hospitable climate for the punitive reforms that would soon follow. Immediately, for example, its decisions made it imperative that prosecutors participate in juvenile court proceedings for the first time. Prosecutors established juvenile divisions, staffed them with traditionally trained attorneys, and infused the court with an adversarial criminal law orientation.

An additional impetus to the Get Tough Era was the publication in the 1970s of a series of widely publicized reviews of research on the (in) effectiveness of treatment programs. Especially influential was the Martinson Report (Martinson 1974), which drew the bold conclusion that "nothing works." Critics responded that the negative results could be explained by research flaws and poor program implementation, rather than by the absence of positive treatment effects. But the critics' cautions – and even the subsequent retraction of the report's conclusion by its authors – received little notice. Instead, the rehabilitative mission of the juvenile court was increasingly viewed with skepticism.

Rising juvenile crime rates further contributed to punitive shifts in juvenile justice policy. Juvenile arrests increased substantially from the mid-1960s until 1980, reinforcing the view that the juvenile justice system was ineffective. Although juvenile crime then declined briefly in the early 1980s, another much more dramatic upswing followed. This one turned out to be a watershed.

Moral Panic and the Get Tough Era: From the mid-1980s to 1994, rates of juvenile gun homicide escalated sharply, especially among minority youth in impoverished areas of the nation's inner cities. The violence received an extraordinary amount of media attention. Images of young black youths wielding guns tapped into racial stereotypes, ignited public fears, and fueled what has been described as a "moral panic" (Chiricos 1994). In a moral panic, the media, politicians, and the public reinforce each other in an escalating alarmist response that exaggerates the magnitude of the threat and produces urgent calls to "do something." In the midst of a panic, legislators rush to contain the threat, frequently by adopting drastic measures that are ill-conceived and overreaching.

The media responded to the urban, predominantly black youth gun violence with heavy and sensationalized coverage. Media portrayals of juvenile offenders shifted from the traditionally rather benign images of puerile and corrigible delinquents to menacing portraits of savvy, ruthless, and morally impoverished "superpredators," whose numbers were forecast to swell rapidly. Political scientist John Dilulio (1995 p. 23) famously claimed that "Americans are sitting atop a demographic crime bomb," while others warned of a coming "bloodbath" of youth violence (Fox 1996).

Politicians fueled public fears for electoral advantage. They pushed violent crime to the top of the political agenda and, wary of being labeled "soft on crime," vied to outdo their opponents in the rush to take a hard line on juvenile offending. They sharply challenged the assumptions about youth that had animated the earlier juvenile court movement. By embracing the imagery of shrewd, adult-like predators, they gave traction to a new, retributive sound bite – "adult crime, adult time." Further, and without any evidence of its efficacy, they claimed that severe punishment of young offenders would protect the public safety.

Get Tough Measures: Legislatures in nearly every state responded by taking steps to facilitate the transfer of greater numbers of juvenile defendants to criminal court for prosecution and punishment as adults. Historically, juvenile court judges had the power to waive youths to criminal court, but it was a power they exercised rarely. A 1966 Supreme Court decision (*Kent v. United States*, 383 U.S. 541) made it more difficult for them to do so. They first had to conduct a "full investigation" and hold an adversarial hearing, then set forth in writing facts sufficient to support a determination that the child was either too dangerous to remain in the juvenile system or was not amenable to treatment. Believing that juvenile court judges were loath to waive even serious offenders, legislators created alternative, expedited transfer methods that altogether circumvented the juvenile court or that sharply constrained juvenile court judges' discretion to retain youths in the juvenile system (Bishop and Frazier 2000).

In many states, lawmakers shifted authority to choose the forum in which a youth would be tried from the juvenile court judge to the prosecutor, who was now permitted to "direct file" a case in either juvenile or criminal court. Most often, prosecutorial direct file laws fail to specify any standards or considerations for decision-making. Direct file is carried out without a hearing, without explanation, and with no opportunity for judicial review. In the 1970s, only two states permitted prosecutorial direct file; by 2000, the number had risen to 15 (Griffin et al. 2011). In addition, most states made transfer "automatic" for certain crimes or offense/prior record combinations, often without regard to the offender's age. Before1970, only eight states had automatic transfer laws, and these most often applied only to murder and other then-capital crimes; by 2000, 38 states had enacted these laws and had expanded their scope to include lengthy lists of offenses. The adoption of "once an adult, always an adult" provisions amplified the effects of these other changes by mandating criminal court processing of all post-transfer offenses. Finally, two states (New Hampshire and Wisconsin) took the most sweeping steps to get tough on juveniles: They lowered the maximum age of juvenile court jurisdiction from the 18th to the 17th birthday, which transformed all 17-year-old juvenile offenders into adult criminals, no matter how minor their offenses. Analysts estimate that, as a result of these reforms, somewhere between 200,000 and 250,000 youth under age 18 were being tried annually in American criminal courts by the turn of the century. Many were neither particularly serious nor particularly chronic offenders, and some had not yet reached their teens (Feld and Bishop 2012).

In the criminal courts, judges did not treat youthfulness as a mitigating factor in sentencing transferred youths. Indeed, they imposed harsher sentences than those imposed on comparable adult defendants. Even extreme punishments were not deemed inconsistent with youth. Until the Supreme Court's decision in 2005 (*Roper v. Simmons*, 543 U.S. 551) to ban capital punishment of offenders under age 18, judges in several states sentenced teens to death. By the turn of the century, nearly ten thousand inmates were serving life sentences for crimes they committed before they were 18. Moreover, more than two thousand were serving sentences of life without the possibility of parole (LWOP) in contravention of the United Nations Convention on the Rights of the Child. The harshness of youth crime policy in the USA clashed with policy and practice in the rest of the world. Juveniles received LWOP sentences in only three other countries, and in these three, a total of about a dozen offenders were serving these sentences (Human Rights Watch/Amnesty International 2005).

Punitive policy changes were not limited to the removal of juveniles to the criminal courts. Legislatures in nearly every state also amended their juvenile code purpose clauses to endorse "punishment," "holding youth accountable," and "protecting the public safety" as new objectives of the juvenile court. Although the traditional goal of rehabilitation remained, it was eclipsed by these other objectives. Legislatures in nearly half the states adopted offense-driven sentencing in their juvenile courts. Some adopted sentencing guidelines to impose presumptive, determinate, and proportional sentences based on age, offense seriousness, and prior record. Others enacted mandatory minimum sentencing provisions that prescribed either a minimum period of confinement or a minimum level of secure placement commensurate with the seriousness of the offense. Finally, some created a "blended sentencing" option that permitted or required juvenile court judges to impose criminal sentences (40 years, at the extreme) on youth adjudicated delinquent for certain crimes. Each of these sentencing methodologies applied offense-based principles of proportionality to rationalize sentencing decisions, increase the penal bite of juvenile sanctions, and demonstrate legislators' toughness (Feld 1998).

Other changes chipped away at special protections that youths in the juvenile system had traditionally enjoyed. Juvenile court proceedings had historically been closed to the public, juvenile records were confidential and subject to later expungement, and at least nonserious juvenile offenders were exempt from photographing and fingerprinting after arrest. During the Get Tough Era, the vast majority of states opened juvenile proceedings to the public, allowed juveniles to be photographed and fingerprinted, and required them to give DNA samples (Szymanski 2009). States increasingly used delinquency adjudications obtained without a jury trial to enhance adult criminal sentences and to subject youths to longer terms (Feld 2003). Especially controversial were decisions to make juvenile sex offenders – even those adjudicated in juvenile court – subject to Megan's Law, which required them to register with police and, in some instances, provided for community notification of their identities, whereabouts, and offenses (Zimring 2004). By the turn of the century, most states permitted or required juveniles convicted of sex crimes to register as sex offenders. In about half of the states, juvenile sex offenders faced a possible lifetime of registration.

The frenzy to "get tough" on juveniles reflected a broader climate of fear of young people – especially other people's children – and a simplistic view of "punishment as panacea" that soon spread to other arenas. In response to escalating youth violence, Congress passed the Gun Free Schools Act of 1994 (20 U.S.C. § 7,151 [2003]), which required that states receiving federal funding mandate expulsion for at least 1 year of any student found in possession of a firearm on school grounds. States and schools responded by adopting zero tolerance policies, often expanding the prohibition beyond possession of firearms to include all manner of weapons or drugs, as well as violation of school rules. In some jurisdictions, school administrators applied these draconian policies broadly and senselessly to children who made innocent mistakes, such as bringing scissors or over-the-counter medications to school. Zero tolerance policies have been linked to increased dropout rates and referrals to juvenile court for behaviors that school officials have traditionally handled informally (American Psychological Association Zero Tolerance Task Force 2008). Further, because these policies have more often been implemented in urban schools, they have had a disproportionate impact on minority youth (Fenning and Rose 2007).

In the 1980s, school departments also began hiring police as School Resource Officers (SROs) to combat drugs, enforce school rules, and teach antidrug and antigang curricula and, in the 1990s, to provide heightened security following some high-profile school shootings (Redding and Shalf 2001). Expanded use of metal detectors and drug sniffing dogs accompanied the heightened police presence. Increasingly, police arrested young violators not for drug and weapons offenses but for disorderly conduct, disturbing the peace, and disruption of school assembly – based on normative adolescent acting-out behaviors, like cursing, clowning, and participating in cafeteria food fights, that used to be handled informally by school officials through school detention or intervention with the youth's parents. The combination of zero tolerance policies and SRO programs resulted in the removal of thousands of youths from mainstream educational environments and produced a dramatic escalation in arrests and referrals to juvenile courts – a phenomenon that has come to be known as the School-to-Prison Pipeline.

In sum, as the twentieth century came to a close, the United States embraced policies that increased the punitive powers of juvenile courts, expanded the reach and bite of transfer laws, and criminalized much ordinary adolescent misbehavior. The harshness with which the United States responded to youthful misconduct was unparalleled, and the punitive fervor showed few signs of abating.

Legacy of the Get Tough Era: At the start of the twenty-first century, the future of juvenile justice looked bleak. But a number of developments in the first decade of the twenty-first century hint at a counterbalance to the repressive policies of the recent past. Beginning in 1994, youth violence plummeted and stabilized in the 2000s at levels not seen since the 1970s (Snyder 2012). This precipitous decline seems to have alleviated the moral panic that sparked the unprecedented spate of punitive legislation, allowing for consideration of more moderate, humane, and sensible policies.

Important new discoveries in developmental psychology and neuroscience have affirmed the Progressives' belief that adolescents are immature, vulnerable, and prone to poor and impulsive decision-making. In a signal development, the Supreme Court gave its imprimatur to notions of adolescent immaturity, impetuosity, and vulnerability and to their legal corollary – lesser culpability – in two decisions that limited the punishments to which even the most serious young offenders can be subject. In 2005, the Court in *Roper v. Simmons* abolished the death penalty for persons convicted of crimes committed before they were 18 years of age. In *Graham v. Florida* (2010), the Court banned sentences of life without possibility of parole for youths convicted of nonhomicide crimes. The Court in *Graham* emphasized youths' immature judgment, reduced self-control, susceptibility to negative peer influences, and ongoing character development and cited recent developments in developmental psychology and neuroscience as the linchpin of its decision. *Roper* and *Graham* are groundbreaking decisions that shatter the superpredator theory of juvenile offending and reaffirm bedrock principles on which the juvenile court was founded.

Signs of disenchantment with harsh punishment as a response to juvenile crime are evident in a number of arenas. Expansion of transfer policies has slowed almost to a halt; in some instances, legislatures have retrenched and modified some of the harshest laws. Most dramatically, the Connecticut legislature recently raised the lower bound of the criminal court's jurisdiction, from 16 to 18, while the Illinois legislature shifted the lower bound of criminal court jurisdiction from 17 to 18 for youths charged with misdemeanors. In 2008, the voters of California defeated Proposition 6, which would have created a presumption that 14-year-olds charged with gang-related felonies are unfit for juvenile court. Some states have recently restricted the offense or offender criteria for transfer or mitigated the criminal sentences to which transferred youths may be subject. Others have taken steps to rein in prosecutorial discretion either by severely restricting the scope of offenses subject to direct file or by requiring prosecutors to provide criteria and assessment procedures for choosing the forum in which youths will be tried (Bishop and Feld 2012).

Recent developments in juvenile corrections also suggest a softening of the punishment agenda. The 1980s saw the establishment of boot camps, first in the adult system (1983), then in the juvenile system (1985). The federal Office of Juvenile Justice and Delinquency Prevention (OJJDP) supported the boot camp initiative and funded an evaluation of three programs in three different states, which showed that boot camp participants had higher recidivism rates than controls. Despite the negative results and allegations of staff abuse, boot camps "caught on" in the same way that other deterrence-based programs have. However, the tide is beginning to turn. Several states have eliminated juvenile boot camps, and a comparison of OJJDP's Juvenile Residential Facility Census for 2006 with that for 2002 shows that the number of boot camps declined by nearly 50 % over that period.

In addition, several states have closed (or been forced by the courts to close) training schools following the disclosure of terrible conditions of confinement (California, New York, Mississippi, Texas, Louisiana). Under court order, California has shut down all but two of its training schools and is slated to close the remainder in the very near future. Texas also shut down four maximum security juvenile facilities and reduced its juvenile institutional population by more than half. Florida not only shut down all of its boot camps but also downsized its training schools and youth development centers and placed a cap of 165 beds on all residential placements. The downsizing that is taking place across the nation is motivated in part by external pressures to close large institutions where conditions of confinement are most problematic, in part by budgetary constraints, and in part by research evidence that smaller institutions and community-based programs are more likely to realize rehabilitative aims.

Recently, the results of a number of public opinion polls have received considerable publicity. They show that, although the public supports punishment of serious juvenile offenders as a means of protecting the public safety, there is much broader public support for rehabilitation than was previously believed (Nagin et al. 2006). The vast majority of survey respondents support treatment as a response to all but the most violent juvenile offenders. Consistent with this public support, there are signs of a revitalized treatment orientation in juvenile justice practice. This is apparent in the rapid proliferation throughout the nation of juvenile drug courts, which harken back in many respects to juvenile courts of a century ago. In drug courts, judges are expected to establish strong supportive relationships with juvenile offenders, to monitor closely youths' progress in treatment, and to apply modest sanctions for noncompliance and strong positive reinforcements for youths' active participation in the court's treatment plan (Butts et al. 2012).

While research has shown that punitive sanctions are largely ineffective in reducing the risk of recidivism, there is considerable evidence that some correctional treatment strategies are effective when implemented well. In the last 15 years, a number of private, state, and federal initiatives have produced reviews of treatment program evaluation research and provided authoritative lists of "what works" (Center for the Study and Prevention of Violence n.d.; Campbell Collaboration 2009; Lipsey 2009) These, in turn, have supported a movement toward "evidence-based practice." In an increasing number of jurisdictions, governmental funding of programs is contingent upon the adoption of evidence-based best practices. The combination of solid public support for rehabilitation coupled with social science evidence of effective treatment methodologies bode well for a return to more traditional, treatment-oriented juvenile justice systems.

Signs of a counterbalance to the repressive policies of the recent past are evident in the Supreme Court's endorsement of views of youth much more in line with those of the Progressives and in the softening of criminal punishments, the modest retrenchment of transfer laws, the introduction of specialized treatment-oriented courts, and the renewed focus on evidence-based treatment in juvenile corrections. This is not to say that the Get Tough approaches of the 1980s and 1990s will soon disappear. Punitive approaches institutionalized through legislative reforms are stubbornly resistant to reversal and are unlikely to be quickly undone. The legacy of the Get Tough Era will surely continue for some time to come.

Juvenile Justice System Responses to Minority Youth

Michael J. Leiber and Jennifer H. Peck
Department of Criminology, University of South Florida, Tampa, FL, USA

Synonyms

Differential offending; Disproportionate minority contact; Juvenile justice; Race; Selection Bias

Overview

The issue of racial and ethnic disparities has been a controversial topic within the juvenile justice system, as the overrepresentation of minority youth is a continued concern. In 2008 alone, minority youth represented 13.3 % of the United States population, yet represented 36.9 % of all cases handled by the juvenile courts. Differential offending (i.e., minorities commit more and more serious delinquent acts compared to Whites) and racial bias among juvenile justice decision-makers are the two main explanations for understanding the relationship between race and juvenile justice system proceedings. The following chapter will demonstrate how the juvenile justice system responds to minority youth through the use of theory, empirical research, and policy. From a review of the literature throughout these three areas, possible reasons for minority overrepresentation will be explained, including specific policy recommendations to lead to the equitable treatment of all youth, regardless of race and ethnicity.

Conceptualization of Racial Bias

Compared to Whites, minorities are disproportionately involved within all stages of the juvenile justice system. They are more likely to be arrested, petitioned, held in secure detention, adjudicated (found guilty), and receive harsher sentences at disposition. One explanation focuses on differential offending, while the other argues that racial bias by juvenile justice decision-makers (police, prosecutors, officers, judges, etc.) influences the way minority youth are treated throughout each stage. Researchers generally acknowledge that both of these explanations may account for the overrepresentation of minority youth in the juvenile justice system. For the purpose of this chapter, the focus will be on racial and ethnic bias as an explanation to explain race/ethnic differences in the juvenile justice system.

Racial/Ethnic Bias

Underlying most empirical research examining race and the adult and juvenile justice systems centralizes on the concept of "racial/ethnic bias." Up until the 1980s, people perceived that blatant, overt, or intentional racial bias and racism occurred against minorities. However, this was not necessarily the case. Zatz (1987) reviewed over 50 years of sentencing research and concluded that from the time of the civil rights movement, there has been a transition from overt to covert racial bias. While overt discrimination was present throughout the 1930s to mid-1960s (race was directly related to more harsh sentencing outcomes), sentencing decisions from the late 1960s to the early 1980s confirmed the effects of race were more implicit, subtle, or subconscious. Recent research has found the presence of unconscious negative race stereotypes that result in Black youth being viewed as more blameworthy, resulting in harsher outcomes in juvenile justice proceedings, while overt or conscious race bias had little impact (Graham and Lowery 2004). However, subtle bias is no less harmful than overt bias.

Examinations of the existence of implicit bias have found that that not including African Americans, every racial group unconsciously associated "African American" with the terms crime or danger. Specifically within the juvenile justice system, probation officers have been found to inhibit a form of implicit racial bias, by describing Black offenders as actively making poor and destructive choices to maintain a criminal lifestyle (Steen et al. 2005). However, this thought process was not extended to White youth. Additional research has also suggested that juvenile justice decision-makers perceive Hispanic youth as a social threat, therefore are treated more severe within court proceedings.

From this overt to hidden transition, racism or racial bias was evident through the effects of race that operate indirectly or in interaction with other conditions (e.g., age, employment status, prior record, family situations). For example, age and employment status may seem race neutral but can increase racial disparities at numerous decision-making stages (Leiber and Johnson 2008). Within the juvenile justice system, age is considered a mitigating factor due to the belief that younger youth lack *mens rea* (intent) due to immaturity, inexperience, and inability to resist peer pressure. From this, older youth are seen as more responsible and handed more formally than younger youth, who receive a "youth discount." However, Leiber and Johnson (2008) found that White adolescents received a "youth discount" at intake, yet similarly situated Black youth were referred to further proceedings. Therefore, the "youth discount" did not extend to African American youth, regardless of the age criterion supported by the juvenile court.

Another example of race effects that are masked by other conditions is the research by Bishop and Frazier (1996) who found by juvenile justice officials perceived single-parent minority families as more broken and dysfunctional than single-parent White homes. In sum, additional research has found that both African Americans and Hispanics are treated more severely than similarly situated Whites, even though other legal and extra legal factors (including the gender of the decision-maker) were taken into consideration (Bishop et al. 2010).

Contexts of Juvenile Justice Decision-Making

Traditional Theories

Prior research examining race and decision-making in the juvenile justice system have traditionally explained minority overrepresentation based on consensus or conflict approaches. Established by Emile Durkheim, the consensus approach is based on the idea that laws, punishment, and treatment are formed from a broad consensus of societal norms and values. From this, racial bias in the criminal justice system is seen as a random occurrence for the reason that laws bound the discretion of decision-makers to follow strict legal criteria. In other words, race differences in offending are due to minorities' differential involvement in crime.

The conflict approach assumes the opposite of the consensus approach, which argues that there is a lack of consensus within society. According to the conflict tradition, majority groups utilize their power to exert control over minority groups. By controlling the "powerless" groups, majority groups are able to protect their own interests and power by controlling the political, economic, and social realms of society, including the law, law enforcement, and the court system. Majority groups exercise social control over the powerless group, which results in minorities becoming labeled as outsiders, deviants, delinquent, and criminal, and therefore subject to harsher sanctions.

The labeling process is central to one theory within the conflict tradition, labeling theory. The labeling perspective stresses that minorities are stereotyped based on negative labels and the inability to acquire necessary resources, which results in differential treatment compared to Whites. Juvenile justice decision-makers may take into consideration negative images and stereotypes of minorities (e.g., dangerous, drug users) to assess culpability, blameworthiness, or treatment possibilities (Graham and Lowery 2004).

A criticism related to both conflict theory (deemphasizes the role of stereotypes) and labeling theory (deemphasizes the role of power) is the inability of both theories to account for research that has shown equitable treatment for both minorities and Whites or instances where Whites are treated more harsh. Due to the economic orientation of conflict theories, the majority and minority groups were based on class, ignoring the specific effect of race. In other words, race effects were masked by economic status, and the reason for differential treatment was due to Blacks being disproportionately poor and powerless (Blalock 1967). Consensus theory also been critiqued due to its inability to conceptualize the complexities between structural and interactional characteristics within race and decision-making (Sampson and Lauritsen 1997). From these criticisms, recent research has begun to include the role of contextual and structural factors into the understanding of decision-making outcomes within the juvenile justice system (Rodriguez 2010; Sampson and Laub 1993). The types of contextually situated theories expand beyond consensus, conflicts, and labeling perspectives to take into account structural characteristics that may also influence decision-making.

Macrolevel Theories

As discussed earlier, the emergence of contextual approaches to understanding minorities and differential treatment compared to Whites was due to shortcomings from consensus and conflict perspectives. In the sections that follow, both macro- and microlevel theories are examined within the context of juvenile justice decision-making with possible reasons for minority overrepresentation. First, macrolevel theories are discussed and can be identified by a focus on structural and contextual characteristics of neighborhoods and communities. Crime rates, impoverishment, minority representation, community urban-rural composition, and political orientation are some of the factors that research has found to influence decision-making within juvenile courts. Second, microlevel theories are examined utilizing evidence focused at the individual level for racial disparities within the juvenile justice system, including race stereotypes, decision-makers use of discretion, and attribution bias.

Urbanism and Formal Rationality

The theoretical foundation for much of the earlier research that examined community characteristics and criminal justice decision-making was the work by Max Weber (1969). His research called attention to the interrelationships between urbanization and bureaucratization and its influence on social control. Weber wanted to understand why and how people orient themselves to the legal system based on their own values and rules. He argued that the two institutions that regulate and guide people within a society are the economy and legal system. The link between the two systems is formal rationality, which refers to universally applied laws, standards and rules. Weber believed that in a capitalist society, all decision-making within the formal rational legal system is grounded the rules themselves, therefore the law is applied to similarly situated individuals in an equal manner based on legal criteria. From this, discretion on the part of the decision-maker is limited. Once differences in crime severity are taken into account, few differences should exist between minorities and Whites concerning their contact and involvement with the criminal justice system.

In contrast to formal rationality, there is also informal or "substantive" rationality, which refers to a plethora of external values including beliefs about justice and respect. In this situation, decision-making depends more on informal criteria and social tradition, instead of an equal manner based on legal criteria (formal rationality). Within this type of legal system, discretion is enhanced among decision-makers, concluding that similarly situated individuals may be treated differently. For example, in a more rural environment, minorities should experience higher rates of involvement in the criminal justice system compared to Whites, due to decision-makers reliance on racism, stereotypes, and other subjective discretionary factors.

However, other theorists have argued that urban courts will demonstrate greater racial discrimination than rural courts. According to this perspective, decision-makers who adhere to a formal rationalized legal system may not question the procedure or substance of the law but will accept them as binding and therefore rely on factors that may be biased (e.g., prior record, family situations). Also, because urban courts are bombarded with a large number of cases, decision-makers might classify offenders into routine types. In doing this, the types are based on stereotypes about minorities, the poor, moral character, motivation, and behavior (Gaarder et al. 2004). Therefore, the influence of race and other extralegal variables (e.g., stereotypes) on more severe outcomes will be greater in urban than rural settings. Overall, research is mixed within these varying perspectives. Some research has revealed that rural courts are less formal and more discriminatory against minorities, while other research has shown that urban courts are more likely to be punitive and influenced by racial stereotypes.

Minority Group Threat/Racial Threat Theory

Another theoretical perspective important for understanding the influence of structural characteristics, race, and social control is Blalock's (1967) minority group power threat thesis. This perspective is in contrast to the traditional interpretation of conflict theory, where the focus is on the perceived or actual threat that minority groups pose on majority/advantaged groups. From this, the interchangeable terms "racial treat" or "minority group threat" are contained within a general "group threat" orientation of the traditional conflict theory. Within this group threat orientation are two interrelated factors: the size of the minority population and the economic situation of minorities compared to the majority/advantaged group.

Blalock (1967) argues that the larger the proportion of the minority group population, the greater the competition for economic resources (jobs, money, property, prestige), which results in perceived challengers to the majority group's status. Also argued by Blalock is that increases in income and wealth by the minority group compared to Whites should make the majority group (Whites) feel more threatened. Prejudicial and discriminatory attitudes and practices will be employed by the majority/dominant group in order to diffuse the minority group threat.

However, research examining the power threat thesis within the context of the juvenile justice system has shown mixed results. Some research has found that police within communities with a higher proportion of minorities have responded in a prejudicial manner towards minority youth, yet the bias was corrected in later stages of juvenile justice proceedings (Bishop et al. 2010). Other research has found that racial composition of a community did not have effects on the level of minority youth confinement.

In 1992, Frazier and colleagues tested Hawkins version of the power threat thesis (a revised conflict approach) who believed that the historical contexts of race and punishment should be included within Blalock's (1967) power threat thesis. However, Frazier and associates argued that Hawkins' thesis was directly opposite of numerous traditional conflict theories. In traditional conflict theories, a lower proportion of minorities allows the majority group to exert social control, yet Hawkins argued that a higher proportion of minorities would lead to more political and economic threat towards the majority group, resulting in the advantaged group to exert social control. Results from Frazier et al. (1992) supported the traditional conflict perspective rather than the power threat thesis, indicating White majority populations exert social control over minorities.

Theory of Inequality and Social Control

An integrated perspective including structural contexts and racial stereotyping based on Tittle and Curran's (1988) symbolic threat thesis, the war on drugs, and increased sanctioning of juvenile offenders was developed by Sampson and Laub (1993). They argue that the poor, underclass, and minorities will be perceived by juvenile justice decision-makers as threatening and in need of social control from residing in communities with high levels of economic and racial inequality. In line with Tittle and Curran (1988), Sampson and Laub (1993) emphasized that decision-makers view minority youth as aggressive, sexual, and lacking discipline. In conjunction with certain social psychological emotions of juvenile court officers and how these emotions interplay between the perceived characteristics of minority youth, feelings of fear and jealousy from juvenile court officers are manifested into beliefs that minority youth pose symbolic threats to public safety and middle-class standards (Sampson and Laub 1993, pp. 289–290).

The interplay between the war on drugs, the use of stereotyping, and disadvantaged structural characteristics further refined the symbolic threat thesis at the macrolevel. More specific, Sampson and Laub (1993) emphasized the evolving stereotype of minority males as drug users and dealers. Due to two trends within the 1980s (the dramatic increase in incarceration of Black males and drug offenders), this prominent stereotype leads to the overall effect that poor, Black men (especially those who were involved with drugs) would be subject to increased social control by the juvenile justice system.

Support for this perspective was found in Sampson and Laub's (1993) examination of over 200 counties across the United States. Results indicate that measures of underclass poverty and racial inequality were significantly related to increase sanctioning of juvenile offenders especially within the stages of predisposition detention, and out-of-home placement. These results were also more pronounced for African Americans and to some degree, those involved in drug offenses. Additional support for Sampson and Laub's (1993) perspective was found in the research by Leiber (2003), including suggestions for the refinement of the theory to encompass aspects of historical organization, sociopsychological processes, and the role of stereotyping involving the family and respect for the court. Additional research within the context of Sampson and Laub's (1993) perspective is the work by Rodriguez (2010), who found that racial and ethnic biases exist throughout numerous stages of the juvenile justice system. Black and Hispanic youth were more likely to be detained compared to White youth. Also important, youth who lived in structurally disadvantaged areas were more likely to be detained, and indirectly were treated more severely in later stages of juvenile justice proceedings. These results show the interrelated nature of race, structural disadvantage, and the juvenile justice system. Other research has shown race to have an indirect effect on case outcomes through detention that further results in a cumulative disadvantage as detained youth move on from intake to adjudication to disposition and receive more severe case outcomes than non-detained youth (Holman and Ziedenberg 2006, p. 4). In other words, decisions made at earlier stages (such as detention) affect outcomes at later stages and in particular judicial disposition. This means that being detained strongly predicts more severe treatment at judicial disposition. From this, if racial bias occurs at earlier stages, it may reappear indirectly at later stages, masked by youth who are previously detained.

Microlevel Theories

In contrast to macrolevel perspectives, microlevel theories focus on the individual level of social psychological characteristics of juvenile justice decision-makers, including the roles that stereotypes and discretion play in this process. The following microlevel perspectives will be discussed in relation to minority overrepresentation: symbolic threat thesis, racial stereotyping within the realm of attribution theory, the liberation hypothesis, and the focal concerns perspective.

Symbolic Threat Thesis

As briefly mentioned earlier in the chapter, Tittle and Curran's (1988) symbolic threat thesis focuses on the interplay between the characteristics of minority youth, and the emotions of juvenile justice decision-makers. The perspective argues that juvenile justice decision-makers may view minority youth as aggressive, sexual, lacking discipline, and other fear or resentment – provoking qualities. These emotions make juvenile court officers feel uneasy, uncomfortable, and unable to identify with the youth, leading to greater social control. These stereotypes of minority youth lead juvenile court officers to base decisions on perceived thoughts about juvenile offenders, not the specific behavior of the youth. Symbolic threats are connected to structural characteristics, minority threat, inequality, and public perceptions of gang involvement (Fagan 2010). In turn, while this threat is more symbolic (threat to middle-class standards and public safety) than real, it still may have an impact on how minority youth are treated within juvenile justice proceedings.

Differential treatment within the juvenile justice system could be based on decision-makers' perceptions and emotional reactions to what minority youth represent. Tittle and Curran (1988) found support for this perspective, indicating that a larger minority and younger population resulted in different case outcomes of minority you who were charged with drug and/or sexual offenses. Research has also found that minority youth who are involved with drug offenses lead to differential treatment compared to other youth (Leiber and Johnson 2008). For example, Bishop, Leiber, and Johnson (2010) found that minorities charged with drug crimes were more likely to continue into further juvenile justice proceedings than similarly situated White drug offenders.

Attribution Theory and Racial Stereotyping

The reliance of racial stereotypes by juvenile justice decision-makers has been utilized as an explanation on how subjective thought processes influence case outcomes. For example, Bridges and Steen (1998) integrated theory and prior research concerning racial stereotyping and attribution theory to explain differential treatment of African Americans compared to Whites. According to attribution theory, attributions provide individuals with explanations for previous experiences and criteria for evaluating one's own behavior, as well as others behavior, actions, and attitudes. Prior research has indicated that individuals who are more punitive or retributive in treatment philosophies have been more likely to blame the person. Bridges and Steen (1998) incorporated attribution theory, prior research on racial discrimination, and arguments that decision-makers develop and rely on past experiences and prior cases to influence case outcomes, and found support for their argument.

More specific, results indicated that probation officers used different types of attributions to assess delinquent behavior between Black and White youth. Involvement in delinquent acts committed by African American youths' were seen by decision-makers as related to internal or dispositional attributions (e.g., defects of character, lack of responsibility), while White youths' involvement in delinquency was related to external causes (e.g., disadvantaged neighborhoods, delinquent peers, poor school performance). Internal attributions compared to external attributions resulted in perceptions by decision-makers that youth were more at risk to re-offend, less amenable to treatment, and more dangerous, which resulted in longer sentences for Black compared to White youth. Overall, Bridges and Steen (1998) concluded that certain values and beliefs of juvenile probation officers lead to a stereotyped image of juvenile offenders that resulted in differential treatment throughout the decision-making process.

Research has also found that differential treatment with respect to ethnicity has also been found within the decision-making proceedings. Gaarder et al. (2004) found that attributions related to delinquency and victimization assigned to Hispanic females by juvenile justice decision-makers were linked to racial and gender stereotypes. In another study, the juvenile justice system responded to Hispanic females more severe than their White counterparts, finding that Hispanics from economically advantaged and disadvantaged communities are treated harsher than Whites (Rodriguez 2007).

The Liberation Hypothesis

Certain macro- and microlevel theories that seek to explain racial and ethnic bias and disparities have an underlying theme that incorporates what types of outcomes occur depending on the amount of discretion by decision-makers. The basic premise of the liberation hypothesis is that it identifies certain conditions that result in decision-makers ability to "liberate" to and from certain legal criteria and uniformity. When involving adult offenders, jurors were found to be more likely to exercise discretion when evidence against the defendant was weak and a less serious crime occurred. In other studies, judges were less likely to exercise discretion involving cases of murder, robbery, or rape, but in less serious cases, both legal and extralegal variables influenced judges' decision-making. Blacks who were convicted of less serious crimes were treated harsher at sentencing, while Blacks who were convicted of more serious crimes were no more likely than Whites to receive a harsher sentence.

The liberation hypothesis has also been examined within the juvenile justice system, suggesting that for more serious cases, court outcomes will be influenced by legal factors, while for less serious cases, court outcomes will be influenced by extralegal factors, such as race. Research suggests some support for the liberation hypothesis at the juvenile level; however this depends on which stages are examined (Guevara et al. 2011). In one study, minorities were more likely to be adjudicated compared to Whites (Freiburger and Burke 2010); yet another study did not find support for the hypothesis at the stage of detention. Overall, while some support has been found for the liberation hypothesis, the issue of *why* decision-makers liberate from strict legal criteria when evaluating less serious crimes is missing from the theory, especially the notion *why* increased discretion by juvenile court officers results more severe treatment for minority offenders compared to Whites.

A "Focal Concerns" Perspective

Originally, Steffensmeier and associates developed and tested a "focal concerns" perspective to explain discretion and increased social control within adult court processing decisions. This perspective has also been applied within the juvenile justice system. The underlying premise of this perspective is that judges have a limited amount of time and information about defendants and may rely on three focal concerns or attributions involving race, gender, and class stereotypes when making decisions. The three focal concerns include (1) the defendants' blameworthiness and culpability based on the seriousness of the offense, (2) society's concern to protect the community, and (3) organizational considerations involving available correctional resources (Steffensmeier et al. 1998). Even though the three focal concerns are interrelated, Steffensmeier and colleagues argue that judges do not have complete information about each. From this, judges exercise their own discretion and rely on attributions such as age, race, and social class while making decisions. In other words, judges develop a "perceptual shorthand," where they rely on legal factors (crime severity, prior record) and racial stereotypes to determine case outcomes.

In order for this perspective to be applicable to the juvenile justice system, the focal concerns approach requires some modification. Compared to the adult system, the juvenile justice system has a dual focus of social control and social welfare of all youth, directing attention towards treatment and rehabilitation of juvenile offenders. For example, the social welfare orientation of the system influences decision-makers to focus on extralegal factors such as school, family, and peers, when assessing possible treatment outcomes. However, just as adult court officers may rely on stereotypes when making outcome decisions, juvenile court officers may also rely on stereotypes concerning juveniles' family, peers, and school situations. Utilizing a previous example, juvenile court officers who believe that single-parent family are unable to adequately provide for youth has been shown to influence decision-making (Bishop and Frazier 1996).

More recent, Bishop and colleagues (2010) integrated the focal concerns perspective with the "loose coupling" perspective. They argued that race effects may vary by each stage in juvenile justice proceedings due to numerous decision-makers involved and associated responsibilities and concerns. On the one hand, Bishop et al. (2010) contend that the influence of race will be more likely to exist at the loosely coupled stages of intake and judicial disposition; stages where multiple actors have a say, multiple goals of decision-making exist, are often tied to racial stereotypes, and discretion is prominent. On the other hand, at the tightly coupled stages of petition and adjudication where there are fewer decision-makers involved, legal factors and in particular the severity of the crime drive decision-making. In other words, discretion is constrained, and race effects are predicted to have a diminished role in decision-making. Consistent with the focal concerns and loose coupling perspective, results from Bishop et al. (2010) confirmed these expectations.

In addition, support for the focal concerns perspective has been found throughout numerous studies (Steffensmeier et al. 1998). Steffensmeier and colleagues (1998) found that young, Black males received more severe sentenced compared to any other age, race, or gender subgroup. This result confirmed the stereotype that young, Black, males are perceived as more dangerous, threatening, and unsuitable for release.

However, some researchers have questioned that the focal concerns concept is not a true theory but rather a perspective. On the one hand, there are no testable propositions, and the focal concerns concepts are underdeveloped and in need of refinement. On the other hand, empirical tests of the perspective have lead to supportive conclusions, and overall may only need some additional modifications.

Summary

In sum, traditional consensus, conflict, and labeling theories paved the way for the incorporation of more recent contextual and structural perspectives to better understand race and juvenile justice decision-making. At the macrolevel, the social control of minority youth has been fostered by structural and contextual characteristics, and stereotypes enforced by juvenile justice decision-makers. At the microlevel, juvenile court officers may be dependent on racial stereotypes, biases, symbolic threats, and internal attributions that have resulted in differential treatment and harsher sanctions of minority youth. In the final section, a specific policy implication called the disproportionate minority confinement/contact mandate (DMC) will be described in detail, in order to explain a present-day response to racial disparities in the juvenile justice system.

Policy Implications

It has already been established that minority youth are overrepresented throughout all stages of the juvenile justice system. However, it was not until the 1980s that this occurrence was officially acknowledged as a "problem." A policy implication and potential solution to this "problem" was the implementation of the DMC mandate. The following paragraphs will describe the history of DMC, specific stages within the mandate, results of present assessment studies, the overall effectiveness of DMC, and future research and efforts.

The Disproportionate Minority Confinement/ Contact (DMC) Mandate

History

In 1989, the disproportionate minority confinement mandate (DMC) was passed as part of the reauthorization of the Juvenile Justice and Delinquency Prevention Act (JJCPA) of 1974. In 2002, the JJDP Act was modified, shifting the emphasis from "disproportionate minority confinement" to "disproportionate minority contact" requiring the examination of possible minority youth overrepresentation throughout all decision points in the juvenile justice system. This examination is continuously conducted throughout five interconnected phases of the DMC mandate. Throughout DMC's history and continuing today, the underlying goal of the mandate is the equitable treatment of all youth within the juvenile justice system (Department of Justice 2009).

Stages

As stated earlier, the DMC mandate has five interrelated and ongoing phases: identification of DMC, assessment into possible causes, intervention, evaluation, and monitoring. The identification stage includes identifying and monitoring if and at which stages of the juvenile justice system DMC exists. More specific, the identification stage provides a count of the occurrence of DMC, as well as the extent of minority overrepresentation within different stages and jurisdictions. This phase sets the stage for the assessment studies of DMC by presenting descriptive data about the occurrence and location of DMC. At this stage, research has found that minority youth are overrepresented most often during arrest, detention, and waiver decisions. Compared to Whites, minority youth are also more likely to be petitioned and receive a disposition of placement outside of the home. From this, research aimed at identifying DMC has found that minority overrepresentation occurs at the beginning stages of juvenile justice system, which results in a cumulative effect of increased disparities throughout later case proceedings as well.

The second interrelated phase is the assessment phase which includes the examination of possible causes or factors that contribute to minority youth overrepresentation. The assessment stage examines in greater detail the specific decision points that DMC has been shown to exist from the identification phase. In addition, the assessment stage identifies certain mechanisms that are occurring in different jurisdictions that contribute to DMC. Research at this stage has found numerous contributing characteristics of DMC throughout many states and jurisdictions, which is described later in this section.

The intervention stage is based on taking information that is gather from the previous two phases and develop a comprehensive list of intervention strategies that have that ability to reduce minority youth overrepresentation. Several initiatives have been created and implemented across numerous jurisdictions and stages that center on direct services of youth, training of key personnel within the juvenile justice system, and to some extent, encourage change in the system itself. Jurisdictions are encouraged to rely on the results from the identification and assessment stages to guide decision-making concerning what specific initiatives and interventions should be implemented. For example, direct services attempt to address and provide at-risk youth with skill development, educational attainment, and positive relationships with family and peers. Prevention programs may include strategies that focus on familial relationships and educational deficiencies, while intervention programs seek to reduce antisocial behavior. Other types of direct services include diversion programs/services, advocacy, and alternatives to secure detention. Cultural diversity training is another strategy used to expose and educate individuals about DMC and racial bias in the juvenile justice system. Some examples of this type of strategy include training of law enforcement and juvenile court officers, participation in national and regional conferences, and day-long workshops.

Unfortunately, significant system change within juvenile court proceedings has been a slow occurring process. However, changes that have been implemented include legislative reform, administrative changes, and structural and procedural changes that impact decision-making (US Department of Justice 2009). One of the most popular changes involving the DMC mandate has focused on changing detention procedures with an emphasis on alternatives to secure detention, which previous research has found that minority youth are more likely to be detained compared to White youth (Rodriguez 2010).

The final stages of the DMC mandate include the evaluation and monitoring of the DMC mandate. It is important to evaluate the effectiveness of interventions that have been implemented on a continued basis. Overall, there are some interventions that have been evaluated, and results indicate that there has been some success at reducing minority youth overrepresentation (US Department of Justice 2009). However, relatively few known evaluations of strategies have been conducted, including a lack of systematic evaluation of certain interventions across multiple jurisdictions. Overall, it is the evaluation and monitoring stages that have seen a lack of implementation, which will later be discussed involving a discussion of the failure or success of the DMC mandate.

Results of Assessment Studies

Recall that the second phase of the DMC mandate is the assessment into possible causes or factors that contribute to minority overrepresentation. Once again, the assessment process examines at which decisions points DMC occurs from the identification phase. From this, information will be obtained to help policy makers choose appropriate interventions and strategies to reduce DMC. Presently, results from assessment studies found that explanations for the occurrence of DMC center on the juvenile justice system itself and differential involvement in offending. It is also important to note that the results from assessment studies parallel and mirror empirical research in general of how the juvenile justice system responds to minority youth.

Within the juvenile justice system, four specific factors contribute to DMC. First, racial stereotyping and cultural insensitivity on the part of police, juvenile court officers, prosecutors, and judges have been found to further move minority youth into the system. Second, there has also been evidence from assessment studies concerning unintended consequences that impact minority youth through the implementation of certain laws and policies. Examples of these include zero-tolerance and transfer/waiver adult certification of youths. Third, research has found that due to a lack of alternatives to diversionary programs, minority youth receive more severe outcomes and further movement into the juvenile justice system, ultimately resulting in placement in secure corrections. In other words, minority youth are not provided the same opportunities to participate in diversion programs in general, and specifically as an alternative to secure detention. Last, assessment studies have found that a lack of bicultural and bilingual staff and the use of English – only information materials lead to an inability to effectively communicate with non-English-speaking youth and families, resulting in a hindered ability to successfully navigate the juvenile justice system.

Assessment studies have also found that some of the strongest explanatory factors involving DMC are legal and extralegal criteria. Differential involvement in crime has been said to lead to a cumulative disadvantage that continues to hinder the life chances of minorities, further increasing the chance of continued criminal involvement in both juvenile and adult systems. Once again, four factors were found to be related to the continued occurrence in minority overrepresentation as offenders. First, educational deficits in the form of poor school attendance, lack of an emphasis on the value of education, disciplinary problems, and learning and cognitive abilities have been related to minorities committing more delinquency. Second, certain types of family dysfunctions have also shown to predict more harsh case outcomes, especially minorities who live in single-parent homes, reside in high-poverty neighborhoods, experience parental abuse, and have insufficient supervision. Third, assessment studies have found that many youth referred to juvenile court suffer from mental and emotional disabilities, often lacking the necessary services to address these issues due to family and financial problems. Finally, assessment studies have also considered certain structural characteristics of juvenile courts that may lead to minority overrepresentation. Results have found that juvenile courts in urban areas that are characterized by racial inequality, underclass poverty, and high crime rates are more likely to formally process, detain, and impose harsher sentences on minority youth.

Overall Effectiveness of the DMC Mandate

Over the last 20 years since the implementation of the DMC mandate, key improvements and advancements have emerged. For example, research has expanded its focus to include numerous minority groups (Hispanics, Native Americans, etc.) in addition to African Americans. In addition, factors that decision-makers take into consideration when deciding case outcomes for youth (school problems, assessments of the family, and mental health issues) have been more closely examined than in previous years. Assessment studies have also begun to examine how certain factors such as age, detention, and technical violations by the youth may work to the disadvantage of some minority groups relative to Whites. Lastly, recent assessment studies have adopted a more macro-sociological perspective, inquiring whether racial and ethnic disparities may be explained or linked to the larger social or structural context of where individual courts are located. Stated differently, research on DMC has expanded its inquiry to attempt to understand if differential offending and racial disparities in juvenile justice processing may be mutually affected by underlying social, structural, and cultural context in which they occur.

While key improvements and advancements have emerged in the last 20 years, the overall effectiveness of the DMC mandate has lead to three different opinions and positions concerning its success (Leiber and Rodriguez 2011). The first position argues that the issue of DMC is misguided and instead should focus on the prevention of delinquency of minority youth. In other words, this position believes that resources and strategies should divert its efforts towards differential offending by minority youth, instead of attempting its previous efforts to understand racial and ethnic bias.

The second position believes that overall, the DMC mandate has failed to bring about change to reduce racial and ethnic bias, and therefore more aggressive measures need to be taken into consideration. Some researchers have specifically argued that a lack of benchmarks and the failure to change procedures in the juvenile justice system reveals reluctance from jurisdictions to change procedures and policies that deal with overall system issues. In some cases, evidence was found that the DMC legislation was unsuccessful at changing decision-makers view of relying less on race and more on legal and extralegal considerations. From this, OJJDP has been criticized about not doing enough to address the issue of DMC. Overall, procedural changes within the juvenile system have been too slow to occur.

A third position focuses on broadening the inquiry of DMC to include both the causal factors associated with juvenile involvement in offending and increased social control, as well as the understanding the perceptions of racial stereotypes that further disadvantages minority youth in the juvenile justice system. In other words, supporters of this position believe that efforts need to focus on both the conditions that contribute to involvement in delinquency, including factors that foster the reproduction of stereotypes and biases of minority offenders through the eyes of juvenile justice decision-makers.

Future Research and Efforts

There is still a need for states and jurisdictions to continue to conduct assessment studies. In other words, future research needs to continue and extend analyses to gain a better understanding of the complex intricacies involved in the relationship between race, crime, and juvenile justice system involvement. For example, research needs to begin to assess the relationship between race and gender (e.g., being a Black male compared to a White female in the juvenile justice system). Some research has suggested a community commitment to reduce DMC, through addressing issues including a truancy program as well as collaborations with school systems, law enforcement officials, juvenile courts, and political offices.

Future efforts should also continue to sensitize individuals working within the juvenile justice system that the laws in general, legal and extra legal criteria, and system procedures may disadvantage minority youth compared to their White counterparts. More generally speaking, structural, neighborhood, and community changes need to be made to decrease the amount of minority overrepresentation but acknowledge that this specific recommendation will be a difficult and slow process to conquer. Lastly, additional research is needed to examine *why* minority youth continue to be overrepresented within the juvenile justice system. Even though it has been 20 years since the implementation of DMC, there are still numerous conflicting views of its success, as well as a need to continue future research and efforts.

Conclusion

In sum, while the overrepresentation of minority youth within the juvenile justice system has been a concern for many years, recent policy implications like the DMC mandate have attempted to identify, assess, intervene, evaluate, and monitor the occurrence and location of racial disparities within juvenile court processing. Through the use of traditional, macrolevel, and microlevel theories, researchers have attempted to understand how and why minority youth are treated more severe. Even though there have been gaps in the implementation and monitoring of certain DMC initiatives, progress has occurred. This proves that the DMC mandate is an ongoing and interrelated progress that in the end will hopefully lead to the equitable treatment of all youth, regardless of race and ethnicity.

Juvenile Victimization

Christopher J. Schreck
Department of Criminal Justice, Rochester
Institute of Technology, Rochester, NY, USA

Overview

Juvenile victimization can take many forms, and research has documented that victimization during childhood is connected with negative long-term patterns in criminal activity, health, and prospects for the future. Research on victimization patterns began in earnest during the 1970s, with the advent of the National Crime Victimization Survey (NCVS). Although the victimization of youth is a topic of considerable importance and interest to the scientific community, less is known about young victims of crime either because large-scale data collections, such as the NCVS, refrain from collecting data from this group or else information is only available from official sources. Nevertheless, a sizable scholarly literature has developed in order to better understand the causes, extent, and consequences of juvenile victimization, whether in the family or outside the family.

In recent years, research has begun to offer a much clearer picture about juvenile victimization, finding that many forms of victimization among youth are concentrated among African-Americans and the poor. As a result, researchers have begun to build theories to account for patterns of juvenile victimization as well as to evaluate programs designed to prevent youth from becoming victims.

Extent of Juvenile Victimization

The main source of our knowledge about victimization patterns comes from the National Crime Victimization Survey (NCVS), which collects data from a representative sample of Americans age 12 or older. Although the NCVS is the largest source of data on victimization, there are important limits with respect to understanding juvenile victimization. First, the focus of the NCVS is on street crimes (such as assaults, thefts), and so information on child maltreatment is therefore lacking. Second, although street crime victimization data is available for teenagers, younger children are excluded. Because of this omission, relevant information about those crimes and groups must come from alternative and more limited data sources. This entry will turn to these sources of information later.

With these limitations in mind, the National Crime Victimization Survey generally shows that violent victimization is most highly concentrated among those aged 24 or younger. This pattern has held true since the advent of the NCVS in 1973. From 1973 well into the 1980s, the violent victimization of youth was at a fairly stable and relatively high plateau, with rates of victimization ranging from 75 to as much as 100 incidents per 1,000 people each year. Starting in the late 1980s, however, violent victimization began to trend significantly upward. In 1994, the annual rate peaked at 125 per 1,000 individuals and then began a precipitous decline that has continued through the most recent year for which there is data. In 2009, the rate of violent victimization for youths aged 12–19 had fallen to less than 37 per 1,000. Juvenile violent victimization is thus presently at its lowest recorded levels. Of the violent crimes, simple assaults were the most likely to occur among juveniles. Property crime victimization, however, was substantially more frequent among juveniles than violence. Juveniles (age 12–19) who were classified as "heads of households," reported a property victimization rate of 268 per 1,000 in 2008, which was the highest rate of any age-group by a considerable margin. Most of these victimizations were thefts. In short, while juveniles have the highest risk of victimization for any age-group, most youths will not become victims and of those that do the most likely victimization will take the form of a theft.

The NCVS does not collect data on murder victims, but juveniles are sometimes the victims of homicides. The Supplemental Homicide Report (SHR) is the key source of data, and the SHR records the age of those who die in a criminal attack no matter how young. The data show that juveniles have rates of homicide victimization that are relatively low compared to other age-groups. Since 1975, children who were 13 or younger have consistently had the lowest murder rate of any age-group (an annual rate of approximately 1–2 per 100,000 between 1975 and 2005), even when contrasted with rates for the elderly. Youths aged between 14 and 17 had somewhat higher rates (less than five incidents per 100,000 people in 2005), but these rates were generally comparable to middle-aged adults. These older juveniles, however, have shown more fluctuation in their homicide victimization pattern over the years. Starting in the late 1980s and through the mid-1990s, their homicide victimization rates jumped to 12 per 100,000. This bulge was only mirrored in the 18–24 age-group (the group with consistently the highest rate of murder victimization); all the remaining age-groups generally reported stable levels of homicide victimization during this period.

Although the NCVS shows that violent victimizations are rare, even among the young, youth may also be exposed to child maltreatment. Child maltreatment, as generally understood, encompasses the sexual and physical abuse of minors as well as neglect. Beyond this, however, there is no consensus about what these terms exactly mean, and states have accordingly established differing criteria as to what constitutes maltreatment. As a result, precise estimates of how many children are maltreated, and developing a profile of who they are, are somewhat problematic tasks. The two major sources of child abuse and neglect data are the National Child Abuse and Neglect Data System (NCANDS) and the National Incidence Study (NIS). Unlike the NCVS, NCANDS does not collect relevant data directly from the youth but rather from state Child Protective Services (CPS) records. Because of this, unreported maltreatment or those that in fact occur and that CPS cannot substantiate are not reflected in the data. According to 2009 data, approximately 64 % of allegations made to CPS were found to be unsubstantiated. The NIS goes beyond CPS and surveys community professionals who have contact with children, but this is not an annual survey.

The NCANDS data, since 2005, shows that child victimization rates are low and fairly stable over time. In 2005, the victimization rate for children age 17 or younger was 12 confirmed incidents of maltreatment per 1,000 juveniles, or only 1.2 %. The prevalence rate that year, which is the number of children victimized at least once, was 10.9 per 1,000. Each year since 2005, the child victimization rate has declined slightly. By 2009, the victimization rate was ten per 1,000, with the prevalence rate being less than 1 %.

The children most likely to be reported as victims of child maltreatment tended to be less than 3 years old and most of these were less than a year old. Juveniles least likely to be substantiated as victims of maltreatment typically are older (for instance, 16–17 years old). These substantiated cases were almost equally divided between boys (48.2 %) and girls (51.1 %; the remainder were "unknown"). White children comprised 44 % of victims of child maltreatment, followed by African-Americans (22 %) and Hispanic (21 %). African-Americans, however, had the highest rate of victimization. Neglect figured in more than three-quarters of all cases reported in the NCANDS data, with physical abuse (17.8 %) being the next most common form of child victimization. These patterns have remained generally stable since 2005.

Although substantiated allegations child abuse and neglect, according to these estimates, is statistically rare, a large amount of research has examined the predictors of maltreatment. Research has located consistent risk factors for maltreatment since research on the topic began in earnest in the 1960s. These risk factors appear to be correlated with one another; that is to say, the presence of one risk factor is likely to be accompanied by one or more additional predictors. Research has shown that families where the parents are isolated from stable social support networks tend to have higher incidences of abuse victimization. Likewise, abuse is more prevalent among those families living in poverty. Theorists have speculated that impoverished families are less able to properly allocate financial resources, which create stress within the family. Abuse appears to be more concentrated among racial/ethnic minorities, particularly African-American households. This pattern likely arises from the fact that racial minorities are often ranked lower on the economic ladder, and they tend to live in severely disadvantaged areas where social support structures for families are very weak. Parents who themselves have problems with alcohol and drug addiction, or mental health issues, are more likely to mistreat their children.

Consequences of Victimization for Juveniles

Apart from estimating the extent of victimization among youth, scholars have also invested some attention on the effects of victimization. The life course approach develops the idea that quality of life over the years, including antisocial behavior, is largely (although not completely) shaped during childhood. Children acquire, during these years, the social capital needed to build their lives: education, experience with relationships, work, and so forth. The basic idea is that childhood victimization represents a life course event that can have long-term adverse effects on child development and adult outcomes. To the extent that victimization impairs the acquisition of social and personal capital, then it represents an important domain for research.

There is a considerable body of literature exploring the long-term effects of familial maltreatment on children, and the findings consistently show that children whose parents victimize them are more likely to experience adverse effects going forward. Abused children tend to:

- Experience delays in physical development
- Show higher levels of antisocial behavior
- Have lower self-esteem
- Have lower levels of academic achievement
- Experience symptoms of depression, posttraumatic stress disorder (PTSD), and anxiety

Beginning in the 1960s, scholars discussing the long-term effects of physical victimization of children spoke of the "cycle of violence." The cycle of violence can refer to two phenomena. First, abused children may, when they become parents, turn toward abusing their own children. Second, abused children may have offense repertoires that are characterized by higher levels of violence. Considerable research shows that abused children have a greater probability of engaging in violent and sexual offending in adulthood. Although the cycle of violence as an idea is well ensconced in the child abuse field and among policy-makers and advocates, the research suggests some caution. Such experts as Cathy Spatz Widom found that most physically maltreated children did not get arrested, whether as juveniles or adults. Children who were maltreated did tend to have a greater probability of arrest than other children, but arrests were for a range of crimes – sometimes violent but often not. Or, put another way, physical abuse increased the risk of arrest for not only violence but also nonviolent crime.

The literature is less large with respect to victimization's effects on children more generally; however, there do appear to be similar patterns to those reported in the child abuse literature. For instance, child victims of nonfamilial violence and sexual assault are more likely to experience PTSD and feelings of distress and depression. These feelings, as with abuse victimization, appear to persist into adulthood. Other long-term effects include stunted educational and socioeconomic consequences. Adolescents who were victimized were less apt to have a record of quality educational achievement. This, in turn, undermined work-related accomplishments and occupational status. Victimized children also have a greater probability of offending as well. In short, research indicates that many of the problems experienced by abused children are evident among those children who are victimized by those outside the family. In both cases, maltreatment and victimization among juveniles were more likely to result in a degraded quality of life as adults.

Victimization in School

Youth spend a considerable amount of their waking hours at school, and it therefore follows that school may be a context in which victimization frequently takes place. Victimization at school can take many forms – street crimes but also harassment and bullying. For different reasons, the topic of school crime has drawn great interest from parents, policy-makers, and students. Students who are victims of crime often have a more difficult time meeting the academic and social expectations of school life, such students can drop out of school, which can have adverse long-term effects on higher education and employment prospects. In turn, struggling students could endanger the existence of the school itself, as such programs as No Child Left Behind can mandate the closure of schools that repeatedly fail to make progress toward meeting educational benchmarks for reading and math.

Since 1992, the National Crime Victimization Survey has reported victimization incidents that occurred on school grounds. That year, the rate of theft victimization per 1,000 students was 95; the corresponding rate for violent victimizations was 48 ("serious violence" had a rate of only ten per 1,000 students). The level of victimization for all types of crime has decreased dramatically since the early to mid-1990s, particularly for theft victimizations. As of 2008, both theft and violent victimization rates were 24 per 1,000 individuals (serious violence at only four per 1,000). A comparison of the overall rates of victimization across the years suggests that school is an unsafe place for juveniles. In 1992, for example, the combined rate of victimization was 138 per 1,000 (compared to 144 per 1,000 at school). By 2008, schools still had a higher rate of victimization for juveniles than elsewhere (47 per 1,000 at school, versus 38 per 1,000 away from school). These numbers are somewhat misleading, at least by the metric of safety. Most of these victimizations are thefts. Rates of victimization in 2008 for "at school" and "away from school" are also tiny, especially when compared to what they were 15 years previous. Most importantly, however, serious violent victimization is more likely to occur away from school (rate of eight per 1,000) than at school (four per 1,000). This pattern is reflected in other data sources. For instance, National Incident-Based Reporting System (NIBRS) data shows that during the school week violent offending committed by juveniles (and, presumably, violent victimization) peaks at approximately 3 pm, which is around the time when students are dismissed from school and are unsupervised. Although a considerable amount of victimization takes place at school, its levels are small and the most serious forms of violent victimization are most likely to transpire, not at school, but rather on nearby playgrounds and en route home from school.

Information on bullying is considerably scantier. Some research indicates that bullying affects a relatively small portion of students (less than 15% are either perpetrators or victims of bullying). Estimating the extent of bullying is somewhat difficult. Aggressive behavior calculated to intimidate or harass someone, such as by threatening them or calling them names, is commonly included as part of the definition of bullying. Some scholars, however, include passive-aggressive behaviors that the bullying victim might not even be aware of – where bullies ostracize disliked peers or spread rumors and gossip. Many of the long-term consequences of bullying victimization resemble those for victimization and child maltreatment, such as degraded educational achievements and depression.

Of particular concern, however, are school shootings. For instance, in a 2001 Gallup survey administered at a time when the Columbine and Jonesboro school massacres were a fresh memory in the minds of the public, 70 % of parents felt that a shooting was “likely” at their school. While school shootings garner much media attention, during 2008–2009 academic year there were only 15 homicides that took place on a United States elementary or secondary school campus. This is contrasted with the approximately 1,700 homicides of youths age 5–18 over that same period. Homicide is itself a very rare event; however, when the murder of children does take place, they are extremely unlikely to occur at school. The rate of homicide at school amounts to approximately one youth each year per 2.5 million students. Since 1992, the number of school homicide victimizations has held fairly steady between 14 and 34 per year, with recent years tending toward the lower boundary of that range.

What sort of student is most likely to fall victim at school? The findings are clear that victimization at school, although unlikely to befall any given student during a single year, is not a random occurrence; if it was, then everyone would share equal risk. Researchers have examined the correlates for school victimization, and findings have begun to emerge implicating a combination of factors, such as particular aspects of the community where the school resides, the school context, and the students themselves. Given that much victimization occurs off school grounds after children are dismissed, the quality of the neighborhood plays a significant role in promoting the risk of victimization. The most important school-related risk factor for victimization appears to be the concentration of offenders at the school, such as children who bring weapons or else gang activity. The most consistently salient contributor toward youthful victimization, however, seems to be factors connected with the individual student. Students who bring weapons to school, who resent school and feel isolated, and who have friends who are delinquent are more likely to experience victimization.

Research on the effectiveness of school security strategies – guards, metal detectors, corporal punishment – have generally produced unimpressive results, especially after controlling for the other known correlates of youthful victimization. This is likely because many school preventative strategies are irrelevant to when and where victimization actually occurs. The presence of a school resource officer and locked school doors has little to do with theft, which is the most common type of victimization at school. Rather, these strategies are most clearly targeted toward preventing violence; however, research has yet to demonstrate a significant beneficial effect even for reducing the occasional and usually low-level scuffling that occurs during the school day. Since serious forms of victimization are most likely to happen after final dismissal from school, then the usefulness of guards and metal detectors is neutralized. Research has even shown that students where there are invasive forms of security do not feel any safer and are somewhat more likely to be afraid. Nevertheless, numerous other factors are much more strongly connected with higher levels of fear – for instance, experiencing victimization and observing criminal activity while at school.

Explanations of Nonfamilial Juvenile Victimization

Given these patterns of juvenile victimization, it is clear that victims possess distinct characteristics that somehow increase their risk. Victimization researchers have, over the past several decades, developed several important theories in an effort to explain why some people fall victim while others do not. The most long-standing theoretical tradition in victimization work is the routine activities/lifestyles approach. Lawrence Cohen and Marcus Felson, Michael Hindelang, Michael Gottfredson, and James Garofalo were the creators of this approach. Over the following years, other theorists would offer additional perspectives on victimization that included social-psychological or cultural risk factors. Recently, building on studies that show that offenders and victims share demographic characteristics and profiles, researchers have even applied criminological theories to account for victimization risk. Note that these theories are organized to explain nonfamilial forms of victimization; the risk factors for child maltreatment were presented earlier.

Lifestyles-Routine Activities Theory. The lifestyles/routine activities (lifestyles/RAT) approach is a long-standing theoretical tradition in victimization research and was the first victimization explanation to be widely accepted and researched. The approach argues that for victimization to occur, a given situation or context must have a combination of (1) a likely offender, (2) a worthwhile target, and (3) ineffective guardianship. Circumstances where these three factors are present will have the highest incidence of victimization. Other, relatively more recent, scholarship has identified the qualities of routine activities or lifestyles that ought to be predictive of victimization: that those who engage in unsupervised and unstructured social activity with peers will have a higher risk. Such activities would include hanging out with friends and going to parties, activities that are often characteristic of youth.

In the late 1970s through the mid-1980s, research was primarily concerned with the demographic correlates of victimization such as those mention earlier. Starting in the 1980s and continuing into the 1990s, research turned toward specific situations and activities that enhanced the probability of victimization. For instance, researchers noted that self-reported offending was highly correlated with victimization among not only adults but youth as well. In other words, offenders tend to also be victims. The lifestyles/RAT approach accounted for this by claiming that those who engaged in a deviant lifestyle were more likely to spend time with those who commit crime, the very people who would not scruple at victimizing their own peers (thus implying proximity to motivated offenders). Not all juvenile victims are also deviants, but studies show that there is considerable overlap between offending and victimization. Note that the child maltreatment and child victimization literatures point to offending as a byproduct of victimization, thus offering their own somewhat differing accounts of the victim-offender overlaps.

Self-Control Theory. Michael Gottfredson and Travis Hirschi's self-control theory suggests that a person's ability to focus on long-term consequences of behavior, as opposed to short-term solutions to problems, explains conformity. People with low self-control, in contrast, make self-centered decisions that address short-term problems that fail to consider the long-term consequences of those decisions. One can understand how much self-control a juvenile has by identifying actions that consistently speak to ignoring long-term risk, such as acting angrily, impulsively, in flagrant disregard for risk, and selfishly. Such actions also elevate the risk of victimization as well. Children who are aggressive toward others may be attacked and beaten. Impulsive behavior can result in greater vulnerability. Selfish behavior can ruin friendships that have the potential to become strong, and thereby weaken guardianship potential. In this respect, victimization is not something that those low in self-control voluntarily seek out; however, their decisions place them at greater risk than would otherwise be the case. Research so far shows that those with low self-control are more likely to become victims of all manner of crime.

The theory asserts that through childhood differences in self-control tend to be unstable; younger children, in particular, are going to have great difficulty in being able to act consistently with self-restraint. In this respect, low self-control may not offer much of an account for early childhood maltreatment because low self-control is assumed to be universal in that population. Indeed, Gottfredson and Hirschi attributed childhood maltreatment to parents who were poorly equipped to teach their children self-control. Once children can be reliably rank-ordered in terms of their self-control, however, then the theory can offer a plausible account of why some individuals become victims.

Social Interationist Theory. Richard Felson introduced the "social interactionist" (or SI) theory to explain violent victimization. The main argument of the theory is that victimization occurs as a result of interplay between two or more individuals involved in social exchange. The basic process begins with a person who has experienced a negative event and who is consequently feeling emotionally down. The emotional response of the stressed individuals is usually to become short-tempered, irritated, or angry. These behaviors elicit backlash from those around the individual who, rather than take pity on the stressed person, become annoyed or angry themselves. As a consequence, the other person in the interaction will have a grievance, which may provoke physical attack if the distressed person is unable or unwilling to make satisfaction (e.g., apologize). This social interaction produces a cycle of retaliation and counter-retaliation that is hard to stop. A few major studies have tested the tenets of the theory to explain victimization. Richard Felson examined the role of negative events as predictors of victimization, finding that they indeed made victimization more likely to occur. Later work has connected negative affect or emotions with significantly elevated victimization risk among youth.

This particular framework is of particular relevance to those interested in juvenile victimization insofar as early maltreatment and victimization appear to produce the emotional distress that is implicated in this theory. That is, childhood victimization (familial or nonfamilial) results in emotional disorders and worsened performance at a variety of tasks. These circumstances, according to SI, would create the grievances that might provoke attack.

Subcultures of Violence Theories. For many years, researchers have studied how subcultural norms of violence are connected with victimization. These subcultures of violence place value on acting tough and retaliating when disrespected. Inherently, this creates a cycle where victims retaliate and become offenders against the initial offenders (who now become the victims). Therefore, the subculture is characterized by individuals who alternate roles as offenders and victims. In fact, this literature has consistently found that violent offenders living in areas where norms of violence predominate experienced high rates of victimization.

More recently, scientific research has begun to directly test the influence of subcultural norms. Elijah Anderson, for instance, introduced an influential theory of offending in his book *Code of the Street*, an ethnographic study of African-Americans in disadvantaged neighborhoods in Philadelphia. The street code is a system of rules governing the use of violence to informally address grievances. These codes are adopted by many individuals in disadvantaged communities, and even if they are not ascribed to by all, they are known by almost everyone living in that area. Here, the individual has a system of beliefs that allow him or her to become physically violent toward others in situations where social control is perceived as necessary. These beliefs are seen as a way to obtain respect among peers and in the community as a whole. The reputation gained through adhering to these codes provides protection against violence. These codes also allow for functional recourse against violations against the individual. Unlike their counterparts outside disadvantaged communities, who can use the police and the courts as allies, individuals in communities marked by street codes rely on violence. Put another way, having a reputation for violence enhances "respect," which in turn deters would-be offenders (who would thus risk their lives by trying a person who has "respect").

Contrary to Anderson's assertion that the code of the street protects individuals from harm, research has shown that African-American youth who reported having attitudes favorable to the use of violence, in fact, had a greater risk of experiencing violent victimization. A system of beliefs that espoused violence and retaliation, rather than being protective, was correlated with more violent victimization. Similar conclusions have been drawn from studies on youth gangs. Although many youth join together to form delinquent gangs for protection, research has shown that gangs, in fact, increase the likelihood that a person will experience violent victimization. In short, victims of violence often have profiles similar to offenders when it comes to attitudes toward violence; both tend to show support for violence as a mechanism for addressing disrespect and physical injury.

Conclusion

Juvenile victimization is a topic of concern, but it is nevertheless perplexing. On the one hand, there are the occasional horrific accounts of youthful victimization reported in the media, which in turn creates a demand for a response from government authorities. This has resulted in considerable investment in school security, for instance. Research consistently shows that the effects of victimization upon youth appear connected with unfortunate decisions and outcomes later in life. Children victimized in school and maltreated at home are more likely to quit school, have a lower income than everyone else, and suffer employment and legal problems throughout their lives. From this perspective, any effort to protect children, no matter how expensive or invasive, would appear to be warranted.

On the other hand, victimization is an exceedingly rare occurrence even for children. Youth who become victims are most likely to have been targets of theft. The percentage of children who have been maltreated at home, who have been violently attacked elsewhere, and who have directly experienced bullying at school is very small. When violence happens, the incident itself tends to be not very serious in terms of immediate effects; however, research indicates that there are many adverse long-term effects that degrade a youthful victim's quality of life as an adult. Levels of victimization are slightly higher at school than outside of school, but this paints a somewhat misleading picture. Much of the victimization is in the form of theft and minor assaults. Serious violence is most likely to occur off of school grounds, where school security cannot offer any protection.

The research also indicates that many efforts intended to curtail the onslaught of youthful victimization are disconnected from the reality of where and when the victimization occurs and to whom. Increasing the safety of students is of course a laudable goal, but misallocating resources toward ineffective programs – and even policies that elevate student fear – undermine the efforts of society to produce children who can function independently as adults.

Research is still attempting to understand the reasons some youths fall victim and not others. There is a clear profile of the families that are most likely to mistreat their children. These theories have focused on the situations that juveniles often are in (and how they fuel victimization risk), their levels of self-control, degrees of emotional distress, and their attitudes toward violence. It is interesting to note that many theories of victimization highlight variables that are consequences of childhood maltreatment, which in turn are correlates of victimization in adolescence and adulthood.

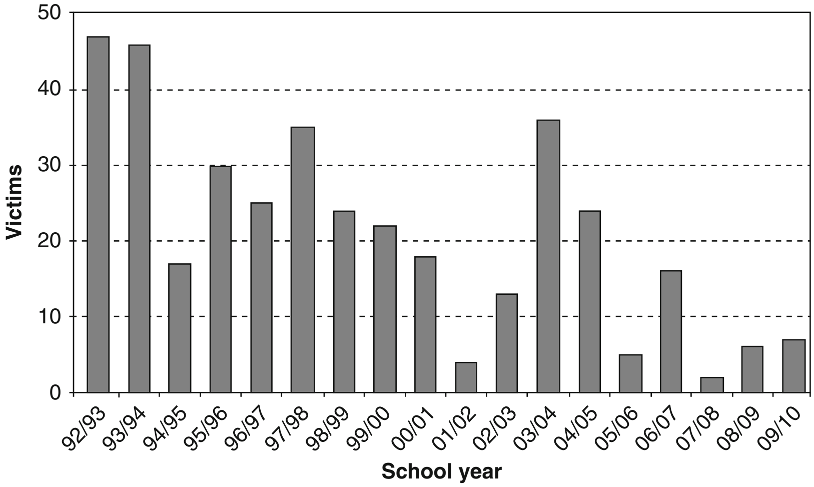
Overview

In the mid- to late 1990s, America was seemingly faced with a frightening epidemic: senseless acts of large-scale violence taking place in ostensibly safe, middle-class schools. Multiple instances of rampage-style shootings occurred in suburban and rural locales across the nation, the most deadly of which was the April 20, 1999 massacre at Columbine High School. Schools no longer *felt* safe. However, despite several isolated cases of school shootings involving multiple (oftentimes random) victims, schools *were* safe. In fact, by the late 1990s, school-related homicides were on the decline – a trend that has continued to the present. Thus, notwithstanding the seriousness of the rampage school shootings of the late 1990s, defining the problem as an epidemic was a hyperbolic overreach. Figure 1 displays school-related homicides since the early 1990s. As shown, the actual count of homicide victims has remained relatively low over time.

Despite this disjuncture between impression and reality with respect to school danger, juvenile violence – both inside and outside of school – remains a pressing concern for the public, criminologists, and criminal justice professionals alike. As such, it is important to have timely and accurate data on which to base policy. Without such data, criminal justice policies are more likely to be based on media-driven panics, as in

Juvenile Violence, Fig. 1 School-related homicides, 1992–2010



the last 10–15 years, when ineffective and unnecessary measures, including zero-tolerance and fortress-like access control, were implemented within schools.

The purpose of this entry is to review patterns and trends in juvenile violence, using the most up-to-date data available. The first section of the entry provides definitions and describes the categories of violence used by law enforcement officials and researchers. The second section provides some historical context for the state of juvenile violence in the United States today. This is followed by a review of trends in juvenile violence, examining how different types of offending have shifted or remained stable over the years. This section also briefly highlights several explanations for juvenile violence. The entry concludes with a discussion of policy implications emerging from the juvenile violence data.

Definitions of Juvenile Violence

Juvenile violence is defined as the threat, attempt, or actual use of force by one or more persons that results in physical or nonphysical harm to one or more persons, committed by a person under the age of 18 (Barkan 2009). Generally, behavior is only considered "violence" if the perpetrator caused harm (either physical or emotional) to a victim. Juvenile violence can be classified in a number of different ways, including the Federal Bureau of Investigation's designation of Part I (criminal homicide, forcible rape, robbery, and aggravated assault) and Part II (less serious acts such as carrying a weapon and simple assault) violent crimes.

A Brief History

A comprehensive history of juvenile violence is beyond the scope of this entry. However, because the majority of the information presented here refers to the modern period (i.e., mid-1970s to the present), it is important to provide some context. Juvenile violence is hardly a new phenomenon. While data and research on such behavior have increased in sophistication over time, juveniles have presumably engaged in illegal acts of violence throughout history. Records indicate that the first juvenile to be sentenced to death in Colonial America was Thomas Graunger, for the offense of bestiality committed in 1642 (Twersky-Glasner 2007). Reasonably valid statistics are not available until the nineteenth century. Before that time, juveniles accused of crimes were often treated as, and imprisoned with, adults by the criminal justice system. William Blackstone's *Commentary on the Laws of England*, from which American Law in the eighteenth Century was largely derived, argued that the "malice supplies the age" – that is, the seriousness of the offense determined how the offender was treated (ABA 2007). With the establishment of houses of refuge in 1820, juvenile offenders began to be increasingly separated from adult offenders. Records of offenders incarcerated in reformatories from 1890 show that juveniles were imprisoned for such crimes as homicide, rape, and assault, though these cases were rare (Walker 2007).

In 1899, the juvenile justice system with which most people are familiar today was ushered in with the formation of the first juvenile court in Cook County, Illinois. The model was initiated to provide guidance for wayward youth, rather than punishment. However, the middle part of the twentieth century saw many changes to juvenile justice, leading to a system that is increasingly similar to the adult system. While there remains a separation between juvenile and adult criminal justice systems, the distinction is blurring, with increasing stipulations allowing juveniles to be tried as adults (Singer 1996).

Juvenile Violence: Correlates, Trends, and Theory

There are two main sources of data that researchers use to study juvenile violence. First, is the Uniform Crime Report (UCR) which is released yearly by the FBI. The UCR is based on information gathered by local police departments who submit their data to the FBI. Thus, the UCR is comprised of "crimes known to the police." The FBI also assembles and disseminates arrest data, which are more detailed – because of the inclusion of offender information – but underestimate the number of actual crimes that occur, and so may be somewhat biased (relatively few crimes, e.g., result in an arrest). UCR data for juveniles show that the number and rate of arrests for violent crimes is inversely related to the seriousness of the act – in other words, the likelihood of a juvenile committing and being arrested for a violent act declines as the seriousness of the crime increases.

In addition to the long-standing UCR program, the National Incident-Based Reporting System (NIBRS) is a relatively recent development in which the police report a wide array of details on crimes, offenses, arrests, and victims, providing researchers with extensive information with which to examine the correlates and causes of crime. However, most police agencies (especially larger ones) do not as yet participate in the NIBRS initiative, thereby limiting its value for tracking patterns and trends in criminal behavior. Finally, the Supplementary Homicide Reports (SHR), available in its current form since 1976, provides detailed information on over 90 % of the homicides in the United States. Because of the level of detail and high degree of coverage, SHR data are used here extensively for examining the nature and extent of juvenile violence.

With respect to "unofficial" sources of data on juvenile violence, the most common method used by researchers involves surveys. When conducting self-report surveys, researchers gather a sample of youth and ask them about whether they have committed various criminal acts. Examples of such studies are the National Longitudinal Study of Youth, the National Youth Study, and the Behavioral Risk Factor Surveillance System. Research has indicated that despite some shortcomings, self-report surveys of violence tend to be fairly reliable and valid sources of information (Hindelang et al. 1981; Mosher et al. 2002).

One reason that academics and practitioners are concerned with juvenile delinquency is the disproportionate amount of crime committed by adolescents. Another reason for concern is the consistent finding that individuals who are involved in offending are also more likely to be victimized (Posick 2013). In other words, offenders are more likely to end up as victims compared to those who avoid criminal behavior. Taken together, juveniles are disproportionately involved in violence as both offenders and victims. Trends in juvenile delinquency allow researchers to highlight potential patterns and causes of crime and delinquency that can be addressed through prevention and intervention programs.

The Rise and Fall of Juvenile Violence

The late 1980s and early 1990s saw a significant and disturbing surge in youth violence, including homicide. While the overall violent crime rate also rose as a whole during this period, this was largely due to increases in violence among juveniles and young adults. Criminologists disagree about exactly why the youth crime rate rose so rapidly during this period. Some have pointed to the emerging crack markets and the violence that surrounded drug selling in the 1980s, while others implicated the decline of intact families and family values. Regardless of the explanation of this increase, the rise in juvenile violence was experienced nearly ubiquitously across the nation, although it was far more pronounced in urban areas.

Following the sharp rise in juvenile violence that peaked in the early 1990s, the USA experienced a major decline in youth violence that in large measure continues to this day. Some of this decline was expected as rates were already so high that they essentially had almost nowhere else to go but down. However, research has indicated that this decline was steeper than expected and not only due to a return to normal levels. For example, by some measures, crime fell so much during the mid- and late 1990s that it reached levels not seen since the 1960s. Just as criminologists were interested in explaining the rise in crime rates from the 1980s until the early 1990s, they were equally interested in explaining the decline. Criminologists also disagree about why there was a drop in violent crime in particular, especially among juveniles. Researchers have attributed the drop to several factors, including:

- Shifting demographics (e.g., aging of the population)
- The decline of crack markets
- Effective policing strategies
- Legalization of abortion (reducing the supply of youths likely to commit crimes)
- Enhanced enforcement of gun laws
- Increased use of incarceration and longer sentences

Incarceration may or may not have been a major contributor to declining, rates of juvenile crime rates in the 1990s; however, with the "get tough" approach that began to characterize justice systems during that time period, juveniles were increasingly charged and punished as adults. Thus, incarceration of juveniles may have played a role in the juvenile crime drop. Despite the disagreement on the cause of the crime decline, there is little debate over the extent of this decline.

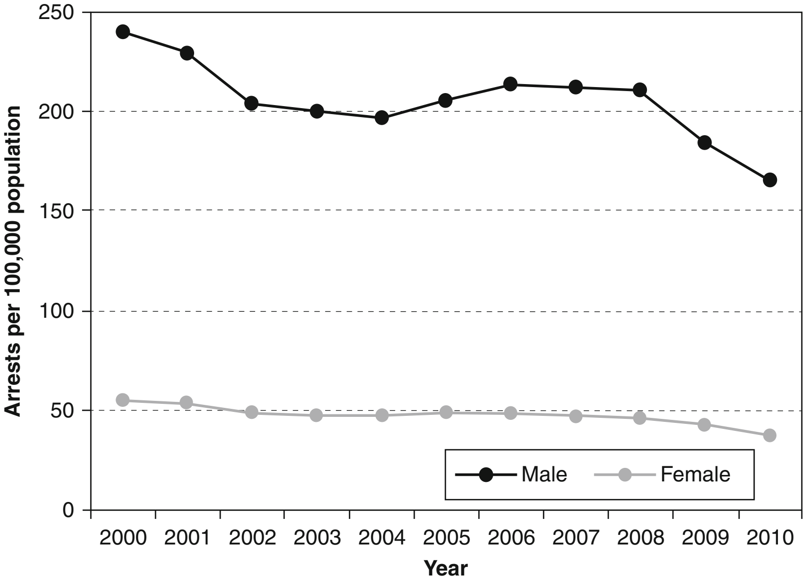
More recent trends in juvenile violence show that while rates declined from the early 1990s to the early twenty-first century, they now appear to be plateauing. Research suggests, however, that some forms of juvenile violence, such as gang activity, are rebounding. Predicting where the trend will move over the next decade is rather difficult; only time will tell.

Trends within the United States show peaks and valleys, but the rank order of the country in comparison to others around the globe has remained steady. There is little controversy over the violent nature of the United States in comparison to other developed countries. The USA remains consistently ranked near the top in violent crime, particularly murder. Per capita, the USA is one of the most lethal developed nations in the world. These rates are largely driven by violence by teens and young adults. Self-report surveys also confirm this pattern. The International Self-Report of Delinquency-II (ISRD-II) study has shown that youth in the "Anglo-Saxon" country cluster (which is comprised of Ireland, Canada, and the United States) has the highest rates of violence (Junger-Tas et al. 2012).

Juvenile crime rates have risen and fallen but there are certain elements of juvenile offending that have remained fairly consistent across time. For example, males are more likely than females to be involved with violent crime, and this holds across all ages and demographic groups. This fact is illustrated in Fig. 2.

As can be seen in Fig. 2, which displays UCR arrest data from 2000 to 2010 for males and females under the age of 18, males have a consistently higher arrest rate than females. The figure shows all Part I violent crimes combined (homicide, rape, robbery, and aggravated assault). Interestingly, the trend for that time

Juvenile Violence, Fig. 2 Juvenile arrest rates by sex, 2000–2010



period was very similar for both males and females, dipping a bit around 2002, peaking around 2008 and then falling again in 2010. While males have higher arrest rates than females for all violent crimes, the disparity is most stark for homicide, robbery, and especially rape. The violent crime in which male and female rates are the closest is aggravated assault (where male rates are around three times higher than female rates).

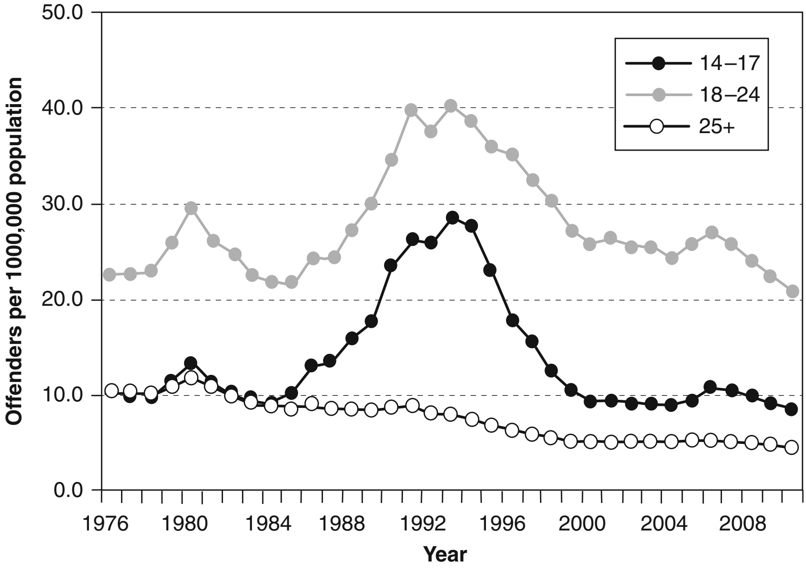
Youth Homicide

Homicide, or lethal violence, is the most feared crime and also the one for which the most detailed information (provided by the Supplementary Homicide Reports) is available. Data indicate that lethal violence is not distributed evenly across the population. In other words, there are certain clear and consistent demographic, geographical, and temporal patterns that data have revealed with respect to juvenile homicide. The following figures explore how lethal violence is distributed demographically and geographically, and how these patterns have changed over time.

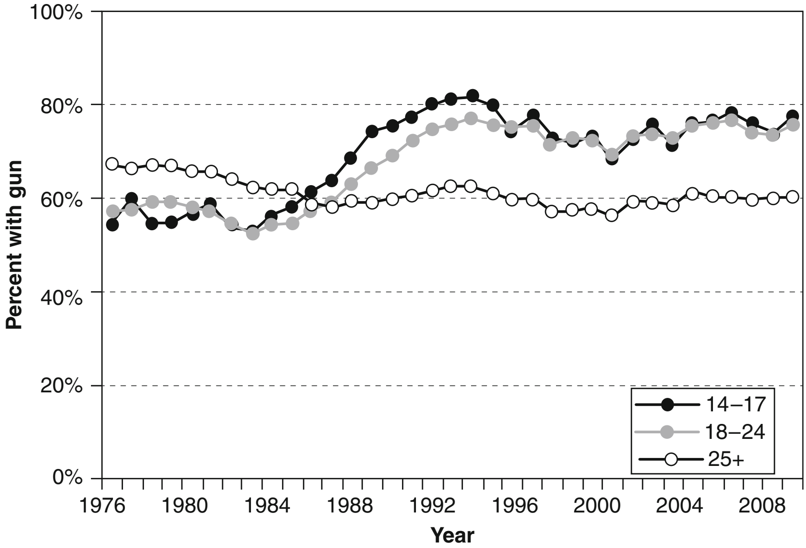
As is shown in Fig. 3, homicide is an offense committed disproportionately by juveniles and young adults. People over 25 years of age have a much lower rate of homicide. Young adults ages 18–24 are the most likely homicide perpetrators followed by youth ages 14–17. In terms of trends, homicide rates for all age groups increased in the 1970s and then began to decline in the early 1980s. Prior to the 1980s, the homicide rates for youths aged 14–17 and those aged 25 were virtually indistinguishable. However, as noted above, at that point, there was a noticeable spike in homicide by young offenders. By the early 1990s, the homicide rates for both the 14–17 and 18–24 age categories had nearly doubled their 1980 levels. Interestingly, the homicide rate for the over 25 age group remained relatively unchanged during the 1980s, compared to the other two age groups. During this time, some scholars worried about a violence epidemic gripping the nation’s youth and argued that the existence of “super-predators” may account for some of this increase in violence and indeed would continue to keep homicide rates high (Bennett et al. 1996).

However, as discussed earlier, in the United States as well as other western, industrial nations, beginning in the early 1990s, crime began to fall. Homicide rates dipped to the lowest they had been in decades. As is shown in Fig. 3, homicide rates for juveniles and young adults stabilized

Juvenile Violence, Fig. 3 Homicide offending rate by age group, 1976–2010



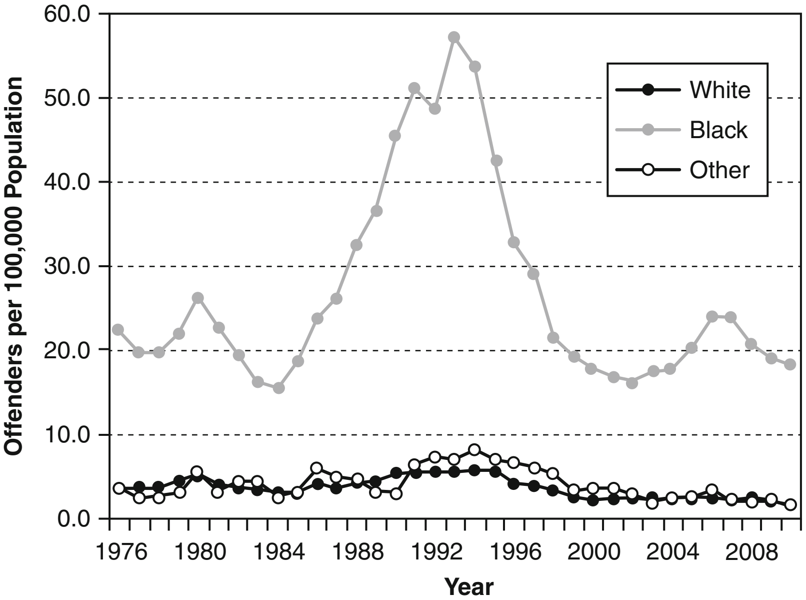
Juvenile Violence, Fig. 4 Percent gun homicide by age group, 1976–2010



around the year 2000, but since then have continued to dip. This “great American crime decline” remains largely unexplained, although the reductions in the crack cocaine market and use of handguns by juveniles likely are contributing factors (Blumstein and Wallman 2006). As Fox et al. (2012) note, the rise of the crack market in inner cities during the late 1980s and early 1990s resulted in a dangerous and often very violent “arms race” in which profits had to be protected by the youths directly involved. It appears that when this market declined, the juvenile homicide rate followed suit.

The emerging crack market required that drug couriers defend themselves and their territories with deadly weapons, namely, guns (Blumstein 1995). As shown in Fig. 4, homicides involving guns increased in the mid-1990s and then declined for both juveniles and young adults. Much like the trend shown in Fig. 3, the rate of

Juvenile Violence, Fig. 5 Homicide offending rate by race, 1976–2010



homicides using a gun did not follow the same pattern for those aged 25 and older. Thus, it would seem that much of the decline in violent crime for juveniles and young adults was due to the changing crack market and the use of guns accompanying it. While crack use was still fairly prevalent, the marketplace for the drug was not nearly as volatile, competitive, and/or violent.

As can be seen in Fig. 4, in the past four decades, a solid majority of all homicides were committed with a gun. This finding is consistent across all age groups; in fact, the 14–17 and 18–24 age groups are almost identical in their pattern throughout the past several decades. During the peak of the violent crime spike, over 80 % of the homicides committed by the youngest group were committed with guns. Many researchers suggest that it may be the widespread availability of guns that contributes to high homicide rates in the USA and that this may explain some of the peaks and valleys in the patterns of lethal violence.

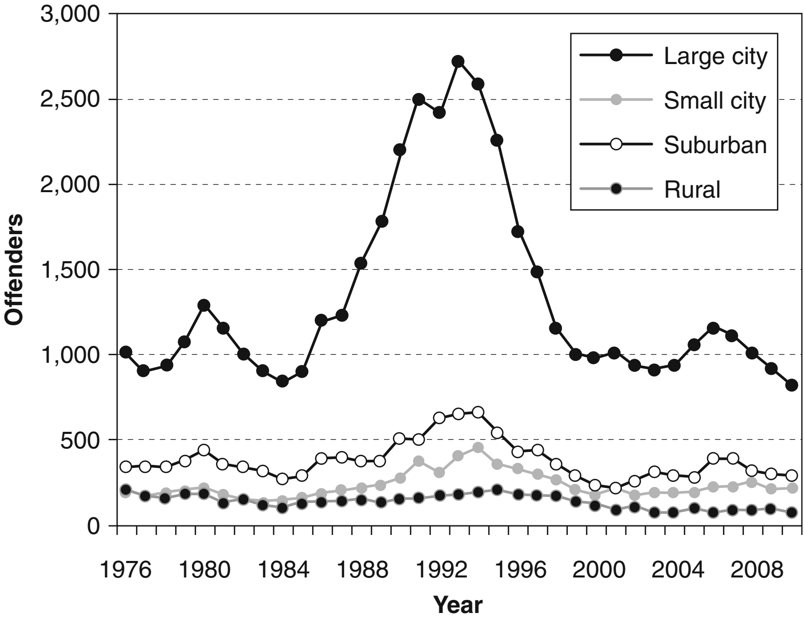
When one considers the saga of the crime decline in the 1990s following the "near-epidemic" levels in the late 1980s, perhaps the starkest trend can be found with respect to race. As shown in Fig. 5, the peak in homicides was much more drastic for blacks than for other racial groups. As is well known, the crack market was concentrated among minority groups, particularly blacks. This lends more credence to the thesis that the crack market was a large contributing factor to the rise and fall of juvenile violence since the mid-1980s.

In comparison to other crimes, homicide is unevenly distributed across racial groups. Regardless of the trend, blacks have a much higher homicide rate than any other racial group. Whites and other races have had almost identical rates throughout the last few decades, which range from about four times lower (in the early 1980s) to about six times lower (in the mid- to late 1980s) than the rate for blacks.

The crack market, as previously noted, was concentrated in the minority-dominated, inner cities. As shown in Fig. 6, the rise and fall of juvenile homicides was most pronounced in large cities. This again supports the thesis that the crack market and associated gang activity played a large role in juvenile homicide patterns since the early 1990s. Nonetheless, juvenile homicide rose and fell in cities of all sizes, suggesting that crack and gun use were not the only factors affecting violent crime rates.

In general, homicide is not evenly distributed geographically and this is true for juvenile

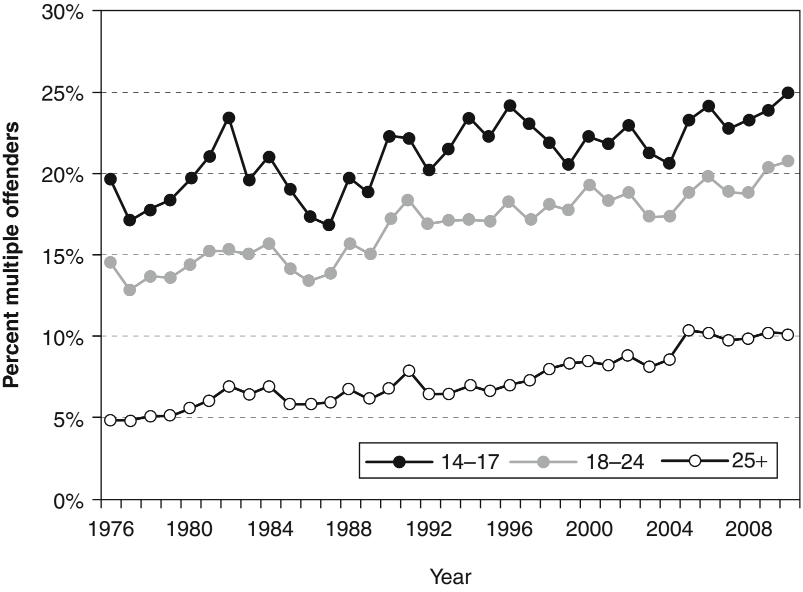
Juvenile Violence, Fig. 6 Juvenile homicide offenders by location, 1976–2010



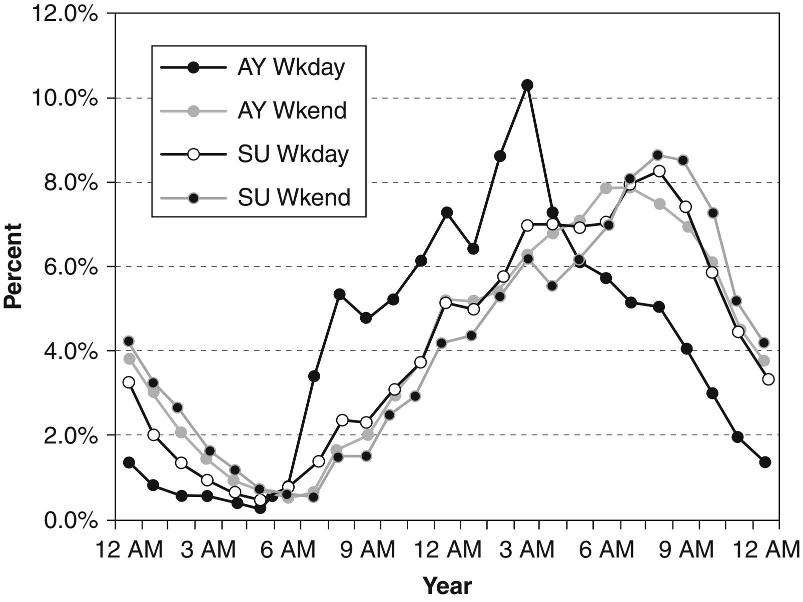
homicide as well. As Fig. 6 indicates, the highest juvenile homicide rates are found in large cities. These are followed by suburban, small cities, and rural areas. The disparity between large and smaller cities with respect to juvenile homicide is similar to that between blacks and other races, as discussed previously. For example, at the point of the homicide peak, large cities had a homicide rate of more than four times that of other city sizes. That this disparity (despite some fluctuations) is relatively consistent across time suggests that factors such as poverty, relative deprivation and "subcultures of violence" may contribute to the variation in homicide rate by city size. A counterargument to the "more guns, more violence" hypothesis is that guns are also prevalent in rural areas where hunting and gun culture is prominent. Perhaps it is not guns alone, but guns in conjunction with a culture of violence that influences violent crime rates.

Figure 7 illustrates trends by age group for homicides committed by multiple offenders. There is a near-linear increase over time for each age group, suggesting that more homicides are being committed in partnerships. While homicide is generally committed by a lone offender, younger individuals are more likely than older individuals to commit homicide with other offenders. In other words, violent offending is more of a group activity among youths. Younger individuals are more likely to associate with and be influenced by delinquent peers, while older individuals are more likely to be involved with family or work. This is concordant with research that shows juveniles are more affected by peer influence and more likely to offend in groups early in life as compared to later (Farrington 2003). About 20–25 % of homicide offenders ages 14–17 commit the crime with the help of accomplices, compared to 15–20 % for 18–24-year-old assailants and only about 10–15 % for offenders over age 25. When older individuals do commit lethal violence, it is more likely to be done alone – perhaps related to domestic or intimate partner violence. In general, the literature suggests that adults tend to commit crime alone, although lethal violence in particular is among the least likely to be committed with co-offenders.

The timing of juvenile violence (e.g., time of day, day of week, and season of year) is another key piece of information with clear policy implications. Logic would suggest that youth crime should peak in the early afternoon, directly after school lets out), and data support this notion. In Fig. 8, NIBRS data are used to examine patterns of violent



Juvenile Violence, Fig. 7 Percentage multiple offenders by age group, 1976–2010



Juvenile Violence, Fig. 8 Time of day patterns for juvenile offending by time of the week, 2009

crime committed by juveniles by time of day for the academic year (AY) and summer months (SU), for weekdays and weekends separately. While the overall patterns for offending are fairly similar, there are two deviations that are worthy of attention. First, a spike is apparent in offending around 3 pm on weekdays during the school year. This uptick is related to the routine school-day activities of likely offenders and victims in the after-school hours. Students leave school around 2–3 pm, bringing together many youth who, now out of school but not yet at home, tend to be less supervised by teachers and parents. This situation is prime for both offending and victimization.

A second deviation from the general offending pattern is seen in offending around 9 pm in the

Juvenile Violence, Table 1 Patterns in juvenile homicide by time period

		Year group		
Item	Category	1976–1985	1986–1995	1996–2010
Victim age	Under 14	5.00 %	4.20 %	4.20 %
	14–17	17.00 %	20.60 %	19.50 %
	18–24	27.20 %	31.70 %	33.30 %
	25–34	16.10 %	20.50 %	17.40 %
	35–49	16.30 %	15.10 %	16.30 %
	50–64	9.50 %	4.60 %	6.00 %
	65+	8.90 %	3.30 %	3.30 %
Relationship	Intimate	3.30 %	2.40 %	2.20 %
	Family	13.40 %	8.50 %	9.20 %
	Acquaintance	47.10 %	52.70 %	52.10 %
	Stranger	36.10 %	36.30 %	36.50 %
Weapon	Gun	56.00 %	76.00 %	74.50 %
	Knife	22.90 %	10.90 %	9.90 %
	Other	21.10 %	13.10 %	15.60 %
Circumstances	Felony	35.50 %	33.70 %	32.60 %
	Argument	36.30 %	34.70 %	33.70 %
	Other	28.50 %	31.60 %	33.70 %

summer and on the weekends. Again, this is likely due to the routine activity patterns by young people (those aged 18 and under) during these hours. After work and during the weekends, adolescents often enjoy partying and carousing. This brings together young people who may be under the influence of alcohol or drugs in environments with little formal supervision. During the academic year, when youth are in school, the percentage of total offending during these later hours is smaller because students are more likely to be involved with schoolwork or asleep during this time of day.

Figure 8 suggests that crime prevention efforts should be focused on peak hours of offending (which covary with victimization) to prevent violence. Some research in criminology has examined the extent to which after-school programs can reduce offending. This research has shown that the peak in offending after school tends to be starker for official records than for self-reports. In addition, after-school programs do, in fact, reduce juvenile offending, in part because of an increase in supervision, but more importantly because of effective socialization that reduces antisocial tendencies (Gottfredson et al. 2001, 2004).

The discussion of trends and correlates of juvenile violence closes with a look at the characteristics of juvenile offenders, including their victims across several decades. These data are shown in Table 1. The first panel of Table 1 illustrates patterns with respect to victim age. Since the first time period (1976–1985), victims of teenagers have tended to be younger. For example, in the period between 1976 and 1985, 17 % of victims were aged 14–17 compared to around 20 % in later years. In addition, about 18 % of victims were over the age of 50 in the first time period, compared to around 8–9 % in later years. Overall, mirroring the offender ages for homicide, the largest age category for victims in all years is 18–24. This supports the argument that offenders and victims of lethal violence tend to share demographic characteristics.

In terms of the relationship between victim and offender for juvenile homicide, most are acquaintances. The relative rank ordering of these relationships has remained consistent over time. However, there has been an increase in the percentage of victims who are acquaintances, and a decrease in family homicides since the 1976–1985 time period. The percentage of homicide victims who are intimates or strangers has remained relatively consistent over time.

Juvenile homicides also predominantly involve guns. This is shown in the third panel of Table 1. Interestingly the percentage of juvenile homicides using a gun increased dramatically in the mid-1980s from 56 % to 76 %. This follows the trend shown in Fig. 4.

The circumstances leading to juvenile homicide have not changed much over time. As shown in the bottom panel of Table 1, the three classifications of circumstances (felony-related, argument-related, or other) are relatively evenly distributed, with argument-related episodes slightly more commonplace. Adolescents tend to act impulsively and have lower self-control. As a result, most juvenile homicides appear likely spontaneous or episodic, rather than being planned and premeditated.

Conclusion

Juvenile violence remains a significant concern for policy-makers, criminologists, and the public alike. Too often, however, misconceptions fueled by sensational media reports lead to policies or programs that either do not work or actually serve to make things worse. In the 1980s, two particular programs (Scared Straight and D.A.R.E.) were popular and supported handsomely by government funding. Unfortunately, evaluations of these initiatives have shown that they did not work; in fact, in some situations, they actually increased the risk of offending (see Mackenzie 2006).

Because juvenile crime – especially violence – remains a significant concern, reducing its occurrence continues to be a priority. The best interventions and prevention strategies are based upon a solid understanding of the patterns of juvenile violence, including prevalence, trends, and correlates. As discussed here, juvenile violence has followed some pronounced trends over the last 30 years, including a major spike in the 1980s (especially for inner-city, minority youths using handguns), followed by a large decline that in large measure continues to this day.

Juvenile violence also seems to cluster in terms of day of the week and time of day. As we have shown, crime tends to increase on the weekends and during after-school hours. This information represents a powerful tool for policy-makers who wish to design effective interventions that will decrease juvenile violence. However, it is important to bear in mind that it is not solely supervision or surveillance that seems to be what matters with respect to reducing violence, but impacting attitudes and other risk factors related to crime. Those wishing to reduce or prevent juvenile violence would do well to remember that it is not a simple phenomenon, but one that is complex and influenced by a variety of factors, including peer influences and lack of self-control (see Farrington 2007). Understanding what juvenile violence is (and is not) as well as its trends and correlates is an important first step in achieving this goal.

Labeling Theory

Erich Goode
Sociology Professor Emeritus, Stony Brook
University, Stony Brook, NY, USA

Overview

Deviance is a label attached to certain acts and individuals; those acts need not be harmful to be designated as bad, and those individuals may not have even committed the acts in question, but it is the label – the designation, the *judgment* – that renders the acts and the individuals as deviant. Other acts may be more harmful but considered less heinous; other individuals may be more dastardly without attracting an equal measure of stigma. Labeling theory argues that, from a sociological perspective, what *counts* is this designation. Other theories of deviance attempt to explain the incidence or prevalence of concretely real acts with concretely real consequences – robbery, adultery, murder, drug use, rape, and the like. Labeling theorists do not say that such designated behavior is not real, or that its consequences are not real, until they are labeled; they say that the behavior is not specifically *deviant* until the label (self-labeling included) is applied. One man may kill another, but it is not *murder* – a deviant category of killing – until audiences (a judge, a jury, a community, oneself) label the act *as* murder. It is still a killing: Someone has died, and forensics may be able to determine whether the first man caused the second's death. What is deviant is determined socially and culturally. Labeling theory is a constructionist perspective *par excellence*.

Deviance may be viewed *horizontally* or *vertically*. At the micro level, deviance is manifested by how one or more persons or members of one small collectivity react to another; labeling entails judgments made by individuals or social circles. When Person A evaluates and reacts to Person B's behavior, Person A acts as an "audience." Multiplied dozens of times, this represents the labeling process at the horizontal level. In contrast, *vertically*, labeling can be viewed at the cultural, institutional, and social-structural level. When labeling is institutionalized, it is coagulated into preexisting potential judgments, analogous to socioeconomic status or occupational prestige; anyone who is a member of the relevant society is likely to be subject to them. And institutionally, organizations possess the capacity to label and deal with individuals as *deviants*. A prison has the power to label, and treat an inmate as, a *convict*; a school, college, and university possess the power to judge student a *failure* – a loser, an educational flop; the psychiatric profession, both individually and

collectively, dispense diagnoses of schizophrenia, autism, and bipolar disorder that can have consequences for the labelee as momentous as the conditions themselves. Hence, labeling tends to be *asymmetrical*: Although audiences with equal power and influence can label one another, vertically, the most consequential deviance-labeling processes flow from institutions to individuals who are so labeled.

The Emergence of Constructionism

Hints of the central concepts of deviance-labeling can be found in the works of Émile Durkheim, in *Suicide* and *The Elementary Forms of the Religions Life*; nonetheless, most scholars locate the roots of the labeling theory of deviance in the pragmatic school of George Herbert Mead (1863–1931). Pragmatism denies the significance of mysticism and essentialism, emphasizing instead that *the meaning is in the response* – what defines something is not its abstract, indwelling "isness," material or spiritual, but the concrete, identifiable consequences it has, the results it affects.

The connection between pragmatism and the perspective that defines deviance as a consequence of labeling is obvious. Rather than regarding deviance as a type of action with objective features, the labeling perspective views the violation of rules as an *infraction*, that is, what *makes* certain actions (and beliefs and conditions) infractions. Why are rules constructed and enforced? Who makes and forces the rules? Why are *certain kinds* of rules made? Why are certain *persons* or *types of persons* apprehended and punished? What *consequences* do rule-making and rule-enforcement have? This approach turns the focus of attention around. Now the spotlight is not on the rule-violator or the conditions that make for rule violation but on the society and the groups in the society that *make and enforce the rules*. And rules take on meaning only insofar as they are applied; deviant behavior is what tends to attract punishment, condemnation, stigma, censure; a deviant person is someone whose identity is saturated with public scorn.

Labeling or Interactionist Theory

In 1938, Tannenbaum published the volume *Crime and the Community*, which argued that in a slum area, nearly all boys engage in a wide range of mischievous, sometimes illegal behavior – getting into fights, skipping school, stealing apples, throwing rocks at windows. These actions, taken for granted by the boys themselves, are often regarded as deviant, even criminal, by the authorities – by the teachers, the police, and the courts. The police may admonish, informally punish, or arrest these boys. If these boys persist in this behavior, they may be sent to reform school. However, punishment could have the unintended, undesired, and ironic effect of escalating the seriousness of the deeds that these boys commit. Arrest and incarceration often result in the community regarding a boy as incorrigible, rebellious, unmanageable – a deviant. By being treated as a delinquent and forced to associate with slightly older and more experienced young criminals in reform schools, the troublemaker may come to adopt the identity of the delinquent. In all likelihood, this will escalate his deviant career – increasing the chance that he will go on to a life of crime. Labeling creates major crimes out of minor sins. Tannenbaum also emphasized that social characteristics – specifically social class – play a role in deviance labeling. Though he added labeling to the roster of the causes of deviance, Tannenbaum did not deny that other factors caused delinquency. *Crime in the Community* did not address the social construction of deviance, a central tenet of labeling theory; hence, Frank Tannenbaum is a *precursor* of labeling theory.

In 1951, Edwin Lemert published a textbook with the anachronistic title, *Social Pathology* (1951); Tannenbaum does not appear among its author index. Lemert distinguished between *primary* and *secondary* deviation. Primary deviation is simply the enactment of deviant behavior itself – any form of it. Lemert argued that primary deviation is *polygenetic* (1951, pp. 75–76) – caused by a wide range of factors. For instance, someone may drink heavily for a variety of reasons – the death of a loved one, a business failure, belonging to a group whose members call for heavy drinking, growing up in a subculture or a society in which heavy drinking is taken for granted. In fact, Lemert asserted, the original causes of a particular form of deviance is not especially important, and pursuing them, not especially fruitful. What counts is the social reaction *to* the behavior. Lemert's treatise represented a major departure from the mainstream of essentialistic/positivistic, or scientific cause-and-effect, reasoning about deviance.

Secondary deviation occurs when the individual who enacts deviant behavior deals with the problems created by social reactions *to* his or her primary deviations (1951, p. 76). "The secondary deviant, as opposed to his [or her] actions, is a person whose life and identity are organized around the facts of deviance" (1972, p. 63). When someone is isolated, singled out, stigmatized, or condemned for engaging in deviant behavior, it becomes necessary to *deal with* and *manage* this social reaction in certain ways. One comes to see oneself in a certain way, define oneself in different terms, adopt different roles, associate with different individuals. Being stigmatized forces one to become a deviant – to engage in secondary deviation. The concept of "secondary deviation" does not *necessarily* imply that labeling causes more frequent enactment of the behavior that generated the label, but it is more likely than in the absence of labeling.

During the late 1950s, Howard Becker circulated a manuscript, along with four previously published papers, that constituted the core of *Outsiders*. He mentions that he wrote the first draft of the volume without having read or cited Lemert's book (Debro 1970, p. 165), and so his reference to *Social Pathology* in the published version of this book (p. 9) was tacked on after the fact – in effect, a *bogus genealogy*. In the 1960s, Becker, along with a small group of like-minded researchers, produced a small body of work that exerted an enormous influence on the sociological approach to deviance; it came to be looked upon as a more or less unified perspective that is widely referred to as *labeling theory*. Labeling theory grew out of a more general perspective in sociology called *symbolic interactionism*. The interactionist approach is based on "three simple premises." First, people act on the basis of the *meaning* that things have for them. Second, this meaning grows out of *interaction* with others, especially intimate others. And third, meaning is continually modified by *interpretation* (Blumer 1969, p. 2). These three principles – meaning, interaction, and interpretation – form the core of symbolic interactionism and likewise of labeling theory as well. People are not simple "products" of their upbringing or socialization or of their environment, but they are active and creative in how they see and act on things in the world and arrive at what they think, how they feel, and what they do through a dynamic, creative process. All behavior, deviance included, is an interactional product; its properties and impact cannot be known until we understand how it is defined, conceptualized, interpreted, apprehended, and evaluated – in short, what it *means* to participants and relevant observers alike. Labeling theory is not a separate theory but a direct application of symbolic interactionism to phenomena than are designated as deviant.

According to Becker (1973, pp. 177–208) and Kitsuse (1972), labeling theory is not so much an explanation of why certain individuals engage in deviant behavior as it is a perspective whose main insight tells us that the labeling process is crucial and cannot be ignored. And labeling "theory" is not so much a theory as it is an orientation perspective, a set of useful concepts with no clear-cut propositions. In fact, most "labeling theorists" preferred the term, "the interactionist approach to deviance" to the easy-to-remember tag their perspective was stuck with – "labeling theory" (Becker 1973) – here we have an irony that even labeling theory came to be labeled. The labeling approach shifts attention away from the traditional question of "Why do they do it?" to a focus on how and why judgments of deviance come to be made and what their consequences are. What consequences does labeling have for stigmatization? What is the difference between enacting rule-breaking behavior which does not result in getting caught and enacting that same behavior and being publicly denounced for it?

These are some of the major issues labeling theorists have concerned themselves with.

In many ways, labeling theory is a model or quintessential example of the constructionist approach. It addresses issues such as the creation of deviant categories, the social construction of moral meanings and definitions, social and cultural relativity, the how and why of social control, the politics of deviance, the criminalization of behavior, and the role of contingency in the labeling process. Together, these issues constitute the foundation stone of constructionism. Several issues or concepts represent the hallmark of the labeling theory's central concerns: *audiences, labeling and stigma*, *reflexivity*, and *the "stickiness" of labels* and *the self-fulfilling prophecy*.

Audiences. An audience is an individual or any number of individuals who observe and evaluate an act, a condition, or an individual. An audience could be one's friends, relatives, or neighbors, coworkers, the police, teachers, a psychiatrist, bystanders or observers – even oneself, for one can be an observer and an evaluator of one's own behavior or condition (Becker 1963, p. 31). *Audiences* determine whether something or someone is deviant: no audience, no labeling, therefore, no deviance. However, an audience need not *directly* view an act, condition, or person; audiences can witness behavior or conditions "indirectly," that is, they can hear or be told about someone's behavior or condition, or they can simply have a negative or condemnatory attitude toward a class or category of behavior: "The critical variable in the study of deviance . . . is the social audience rather than the individual actor, since it is the audience which eventually determines whether or not any episode of behavior *or any class of episodes* is labeled deviant" (Erikson 1964, p. 11; my emphasis). In other words, audiences can evaluate *categories* of deviance and stand ready to condemn them, even before they have actually witnessed specific, concrete cases of these categories. Audiences are absolutely central in the sociological definition of deviance. Whether an act, a belief, or a trait is deviant or not depends on the audience who does or would evaluate and react to the actor, the believer, or the possessor accordingly. Without specifying real-life audiences, the question of an act's, a belief's, or a trait's deviance is meaningless. Audiences include the society at large, agents of formal social control, and the significant others of the actor, such as intimates – or any minority collectivity within a given society. Different audiences may or may not evaluate or react to the actor's behavior in the same way.

Labeling and stigma. The key elements in "becoming" deviant are labeling and stigma. The processes of labeling and stigmatizing are done by a relevant audience. The audience is relevant according to the circumstances or context. Gang members can label the behavior of a fellow member of the gang, for instance, the refusal to fight, as deviant *within the gang context*; the police can label an action of a gang member, for instance, fighting, as deviant, wrong, or illegal, by arresting or harassing him. Each and every audience or person can label each and every action, belief, or condition of each and every person as deviant – but the weight or *consequences* of that labeling process vary according to the context, as we saw in considering the *vertical* conception of deviance labeling.

The labeling or stigmatization process entails two steps. First, an audience labels an *activity* (or belief or condition) deviant, and second, it labels a specific *individual* as *a* deviant. In these two labeling processes, if no audience labels or would label a given person or someone deviant, strictly speaking, *no deviance exists*. An act, belief, condition, or person cannot be deviant *in the abstract*, that is, without reference to how an audience does or would label it. Something or someone must be defined as such by the members of a society or a group *as* deviant – it must be *labeled*, concretely or potentially, as reprehensible or wrong. An act, belief, or condition need not be *actually* or *concretely* labeled to be regarded as deviant, however, but it is deviant if it belongs to a category of similar actions, beliefs, or conditions. In other words, *we already know* that the public regards shooting the proprietor of a store and taking the contents of that store's cash register as deviant. Even if the robber gets away with the crime, *if known about*, the act is likely to be regarded as deviant in the society at large – that is, it is an instance of "societal deviance." At the same time, the role of *contingencies* – who, what, where, why, and so on – may influence the outcome of the labeling process.

Labeling involves attaching a *stigmatizing* definition to an activity, a belief, or a condition. Stigma is a stain, a sign of reproach or social undesirability, an indication to the world that one has been singled out as a shameful, morally discredited human being. Someone who has been stigmatized is a "marked" person; he or she has a "spoiled identity." Once someone has been thereby discredited, relations with conventional, respectable others become difficult, strained, problematic. In other words, "being caught and branded as a deviant has important consequences for one's further participation and self-image. . . . Committing the improper act and being publicly caught at it places [the individual] in a new status. He [or she] has been revealed as a different kind of person from the kind he [or she] was supposed to be. He [or she] is labeled a 'fairy,' 'dope fiend,' 'nut,' or 'lunatic,' and treated accordingly" (Becker 1963, pp. 31, 32).

So crucial is this labeling process that, in some respects, it does not necessarily matter whether or not someone who has been stigmatized has actually engaged in the behavior of which he or she is accused. According to the logic of labeling theory, *falsely accused* deviants – if the accusation sticks – are still deviants (Becker 1963, p. 20). In many important respects, they resemble individuals who really *do* commit acts that violate the rules. For example, women and men burned at the stake for the crime of witchcraft in the fifteenth and sixteenth centuries were deviants in the eyes of the authorities and the community, even though they clearly did not engage in a pact with the devil. Two individuals, one who engaged in a deviant act and the second of whom is falsely accused, will share important experiences and characteristics in common, *by virtue of the labeling process alone*, even though they are poles apart with respect to having committed the behavior of which they were accused. While their lives are unlikely to be *identical* simply because both are seen by the community as deviants, the similarities they share are likely to be revealing.

Reflexivity. Reflexivity means looking at oneself in part through the eyes of others. It is what is widely referred to, although too mechanistically, as the "looking glass self." Labeling theory is based on a seemingly simple but fundamental observation: As Mead and his pragmatic peers said, we tend to see ourselves through the eyes of others, and when others see us in a certain way, we tend to begin seeing ourselves that way, too. In other words, deviance labeling by others, if those others are sufficiently influential and the labeling persists long enough, may become *internalized*.

Both direct *and* indirect, or concrete *and* symbolic, labeling operate in the world of deviance. "Indirect" or "symbolic" labeling is the awareness by a deviance enactor that his or her behavior is saturated with public scorn, his or her identity is potentially discreditable, that he or she *would be* stigmatized if discovered. People who violate norms have to deal with the probable and potential, as well as the actual and concrete, reactions of the respectable, conventional, law-abiding majority. All violators of major norms must at least ask themselves how others react to them and their behavior. If the answer is that others will condemn and humiliate them, then the rule breaker must try to avoid detection, remain within deviant or minority circles, or be prepared to be punished and stigmatized.

The "stickiness" of labels and *the self-fulfilling prophecy*. Labeling theorists argue that stigmatizing someone as a socially and morally undesirable character has important consequences for that person's further rule-breaking. Under certain circumstances, being labeled may intensify one's commitment to a deviant identity and contribute to further deviant behavior. Some conventional, law-abiding citizens believe, "once a deviant, always a deviant." Someone who has been stigmatized and labeled "is ushered into the deviant position by a decisive and often dramatic ceremony, yet is retired from it with hardly a word of public notice." As a result, the deviant is given "no proper license to resume a normal life in the community. Nothing has happened to cancel out the stigma imposed upon him" or her. The original judgment "is still in effect." The conforming members of a society tend to be "reluctant to accept the returning deviant on an entirely equal footing" (Erikson 1964, pp. 16, 17).

Deviant labels tend to be "sticky." The community tends to stereotype someone as, above all and most importantly, a deviant. When someone is identified as a deviant, the community asks, "What kind of person would break such an important rule?" The answer that is given is "one who is different from the rest of us, who cannot or will not act as a moral being and therefore might break other important rules" (Becker 1963, p. 34). Deviant labeling is widely regarded as a quality that is "in" the person, an attribute that is carried wherever he or she goes; therefore, it is permanent or at least long lasting. Deviant behavior is said to be caused by an indwelling, essentialistic trait; it is not seen as accidental or trivial, but a fixture of the individual. Once a deviant label has been attached, it is difficult to shake. Ex-convicts find it difficult to find legitimate employment upon their release from prison; once psychiatrists make a diagnosis of mental illness, hardly any amount of contrary evidence can dislodge their faith in it; ex-mental patients are carefully scrutinized for odd, eccentric, or bizarre behavior.

Such stigmatizing tends to deny to deviants "the ordinary means of carrying on the routines of everyday life open to most people. Because of this denial, the deviant must of necessity develop illegitimate routines" (Becker 1963, p. 35). As a consequence, the labeling process may actually increase the deviant's further commitment to deviant behavior. It may limit conventional options and opportunities, strengthen a deviant identity, and maximize participation in a deviant group. Labeling someone, thus, may become "a self-fulfilling prophecy" (Becker 1963, p. 34) in that *someone becomes what he or she is accused of being* – even though that original accusation may have been false (Merton 1948).

Labeling Theory Today

Labeling theory left two legacies to the contemporary study of deviance. The first, its "major" mode, which Plummer refers to as its "broader" version (1979, p. 88, 2011, pp. 84–85), was its constructionist vision. Other, earlier approaches were careful to point out that deviance and crime were a matter of violating rules, norms, and laws, which are socially constructed and vary somewhat historically and culturally. But labeling theory stressed and highlighted this point more forcefully. Indeed, it went further and emphasized that definitions of wrongdoing vary not only from society to society but from one *category* or *social context* to another. This remains a basic and crucial assumption in all sociological work on deviance. The second legacy of labeling theory, its "minor" mode (which, unfortunately, critics stress as its main point) – which Plummer refers to as its "narrow" version (2011, pp. 83–84) – is its argument about the causal mechanism of deviance: Being labeled as a wrongdoing inevitably or usually leads to a strengthening of a deviant identity and hence, an escalation in the seriousness and frequency of deviant behavior. This argument is as often wrong as it is right; its lack of empirical verification should not negate the perspective's "major" mode or constructionist legacy.

The foundational works of labeling theory were published in the 1960s; the number of citations or "hits" in Harzing's "Publish or Perish: Google Scholar" to "labeling theory" increased from 85 per year in the 1965–1969 period to over 825 in 1970–1974, then peaked in the 1990s (5,720 per year in 1990–1994 and 5,660 in 1995–1999), and declined into the 2000s. In the 1960s, the field's younger scholars and researchers yearned for a fresh, unconventional, and radically different way of looking at deviance. At the same time, the labeling perspective was immediately and subsequently widely and vigorously attacked, and many of these criticisms stuck; common wisdom has it that, today, both labeling theory and the sociology of deviance are dead or dying (Sumner 1994; Best 2004). Eventually, researchers generated competing perspectives, and, in reaction to critiques, the perspective's supporters modified or adapted labeling theory's insights. Currently, no single approach or paradigm dominates the study of deviance in the way that labeling theory did circa 1970–1974. What we see now is diversity, fragmentation, and theoretical dissensus. In spite of the criticisms, however, the labeling school left a legacy to the field that even its critics incorporate into their work, albeit, for the most part, implicitly.

By the 2000s, the central insights of labeling theory have become so taken for granted, so densely interwoven into the conventional wisdom of criminology and the sociology of deviance – a kind of "quiet orthodoxy" that appears in "different guises" (Plummer 2001, pp. 193–194) – that its place in these fields offers a case of "obliteration by incorporation" (Merton 1979). In other words, "the central strands of the perspective live on in cognate areas of inquiry" (Grattet 2011a, p. 186). Ongoing research has demonstrated that the consequences of negative labeling tend to be long lasting and often dire. Grattet's summary of this literature is most revealing (2011a, b). Matsueda's study of troublesome boys reveals that parental definitions ("informal social control") often results in self-conceptions that increase the likelihood of further delinquencies (1992). The research of Bruce Link and his associates on mental disorder likewise demonstrates the baleful impact of stigma and deviance labeling. Working with a "modified labeling theory," Link uncovered how mental illness processing agencies reinforce "perceptions of patient dangerousness" and put social distance between themselves and the patient, making their conditions more serious (Link et al. 1989). Sampson and Laub test the hypothesis of "cumulative disadvantage" (Grattet 2011b, p. 124) – that criminal justice sanctioning commonly results in offenders repeating and increasing the seriousness of their involvement in offending over the life course. Sampson and Laub's contention is that there is only "one theoretical position in criminology that is inherently developmental in nature – labeling theory" (1997, p. 3). Cumulative disadvantage represents a kind of "snowballing effect" which increasingly "mortgages" the offender's future, especially when negative evaluations in the realms of school and employment further reduce their life chances. For instance, convicted felons face increasingly difficult conditions for reintegrating into civil society, disenfranchising them and making the choice of further criminal activity increasingly attractive; negative labeling by work settings, marriage, and family dynamics all make desistance from crime and wrongdoing increasingly difficult (Petersilia 2003; Uggen and Manza 2006; Western 2006). A criminal record has a powerful chilling effect on employment outcomes. Pager introduces the concept of "negative credentials" to stress this process; these are the "official markers that restrict access and opportunity rather than enabling them" (2007, p. 32). As Grattet argues (2011a, b), recent research powerfully argues for the ongoing influence of the labeling/interactionist tradition in the study of crime and deviance.

Overview

The labelling perspective emerged as a distinctive approach to criminology during the 1960s and was a major seedbed of the radical and critical perspectives that became prominent in the 1970s. It represented the high point of an epistemological shift within the social sciences away from positivism – which had dominated criminological enquiry since the late 1800s – and toward an altogether more relativistic stance on the categories and concepts of crime and control. It inspired a huge amount of work throughout the 1960s and 1970s and still resonates powerfully today. This short entry maps out some of the ways in which labelling, deviance, media, and justice interact at the levels of definition and process. It presents an overview and analysis of key mediatized labelling processes, such as the highly influential concept of moral panics. It discusses how the interconnections between labelling, crime, and criminal justice are changing in a context of technological development, cultural change, and media proliferation. The conclusion offers an assessment and evaluation of labelling theory's long-term impact on criminology.

The Roots of the Labelling Perspective

The labelling perspective emerged at a time of radical intellectual change in the 1960s. The intellectual problem, as labelling theorists saw it, was that the study of crime had narrowed into two key questions: (1) Why do they do it and (2) how do we stop them from doing it? Government bodies and funding agencies reinforced the notion that "they" were different from "us," and that "crime" was entirely distinct from "criminal justice." Such thinking had laid foundations for the resurgence of a separate academic discipline of "positivist criminology," which functioned as policy science of crime, the criminal and crime control. There was an assumed consensus over what constituted crime, and the operations of criminal justice were seen as of interest only in terms of making them more effective in controlling crime. Yet nobody appeared to be asking why some behaviors were deemed criminal in certain contexts, while others were not. And why some people were deemed deviant and in need of correction or punishment, while others – who engaged in similar behaviors – were not.

Though Durkheim had discussed the problematic definition of crime in the late nineteenth century (Durkheim 1895/1964, pp. 69–72), and scholars such as Frank Tannenbaum, George Herbert Mead, and W. I. Thomas had been writing more or less directly about labelling processes since the 1930s, it is Howard Becker's (1963) *Outsiders: Studies in the Sociology of Deviance* that has become the best known and most influential statement of labelling theory. Building on the theoretical foundations of social constructionism and symbolic interactionism, Becker sought to problematize systematically precisely those questions that mainstream "correctionalist" criminology left unexplored. He argued (1963, p. 14), "The same behaviour may be an infraction of the rules at one time and not at another; may be an infraction when committed by one person, but not when committed by another; some rules are broken with impunity, others are not. In short, whether a given activity is deviant or not depends in part on the nature of the act (that is whether or not it violates some rule) and in part on what other people do about it."

Understanding the highly selective nature of labelling, the equally selective nature of the social reaction to which it may or may not give rise, and the consequences for those who are labelled required analyzing complex and contested power relations as both micro-interactional and macro-social processes. For Edwin Schur (1979, p. 160, italics in original), the labelling perspective is thus concerned with both "*definition* and *process* at all the levels that are involved in the production of deviant situations and outcomes. Thus, the perspective is concerned not only with what happens to specific individuals when they are branded as deviant ('labeling' in the narrow sense) but also with the wider domains and processes of social definitions and collective rule-making that frequently lie behind such concrete applications of negative labels."

Key questions for labelling theorists therefore include the following: How are labels created or socially constructed? How are labels imposed? How and why do particular behaviors become defined as "normal" or "deviant"? What enables labellers to impose their particular definitions upon behaviors, actions, and situations? How does the labelling process work and with what consequences?

Key Issues/Controversies

Labelling, Media, and Crime

The mass media play at least a subordinate role in all the major theoretical perspectives attempting to understand crime and criminal justice. To illustrate this, the predominant theories of crime can be assembled in a simple model. For a crime to occur, there are five logically necessary preconditions, which can be identified as labelling, motive, means, opportunity, and the absence of controls (Reiner 2007, pp. 80–90). The media potentially play a part in each of these elements and thus can affect levels of crime in a variety of ways (Greer and Reiner 2012, pp. 256–61).

Labelling

For an act to be "criminal" (as distinct from harmful, immoral, antisocial, etc.), it has to be labelled as such. This involves the creation of a legal category. It also requires the perception of the act as criminal by citizens and/or law enforcement officers if it is to be recorded as a crime. The media are an important factor in both processes, helping to shape the conceptual boundaries and recorded volume of crime.

The role of the media in helping to develop new (and erode old) categories of crime has been emphasized in most of the classic studies of shifting boundaries of criminal law within the "labelling" tradition. Becker's (1963) seminal book *Outsiders* analyzed the emergence of the Marijuana Tax Act in the USA in 1937, emphasizing the use of the media as a tool of the Federal Bureau of Narcotics and its moral entrepreneurship in creating the new statute. Since this pioneering work many studies have illustrated the crucial role of the media in shaping the boundaries of deviance and criminality, by creating new categories of offense or changing perceptions and sensitivities, leading to fluctuations in apparent crime (Young 1971; Cohen 1972; Hall et al. 1978). For example, Roger Graef's celebrated 1982 fly-on-the-wall documentary about the Thames Valley Police was a key impetus to reform of police treatment of rape victims (Greer and Reiner 2012, p. 256). This also contributed, however, to a rise in the proportion of victims reporting rape and thus an increase in the recorded rate. Many other studies document media-amplified "crime waves" and "moral panics" about law and order (Goode and Ben-Yehuda 2009).

What all these studies illustrate is the significant contribution of the media to determining the apparent level of crime. Increases and (perhaps more rarely) decreases in recorded crime levels are often due in part to the deviance construction and amplifying activities of the media.

Motive

A crime will not occur unless there is someone who is tempted, driven, or otherwise motivated to carry out the "labelled" act. The media feature in many of the most commonly offered social and psychological theories of the formation of criminal dispositions. Probably the most influential sociological theory of how criminal motives are formed is Merton's version of *anomie* theory (Merton 1938/1957), echoes of which are found in more recent work (see Special Issue of *Theoretical* Criminology 11/1 2007; Reiner 2007, pp. 14–5, 84–5). The media play a key role in these accounts of the formation of anomic strain generating pressures to offend. The media are pivotal in presenting for universal emulation images of affluent lifestyles, which accentuate relative deprivation and generate pressures to acquire ever higher levels of material success regardless of the legitimacy of the means used.

Psychological theories of the formation of motives to commit offenses also often feature media effects as part of the process (Greer and Reiner 2012, pp. 247–62). It has been claimed that the images of crime and violence presented by the media are a form of social learning and may encourage crime by imitation or arousal effects. Others have argued that the media tend to erode internalized controls by disinhibition or desensitization through witnessing repeated representations of deviance ().

Means

It has often been alleged that the media act as an open university of crime, spreading knowledge of criminal techniques. This is often claimed in relation to particular *causes célèbres* or horrific crimes, for example, during the 1950s campaign against crime and horror comics. A notorious case was the allegation that the murderers of Jamie Bulger had been influenced by the video *Child's Play 3* in the manner in which they killed the unfortunate toddler. A related line of argument is the "copycat" theory of crime and rioting. Despite a plethora of research and discussion, the evidence that this is a major source of crime remains weak.

Opportunity

The media may increase opportunities to commit offenses by contributing to the development of a consumerist ethos, in which the availability of tempting targets of theft proliferates. The domestic hardware and software of mass media use – TVs, videos, radios, CDs, personal computers, and mobile phones – are the common currency of routine property crime, and their proliferation has been an important aspect of the spread of criminal opportunities.

Absence of Controls

Motivated potential offenders, with the means and opportunities to commit offenses, may still not carry out these crimes if effective social controls are in place. These might be *external* – the deterrent threat of sanctions represented in the first place by media made criminality the police – or *internal*, the still, small voice of conscience, what Eysenck has called the "inner policeman."

A regularly recurring theme of respectable anxieties about the criminogenic consequences of media images of crime is that they erode the efficacy of both external and internal controls. They may undermine external controls by derogatory representations of criminal justice, for example, ridiculing its agents, a key complaint at least since the days of Dogbery, resuscitated in this century by the popularity of comic images of the police, from the Keystone Cops onward. Serious representations of criminal justice might undermine its legitimacy by becoming more critical questioning, for example, the integrity and fairness or the efficiency and effectiveness of the police. Negative representations of criminal justice could lessen public cooperation with the system, or potential offenders' perception of the probability of sanctions, with the consequence of increasing crime.

Probably the most frequently suggested line of causation between media representations and criminal behavior is the allegation that the media undermine internalized controls, by regularly presenting sympathetic or glamorous images of offending. In academic form this is found in the psychological theories about disinhibition and desensitization, which were referred to in the section above on the formation of motives. In sum, there are several possible links between media representations of crime and criminal behavior which are theoretically possible and frequently suggested in criminological literature and political debate. In the next section I will review some of the research evidence examining whether such a link can be demonstrated empirically.

Labelling, Media, and Moral Panics

The successful labelling of a particular situation or set of conditions as deviant and in need of amelioration can, in the extreme, result in "moral panic." The term was first used by Young (1971) in his study of subcultures and drugtaking. Cohen (1972) developed and extended the concept in his analysis of the sensationalistic, heavy-handed, and ultimately "disproportionate" reaction to the mods and rockers disturbances in an English seaside resort in 1964. Though the damage was in financial terms minor, Cohen traces the spiralling social reaction through initial intolerance, media stereotyping, moral outrage, increased surveillance, labelling and marginalization, and deviancy amplification leading to further disturbances that seemed to justify the initial concerns. The flamboyant misbehavior of youth subcultures, independent and sexually and economically liberated, affronted the postwar values of hard work, sobriety, and deferred gratification. At a time of rapid social change, they were a visible index of a world that was slipping away – "folk devils" who provided a crystallizing focus for social anxiety and "respectable fears." Cohen used the building blocks of labelling theory – social constructionism, symbolic interactionism, deviancy amplification, and social psychology – but also incorporated the lesser known academic literature on "disaster research" to describe the various phases of a moral panic, warning, impact, inventory, and reaction and chart its progression.

Hall et al. (1978) politicized the concept by locating it within a broader political economy perspective in their analysis of a "mugging" moral panic which, they argued, was constructed to address an escalating crisis in state hegemony. Drawing from an eclectic mix of influences, their account connects "new deviancy theory, news media studies and research on urban race relations with political economy, state theory and notions of ideological consent" (McLaughlin 2008, p. 146). For some critical criminologists, it represents the high point of Marxist theorizing about crime, law and order, and the state. While fully acknowledging the sophistication of this work, Cohen (2011) has nonetheless noted a wider tendency to over-politicize the concept at the expense of its sociological meaning and application. Hall (2007) has suggested in response that politicization was a necessary developmental stage and that the full explanatory potential of the moral panic concept was, in fact, only realized through its construction as ideology.

Goode and Ben-Yehuda (2009) developed Cohen's discussion of moral panic by paying particular attention to the criteria that should be in place before it can be suggested that a "moral panic" is occurring. They identify five key features of the phenomenon: (a) *concern* (a reported condition or event generates anxiety), (b) *hostility* (the condition or event is condemned and, where there are clearly identifiable individuals who can be blamed, these are labelled as "folk devils"), (c) *consensus* (the negative social reaction is widespread and collective), (d) *disproportionality* (the extent of the problem and the threat it poses are exaggerated), and (e) *volatility* (media attention and the associated panic emerge suddenly and with intensity, but can dissipate quickly too). Media are central to all of these.

"Moral panic" is one of the most widely used terms in the sociological analysis of crime and justice and has transcended academic discourses to become commonplace in political rhetoric and popular conversation (Altheide 2009). Given its prolific usage, it is surprising that few commentators have subjected the concept to sustained and rigorous critical investigation. With the split in the criminological left in the late 1970s, the concept was dismissed by left realists as "left idealism" and accused of obfuscating the painful "realities" of criminal victimization by propagating the view that "the crime problem" is socially constructed (Young 1979). In exploring the anatomy of the concept, critics have queried the notions of "disproportionality" and "volatility": first, since this assumes a superior knowledge of the objective reality of the issue against which the reaction is measured and a corresponding assumption of what a "proportionate" reaction would look like. Second, because in a contemporary multimedia world characterized by ontological insecurity and state of a permanent free-floating anxieties, the notion of discreet, self-contained, and volatile moral panics may need some rethinking (McRobbie and Thornton 1995). Cohen has responded to all of these criticisms. But such critical interventions, both from within and outside of criminology, have barely interrupted the general tendency to arbitrarily apply the concept to explain everything from global warning to "swine flu." The broadly uncritical application of the moral panic concept has led Garland (2008) to reassert two elements of the original analysis, which are absent from many contemporary studies: (a) the *moral dimension* of the social reaction – most issues can be moralized, but many are not in and of themselves "moral" and cannot automatically be analyzed as such – and (b) the idea that the deviant conduct in question is somehow *symptomatic* of a wider problem, a threat to established values, or a particular way of life. Struggles over the power to label and to label effectively via media discourses, of course, remain fundamental to the moralization of particularly "social problems," the identification of folk devils, the persuasive representation of threats to particular forms of social existence, and the prescription of ameliorative action.

Labelling and Trial by Media

Another way in which the news media are directly involved in labelling is the phenomenon of "trial by media" (Greer and McLaughlin 2011, 2012a). "Trial by media" can be defined as a dynamic, impact-driven, news media-led process by which individuals – who may or may not be publicly known – are tried and sentenced in the "court of public opinion." The targets and processes of "trial by media" can be diverse and may range from prejudging the outcome of formal criminal proceedings against "unknowns" to the relentless pursuit of high-profile celebrity personalities and public figures deemed to have offended in some way against an assumed common morality.

Despite their clear diversity, such "trials" share certain core characteristics. In each case, the news media behave as a proxy for "public opinion" and seek to exercise parallel functions of "justice" to fulfill a role perceived to lie beyond the interests or capabilities of formal institutional authority. Due process and journalistic objectivity can give way to sensationalist, moralizing speculation about the actions and motives of those who stand accused in the news media spotlight. Judicial scrutiny of "hard evidence" yields ground to "real-time" dissemination of disclosures from paid informants and hearsay and conjecture from "well-placed sources." Since the news media substitute for the prosecution, judge, and jury, the target may find themselves rendered defenseless. The default position is "guilty until proven innocent." Those found "guilty" will be subjected to righteous "naming and shaming" followed by carnivalesque condemnation and ridicule. The public appeal of "trial by media" is evidenced by increased circulation and web traffic. And by no means is it restricted to the British press.

Thus, in recent years police commissioners, senior politicians, banking executives, and, in the UK, the entire political establishment, as well as countless members of the public who are suspected of, but not yet charged with, any range of alleged criminal activities, have been subjected to mediatized scandal and trial by media (Greer and Mclaughlin 2010, 2011, 2012a, 2012b). The results of such high-profile labelling and public shaming, depending on the target, can range from deep and lasting reputational damage, public apologies, high-level resignations, radical political reform, or criminal proceedings.

Labelling, Media, and Criminal Justice

Powerful organizations and institutions tend to hold a distinct advantage in defining the nature of reality as represented via news media. Despite considerable variation in theoretical and methodological approach, decades of research has confirmed that the institutionally powerful enjoys privileged positions as "primary definers" at the top of the "hierarchy of credibility" and that a pro-establishment perspective is structurally and culturally advantaged, if not necessarily guaranteed in news media representations (Ericson et al. 1991; Hall et al. 1978). Historically, then, the power to label has tended to rest more or less firmly in the hands of those who command institutional authority. There is good evidence to suggest, however, that with the proliferation and diversification of media in recent decades, the power of institutional authority to effectively "define how things are" and set the terms of public debate is becoming increasingly contested and unstable.

In a digital multimedia age, a proliferation of news platforms, sites, and formats has been paralleled by a rapidly expanding array of news sources and producers of content, leading to the creation of an unprecedented amount of potentially newsworthy information, and a remarkable number of "news spaces" in which to broadcast/publish it. In the process, increasingly sophisticated, interactive news audiences are reconstituted as consumers – once content to be told what the news is, now increasingly interested in being part of the production process. Armed with cellphones, Blackberries or iPhones, all citizens are potential "citizen journalists." A photo can be taken on a mobile phone, tweeted on Twitter.com, picked up by other users, and disseminated like a virus online. Internet monitoring by mainstream news media outlets means that dramatic amateur photographic, audio or video content can become headline news. Citizen journalism has been instrumental not only in providing newsworthy images but also in defining the news itself – in shaping representations of key global events. From the police brutality against Rodney King filmed by camcorder in Los Angeles in 1991, to the 7/7 London bombings of 2005, to Hurricane Katrina, street protests in Tehran, and the Haiti earthquake, many of the defining images that now form a key part of the "official record" of events were taken with handheld recording devices and posted on social media sites. The emergence of the citizen journalist carries significant implications for official institutions that would seek to control the representing of crime and justice in the news. This phenomenon has been seen as a significant modification of existing power relations, offering what has been called "synopticon" (Mathiesen 1997), providing the mass of the population with some potential to record elite deviance.

The police can no longer simply "deny out of existence" incidents of police violence in public protest situations, since these are even more likely to be captured on camera and broadcast to the world (Greer and Mclaughlin 2010, 2012b). The same can be said of governments that would engage in larger scale abuses of their people and seek to conceal this from international scrutiny. And politicians or public officials, who may previously have fiddled expenses, taken bribes, engaged in illicit affairs when they should have been attending to the affairs of state, have all become more "visible" and, thus, more vulnerable to public exposure, labelling, trial by media, and mediatized justice.

The democratization of public involvement with the news production process, and the "new visibility" (Thompson 2005) to which institutional and state authority are continually subjected, is altering the dynamics of "communication power" that shape our constructed realities. Of course, citizen journalists are neither automatically nor naturally imbued with cultural or official authority: They are not "authorized knowers," who command access to mainstream news media "as of right." Their position in the "hierarchy of credibility" is entirely precarious and contingent. Media access is not granted because of who citizen journalists are, but rather because of where they are and what they have. Their credibility and authenticity as news sources derives from their capacity to provide "factual" visual evidence of "live events" which, in a multiplatform news media market, constitutes an important and cost-effective resource for "making news." Nevertheless, citizens are becoming increasingly involved in the processes of public labelling and social construction that determine what, and who, is defined as honest or corrupt, competent or incompetent, legitimate and illegitimate, or compliant or deviant. As such, they are centrally involved in the reconfiguration of notions of "crime" and "justice" in multimedia worlds.

Labelling Theory: Evaluation and Critique

The labelling perspective has transformed criminological theory and practice since the 1960s. It has made many permanently valuable contributions, above all the recognition of criminal law and justice as problematic research areas, that shape at least as much as they control crime. Criminology conferences and textbooks today devote as much attention to research on and analysis of criminal justice, from a non-correctionalist standpoint, as they do to the study of offending, a legacy (albeit often unrecognized) of labelling theory. The two subfields that the authors of this entry have spent most of their careers researching (policing and media representations of crime/criminal justice) were almost entirely absent from criminologists' agendas until the 1960s, and the questions raised then by labelling theorists. The problematic character of crime statistics, now universally recognized, is another contribution of labelling theorists. These impacts reflect the labelling perspective, but its influence is largely unacknowledged, and the developments have come to be taken for granted and domesticated within mainstream criminology.

What is more questionable is the imperialistic version of labelling theory that was trumpeted in its heyday and made large claims about itself as offering a total theory of crime. This grandiose version of labelling theory originated and flourished as the criminology of the 1960s counterculture and could only be plausible as a general theory in that context.

The imperialistic version claimed that concepts of crime were entirely relative and dependent on perceptions and labelling. It further suggested that labelling and social reaction were the principal explanations of crime and deviance. These claims are epitomized by two frequently cited quotes from key architects of the perspective. The relativity assertion is captured by Becker's statement that "deviance is not a quality of the act. . . but of the application. . . of rules and sanctions" (Becker 1963). The explanatory power of labelling is asserted most explicitly by Lemert: "Older sociology tended to rest heavily upon the idea that deviance leads to social control. . . (T)he reverse idea i.e. that social control leads to deviance, is equally tenable and the potentially richer premise for studying deviance in modern society" (Lemert 1967).

Both claims have some validity, but the exaggerated imperialistic versions, postulated by Becker, Lemert, and others, were neither new nor true without considerable qualification. Criminology before labelling theory (and indeed even nowadays) often took the concept of crime for granted. But its problematic character had already been emphasized by Durkheim and others. Seeing the making and enforcement of criminal law as a part of criminology was indeed acknowledged by some criminologists long before the labelling revolution. Moreover, it was assumed by criminal lawyers, both in textbooks and judicial decisions (*Proprietary Articles Trade Assn*. v. *Alt. Gen. for Canada* [1931] AC at 32, per Lord Atkin). Legal scholars had studied the emergence and change of criminal laws long before the advent of labelling theory (e.g., Hall 1935/1952). Recognizing the historical and social diversity of what precisely is criminalized at different times and places (Reiner 2007, Chap. 2; Lacey and Zedner 2012) does not entail complete relativity. As Hart suggested persuasively, there seems to be a "minimum content of natural law," activities that are regulated in all societies because they are conditions of viable social existence, even though the precise content and manner of proscription and sanctioning is variable (Hart 1961, Chapter IX, Part II).

The recognition of labelling as a cause of crime was also not entirely new and had been anticipated even by some criminologists in the positivist tradition (most explicitly Wilkins 1964, whose concept of deviance amplification in turn influenced labelling theorists). While it is the case, as Lemert claims, that often "social control leads to deviance," it is disputable whether it is the "richer premise for studying deviance." Lemert's claim rests on the assumption that "secondary deviance," which follows labelling, is more pervasive and problematic than "primary deviance," which precedes it. But this is an empirical question that is likely to vary in different times and places, and with regard to different kinds of deviance and social reaction, not a "premise."

Any plausibility the imperialistic claims of labelling theory had derived from the limited nature in practice of their empirical research. These tended to concentrate on marginal or exotic forms of deviance, which lend themselves to being seen as harmful or problematic not intrinsically but primarily if not solely because of labelling: marijuana use, the bohemian subculture of jazz musicians (Becker 1963); "hustlers, beats and others" (Polsky 1967); and "crimes without victims" (Schur 1965). An early critique castigated this pithily as the "sociology of nuts, sluts and "preverts" (sic)" (Liazos 1972).

The labelling theory pioneers' focus on the dramatic and colorful made it much easier to ignore the harms done by some primary deviance. They concentrated on the creation of crime by the labelling activities of low-level control agents, reversing the moral assessments of criminal law and justice – as explicitly advocated by Becker in his call for criminologists to ask "Whose Side Are We On?" (1967). This not only neglected the harms done by some crime but bracketed out its structural causes and the structural determinants of control activity – law, culture, political economy, wider social patterns, and institutions (as Gouldner argued in his 1968 repost to Becker "The Sociologist As Partisan"). This critique stimulated the morphing of labelling theory into more politically radical forms of "new criminology" and "deviance theory" in the 1970s (the core classics were Cohen 1971; Taylor et al. 1973; as well as the seminal studies discussed extensively in this paper, Young 1971; Cohen 1972; Hall et al. 1978).

Labelling theory has had a huge impact, fundamentally shifting the criminological paradigm away from a taken for granted correctionalist stance and stimulating a variety of forms of critical perspective. Much of its influence is now hidden, domesticated in the proliferating analyses of policing, media, and criminal justice. Although the sweeping claims of its originators are hard to sustain, its legacy lives on explicitly in contemporary cultural criminology and other qualitative and critical approaches.

Law of Community Policing and Public Order Policing

Tracey L. Meares
Yale Law School, Yale University, New Haven, CT, USA

Overview

It is likely impossible today to find a jurisdiction in the United States wherein a policing agency does not claim to practice community policing. Certainly the term is ubiquitous among law enforcement practitioners and scholars. The discussion around the practice for the last decade or so has not been whether to implement the approach but, rather, how exactly to implement it and the extent to which the practice is effective.

Less discussed is the relationship between law and community policing. By its very nature, community policing is focused upon patrol officers engaging in proactive conduct through exercise of discretion. Police discretion is, of course, framed and constrained by law – very typically constitutional law. However, unlike the constitutional rules that structure searches, seizures, and interrogations, the law pertaining to community policing and public order maintenance often is much more fluid. This entry will sketch out the fundamentals of that body of law as well as document current debates.

Fundamentals

There is a great deal of variation among the definitions of community and public order policing offered by scholars, but most agree that police engagement, collaboration, and partnership with private citizens are central features. An additional key feature of community policing emphasizes willingness on the part of individual police officers to proactively engage citizens to work on neighborhood problems and to promote community safety. While internal agency policy (essentially administrative rules) may regulate street-level policing in communities and neighborhoods, very few statutory rules govern these kinds of police practices. Constitutional law also seems mostly inapposite. Of course, the Fourth Amendment to the United States Constitution protects citizens from unreasonable searches and seizures, and the Fifth Amendment regulates police interrogation of citizens. Together with the Sixth Amendment and the Due Process Clause of the Fourteenth Amendment,courts have developed a muscular, detailed, and complex body of law to govern important police practices. This jurisprudence, however, is focused primarily upon police investigation of crimes. State and federal courts have recognized, though, that a large portion of police responsibilities is not related to criminal investigation (Walker 1992) and that traditional constitutional requirements may be inappropriate for regulating non-investigatory police activity.

Consider police searches as an example. Typically, to satisfy the Fourth Amendment, police must obtain a warrant from a magistrate certifying that they have probable cause to believe that the places, persons, and things to be searched are involved or related to a criminal act. Moreover, it is typically said that warrant requirement is extinguished only for certain categorical exceptions. But what happens when police engage in activities, such as responding to a leak in a private home that may damage property (*United States v. Boyd*, 407F. Supp. 693 (1976)), responding to a serious noise nuisance (*United States v. Rohrig*, 98F.3d 1506, 1522 (6th Cir. 1996)), responding to a missing person's claim (*State v. Brideswell*, 759 P.2d 1054 (Or. 1988); *Commonwealth v. Bates*, 548N.E. 2d 889 (1989)), retrieving a police-issued firearm from a private automobile (*Cady v. Dombrowski*, 413 U.S. 433 (1973)), investigating a potential burglary in progress (*United States v. Johnson*, 9F.3d 506 (6th Cir. 1993)), and assisting injured or endangered persons (*Wright v. State*, 7S.W.3d 148 (Tex. App. Ct. 1999)). In these and related situations, courts have not required police to first obtain a warrant from a judicial magistrate before entering homes and searching people. When discussing these activities, courts often point to the "Community Caretaking doctrine" (CC), in order to grant police relief from some of the traditional Fourth Amendment procedures. Courts typically apply CC where the police invade a traditional area of Fourth Amendment privacy but do so for purposes other than criminal investigation. Given the range of activities to which CC has been applied, there is a very real sense in which it can be considered the constitutional law of community policing.

Federal judge and legal scholar Debra Livingston has articulated two primary justifications for decreased procedural protections in CC cases (Livingston 1998). First, CC intrusions are thought not to impose stigma upon the victim because the police typically are not motivated by criminal suspicion when engaging in the intrusion. Second, many courts have concluded that community caretaking activities are less intrusive than investigative searches. During investigative searches, the police search all locations specified in the warrant in which the evidence may reasonably be found. The search continues until the police locate the relevant criminal evidence or determine it is not present. By contrast, when engaging in intrusions justified by CC, the police usually have no suspicion of criminal activity and thus have no reason to proactively search for criminal evidence.

Specifics of the Community Caretaking Doctrine

The courts are divided on the requirements imposed upon police officers when the CC doctrine applies. There are two primary camps.

One group of courts has interpreted CC as independent of traditional Fourth Amendment jurisprudence. On this view, CC intrusions are not governed by the usual probable cause and warrant requirements. Instead, a warrantless intrusion justified by the CC doctrine is permitted if the officer's actions were reasonable given the totality of the circumstances. For example, in *State v. Pinkard*, 319 Wis. 2d 234 (2010), a private citizen informed the police that two persons were sleeping in a home next to cocaine and other contraband and that the door to the home was open. The police entered the home to "make sure that the occupants . . . were not the victims of any type of crime[,] that they weren't injured . . . and to safeguard any life or property in the residence." Upon entering the home, the police seized drugs and other contraband in plain view. The Supreme Court of Wisconsin held that "the officers were engaged in a bona fide community caretaker function and that the community caretaker function was reasonably exercised under the totality of the circumstances." Similarly, in *Wright v. State*, 7S.W.3d 148, 151 (Tex. App. Ct. 1999), the court held that a "police officer may stop [a car to] assist an individual whom a reasonable person – given the totality of the circumstances – would believe is in need of help." This post hoc reasonableness test contrasts sharply with the traditional categorical approach under the Fourth Amendment. It is not, however, a complete anomaly. The Supreme Court has, for example, applied reasonableness tests to a range of police functions that fall under the special needs exception, such as searches of student property (*New Jersey v. T.L.O.*, 469 U.S. 325 (1984)) and highway roadblocks (*Delaware v. Prouse*, 440 U.S. 648 (1979)).

A second group of courts, rather than interpreting CC as an independent doctrine with its own set of rules, have applied CC as an extension of the traditional exigent circumstances exception to the warrant requirement. The exigency exception extinguishes the warrant requirement when one or more categorically defined exigencies are satisfied (i.e., hot pursuit, destruction of evidence); and it is not practical for police to obtain a warrant. Importantly, under this line of reasoning, the police must still demonstrate probable cause. They are relieved only from the requirement of obtaining a warrant. Thus, some courts have held that the CC doctrine does not permit warrantless Fourth Amendment intrusions that lack probable cause (or reasonable suspicion when appropriate). Nor do such courts permit warrantless intrusions when police had sufficient time to obtain a warrant but did not. Courts have applied this interpretation of the CC doctrine in a number of circumstances including missing person cases (*State v. Brideswell*, 759 P.2d 1054 (Or. 1988); *Commonwealth v. Bates*, 548N.E. 2d 889 (Mass. 1990)) and responses to home burglary calls (*United States v. Erickson*, 991F.2d 529 (9th Cir. 1993)).

Judge Livingston has argued that the first interpretation of the CC doctrine is superior. She writes, CC "does not fit within the central assumptions [of traditional Fourth Amendment theory]. The 'reasonableness theory' … can better and more sensitively accommodate those cases in which police officers have intruded on private places principally to serve legitimate community caretaking ends. Though the Court's 'special needs' cases have been subject to legitimate criticism, these cases in fact respond to the plausible intuition that some intrusions on privacy implicate a different set of social practices than traditional law enforcement and are sufficiently unlike law enforcement intrusions so as to justify a distinct Fourth Amendment approach. This same intuition, however, applies to police intrusions to protect life and property or to serve other important community caretaking purposes" (Livingston 1998 at 261, 265).

In addition to these two primary interpretations of the CC doctrine, some courts have conceptualized CC in terms of a third doctrine, the "emergency doctrine." Recently, the Supreme Court defined the standard for the emergency doctrine as follows: "police may enter a home without a warrant when they have an objectively reasonable basis for believing that an occupant is seriously injured or imminently threatened with such injury"(*Brigham City v. Stuart*, 547 U.S. 398, 403 (2006)). John Decker discusses CC in relation to the emergency doctrine extensively (Decker 1999).

When Does the CC Doctrine Apply?

There are three key legal questions for courts to answer when determining whether the CC doctrine applies in a particular case. First, what kind of public interests and police objectives lay within the scope of CC? Second, what happens when CC objectives overlap with clear criminal investigative objectives? Third, does CC apply to private residences?

The Courts have provided some guidance on the first question and, by implication, the second. The United States Supreme Court in *Cady v. Dombrowski*, 413 U.S. 433, 441 (1973), concluded that the CC doctrine applies, at the very least, to cases in which the police objective was "totally divorced from the detection, investigation, or acquisition of evidence relating to the violation of a criminal statute." Following this logic, lower courts have applied CC to a range of police activities, such as responding to a leak in a private home that may damage personal property (*United States v. Boyd*, 407F.Supp. 693 (1976)), responding to a serious noise nuisance (*United States v. Rohrig*, 98F.3d 1506, 1522 (6th Cir. 1996)), responding to a missing person's claim (*State v. Brideswell*, 759 P2d 1054 (Or. 1988)), retrieving a police-issued firearm from a private automobile (*Cady v. Dombrowski*, 413 U.S. 433 (1973)), and assisting injured or endangered persons (*Wright v. State*, 7S.W.3d 148 (Tex. App. Ct. 1999)). Collectively, case law suggests that the CC doctrine applies to three main categories of police functions: protection of public or private property, protection of individual or community safety, and elimination of public nuisance. Each of these categories, of course, is an area ripe of potential for community policing activity.

Note that the *Dombrowski* Court equivocated on whether the CC doctrine applies when criminal investigative objectives also are present. The reality is that even when such objectives are not present at the outset of an engagement between citizens and police when police are acting in their community caretaking capacity, it is likely that at some point the encounter may take on a criminal investigative character. What to do in such situations? The answer requires resolving two sub-issues.

First, may an officer legally conduct a search under the CC doctrine when his true subjective intent is to investigate criminal activity? At least one court has held that the CC doctrine can apply even if the subjective purpose of the officer is investigative in nature stating that “a court may consider an officer’s subjective intent in evaluating whether the officer was acting as a bona fide community caretaker; however, if the court concludes that the officer has articulated an objectively reasonable basis under the totality of the circumstances for the community caretaker function, he has met the standard of acting as a bona fide community caretaker, whose community caretaker function is totally divorced from law enforcement functions” (*State v. Kramer*, 759N. W.2d 598 (Wisc. 2009)). In contrast, John Decker insists that an “officer’s actions must be motivated by an intent to aid or protect, rather than to solve a crime” in order for the CC doctrine to apply (Decker 1999). Decker then makes an argument similar to the Supreme Court’s reasoning in *Indianapolis v. Edmond*, 531 U.S. 32 (2000). There the Court invalidated a randomized checkpoint utilizing dog sniffs of cars to detect drugs because each sniff of a car was not motivated by individualized suspicion and therefore lacked probable cause.

The second sub-issue is this: given the almost inevitable presence of some criminal/investigative purpose in a CC case, how much is too much? Judge Livingston proposes that for the CC doctrine to apply, “a legitimate community caretaking purpose [must have] clearly predominated over any law enforcement purpose that was present.” Moreover, the CC purpose must “constitute an independent and substantial justification for the intrusion” (Livingston 1998).

Finally, a live question among the courts is whether the CC doctrine applies to private residences. The Supreme Court has never provided specific guidance on this issue, although in a case concerning police use of without a warrant of a heat sensor outside of a home in an attempt to detect increased thermal energy resulting from growing marijuana plants indoors, the Court seemingly has indicated that warrantless searches of homes presumptively are invalid. The lower federal courts are divided on the issue. Three circuits permit the application of the CC doctrine to homes, and four circuits (3rd, 7th, 9th, 10th) do not (Marinos 2012). Commentator Mary Naumann concludes that many state courts are more lenient than the federal courts, and several allow police to argue, when a citizen objects to an intrusion, that their actions as public servants were reasonable in the context of a balancing test wherein an individual’s interest in privacy or autonomy is balanced against the state’s interest in having the police act as public servants (Naumann 1999).

While the police can perform valuable and useful service as community caretakers, the potential danger of sanctioning this activity without limits should be obvious. To the extent that one believes that the Fourth Amendment’s individualized suspicion required provides broad and sturdy protection against invasions of individual rights, then one should be skeptical of a doctrine that not only relaxes the warrant requirement but does not necessarily require even probable cause alone to justify a police action (but see Harcourt and Meares 2011). Thus, there is a risk that the doctrine could be used as pretext for criminal investigation, providing police with a loophole for getting around Fourth Amendment strictures.

Conclusion

In a world in which people increasingly believe that police can and should play a large role in producing public safety, there is an increasing likelihood that police will utilize their discretion to play a proactive rule with respect to the public as opposed to a reactive one. Community policing as a philosophy presupposes this kind of activity. However, the constitutional law that provides a framework for policing has largely assumed that police act in a reactive investigatory fashion activated by citizen complaints regarding crime. The Supreme Court's community caretaking jurisprudence illustrates the dilemmas that both law enforcers and private citizens face as they attempt to navigate the realities of public safety production in their neighborhoods against the backdrop of a constitutional law that has been for the last few decades very skeptical of police discretion. Continued interplay among the judicial, legislative, and executive branches and public activism at the local level will be necessary to work out the rules of engagement that are both protective of individual rights while allowing police enough flexibility to do the jobs as public agents that their principals expect them to do on their behalf.

Law of Crime Concentrations at Places

David Weisburd[1,2] and Cody W. Telep[3]

Overview

Crime is not distributed randomly across jurisdictions but instead clusters geographically. As Eck and Weisburd (1995, 12) note in their chapter on theories of crime and place, “Crime events are not uniformly distributed, a fact known for over a century. At every level of aggregation, some geographic areas have less crime than others.” This has been demonstrated historically at multiple levels of geography (Weisburd et al. 2009a), and it is a fact that is typically well recognized by even private citizens, who may characterize some locations or neighborhoods as “good” and others as “bad.” What has received less empirical attention until recently, however, is the strong concentration of crime at particular small places across cities. Places in this “micro” context are specific locations within the larger social environments of communities and neighborhoods (Eck and Weisburd 1995). Recent studies point to the potential theoretical and practical benefits of focusing research on crime places. In particular there has been a consistent finding that crime is tightly concentrated at just a small number of micro places in a city. These places are typically referred to as crime hot spots (Sherman and Weisburd 1995). They represent small geographic areas with high levels of criminal activity (typically measured by crime incidents or emergency calls for service) relative to other places in the city. This microgeographic conception of place approaches the distribution of crime with much smaller units of analysis than the neighborhoods or communities that have traditionally been of interest to criminologists studying crime and place (Weisburd et al. 2009a).

In one of the pioneering studies in this area, for example, Sherman et al. (1989) found that only 3.5 % of the addresses in Minneapolis, Minnesota, produced 50 % of all calls to the police in a single year. Fifteen years later, in a retrospective longitudinal study in Seattle, Washington, Weisburd et al. (2004) reported that between 4 % and 5 % of street segments in the city accounted for 50 % of crime incidents for each year over 14 years. These findings suggest that a focus on “good” and “bad” neighborhoods misses an important part of the story (see Groff et al. 2010). The unit of interest in understanding the distribution of crime should be much smaller in scope. A very small proportion of places in a jurisdiction are typically responsible for a substantial percentage of citywide crime.

The findings of remarkable concentrations of crime at place raise a more general question about the phenomenon of crime in cities. Is there some general law that applies across cities that dictates the general concentration of crime? This is the question raised in a recent book by Weisburd et al. (2012) entitled *The Criminology of Place: Street Segments and Our Understanding of the Crime Problem*. Studying crime at street segments in Seattle, they found a remarkable stability of crime concentrations each year over a 16-year period. They argue that these data, as well as prior studies showing similar concentrations of crime for specific years in other cities (e.g., see Pierce et al. 1988; Sherman et al. 1989), suggest that crime concentrations at micro places are relatively constant with about 5 % of places producing about 50 % of crime in a city each year.

The idea of a “law” of crime rates is not a new one. Emile Durkheim raised this possibility more than a century ago. Durkheim suggested that crime was not indicative of pathology or illness in society but at certain levels was simply evidence of the normal functioning of communities (Durkheim 1893 [1964], 1895 [1964]). For Durkheim, the idea of a normal level of crime reinforced his theoretical position that crime helped to define and solidify norms in society. While Durkheim’s proposition regarding a normal level of crime in society does not seem to fit recent experience and is seldom discussed by criminologists today, Weisburd et al. (2012) argue that there is indeed a “normal level of crime” in cities, but one that relates to the concentration of crime at place and not to the overall rate of crime. While the absolute levels of crime in cities vary year to year, the extent of crime concentrations remains similar. The idea of a “law of crime concentrations” will be discussed in more detail after first reviewing more thoroughly the empirical research suggesting that crime is highly concentrated at micro units of geography.

Empirical Examples of the Concentration of Crime

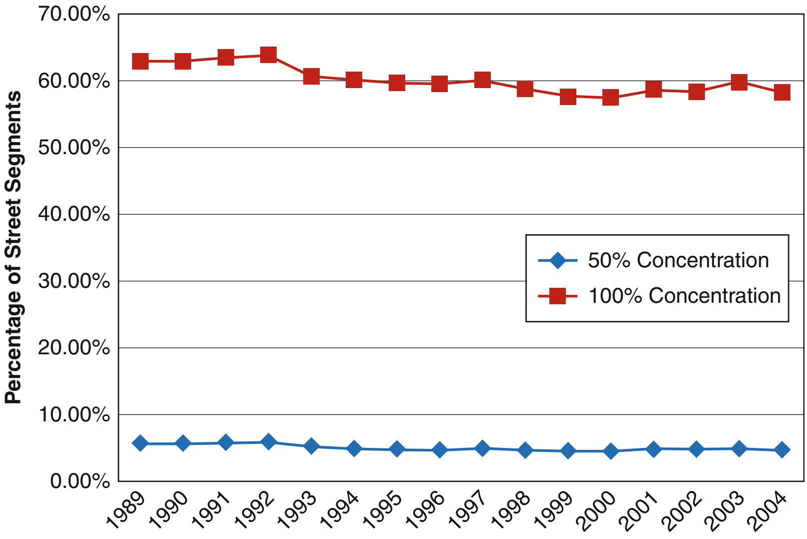
A number of studies over the past 20–30 years have found that a relatively small number of micro places are responsible for a significant proportion of total crime in a city. One of the most important early studies in this area was Sherman et al.'s (1989) analysis of emergency calls for service to addresses over a single year (December 1985–December 1986). Sherman et al. (1989) found that only 3.3 % of the addresses in Minneapolis produced just over 50 % of all calls to the police. If crime were randomly distributed across the 115,000 addresses in Minneapolis, one would not expect any places to have 15 or more calls in a single year. Instead, Sherman and colleagues (1989) found 3,841 such addresses, indicating that crime is far more concentrated than would be expected by chance. Pierce and colleagues (1988) found almost identical results when examining crime call concentrations in Boston, Massachusetts.

Weisburd et al. (1992) examined the distribution of crime in Minneapolis when aggregating address level data for a subsequent year (June 1987–June 1988) to crime hot spots of about one street block in length. Examining blocks with at least 20 hard crime (i.e., serious violent and property crime) calls for service, they found 365 hot spots in the city, which represented about 2.5 % of Minneapolis' street segments. These streets accounted for 27.3 % of all hard crime calls for service in the city. These streets also accounted for 27.8 % of soft crime (i.e., disorder) calls for service across the 1-year period. Overall then, whether examining individual addresses or clusters of high crime addresses, crime was highly concentrated at a small number of places.

More recently, Weisburd, Telep, and Lawton (in press) found high rates of concentration when examining crime incidents in New York City in 2009 and 2010. About 77 % of total incidents were geocoded to street segments. Approximately 52 % of the incidents on street segments were found in the top 5 % of street segments both years. Just under a quarter of crime incidents were found at 1 % of the street segments. Similar concentrations were found when examining incidents geocoded to intersections. About half of incidents at intersections were found at the top 5 % of the intersections, while slightly more than 20 % were found at the top 1 % of intersections. Between 55 % and 60 % of the street segments and intersections each year had no crime incidents.

Weisburd and Amran (forthcoming) found similarly high rates of the concentration of crime at place when examining crime incidents at street segments in 2010 in Tel Aviv-Jaffa, Israel. One quarter of all incidents were found at just 0.9 % of the street segments in the city, and 50 % of incidents were located at about 4.5 % of total street segments. About 60 % of street segments in the city did not experience any crime incidents in 2010. These findings suggest the broad application of the "law of concentrations" for crime at place. Even in a jurisdiction thousands of miles from the United States, similar levels of crime concentration were found.

Spelman (1995) offers some words of caution about the use of cross-sectional data in analyzing the concentration of crime at place (see Eck and Weisburd 1995). He examined calls for service at schools, public housing projects, subway stations, and parks and playgrounds longitudinally in Boston. He found evidence of a high degree of stability of crime at the "worst" of these places over a 3-year period. While the top 10 % of public places in terms of crime were responsible for about 30 % of calls for service (see also Eck et al. 2000), he notes that "Much of the concentration of crime among locations is due to random and temporary fluctuations that are beyond the power of the police and the public to control reliably" (Spelman 1995, 142). Thus, even though many of the highest crime places remained high crime, some of the change over time reflected random variation, suggesting the importance of longitudinal approaches to the study of crime at place. Despite these cautions, Spelman (1995) still advocated for efforts such as community problem-solving to address underlying problems at persistent high crime locations.



Law of Crime Concentrations at Places, Fig. 1 Crime incident concentrations in Seattle, Washington, 1989–2004

More recently, two studies in Seattle have examined the distribution of crime at street segments using a much longer time series. Weisburd et al. (2004) not only confirmed the concentration of crime but also the stability of such concentrations across a long time span. Weisburd et al. (2004) examined street segments in the city of Seattle from 1989 through 2002. They found that 50 % of crime incidents over the 14-year period occurred at between 4 % and 5 % of the street segments each year. This concentration was also very stable year to year.

Weisburd et al. (2012) updated and expanded these analyses, examining crime incidents at street segments in Seattle from 1989 to 2004. They again found that crime was highly concentrated and these concentrations remained fairly stable across the time period under study. They found that each year 50 % of crime incidents occurred on between 4.7 % and 6.1 % of street segments (see Fig. 1). All crime was found on around 60 % of street segments each year, suggesting that about 40 % of street segments recorded no crime each year in Seattle. The 247 highest crime street segments, about 1 % of the total in Seattle, were responsible for over 23 % of crime incidents across the 16-year period. Crime was even more heavily concentrated when examining a smaller proportion of citywide crime. For example, in the year 2000 in Seattle, just 11 street segments out of over 24,000 in total were responsible for 5 % of crime in the city, and only 31 streets produced over 10 % of the crime incidents.

These strong crime concentrations remain when focusing on specific types of offenders or crimes. For example, Weisburd et al. (2009b) examined the concentration of crime incidents in which a juvenile was arrested in Seattle. They found even stronger levels of concentration than for crime incidents more generally. Less than 1 % of street segments were responsible for 50 % of juvenile arrest incidents each year from 1989 to 2002. Only 86 street segments accounted for one third of all official juvenile arrest incidents over the 14-year period. As another example, Weisburd and Mazerolle (2000) examined the number of calls for service in 56 drug hot spots in Jersey City, New Jersey, that made up about 4.4 % of the street segments and intersection in the city. About half (47 %) of both narcotics arrests and calls for service were found in these hot spots, suggesting the strong concentration of drug activity in Jersey City.

In Boston, Braga et al. (2010) found that just 4.8 % of the street segments were the site of 73.9 % of all gun assaults over a 29-year period. Braga et al. (2011) also examined the concentration of robbery incidents at street segments and intersections in Boston from 1980 to 2008.

Each year, about 2 % of street units accounted for 50 % of the robbery incidents in the city. The top 52 street units, which represented just 0.18 % of total units in the city, were responsible for 10,886 of the 135,276 robberies (8.0 %) over the 29-year period. Commercial robberies are even more highly concentrated than street robberies. From 1980 to 2008, just 1.3 % of street segments were responsible for about half of commercial robberies. In Minneapolis, Sherman et al. (1989) found that the 54 addresses (about 0.047 % of the total addresses in the city) that had at least ten calls for service for public predatory crime (a combination of robbery, auto theft, and rape) were responsible for over 7.5 % of all such calls.

These trends for specific crime types are once again consistent when looking at data from outside the United States. Andreson and Malleson (2011) examined the distribution of calls for service for seven offense types in Vancouver, Canada, in 1991, 1996, and 2001. They found that for each crime type, 50 % of calls were found on between about 1 % and 8 % of street segments. Burglary showed the lowest level of concentration, although in 2001, for example, 50 % of burglary calls were on 7.61 % of street segments and only 39.43 % of streets had any burglary calls. Robbery was incredibly concentrated in Vancouver. In 2001, 50 % of robbery calls were found on just 0.84 % of street segments in the city, and only 5.32 % of streets had any robbery calls.

Sherman (1995) argues that such clustering of crime at places is even greater than the concentration of crime among individuals. Weisburd et al. (2004) found that 5 % of streets produced 50 % of crime throughout the 14-year study period. In Wolfgang et al.'s (1972) groundbreaking Philadelphia, Philadelphia birth cohort study, they found that 6 % of the cohort produced 50 % of the offenses committed by the cohort. While these statistics seem similar, 6 % of a city's population is likely to yield thousands of targets, while 5 % of street segments in a city like Seattle is only around 1,500 places. And those places are not "moving" targets for police since they stay in the same place. This suggests that focusing on places may be more efficient than focusing on people (Weisburd and Telep 2010). As Sherman (1995, 37), "Why aren't we thinking more about wheredunit, rather than just whodunit?"

Importantly, Weisburd and colleagues (2012) also found that the micro place concentrations in Seattle were not just proxies for neighborhood-level effects (see also Groff et al. 2010). While they did find some evidence of larger area effects in their analyses and some clustering of high crime streets, particularly in the Central Business District, their overall conclusion was that there is a great deal of street-by-street heterogeneity in crime patterns. In other words, crime hot spots can be found throughout the city, and so there is a great deal of variability street-to-street within both "good" and "bad" neighborhoods.

A Law of Crime Concentrations

These findings about the concentration of crime are particularly interesting in light of Emile Durkheim's classic proposition that the level of crime is stable in society or rather that there was a "normal level" of crime in society. For Durkheim, this meant that crime was not necessarily an indication of an illness or pathology in society but rather that healthy societies would inevitably have some normal level of crime. Crime waves and crime drops in this context can be seen as the result of some "abnormality" in a society that results from crisis or dramatic social change.

Underlying Durkheim's proposition was his understanding of crime as a product of social definition. Kai Erickson (1966) was to build upon this idea in his classic study *Wayward Puritans*, where he sought to show that the definition of crime had a social function. By defining others as deviant, society can help draw the boundaries between acceptable and unacceptable conduct (see also Adler and Adler 2009). Defining people as criminal in this sense serves a function in defining the moral boundaries of society. One can know the boundaries of acceptable behavior by observing "deviants" who are sanctioned for violating societal norms.

Crime rates over the last few decades would seem to strongly contradict Durkheim's conception of normal levels of crime in society. Between 1973 and 1990, violent crime doubled, and then in the 1990s, the USA experienced a well-documented "crime drop" (Blumstein and Wallman 2000). In the 1970s, Blumstein and Cohen (1973) hypothesized that Durkheim's proposition could be applied to punishment in America, where imprisonment rates had remained static for a long period of time. But recent dramatic increases in the US incarceration rate in the 1980s and 1990s would seem inconsistent with the normal crime or "normal punishment" (Blumstein and Cohen 1973) hypothesis.

Weisburd et al. (2012), however, take a different approach to Durkheim's theory and instead argue that there is indeed a "normal" level of crime in cities, but one that relates to the concentration of crime at place and not to the overall rate of crime. They claim that a different proposition from Durkheim's can be raised at this juncture and should be examined in future studies. There appears to be a "law of concentrations" of crime at place. The consistency of crime concentrations at micro places over time and across geographic locations as diverse as Minneapolis, Minnesota, and Tel Aviv-Jaffa, Israel, suggests that there is some underlying social process pushing crime to certain levels of concentration in modern cities.

What might lead to this stability? It is important to note at the outset that the concentration of crime follows patterns of concentration in many other areas of scientific inquiry (e.g., see Eck et al. 2007; Koch 1999; Sherman 2007). Joseph Moses Juran (1951) first noted this concentration in looking at economic activities, coining the phrase "the vital few and the trivial many." Juran sought to emphasize to managers that they should focus on the small number of events or cases that produce the majority of relevant business activities, for example, the small number of defects that cause most complaints about products or the small number of clients that are responsible for a majority of revenue. Juran termed this phenomenon the "Pareto Principal" after Vilfredo Pareto (1909), who first brought attention to what is sometimes referred to as the 80-20 rule (see Koch 1999). Pareto observed that a number of distributions seem to follow this specific pattern of concentration. For example, in studying land ownership in Italy, he found that 80 % of the land was controlled by just 20 % of the population. He also observed that 20 % of the pea pods in his garden produced 80 % of the peas. The 80-20 rule is generally seen only as an approximation, but it applies fairly well to Weisburd et al.'s (2012) data in Seattle. Eighty percent of the crime incidents each year were found on between 19 % and 23 % of the street segments. Of course, the question remains, what leads to the tremendous concentration and stability of crime at microgeographic places over time?

In their discussion of the concentration of crime at facilities, Eck and colleagues (2007) discuss how crime follows the J-curve pattern found in a number of other phenomena. As they describe, "To reveal a J-curve, the number of crimes in a given time period at each facility needs to be known, and then the facilities ranked from those with the most crimes to those with the fewest. If a bar chart of the crime frequency is drawn, a few facilities at the left end of this distribution will have many crimes, but as one moves to the right there will be a steep drop-off in crimes that flattens out at a very few or no crimes for the majority of the facilities. The resulting graph resembles a reclining J" (Eck et al. 2007, 228). The words "micro place" can easily be substituted for "facilities."

They point to five potential reasons why crime might be concentrated at particular facilities, which are relevant to consider when understanding the concentration of crime at micro places. The first was noted above; some portion of the concentration can be explained by random variation. That is, some hot spots of crime would likely cool off without any intervention. Random variation, however, is not the whole story, as Weisburd et al. (2012) demonstrated by showing that the hottest street segments in Seattle remained high crime throughout the 16-year study period. A second explanation is changes in reporting processes. If the police changed their crime incident reporting protocols, for example, this could have some impact on the level and concentration of crime, although again this does not explain the stability of concentration in Seattle, which experienced no major change in reporting patterns from 1989 to 2004.

The last three potential explanations focus on the characteristics of particular facilities (or places). Eck and colleagues (2007) point to offenders, targets, and place management as potential reasons why some facilities may be riskier than others. Some places may be crime attractors if they tempt potential offenders with rampant opportunities for criminal activity. Places can also be rich in targets and be crime generators. Finally, poor place management (i.e., a lack of supervision and guardianship) can be a crime enabler. Examining the characteristics of places was the focus of Weisburd et al.'s (2012) research in Seattle, and they demonstrated that crime opportunity factors play a key role in explaining the concentration of crime in hot spots. These factors are important for understanding why some places become hot spots, but they do not necessarily explain why such a small number of hot spots are responsible for such a high percentage of crime citywide.

Can Durkheim's initial insights also be used to consider possible reasons for this law of concentrations of crime at place? Following Durkheim and other theorists that built on his work, one would look to the role of crime at place in defining normative boundaries in society. In this case, it could be argued that a certain number of places in the city with severe crime problems serve as lessons for the city more generally. This would fit well with the finding by Weisburd et al. (2012) that crime hot spots are found throughout the city. Accordingly, everyone would have direct visceral experiences with the "bad places" in the city, and perhaps that serves to define the "moral boundaries" of place for individuals. The normal level of crime concentrations in this context would relate to the proportion of problem places that are needed to bring the lessons of moral boundaries to the city's residents.

Another possible explanation for a law of concentrations comes from the concentration of other characteristics of places in the city. For example, Weisburd et al. (2012) note that the concentration of bus stops or number of public facilities, like crime, stays relatively stable over long periods. Perhaps the law of concentrations of crime is related to the overall distribution of social and environmental characteristics of places in cities. Does the stability of patterns of business and employment in a city, for example, reflect more general patterns of concentration that are related to the growth and development of urban areas? Cities regulate such concentrations, by defining commercial, business, and industrial use of property. Perhaps the normal concentrations of crime are simply a reflection of the normal concentrations of other social activities in the city. The law of concentrations of crime at place may simply be a reflection of a more general law of the stability of concentrations of specific aspects of social and economic life in the city, as discussed above with Juran's (1951) notion of the Pareto Principle.

But this brings the discussion back to Durkheim, because crime is a social phenomenon and its tolerance is a social construct. Is society willing to tolerate crime at only a certain proportion of the landscape of a city? Is the law of concentrations a result of the boundaries of crime at place that citizens are willing to tolerate? Will people become worried and call for action when crime hot spots increase beyond a specific proportion of places in the city, and will they become more lax when the concentrations are below that level? Certainly, this law of concentrations needs to be studied across other metropolitan centers around the world to see how widely it applies. More generally, it is time for scholars to explore more directly the explanation for the law of concentrations of crime trends at micro places. In the spatial context, scholars should explore both social and environmental characteristics of street segments that are important to understanding the concentration of crime at place.

Law of confessions; Police interrogation

Overview

The law of interrogation in the United States is largely a product of United States Supreme Court cases interpreting the United States Constitution. Three parts of the Constitution regulate interrogation practices. The most obvious regulation is found in the Fifth Amendment right not to be compelled to incriminate oneself. The United States Supreme Court also found in the Due Process Clause of the Fifth and Fourteenth Amendments a right not to be coerced into confessing. The Court read the Sixth Amendment right to the assistance of counsel to offer protection against interrogation in some circumstances. Each of these rights provides a slightly different protection, but together they seek to ensure that a suspect makes an uncoerced decision about whether to confess and has the assistance of a lawyer when desired.

Due Process Requirement that Confessions Be Voluntary

The Court's due process analysis initially drew heavily on the English common law. As far back as the late seventeenth century, English judges were skeptical of confessions that were influenced by threats or promises of favor. By 1788, the leading technical treatise of English law reported that the law of confessions refused to admit statements obtained "by the flattery of hope, or by the impressions of fear, however slightly the emotions may be implanted . . . for the law will not suffer a prisoner to be made the deluded instrument of his own conviction" (Hawkins 1788). Confessions taken under those conditions were later referred to as "involuntary."

The core notion of "involuntary" follows the English common law, with "flattery of hope" understood as promises of benefit and "impressions of fear" understood to be threats. In the infamous case of *Brown v. Mississippi*, 1936, for example, the United States Supreme Court held that the Fourteenth Amendment Due Process Clause forbids the use of confessions that are produced by brutal beatings and threats that the torture would continue. The Court held in several cases that threats made the confessions involuntary even where there was no torture. In *Payne v. Arkansas*, 1958, the chief of police said that he would probably be able to protect the suspect from the mob outside if he told the truth about what happened. In *Lynum v. Illinois*, 1963, the police told the suspect that she would lose custody of her children if she did not "cooperate" with them. In *Arizona v. Fulminante*, 1991, a government informant promised to protect the suspect from violent reprisals from other prisoners but only if the suspect told the truth about raping and murdering his stepdaughter.

The Supreme Court also applied the term "involuntary" to confessions that did not include classic examples of threats or promises of benefits. One way to describe the Court's involuntariness doctrine as it evolved is that it serves "a complex of values . . .; which, by way of convenient shorthand, this Court terms involuntary, and the role played by each in any situation varies according to the particular circumstances of the case" *Blackburn v. Alabama*, 1961. In its more than 40 involuntary confessions cases, the Court has expressed concern about unreliable confessions, about protecting the will of the suspect, and about morally offensive police conduct.

For example, *Ashcraft v. Tennessee*, 1944, held that 36 h of nonstop questioning made the defendant's confession involuntary, even though police made no threats or promises, because the questioning deprived him of the "mental freedom" to decide whether to answer. *Townsend v. Sain*, 1963, reached the same result under a mental freedom theory when the police gave the suspect a drug that functioned as a form of truth serum. In *Spano v. New York*, 1959, a combination of factors rendered the confession involuntary. First, the suspect was "emotionally unstable and maladjusted." Police also repeatedly refused his requests for counsel and told him, falsely, that if he did not confess, his police officer friend might lose his job. The Court held that this combination of factors made the suspect's confession involuntary, in part because the police conduct was itself outside the law and thus morally offensive. In *Malinski v. New York*, 1945, the police strip-searched the suspect, gave him a blanket, and interrogated him while he was naked in an effort, the prosecutor said, "to humiliate him." The Court held the confession involuntary even though the interrogation was relatively brief.

Cases involving threats and promises of favor have traditionally raised issues about the reliability of the confession. Brutal torture, such as was used in *Brown v. Mississippi*, 1936, is as likely to produce a false confession as a true one. But in 1986, the Court held that the unreliability of a confession, standing alone, is not relevant to whether the Due Process Clause has been violated. *Colorado v. Connelly*, 1986, held that as long as the confession is not coerced or compelled by state actors, its reliability is completely a matter of state law. DNA evidence has recently made plain that police methods well short of torture can produce false confessions that are used to convict innocent defendants. These DNA exonerations have caused courts to focus on police deception and trickery – for example, lies about evidence – used to obtain confessions. The underlying notion is that if the police make the case against the innocent suspect look hopeless, he might falsely confess to some lesser involvement to escape the most severe punishment.

Police have long relied on deception during interrogation; in the famous case of *Miranda v. Arizona*, 1966, the Court noted a police strategy in which someone pretending to be an eyewitness would pick the suspect out of a lineup. Other deceptive techniques include fake lie detector results, fake tests that "prove" the suspect had recently fired a gun, lying about the suspect's fingerprints being at the scene of the crime, and lying about the existence of eyewitnesses. The issue that courts must address in deception cases is whether police techniques, either alone or in conjunction with other high-pressure interrogation strategies, render a subsequent confession involuntary. This might be true because the technique overbore the suspect's will, was a morally offensive police technique, or created too high a risk that an innocent suspect might confess falsely. American courts have generally permitted the use of confessions obtained by deception, while sometimes condemning the police conduct, on the ground that an innocent suspect would know that the evidence was false and could resist the temptation to confess.

But there are limits beyond which police may not go. A New Jersey Court held that it violated due process to play an audiotape of a fake eyewitness who claimed to have seen the shooting and identified the suspect as the shooter (*State v. Patton*, N.J. Superior Court, Appellate Division 2003). In *Cayward v. Florida*, Florida District Court of Appeal, 1989, the police showed the suspect two official reports that "proved" that his semen was found on the rape/murder victim. "One false report was prepared on stationery of the Florida Department of Criminal Law Enforcement; another was prepared on stationery of Life Codes, Inc., a testing organization." The Florida Court held that the use of manufactured documents crossed the line between permissible and impermissible deception.

As the cases discussed to this point suggest, the voluntariness test was difficult to apply. There are many factors to consider. More fundamentally, the inquiry itself is hopelessly indeterminate. Absent the kind of torture in *Brown* or overt threats of severe harm, it is not obvious whether a suspect answers police questions because it is his will to answer or because the police have overcome his volition. These difficulties led the

Supreme Court, and all the state courts of appeal, to review many state court decisions, each with unique facts.

When 1966 dawned, the Court realized that it needed a confession rule that made the volition inquiry easier and thus could be applied more mechanically than the voluntariness test.

Miranda v. Arizona's Requirement of Free Choice

In *Miranda*, 1966, the Court turned to the Fifth Amendment right not to be compelled to be a witness against oneself, often called the privilege against compelled self-incrimination. While freedom from compulsion seems roughly the same as freedom from forces that produce involuntary confessions, the five-justice majority in *Miranda* read the privilege to guarantee that suspects who answer police questions have to make a "free choice." Noting that little is known about what actually goes on in police interrogation rooms, the Court drew from textbook examples of police interrogation strategies, such as lying about the evidence against the suspect and discouraging him from remaining silent or asking for a lawyer. The Court sketched the history of the privilege against compelled self-incrimination, emphasizing its role in protecting the mental freedom to decide whether to cooperate with the State when it is seeking evidence of crime. From all of this, the Court concluded that the atmosphere of custodial police interrogation was inherently compelling. Thus, the Court held that *all statements* made in response to custodial police interrogation are compelled unless steps are taken to ameliorate the compulsion of the interrogation. Otherwise, the suspect could not make a "free choice" whether to answer police questions.

Though the Court left the door open for the states and Congress to come up with another way to ameliorate the inherent compulsion of police interrogation, it held that in the absence of an equally effective remedy, the Constitution required the famous *Miranda* warnings. Suspects must be told that that they have a right to remain silent, that anything they say will be used against them in court, that they have a right to counsel, and that if they cannot afford counsel, a lawyer will be appointed at no cost to them. If a suspect answers questions after being told that he has these rights, answering might be his free choice. If so, the voluntariness question would, in a sense, answer itself in a *Miranda* world.

Most observers thought that *Miranda* would reduce the incidence of incriminating statements, perhaps drastically. While innocent suspects have an incentive to answer questions and explain why the police have arrested the wrong person, a guilty suspect's most rational course of action is to exercise the right to silence and to counsel. In the immediate wake of *Miranda*, some police officials, including the police chief of Los Angeles, accused the Court of trying to "end the use of confessions in convicting criminals" (Baker 1983).

Though the precise effect of *Miranda* on the confession rate is yet unknown, there is widespread agreement that at least 80 % of suspects waive their *Miranda* rights and consent to answer police questions, very often incriminating themselves. Although the *Miranda* Court said that the State had a "heavy burden" to prove the voluntariness of a *Miranda* waiver, later cases held that these waivers may be implied (from the actions or the words of the suspect) rather than explicit (*North Carolina v. Butler* 1979). Moreover, the Court recently held that "a suspect who has received and understood the *Miranda* warnings, and has not invoked his *Miranda* rights, waives the right to remain silent by making an uncoerced statement to the police" (*Berghuis v. Thomkins* 2010). When suspects waive *Miranda* (whether implicitly or explicitly), its protections typically play no role in mitigating the process or outcome of the subsequent interrogation. In almost all cases, the only protection available after *Miranda* has been waived is the protection against involuntary confessions, the very protection that *Miranda* was designed to supplement. Once waived, *Miranda* neither regulates nor restricts psychologically manipulative or deceptive interrogation techniques, hostile or overbearing questioning styles, lengthy interrogation and confinement, or any of the many stressful conditions of modern accusatorial police interrogation. The leading police interrogation manuals continue to encourage some of the very same deceptive practices that were condemned in the *Miranda* opinion.

It seems likely that suspects who waive *Miranda* are responding to police pressure but that they also, at some level, may *want* to talk to police, to tell their side of the story, and to persuade the police that they should be released from custody. David Simon observed the Baltimore Homicide Department for a year. He concluded that every suspect who faces interrogation imagines a "small open window" that is "the escape hatch, the Out" (Simon 1991). Every suspect who "opens his mouth during an interrogation . . . envisions himself parrying questions with the right combination of alibi and excuse" and then "crawling out the window to go home and sleep in his own bed." Thus, it seems that suspects waive their *Miranda* rights at least in part because they often *want to talk to police*. In most cases, of course, talking to police is a supremely irrational act. As David Simon imagines a detective's reflections: "[E]ven after all these years working homicides, there is still a small part of him that finds it completely mystifying that anyone utters a single word in a police interrogation." After all, "what do homicide detectives do for a living? Yeah, you got it, bunk. And what did you do tonight? You murdered someone."

However irrational it is for guilty suspects to talk to police, waiver is surprisingly easy to obtain. Police can also avoid *Miranda* protections because they do not apply to a substantial amount of police questioning. The warnings are required only when police engage in custodial interrogation, and police are free to engage in persistent, marathon questioning – for hours on end with no warnings – as long as they do not take the suspect into custody. Police often tell the suspect that he is not under arrest, to create a noncustodial situation, and then suggest that it is in his best interests to cooperate with them. Any reluctance to answer questions can be met with reassurances that he is not under arrest and that police just want to get his side of the story. Technically, the suspect is not in custody in this situation, and police interrogation without warnings is completely legal. In 1977, Justice Marshall urged the Court to expand *Miranda* to include coercive interrogations where technical custody was absent, arguing that while *Miranda* was initially limited to custodial interrogation, the "rationale of *Miranda* . . . is not so easily cabined" (*Oregon v. Mathiason* 1977, Marshall, J., dissenting). But by 1977, the Court had settled on a course intended to keep *Miranda* from interfering with what it viewed as legitimate police interrogation.

In addition to the ease of proving waiver and the limitation of *Miranda* to custodial interrogation, four doctrines now permit the State to benefit from evidence learned from a violation of *Miranda*. The Court first created a "public safety" exception that permits police to question without warnings if the officer reasonably believes it is necessary to protect the public safety (*New York v. Quarles* 1984). There, police arrested a suspect in a supermarket; they expected him to be armed but his shoulder holster was empty. One officer asked where the gun was, and the Court allowed the State to use his answer on the ground that the officer had an obligation to find the gun and protect the public. A later doctrine that ignores police failure to comply with *Miranda* is that physical evidence found as a result of a *Miranda* violation can be introduced into evidence (*United States v. Patane* 2004). Thus, in the supermarket case, the State could have used the gun itself as evidence even without a public safety exception.

Evidence is also admissible despite a violation of *Miranda* when police succeed in remedying the violation. In most cases, police are permitted to remedy a failure to warn by providing warnings later even if the suspect has already made an incriminating statement. Thus, if the suspect makes an incriminating admission in his parents' home without warnings and it turns out that this is a violation of *Miranda*, giving warnings later at the police station will permit a second confession to be admissible (*Oregon v. Elstad* 1985). *Elstad* would not apply, however, if the police had intentionally withheld warnings in the hope that the suspect would confess and then repeat the confession after the warnings are given (*Missouri v. Seibert* 2004).

A fourth area where statements taken in violation of *Miranda* can still be used is in impeaching the credibility of a defendant who testifies (*Harris v. New York* 1971). For example, if a defendant testifies that he has never sold narcotics, his statement to police admitting a sale can be introduced to suggest that he is not testifying truthfully, even though the statement was taken in violation of *Miranda*. The jury will be instructed not to consider the statement as evidence of guilt but only as to the defendant's credibility. Conventional wisdom is that juries would have a difficult time ignoring an admission of criminal behavior on the issue of guilt. At least a few police departments have advised officers to be willing to violate *Miranda* because the statements will always be available to impeach the defendant's testimony, a threat that seems likely to deter defendants from testifying.

In sum, the kind of robust guarantee of a "free choice" to decide whether to answer police questions probably intended by *Miranda* does not seem to exist. The most frequent loss of *Miranda* protections is through waiver, which leaves suspects facing police interrogators with nothing to protect them from zealous interrogation beyond the vague due process prohibition of involuntary statements. Moreover, in a *Miranda* world, the suspect's agreement to talk to police in effect creates a kind of soft presumption that statements made later in the interrogation must be voluntary. The choice to talk to police was, superficially at least, a free choice. And the suspect was told that he did not have to answer questions. Thus, answering questions an hour, or 2, or 30 h, later seems to be clothed in voluntariness. As Justice Souter noted in 2004: "[G]iving the warnings and getting a waiver has generally produced a virtual ticket of admissibility; maintaining that a statement is involuntary even though given after warnings and voluntary waiver of rights requires unusual stamina, and litigation over voluntariness tends to end with the finding of a valid waiver" (*Missouri v. Seibert* 2004 (plurality)).

Moreover, there is no right to warnings when the intense questioning takes place in a noncustodial situation. And, finally, even if *Miranda* is violated, four doctrines permit the State to use statements and physical evidence in any event.

Right to Counsel

Two years prior to *Miranda*, the Court held in *Massiah v. United States* (1964) that *indicted* defendants have a Sixth Amendment right to counsel when government actors are seeking to elicit incriminating statements. Thus, the government violated Massiah's Sixth Amendment rights when it used an informant to elicit statements from him after he was indicted. Massiah did not know that he was speaking to a government informant and thus there was no issue of waiver of the right to counsel. Waiver first arose in *Brewer v. Williams* (1978). The Court acknowledged that indicted defendants could waive their *Massiah* right to counsel but, on the facts of *Brewer*, the Court held that the state had failed to prove waiver.

The Court did not address how to prove waiver of the *Massiah* right to counsel until 1988. In *Patterson v. Illinois* (1988), the Court held that when an indicted defendant waived his *Miranda* right to counsel, he had simultaneously waived his *Massiah* right to counsel. This followed, the Court held, even though the two rights have different textual homes – *Massiah* the Sixth Amendment and *Miranda* the Fifth Amendment self-incrimination clause – and even though indictment is the beginning of the adversary criminal process. Like *Miranda*, the vote was 5-4. The dissent argued that the Sixth Amendment right to counsel carries with it duties and responsibilities that go beyond advice about answering questions, but the majority said that the issue was the usefulness of a lawyer in the particular proceeding. In the context of interrogation, *Miranda* provides the measure of the usefulness of a lawyer.

One issue left undecided by *Patterson* was whether it matters if a judge has appointed a lawyer during a pretrial, and post-indictment, proceeding before police seek a *Miranda* waiver. Would a waiver of *Miranda* also waive *Massiah* when the indicted defendant is actually represented by counsel? Continuing a string of 5-4 decisions, the Court in *Montejo v. Louisiana* (2009) held that *Miranda* continues to provide the measure of a usefulness of a lawyer even if the defendant is formally represented by counsel. Thus, a waiver of *Miranda* is a waiver of *Massiah* whether or not the indicted defendant is represented by counsel.

In sum, *Massiah* provides indicted defendants with a right not to have incriminating statements elicited surreptitiously – the actual facts of the *Massiah* case – but it is not clear that the *Massiah* right to counsel adds anything to the *Miranda* right to counsel when police seek to interrogate indicted defendants.

Conclusion

The law of custodial police interrogation in 2012 begins with *Miranda*. Suspects who have been indicted also have a *Massiah* Sixth Amendment right to counsel. But as most suspects waive *Miranda*, and thus also waive *Massiah*, the real story continues to be the voluntariness test that has been evolving in Anglo-American law since the late seventeenth century. Nonetheless, *Miranda* continues to exert an enormous influence on the law of interrogation. Unlike the vague, subjective, and indeterminate due process test, *Miranda* provides police interrogators an easily administered procedure that is clear and whose outcomes are predictable. Its clarity and predictability are of great benefit to prosecutors and judges. In addition, *Miranda* has contributed to a civilizing of police behavior generally and to the professionalism of the interrogation process. It also serves symbolic and educational functions. It has increased popular awareness of the right not to answer police questions and of the right to counsel, so much so that the Rehnquist Court in 2000 concluded that *Miranda* has "become embedded in routine police practice to the point where the warnings have become part of our national culture" (*Dickerson v. United States* 2000).

Law of Police Searches

Fabio Arcila Jr.
Touro Law Center, Central Islip, NY, USA

Overview

In the United States, all governmental law enforcement agents, whether federal, state, or local, must comply with the Fourth Amendment's search and seizure requirements. Unfortunately, those requirements are often unclear, and there is no consensus about the analytical method for determining them. One option is historical analysis, and the United States Supreme Court has increasingly employed it. However, there are significant differences between the law of police searches today and what existed at the nation's founding, and even the Court itself has resisted the consequences of more fully returning to a historical model. This resistance results from one of the great challenges in Fourth Amendment law, which is how to balance conflicting and likely irreconcilable imperatives, such as retaining a historical model in light of social, cultural, and technological change, or limiting governmental discretion or power in a time of increased interest in preventative policing and searching.

This entry covers only that part of Fourth Amendment law that applies to governmental agents engaging in search and seizure activity for traditional criminal law enforcement purposes. For ease of reference, such agents will be referred to as "law enforcement" or simply as "police."

Main Text

Fourth Amendment law as we know it today did not exist for the first century of our nation's existence, despite that search and seizure issues have been at the forefront of public concerns since colonial times. It was not until *Ex Parte Jackson*, 96 U.S. 727 (1877), that the Supreme Court considered the Fourth Amendment in a substantive (albeit brief) way, and the Court did not significantly discuss it until *Boyd v. United States*, 116 U.S. 616 (1886). During the preceding period, search and seizure issues were litigated through common law trespass claims, and partly for this reason, the Fourth Amendment came to be viewed through a property law lens.

As for the scope of its protection, for most of our nation's history, the Fourth Amendment bound only the federal government. This is because the Bill of Rights, of which the Fourth Amendment is a part, was originally understood to limit only federal power. During this period, the Fourth Amendment was technically inapplicable to non-federal actors, such as state or local police, whose actions were constrained only by state and local law. The reason why the Fourth Amendment applies to state and local police today is that the Supreme Court, in the mid-1900s, ruled that the Fourteenth Amendment's Due Process clause made the Fourth Amendment binding against the states (*Mapp v. Ohio*, 367 U.S. 643, 1961; *Wolf v. Colorado*, 338 U.S. 25, 1949).

The Fourth Amendment did not become an active subject of Supreme Court litigation until Prohibition, which had resulted in a large expansion in both federal law enforcement and its search and seizure efforts. Even then, the property-based focus persisted, despite the pressure that technological change was exerting on the jurisprudence. In *Olmstead v. United States*, 277 U.S. 438 (1928), for example, the Court rejected a Fourth Amendment challenge to the wiretapping of telephone conversations, emphasizing that the wiretapping was accomplished "without trespass upon any property of the defendants."

As time and technology advanced, however, concerns about the government's investigatory and surveillance powers continued to increase, to the point where the Supreme Court finally expressed dissatisfaction with the property model and introduced a privacy model in *Katz v. United States*, 389 U.S. 347 (1967), which held that electronic eavesdropping from the exterior of a telephone booth constituted a search subject to Fourth Amendment protections. Since then, *Katz* and its privacy model have served as the touchstones for all Fourth Amendment law. This dominance, however, may be ending.

Recently, in *United States v. Jones*, 132 S. Ct. 945 (2012), the Court clarified that both a privacy model and a property-centric trespass model are available bases upon which to claim Fourth Amendment rights.

In addition to the privacy/property dichotomy, the other debate that has strongly influenced Fourth Amendment jurisprudence concerns the relationship between its two clauses, the Reasonableness and Warrant Clauses. Through the 1960s and into the 1970s, the Court often engaged in Warrant Clause-primacy, in which reasonableness under the opening clause was determined in light of whether a valid warrant had been obtained. This approach underlies the ubiquitous formulation that searches and seizures are per se unreasonable when unsupported by a valid warrant, except in certain carefully limited exceptions. Starting in the 1980s, this approach has tended to give way to Reasonableness Clause-primacy, in which the ultimate touchstone of Fourth Amendment constitutionality is whether the governmental conduct at issue was reasonable. Under this view, the ultimate question of reasonableness need not, and indeed often is not, determined in light of whether law enforcement had obtained a valid warrant, and the Warrant Clause's function is simply to set forth the constitutional minima for obtaining a warrant, while saying nothing about when warrants are actually required. Increasingly, the Supreme Court has settled into the pattern of generally judging the constitutionality of criminal searches under the Warrant Clause, and that of civil searches by reference to the Reasonableness Clause.

Fourth Amendment jurisprudence in general, and that part which governs police searches specifically, is often criticized for lacking coherence. A great deal of that criticism stems from disagreement among Supreme Court justices about whether to apply a privacy or property model, whether to proceed from Reasonableness Clause primacy or Warrant Clause primacy, and from disputes about how to do so once those choices are made. One evident dynamic is that Warrant Clause-primacy has often resulted in increasing Fourth Amendment protections from governmental searches – and concomitantly greater restrictions on police search power – both on a substantive basis and because it results in clearer standards against which to gain suppression of evidence. A challenge to moving toward a Reasonableness Clause approach is assuring a sufficiently high threshold of protections against governmental searches and seizures and assuring sufficient coherence and predictability in the jurisprudence so that it amounts to more than merely the subjective reaction of the judicial officer reviewing a given Fourth Amendment issue.

Fundamentals

The Fourth Amendment's text explicitly mentions both searches and seizures. But the Fourth Amendment does not cover all searches and seizures, only those performed by governmental actors – such as all police searches – or by private actors but in mere acquiescence to governmental authority. Thus, for example, a spouse or landlord acting in a voluntary, private capacity is free to engage in search and seizure behavior that would violate the Fourth Amendment had it been engaged in by police and then share the results with police. That person's conduct might violate some other body of law, such as tort law, but it will not amount to a Fourth Amendment violation because it is private, not governmental, conduct.

The next issue in any Fourth Amendment challenge to police conduct is whether it amounts to a "search" or "seizure" covered by the Fourth Amendment. There are two search tests. *Katz* is ubiquitously understood as having established a two-factor privacy test for a search: a Fourth Amendment search occurs only if the target had (1) an actual, subjective privacy expectation and (2) an objective privacy expectation that society accepts as reasonable. Recently, *Jones* engaged in a historical analysis to clarify that an alternate, property-based search test continues to exist as well: a Fourth Amendment search occurs when (1) government physically trespasses (2) for the purpose of collecting information (3) upon an enumerated Fourth Amendment item (i.e., "persons, houses, papers, and effects"). Either *Katz*'s privacy-based search test or *Jones*'s property-based one or both may be invoked when seeking

Fourth Amendment protection. (When property is involved, the seizure standard is whether government has meaningfully interfered with a possessory interest (*Soldal v. Cook County*, 506 U.S. 56, 1992). Numerous seizure standards exist with regard to the detention of persons, e.g., *United States v. Drayton*, 536 U.S. 194 (2002); *United States v. Mendenhall*, 446 U.S. 544 (1980); *Terry v. Ohio*, 392 U.S. 1 (1968). Because this entry is devoted to police searches, it will not consider seizures in any detail.)

Once it has been established that a Fourth Amendment "search" has occurred, the next question to be determined is what conditions the Fourth Amendment imposes for the search to be constitutional. It is at this stage that a great deal of complexity and ambiguity exists in Fourth Amendment jurisprudence.

Many police searches are assessed under the Warrant Clause. Consequently, often, the next inquiry is whether a valid search warrant was obtained and, if not, whether a valid exception to a warrant requirement existed. The Fourth Amendment's text imposes only three requirements for a valid warrant: (1) probable cause, (2) particularity, and (3) oath or affirmation. Of these, most commonly disputed is whether probable cause existed, though such challenges have been less likely to succeed since *Illinois v. Gates*, 462 U.S. 213 (1983), because it imposed a practical, commonsense, nontechnical totality-of-the-circumstances test. To a lesser extent, particularity is also sometimes disputed. Though not explicitly specified in the Fourth Amendment, the Supreme Court has also imposed a judicial preclearance requirement for warrants. It mandates that police, when applying for a search warrant, explain the factual basis upon which probable cause is claimed to exist such that a neutral and detached magistrate can make an independent determination of whether it, as well as the particularity requirement, is satisfied prior to issuing the warrant (*Lo-Ji Sales, Inc. v. New York*, 442 U.S. 319, 1979; *Giordenello v. United States*, 357 U.S. 480, 1958; *Nathanson v. United States*, 290 U.S. 41, 1933; *Byars v. United States*, 273 U.S. 28, 1927). Search warrants can also be subject to other, nonconstitutional requirements, like those in Federal Rule of Criminal Procedure 41, or in relevant statutes such as those that apply to certain forms of electronic surveillance.

Though it sounds odd, Warrant Clause primacy need not result in imposition of a warrant requirement, strict application of which is incompatible with the realities of quotidian police duties. Often, police are called upon to respond to quickly developing situations, and they could not perform their jobs and adequately protect public safety if required to obtain a warrant prior to intervening. Traffic stops, for example, could not possibly comply with a warrant requirement. As a result, the presumptive warrant requirement quickly began developing exceptions. Though these are claimed to be "carefully delineated," many commentators and at least one Supreme Court justice believe that the list of exceptions is now so broad as to have swallowed the rule (*California v. Acevedo*, 500 U.S. 565, 1991; Scalia, J., concurring).

Of such exceptions, an important one is that seizures can be made based upon only probable cause, with the scope of the seizure (e.g., its duration) being limited by the nature of the probable cause. Traffic stops provide an example. This probable cause standard is considered to be consistent with Warrant Clause primacy given that "probable cause" appears in that clause. Because no warrant is required, this probable cause standard is not subject to judicial preclearance. A probable cause challenge can be raised after the search, however.

Police searches can alternately be analyzed under the Reasonableness Clause. A prime example is police stop-and-frisk activity, which the Supreme Court allowed in *Terry* based upon reasonable suspicion, which is a lower suspicion threshold than probable cause. The move away from the Warrant Clause in favor of the Reasonableness Clause resulted in greater flexibility, allowing the Court to evade an otherwise applicable probable cause requirement. Stops and frisks are comprised of an initial seizure and search encounter (the stop) and may be followed by a second, more intrusive search (the frisk). The stop requires reasonable suspicion that a crime may be afoot and justifies police in detaining (seizing) an individual and engaging in investigatory questioning (a limited search). Frisk authority, because it is more intrusive, does not automatically follow from the stop, but instead requires reasonable suspicion not just of a crime but also of danger. The greater discretion that stop-and-frisk authority provides police has often caused it to be highly controversial and has contributed to claims of abused police authority and to distrust of police, particularly in low-income or minority communities.

There are many circumstances in which police may search based only upon probable cause or reasonable suspicion, and sometimes, no suspicion at all. Many of these circumstances can be grouped under the umbrella category of exigency, and they include hot pursuit, the automobile exception (which allows automobiles to be searched based upon only probable cause), and the search-incident-to-arrest doctrine (which, after an arrest, allows an immediate search of the arrestee as well as the "grabbing area" around him).

Two doctrines that allow police to engage in suspicionless searches, but do not fall under the exigency rubric, are plain view searches and consent-based searches. Plain view searches comply with the Fourth Amendment when police are lawfully in the place from which they observe an item whose incriminating character is immediately apparent. Thus, due to the plain view doctrine, a valid traffic stop can result in a much more serious criminal prosecution if police see illegal drugs in open view inside the vehicle. Consent-based searches are discussed in greater detail below.

Key Issues and Controversies

Role of History: Limited vs. Big Government, Urbanism, and Prohibition

Though the Supreme Court has increasingly called for giving greater weight to history in Fourth Amendment analysis, the utility of history as an analytical tool is actually quite limited because the modern world bears little resemblance to the world that existed at the nation's founding, and consequently, many policy imperatives have changed over time, sometimes completely reversing course. For example, the historical record is quite clear that, at nationhood, the primary Fourth Amendment goal was to constrain governmental search discretion. By contrast, Fourth Amendment jurisprudence today is designed to extend tremendous discretion to governmental searchers. Another reason why history is of limited utility is that, although widespread agreement exists about many of the relevant historical data points, radically different opinions exist about the implications of that history.

When considering history, Anglo-American history naturally dominates. At the nation's founding, constraining official discretion was an understandable goal given colonial history, which included complaints and, especially, extravagant rhetorical warnings that royal agents were infringing or would infringe upon colonial rights through an overbearing search power. This search power was exercised in the customs context to enforce tax laws. An attempt to extend it to excise taxes resulted in the 1765 Stamp Act riots. The Fourth Amendment is generally thought to include the Warrant Clause to constrain search discretion by establishing demanding standards under which search warrants can issue, and thus constitutionalize a ban against "writs of assistance" (official documents that were used to enforce customs laws) and general warrants, both of which provided unconstrained discretion to the search official.

In the years after nationhood, the federal government enacted customs laws that essentially parroted the British ones that had applied to the colonies – and which colonists had protested – including with regard to search and seizure provisions. The British statutes had constrained discretion by extending immunity to the searchers if, after the search, it was determined that probable cause had existed. Federal revenue laws used probable cause in the same way.

Those aggrieved by searches had recourse through a common law trespass action or, if federal revenue laws were at issue, possibly also through a civil law forfeiture action. However, if a federal revenue law was at issue, the probable cause determination was usually taken away from a jury and reserved for a federal judge. Searches that had occurred for purposes other than enforcing federal revenue laws, such as those that we think of today as classic police searches – searches for stolen goods, for example – were also subject to a legal regime that sought to constrain discretion through a combination of warrant procedures and liability for unsuccessful searches. This system, however, bears little resemblance to Fourth Amendment jurisprudence today because in our early history there was no professionalized police force. Thus, investigatory and search authority was left to private parties, who could seek a search warrant and assistance from a constable or sheriff in executing the warrant. Such governmental officials who acted under authority of an ostensibly valid search warrant were immunized from damages. The private party who swore out the warrant, however, would be liable if the search was unsuccessful, which acted to constrain search discretion.

A good example of the disjunction between modern and historical approaches to Fourth Amendment law concerns probable cause. Today, probable cause is often an important mechanism for protecting the public from improper police searches. This is certainly true as to warrant-based searches and is often true with regard to warrantless searches, which often are authorized merely upon probable cause. (One important difference in how probable cause is regulated in these two situations is that, in the former, probable cause can be assessed twice, once through judicial preclearance when the warrant is applied for and again after the search during a suppression or damages proceeding, but in the latter, it is assessed only after the fact.)

But much evidence indicates that during the nation's early history probable cause may have been a much less protective device. Though explicitly mentioned in the Fourth Amendment, when it was included there it was an immature concept that legal treatises indicated could be satisfied under conditions that would never be acceptable today, such as being a nightwalker or living an idle, vagrant, and disorderly life. Moreover, evidence suggests that probable cause played an especially important role only during federal revenue enforcement actions, where statutes used it as an immunity factor. Probable cause may have been a much less protective concept under the common law, for several reasons. It is accepted today that judges have a well-established duty to independently assess the adequacy of probable cause before issuing search warrants to police. But considerable historical evidence indicates that in our nation's early history the validity of probable cause supporting a warrant often would have been subject only to an after-the-fact jury determination through a common law trespass action. Judicial officers who issued search warrants may often have perceived their role with regard to probable cause as being merely ministerial, such that they may have treated an assertion of probable cause as a mere pleading requirement, the validity of which a jury could later decide. Juries, however, could so decide only if a judicial challenge was brought – which was rare then, as now – and even then could have their opinion nullified by a federal judge if a federal revenue law was at issue.

Using history as a guide to current Fourth Amendment law is a challenge because so much has changed over time. The conception and importance of probable cause, and the role of the jury, are just several examples. As time has passed, the original guiding imperative of limiting search discretion has given way to a desire to greatly expand search discretion. The reasons for this switch are numerous and include the move from rural to urban populations, which increased anonymity and hence crime and resulted in the creation of modern professionalized police forces, as well as persistent advances in technology that have vastly magnified both the harm one individual can inflict and the interest in, and capabilities of, surveillance, which increase the pressure to engage in preventative searches. For example, recent research persuasively argues that the key event in transforming the Fourth Amendment law of police searches to what we have today was the advent of the temperance movement of the late 1800s, which culminated in Prohibition and a significant increase in federal law enforcement (Oliver 2011). Indeed, several Prohibition cases, such as *Carroll v. United*

States, 267 U.S. 132 (1925), which involved automobile searches, and *Olmstead*, which involved wiretapping, resulted in important Fourth Amendment decisions (though later *Katz* famously overruled *Olmstead*). These changing circumstances have resulted in a desire to assure adequate governmental power to protect us from third parties, and thus the law of police searches has moved dramatically in the direction of expanding governmental discretion.

Consent, Police Intent, and Discrimination

The law of police searches with regard to consent and police intent operates to greatly expand police discretion. The premises underlying consent searches are that police should not operate at any disability as compared with a private actor and thus may seek voluntary assistance and compliance as could any private actor, and that the target has full knowledge about whether the encounter is truly voluntary or is subject to governmental compulsion (*Kentucky v. King*, 131 S. Ct. 1849, 2011). The latter presumption often operates to make consent-based searches controversial. For example, often there is no way for a person stopped by police on a sidewalk or in an airport or bus terminal to know whether police are acting under probable cause or reasonable suspicion, which would authorize a compelled detention. Similarly, every traffic stop at some point exhausts the probable cause justification for the seizure, but that point is often inscrutable to the driver. Thus, when a person is approached by police and asked, “Do you mind if I ask you a few questions?” or a driver is asked “By the way, do you mind if I look around?” it is often unclear whether a truly voluntary choice exists, particularly given that many jurisdictions make it a criminal offense to cut short a justified police encounter, as in the case of traffic stops. The controversy exists in large measure because the Supreme Court has ruled that consent need only be voluntary, not knowing, and thus police need not inform the target that he or she has a right to refuse consent (*Schneckloth v. Bustamonte*, 412 U.S. 218, 1973) or a driver that he or she is free to go instead of granting consent (*Ohio v. Robinette*, 519 U.S. 33, 1996).

Adding further controversy to the law of police searches is that, generally, only objective police intent is relevant to Fourth Amendment constitutionality, while subjective police intent is immaterial. Consequently, Fourth Amendment law makes it very difficult to prevail on claims of either invidious discrimination in police searches or on pretext claims such as that a minor traffic stop was really a subterfuge for forcing a police interaction (*Whren v. United States*, 517 U.S. 806, 1996). The Supreme Court justifies the focus upon objective intent based on ease of judicial application, a desire to treat similar police actions similarly regardless of whether different subjective motivations animated them, and the difficulty of establishing subjective intent.

Fourth Amendment consent and intent doctrines are often the source of great tension between police and poor or minority communities because these doctrines can effectively immunize police behavior motivated by actual invidious discrimination. For example, they can make it very difficult to challenge racial profiling, despite that it has been documented in traffic stops. Whether the Fourth Amendment law of police searches is properly formulated on these points is a significant issue because, by far, the greatest amount of face-to-face interaction between police and the public is during traffic stops. Thus, these Fourth Amendment doctrines are often highly criticized.

Arrest Authority and Strip Searches

Yet an additional example of the large amounts of deference extended to police under modern Fourth Amendment law is seen in the low levels of protection extended against dubious arrests and their ensuing consequences such as strip searches at detention centers. The Supreme Court has rejected a mother’s claim that the Fourth Amendment protected her from being arrested for the minor criminal offense of failing to secure herself and her two children in her pickup truck, despite acknowledging that “the physical incidents of arrest were merely gratuitous humiliations imposed by a police officer who was (at best) exercising extremely poor judgment" (*Atwater v. City of Lago Vista*, 532 U. S. 318, 2001). A very persuasive case has been made that *Atwater* is completely at odds with a historical view of the Fourth Amendment (Davies 2002). The Court has also refused to provide Fourth Amendment protections from arrests that violate state law, reasoning that Fourth Amendment and state standards are distinct and that the Fourth Amendment is satisfied so long as probable cause supported the arrest (*Virginia v. Moore*, 553 U.S. 164, 2008).

Arrestees are taken to detention centers, and recently, the Supreme Court has ruled that, once there, all adult arrestees may be subjected to suspicionless strip searches, including visual body cavity searches, and that the Fourth Amendment provides no protection even if the arrest was wrongful, such as because it was based upon the erroneous belief that an arrest warrant existed (*Florence v. Board of Chosen Freeholders*, 132 S. Ct. 1510, 2012). The degree of deference that the Supreme Court extended to detention centers was striking because the Court could easily have endorsed a reasonable suspicion requirement for such strip searches given that a prior case, *Bell v. Wolfish*, 441 U.S. 520 (1979), had widely been interpreted as imposing such a suspicion threshold before arrestees – who, after all, have yet to be adjudicated guilty of any offense – could be strip searched. Substantial uncertainly exists as to whether similar institutional deference will be extended in the context of suspicionless strip searches of juvenile arrestees given that the Court has required reasonable suspicion to justify strip searches in high schools, as well as proportionality between a search's intrusiveness and the suspected harm being investigated (*Safford Unified School Dist. No. 1 v. Redding*, 557 U.S. 364, 2009).

Surveillance and Technology

Fourth Amendment law has consistently struggled with whether, and how, to adapt to technological change. This dynamic became evident in the early 1900s as technology started rapidly advancing, which, for example, made wiretapping possible. Today, this is a consistently pressing issue given the accelerating pace of technological change, which has contributed to an increased interest in preventative searches as a result of heightened security concerns in a post-9/11 world.

The Supreme Court usually has taken a careful approach to technological development, often refusing to recognize Fourth Amendment privacy barriers to its use, though infrequently the Court has intervened even at the risk of dramatically changing Fourth Amendment law. One prominent distinction the Court has applied in Fourth Amendment technology cases is whether the technology merely involves sense enhancement or augmentation, on the one hand, or sense replacement or the use of what the Court believes is a disruptive technology, on the other.

Two of the Supreme Court's most important Fourth Amendment rulings fell into the latter category, which shows what an important role technology has had in developing the jurisprudence. One was *Katz*, in which the Court adopted a privacy model, and rejected a property model, in holding that the public enjoyed Fourth Amendment protections against electronic eavesdropping. The second was *Jones*, a recent decision in which the Supreme Court unanimously ruled that police installation and monitoring of a GPS device upon a suspect's vehicle was subject to Fourth Amendment oversight. *Jones* is significant not just for its reaffirmation that a property-based trespass model exists as a basis to seek Fourth Amendment protections (in addition to *Katz*'s privacy model) but also for what the concurring opinions suggest about the future direction of Fourth Amendment law in general and the law of police searches in particular.

Justice Alito wrote a concurring opinion, explaining that he would have resolved the case through a *Katz*-ian privacy analysis that would have focused upon objective privacy expectations. In the context of GPS technology, he would have applied two new, revolutionary factors to the objective prong: a temporal factor and an offense-specific factor. With regard to the temporal factor, he would have ruled that no objective privacy expectation exists in the context of "short-term" GPS tracking but that one does usually exist in the context of "longer term" GPS tracking. He provided no guidance as to what separates brief from prolonged GPS tracking other than to say that the GPS tracking at issue, which spanned 28 days, clearly qualified as prolonged. As for the offense-specific factor, he would have ruled that prolonged GPS tracking would violate an objective privacy expectation in the case of "most offenses" but suggested that this might not be true for "extraordinary offenses." His discussion of the offense-specific exception indicates that it is not defined in terms of distinct offense categories. Rather, it is really a resource-intensity measure, which the government can successfully invoke if it can show that it would have approximated similar surveillance results through traditional means had it not used GPS tracking, even if that meant an unusual commitment of resources. Because three other justices joined Justice Alito's concurrence, there are at least four votes on the current Supreme Court for incorporating these two revolutionary factors into *Katz*'s objective privacy expectation analysis.

There also appears to be a fifth vote available because Justice Sotomayor, though she provided a fifth vote for resolving *Jones* on property/trespass grounds, wrote a separate concurrence indicating that she was prepared to support Justice Alito's privacy approach.

Significantly, she also specified that she was willing to go even further than Justice Alito in extending Fourth Amendment protections against technological surveillance, even if it meant fundamentally reforming Fourth Amendment privacy jurisprudence. Police searches often take advantage of three interrelated Fourth Amendment doctrines, all of which are closely tied to *Katz*-ian privacy. One is the third-party doctrine, under which exposure of information to third parties, even in instances where there is little alternative, can obviate any privacy interest and thus eliminate Fourth Amendment protections (*Smith v. Maryland*, 442 U.S. 735, 1979; *United States v. Miller*, 425 U.S. 435, 1976). Another is the assumption of risk doctrine, under which privacy interests in information can be lost when voluntarily shared with a third party because one assumes the risk that the third party will disclose the information (*United States v. Jacobsen*, 466 U.S. 109, 1984; *Frazier v. Cupp*, 394 U.S. 731, 1969). The assumption of risk doctrine is particularly useful to police in the context of informants and co-occupants (*United States v. Matlock*, 415 U.S. 164, 1974; *United States v. White*, 401 U.S. 745, 1971). Finally, some Fourth Amendment law suggests a private-versus-public space distinction, in which no privacy expectation exists as to activities conducted in public, such as movements through public spaces or roads (*United States v. Knotts*, 460 U.S. 276, 1983). *Jones* is important in part because Justice Alito's and Justice Sotomayor's concurring opinions could have transformative implications for these three Fourth Amendment doctrines.

Additionally, some judicial opinions assessing GPS tracking had embraced mosaic theory as a means for the Fourth Amendment to keep up with technology, and Justice Alito and the three justices who joined his opinion seem to endorse it in *Jones*, and Justice Sotomayor clearly embraces it. In a search and seizure context, mosaic theory posits that privacy interests should be protected in a manner that guards against collections of small bits of information that individually may not be particularly revealing but that when aggregated can reveal a great deal. Justice Alito's temporal factor seems to implicitly endorse mosaic theory because a prime differentiating factor between brief and prolonged GPS tracking is the amount of data revealed to police. Justice Sotomayor was more direct in endorsing mosaic theory, so she clearly seems to be one available vote for importing it into Fourth Amendment jurisprudence. If these five justices are indeed willing to make this outcome law, it would significantly alter the law of police searches, at least in the context of technological surveillance.

Legislation, Technology, and National Security

In part because the Supreme Court often has been cautious in extending Fourth Amendment protections in technological contexts, the political branches have played an important role in defining the law of police searches. For example, when the Supreme Court created the third-party doctrine by ruling in *Smith* that there is no Fourth

Amendment privacy interest in telephone numbers dialed from one's home (because the telephone company keeps records of those numbers) and in *Miller* by holding that no privacy interest exists in one's banking records (because the bank holds them), the political branches responded by creating statutory protections through passage of the Pen Register Act, 18 U.S.C. §§ 3121–27 and the Right to Federal Privacy Act, 12 U.S.C. §§ 3400–22. Privacy standards that the political branches have created and defined have also strongly influenced the law of police searches through the Federal Wiretap Act, 18 U.S.C. §§ 2510–22 and the Stored Communications Act, 18 U.S.C. §§ 2701–12. When such statutory protections exist, it is important to understand that they may not necessarily comply with Fourth Amendment standards, especially in contexts where the political branches have taken the lead. For example, currently there are numerous controversies concerning the terms under which the Stored Communications Act allows the police to access cellular and GPS location data held by third-party service providers and whether those statutory terms meet Fourth Amendment standards.

Some of the uncertainty exists because the law of police searches has been significantly impacted by national security concerns. After the September 11, 2001 terrorism attacks, for example, Congress statutorily authorized the Attorney General, through one portion of the USA PATRIOT ACT, 50 U.S.C. § 1843, to use pen registers without prior court approval in emergency circumstances relating to international terrorism and foreign intelligence. There is evidence that governmental surveillance powers that were expanded post-9/11 for national security purposes have been used in the domestic law enforcement arena.

Remedies: The Exclusionary Rule, the Right to Counsel, and Qualified Immunity

An important issue in Fourth Amendment law is what remedies, if any, exist for a violation of the rights conferred against governmental searches and seizures. The primary question concerns the legitimacy of the exclusionary rule: whether exclusion of wrongfully obtained evidence should be an available remedy. Textually, the Fourth Amendment identifies rights but is silent about remedies. Early on, the Supreme Court in *Boyd* at least presumed that exclusion was proper, and then formally adopted exclusion as a remedy for Fourth Amendment search and seizure violations by the federal government in *Weeks v. United States*, 232 U.S. 383 (1914). Thirty-five years later, in *Wolf*, the Court declined to impose exclusion as a Fourth Amendment remedy against violations by state actors, on the theory that the device by which the Fourth Amendment was incorporated against the states – the Fourteenth Amendment – did not require it, but the Court switched course 12 years later in *Mapp*, in part on the ground that experience had shown that exclusion was the only effective remedy.

The exclusionary rule is controversial because, as famously phrased, "[t]he criminal is to go free because the constable has blundered," *People v. Defore*, 150 N.E. 585 (N.Y. 1926), and as a result, bare majorities of the Supreme Court have been on an active campaign for decades to minimize or eliminate it, as in *United States v. Leon*, 468 U.S. 897 (1984) (adopting good-faith exception for reasonable police reliance on search warrant subsequently held invalid), and this campaign has accelerated in the last decade. As originally conceived, the exclusionary rule was justified on the twin bases of judicial integrity and deterrence value. The campaign against it has rejected the judicial integrity rationale and has used the only remaining justification – deterrence – to require a cost-benefit analysis before wrongfully obtained evidence can be suppressed, while both emphasizing its costs and minimizing its benefits (*Herring v. United States*, 555 U.S. 135, 2009; *Hudson v. Michigan*, 547 U.S. 586, 2006).

A major debate surrounding the exclusionary rule is whether, as *Mapp* conceived, it is the only effective remedy for Fourth Amendment violations. Opponents of the exclusionary rule identify numerous intervening reforms since *Mapp* which, they assert, mean that the rule is no longer needed. They point to the increased professionalism of police forces and to federal civil rights statutes that authorize civil suits and the availability of attorney's fees for prevailing plaintiffs, as well as to increases in the number of public-interest law firms and civil rights lawyers (*Hudson*). Supporters of the exclusionary rule point to the increased professionalism and improved training of police forces as evidence of both the success and necessity of exclusion as a remedy, *Herring* (Ginsburg, J., dissenting), and assert that alternate remedies are not sufficiently available and successful.

In this debate, insufficient attention has been paid to the role of assigned counsel and to the impact of the qualified immunity defense. The Sixth Amendment provides a right to counsel in criminal cases involving a felony or before a sentence of incarceration may be imposed. This provision of counsel has played a singular role in the development of the law of police searches because it has guaranteed the presence of a legal professional to assess each client's situation and to vigorously and aggressively litigate potential Fourth Amendment claims. If, however, the exclusionary rule is eliminated or so emasculated that there is no incentive to litigate such claims during a criminal trial, the development of Fourth Amendment law will greatly suffer. This is because alternative remedies to the exclusionary rule often will be more theoretical than real for several reasons. The number of public-interest law firms and civil rights attorneys available to bring such claims pales by comparison to the number of assigned counsel in criminal cases. An aggrieved Fourth Amendment claimant who cannot enlist a public-interest law firm is left with no other choice but to hire a private attorney, but few such claimants can afford such legal representation. This representation deficit is further exacerbated by the lack of meaningful damages that would be available in most civil cases – particularly where the client was held guilty in the criminal proceeding – and by the difficulty in collecting statutory attorney fees in civil rights cases, a difficulty that has been magnified through rulings spearheaded by many of the same Supreme Court justices who are hostile to the exclusionary rule and point to such attorney fees as an alternative.

The qualified immunity defense also has a significant role in limiting the effectiveness of remedies other than the exclusionary rule. The qualified immunity defense protects police from civil suits for damages when a constitutional right has been violated but was not clearly established at the time of the violation. The law of qualified immunity is often extremely generous to police – again often through efforts by the same group of Supreme Court justices who oppose the exclusionary rule – which often makes it difficult to win on claims that a constitutional right was clearly established. This can be particularly ironic because, though the Court has increasingly insisted that historical analysis should play a leading role in Fourth Amendment law, the Court has at the same time rejected the relevance of historical Fourth Amendment analysis when it would operate to defeat a qualified immunity defense (*Anderson v. Creighton*, 483 U.S. 635, 1987). This rejection is significant because the common law of search and seizure was often quick to impose liability upon a government official who acted improperly.

Conclusion

Fourth Amendment law in general, and as it applies to police searches in particular, is at a crossroads. Though recently the Supreme Court has given more emphasis to historical analysis, in reality the Court's record in aligning modern Fourth Amendment law with the historical law of search and seizure is poor.

This outcome was foreordained because circumstances have simply changed too dramatically for a historical model to dominate. A good example of why can be seen in the advance of technology, which forces a Fourth Amendment reckoning absent any historical analogue. Moreover, technology also puts pressure on the core Fourth Amendment protective concept upon which we have relied – prior suspicion. Prior suspicion has come to occupy pride of place in Fourth Amendment law because of history. Historically, suspicion was the primary concept used to restrict search discretion, which was the overarching goal for which the Fourth Amendment was adopted. For more than a century, suspicion fulfilled this function well. At the nation's founding, the world was simpler and in that context suspicion was a particularly useful mechanism for limiting governmental power and discretion. As time advanced, however, circumstances changed and the world became increasingly complex and interconnected – for example, life in the United States moved from an agrarian to an urban existence, and technological advances accelerated – and consequently suspicion became less protective. This dynamic can be seen in the evolution of Fourth Amendment law, which started from a presumptive warrant requirement, then began departing from that requirement and instead relied more often only upon probable cause, and then in *Terry* created an exception to even probable cause through the creation of a less demanding reasonable suspicion model. Technological advances continue to put pressure upon suspicion because they increase the ability to engage, and interest in engaging, in preventative searches, such as through various forms of electronic surveillance.

Therefore, a significant challenge that currently exists in Fourth Amendment law, including with regard to police searches, is how to assure adequate search and seizure protections when suspicion can no longer play the protective role that it once did. This crisis comes with a benefit – the opportunity to expand and reassess our thinking about the Fourth Amendment – but it is one that must be embraced and pursued. Doing so requires the recognition that suspicion is not alone sufficient to assure a search's constitutionality because the Fourth Amendment protects a host of values, and suspicion protects only some of them. A search can be unconstitutional under the Fourth Amendment for many reasons. It might have been overly invasive or intrusive, the governmental interest being pursued might not have been sufficiently compelling, the search target's privacy interests could have been so substantial as to render the search illegitimate, or the search may not have been sufficiently efficacious or had sufficient deterrence value to justify the measures employed. Such interests are ones that the Fourth Amendment protects, but that suspicion does not. Thus, one avenue that might beneficially be pursued is to reform the Fourth Amendment law of police searches to more precisely and distinctly identify and consider the varied and multiple interests that the Fourth Amendment protects in various circumstances and ask whether the police conduct adequately respected them given the circumstances.

Overview

Our society grants the police extraordinary powers. This is not to suggest those powers are limitless. While many police departments have internal rules and guidelines that limit their behavior with respect to the seizure of persons or property, the most important limitations originate in the Fourth Amendment or more specifically in Supreme Court cases explicating the Fourth Amendment. The Fourth Amendment provides in its entirety, "The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated, and no Warrants shall issue, but upon probable cause, supported by Oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized." From these 54 words, a rich body of case law has developed governing searches and seizures. In addition, the Supreme Court has developed a rule of exclusion that generally requires the exclusion of evidence obtained in violation of the Fourth Amendment. The law of searches and the exclusionary rule are both beyond the scope of this entry, which focuses on the law of seizures and the exercise of discretion.

By its terms, the Fourth Amendment governs two types of seizures: the seizure of things (or more precisely, tangible property) and the seizure of persons. The law of each is different, and each is addressed in turn.

Fundamentals and Key Issues

The Seizure of Tangible Property

The first task in understanding constitutional limitations with respect to the seizure of tangible property is to understand what constitutes a seizure. The Supreme Court has stated that a seizure occurs "when there is some meaningful interference with an individual's possessory interests in that property." In fact, this is a rather common sense approach to defining seizures. As such, a seizure, within the meaning of the Fourth Amendment, occurs when a police officer takes possession of someone's property, for example, a purse or watch. Likewise, a seizure occurs when the police exercise control over property such that it is no longer available to a person.

For example, when a police officer conducts a traffic stop for a traffic violation, a seizure of the vehicle has occurred during the period that the driver or other occupants are prohibited from using the vehicle. The key is that there must be more than only minor interference over the tangible property. Accordingly, moving a sheet of paper a few inches because it is obscuring the serial number of a television does not constitute a seizure of the paper. Similarly, photographing the exterior of a house from a public sidewalk would not constitute a seizure of the house.

However, caution must be exercised in distinguishing between the seizure and search implications of police action. In the examples described above, the movement of the sheet of paper does not so meaningfully interfere with possessory rights to form a seizure of the paper; however, the conduct would constitute a search because it exposes the otherwise obscured serial number to public view. Similarly, photographing the exterior of a house is not a seizure of the house, but "photographing" the interior of the home using heat-detecting thermal technology would constitute a search within the meaning of the Fourth Amendment.

If police conduct amounts to a seizure of property, the second task is to determine whether the seizure is permissible. The Supreme Court has held that police may initiate brief, temporary seizures of property as long as they are reasonable. For example, if the police suspect – but do not yet have probable cause to show – that a suitcase contains narcotics, they can interfere with the owner's possessory rights for a very short period, only so long as necessary to bring a drug-sniffing dog to the scene.

In general, however, the Supreme Court has required that all police seizures of property be supported by probable cause to believe that the item seized will aid in a particular apprehension or conviction. Although the preference is for the determination of probable cause to be made by a neutral and detached magistrate through the issuance of a warrant, in recent years the Supreme Court has relied on the Fourth Amendment's prohibition against "unreasonable" searches and seizures to excuse the warrant requirement when a search or seizure without a warrant is reasonable. In general, when it is practical to secure a warrant, a warrant will be required. When it is not practical, the warrant requirement may be excused. A brief example illustrates this distinction. If the police have probable cause to believe that evidence of an identity theft operation will be found in someone's home, a warrant will normally be required to search and seize the evidence. By contrast, if the police have probable cause to believe that evidence of an identity theft operation will be found in someone's home *and* they have reason to believe that the evidence may be destroyed or relocated before they can secure a warrant, a search and seizure will be permitted without a warrant under the exigency exception. Because of the mobility of automobiles, this exception will often permit a search and seizure of items in an automobile without a warrant, so long as there is probable cause to believe the automobile contains contraband. Similarly, the police may seize, without a warrant, any item that is in "plain view" so long as the officer observes the item from a lawful vantage point, has physical access to the item, and has probable cause to believe the item is contraband or evidence of crime. Consider an example in which the police are summoned to respond to a domestic violence call. If, while responding to the domestic violence call, the police observe illegal drugs in plain view, they may seize it.

Lastly, it should be noted that the warrant requirement, and even the probable cause requirement, may be excused when the government has special needs, other than the detection of crime, justifying a seizure. For example, automobile checkpoints designed to check drivers for evidence of intoxication have been justified under the special needs exception, when the primary goal is to insure public safety on the roads, rather than to make arrests. A similar rationale allows temporary detentions at international borders as well as temporary searches and seizures at airports. Since 9/11, the use of special needs searches and seizures, of both persons and property, has grown exponentially.

The Seizure of Persons: Arrests

The seizure of persons is more complicated. Clearly, an arrest of a person constitutes a seizure. Such a seizure must be supported by probable cause to believe that a crime was committed and that the person to be arrested committed the crime. Beyond the probable cause requirement, the law regarding arrests is fairly straightforward. Absent exigent circumstances or consent, the police must secure an arrest warrant before making an arrest in the arrestee's home. If the police want to enter a third party's home to locate the arrestee, they must go still further and obtain a search warrant for the home. By contrast, the police may arrest a person in a public space with or without a warrant, so long as the probable cause requirement is satisfied. To protect against erroneous arrests, a defendant is entitled to a "prompt" postarrest assessment of probable cause by a magistrate, often referred to as a "probable cause hearing." In *County of Riverside v. McLaughlin*, 500 U.S. 44 (1991), the Supreme Court held that a jurisdiction "that provides judicial determinations of probable cause within 48 h of arrest will, as a general matter, comply with the promptness requirement."

The Seizure of Persons: Terry Stops

A seizure can also occur as a result of activity that falls far short of an arrest. The seminal case permitting seizures short of arrest is *Terry v. Ohio*, 392 U.S. 1 (1968).

In *Terry v. Ohio*, the Supreme Court considered for the first time whether a person could be detained in the absence of probable cause to believe that he had committed a crime, the usual prerequisite for an arrest. On its face, such a seizure would seem to violate the "probable cause" language of the Fourth Amendment. However, weighing the Fourth Amendment in the context of rising crime rates, and placing newfound interest in the Fourth Amendment's reasonableness clause, the Supreme Court interpreted the Fourth Amendment as permitting a limited detention and questioning of a person as long as an officer has specific and articulable facts, that is, reasonable suspicion, to believe that "criminal activity may be afoot." Expressing concern for the safety of officers, the Court went a step further. If the officer also has reasonable suspicion that a person is armed and dangerous, the officer can couple the limited detention and questioning with a pat down for weapons: in common parlance, a stop and frisk.

It should be noted that *Terry v. Ohio* recognized that permitting stops and frisks based on reasonable suspicion would invest officers with a fair amount of discretion. The Court also noted that stop and frisk practices, which the police had already been engaging in for years, were not race neutral and would continue to disproportionately burden minorities. Nonetheless, the Court accepted these disadvantages and interpreted the Fourth Amendment as permitting the practice of forcibly stopping individuals based on "reasonable suspicion."

Several external factors might explain the Court's decision to allow reasonable suspicion as a compromise between barring all stops absent probable cause and ceding complete discretion to the police to engage in stops without judicial oversight. Just 4 months after oral argument, and 2 months before issuing its decision, riots broke out in cities across the nation, including Washington, DC, suggesting that what was needed was more state police power, not more individual rights. In addition, the Court and Chief Justice Warren in particular had been criticized during the 1964 presidential campaign for promoting individual rights at the expense of law enforcement and were expected to be targeted again in the 1968 campaign.

While it is impossible to say with any certainty what role these external events played in *Terry*'s outcome, what is certain is that, by settling for the compromise of reasonable suspicion, *Terry* had the effect of ushering in a shift in direction that, while providing a basis for judicial oversight, would eventually invest officers with almost unfettered discretion to initiate brief, investigatory seizures of individuals.

Because arrests must be supported by probable cause, and stops merely by reasonable suspicion, disputes often arise regarding whether a person's seizure amounts to an arrest or a stop.

Arrests include not only formal arrests but also de facto arrests in which what may have started as a stop takes on the indicia of a custodial arrest. Courts evaluating the level of seizure consider the totality of circumstances surrounding the situation, including the length of the detention, whether the person was moved during the detention, and whether the police seized the person's possessions.

Controversies

What *Terry* has meant in practice, and what *Terry* means to many, is the apprehension of criminals. *Terry* is even preventative. It allows the police to stop and question not only those individuals they suspect of having committed a crime but also those individuals who they suspect may be about to commit a crime.

But the discretion that is inherent in *Terry* stop and frisks remains controversial. The vast majority of individuals stopped and questioned by the police are not engaged in criminal activity nor are they carrying weapons or contraband. That most stops and frisks affect innocent people, however, does not render them unlawful. Put differently, *Terry* authorizes stops and frisks based on mere reasonable suspicion (less than probable cause), regardless of whether those suspicions prove accurate or not.

Furthermore, it is difficult to know what proportion of stops and frisks that affect innocent people are in fact based on suspicions that were, at the time, reasonable. For the vast majority of the law-abiding citizens stopped, questioned, and even frisked by the police before being let go, there is no record of an arrest, no charge number, and no prosecution. Accordingly, those stops and frisks for the most part remain beyond public or judicial scrutiny. By definition, there is no exclusion of evidence, the remedy for a Fourth Amendment violation, because there is nothing to exclude. And because there is nothing to exclude, the affected citizens are unlikely to initiate judicial review of the police conduct, thereby leaving most stops and frisks outside of public scrutiny.

Of equal concern is the malleability of reasonable suspicion. As Justice Thurgood Marshall noted some years after *Terry* was decided, reasonable suspicion is often little more than a "chameleon-like way of adapting to any particular set of observations." This is especially true when it comes to profiling. In *United States v. Sokolow*, 490 U.S. 1 (1989), Justice Marshall offered a string cite of cases in which a suspect matched one of the DEA's profiles to show that almost any behavior can be deemed suspicious and thus satisfy *Terry*'s reasonable suspicion requirement:

> Compare, e.g., United States v. Moore, 675 F.2d 802, 803 (C.A.6 1982) (suspect was first to deplane), with United States v. Mendenhall, 446 U.S. 544, 564 (1980) (last to deplane), with United States v. Buenaventura-Ariza, 615 F.2d 29, 31 (C.A.2 1980) (deplaned from middle); United States v. Sullivan, 625 F.3d 9, 12 (C.A.4 1980) (one-way tickets), with United States v. Craemer, 555 F.2d 594, 595 (C.A.6 1977) (round-trip tickets), with United States v. McCaleb, 552 F.2d 717, 720 (C.A.6 1977) (non-stop flight), with United States v. Sokolow, 808 F.2d 1366, 1370 (C.A.9 1987), vacated, 831 F.2d 1413 (C.A.9 1987) (changed planes); Creamer, supra, at 595 (no luggage), with United States v. Sanford, 658 F.2d 342, 343 (C.A.5 1981) (gym bag), with Sullivan, supra, at 12 (new suitcase); United States v. Smith, 574 F.2d 882, 883 (C.A.6 1978) (traveling alone), with United States v. Fry, 622 F.2d 1218, 1219 (C.A.5 1980) (traveling with companion); United States v. Andrews, 600 F.3d 563, 566 (C.A.6 1979) (acted nervously), with United States v. Himmelwright, 551 F.2d 991, 992 (C.A.5 1977) (acted too calmly).

Moreover, the concern raised in *Terry v. Ohio* that the costs of allowing stops and frisks based on reasonable suspicion would be disproportionately borne by racial minorities appears to have ample merit. Consider recent numbers from New York City, one of the few jurisdictions that require officers to make a record of certain stops and frisks. According to recent data analyzing 867,617 stops over a 2-year period, blacks and Hispanics constituted over 80 % of the individuals stopped, a percentage far greater than their representation in the population. Moreover, of the blacks stopped, 95 % were *not* found to be engaged in activity warranting arrest. When considered as a percentage of the population, the numbers are even more jarring. Stops of whites, if spread across the population of New York City, would amount to stops of approximately 2.6 % of the white population during the period. By contrast, stops of blacks, if spread across the population, would amount to stops of approximately 21.1 % of the population.

The Seizure of Persons: Pretext Stops

Another seminal case in any discussion of the law of police seizures and the exercise of discretion is *Whren v. United States*, 517 U.S. 806 (1996), in which the Court rejected a Fourth Amendment challenge to a pretextual car stop used to search for drugs and other contraband. Justice Scalia, writing for the Court, rejected this argument and concluded that so long as the stop itself was based on an actual traffic violation, the subjective motivation of an officer in singling out a particular motorist, even if race-based, is irrelevant under the Fourth Amendment. Many scholars argue that *Whren* essentially green-lights the police practice of singling out individuals for pretextual traffic stops in the hope of discovering contraband. Given that most drivers routinely violate traffic laws, that is, by slightly exceeding the speed limit, *Whren* in fact gives officers almost unlimited discretion in deciding whom to target for a traffic stop.

Controversies

Like *Terry* before it, *Whren* has had racial consequences. Indeed, the terms "driving while black" and "driving while brown" have become part of the common lexicon to describe the belief that many officers consider race and ethnicity in determining whom to target for a traffic stop. Empirical evidence supports the belief that traffic enforcement disproportionately falls on racial minorities. For example, a report compiled by the Maryland State Police revealed that, during the period examined, African-Americans comprised 72.9 % of all of the drivers that were stopped and searched along a stretch of Interstate 95, even though they comprised only 17.5 % of the drivers violating traffic laws on the road.

Again, numbers like these are only part of the story. The other part is how these numbers impact law-abiding minority citizens. For example, in the Maryland study, even though blacks were disproportionately the subjects of searches, the hit rate for blacks, that is, the rate at which contraband was found, was statistically identical to the hit rates for whites. What this means in numbers is that the vast majority of the individuals stopped and searched were law-abiding minorities not in possession of contraband. A more recent analysis of over 810,000 "field data reports" collected by the Los Angeles Police Department found that the stop rate was 3,400 stops higher per 10,000 residents for blacks than for whites and 350 stops higher for Hispanics than for whites. There is also the issue of the discretionary practices that accompany such stops. The same study found police were 127 % more likely to search stopped blacks than to search stopped whites and 43 % more likely to search stopped Hispanics than stopped whites. Notwithstanding the fact that these groups were searched more often, blacks in fact were 37 % less likely to be found with weapons than searched whites and 24 % less likely to be found with drugs than searched whites. Similar numbers were found for searched Hispanics: Hispanics were 33 % less likely to be found with weapons than searched whites and 34 % less likely to be found with drugs than searched whites.

In addition to race, there is evidence that officers consider economic status in determining whom to target for a stop. For example, there is empirical evidence that police officers are significantly less likely to search vehicles driven by those with above-average incomes than vehicles driven by those with below-average incomes.

The Seizure of Persons: Non-seizures

Finally, any discussion of the law of police seizures would be incomplete without a discussion of a line of Supreme Court cases that categorize many police-citizen encounters as essentially "consensual," mere "encounters" that are not seizures and are thus outside the purview of the Fourth Amendment. In *United States v. Mendenhall*, 446 U.S. 544 (1980), and *Florida v. Bostick*, 501 U.S. 429 (1991), the Supreme Court held that absent a show of force or other circumstances that would lead a reasonable person to believe he or she was not free to leave, a "stop" is not always a "stop" within the meaning of the Fourth Amendment. An officer need not have even reasonable suspicion to initiate an encounter. An officer surprising an individual, asking that individual to accompany the officer, and asking that individual a series of questions – *Where are you going? Do you live nearby? Are you visiting someone here?* – would likely be categorized as a consensual encounter, not a stop within the meaning of the Fourth Amendment. As the Supreme Court has interpreted the Fourth Amendment, "Even when law enforcement officers have no basis for suspecting a particular individual, they may pose questions, ask for identification, and request consent to search luggage – provided they do not induce cooperation by coercive means." The facts in *Mendenhall* are illustrative. In *Mendenhall*, two federal agents approached an African-American woman in an airport, asked to see her identification and airline ticket, and asked her to accompany them to another location for further questioning, where they asked her if she would consent to a strip search. Justice Stewart, proposing the "free to leave" test for the first time, rejected her claim that she was ever "seized" within the meaning of the Fourth Amendment, reasoning that she was always free to leave, and as such the officers needed neither probable cause nor reasonable suspicion to engage her in what could be considered a "consensual encounter." The case of *Immigration and Naturalization Service v. Delgado*, 466 U.S. 210 (1984), is also illustrative. *Delgado* involved a factory sweep to determine the presence of undocumented immigrants. Several INS agents positioned themselves near the buildings' exits, while others dispersed throughout the factory to question most of the workers. The agents "displayed badges, walkie-talkies, and were armed [as they] approached employees and, after identifying themselves, asked from one to three questions relating to their citizenship." Writing for the majority, Justice Rehnquist rejected any claim that the workers were in any way detained and categorized the encounters as entirely consensual and thus outside the purview of the Fourth Amendment.

As with *Terry* and *Whren*, the *Mendenhall* line of cases likely has race and class implications. Notably, all of the "free to leave" cases from the Supreme Court involved racial minorities. Unfortunately, there is little data about the pervasiveness of consensual encounters as a law enforcement tool, precisely because they are outside the purview of the Fourth Amendment. Turning again to New York's stop and frisk data, what this means is that the 867,617 stop and frisk reports tell us virtually nothing of the number of additional individuals who were questioned during supposedly "consensual encounters."

Law of Police Use of Force

Overview

Perhaps no topic in policing has generated more debate than the use of force. In news coverage, as well as in movies and television dramas, police officers seem to confront violent offenders in lethal melee on a constant basis. Sometimes the stories concern allegations of excessive force or misconduct: the beating of Rodney King, the shooting of Amadou Diallo, the sexual assault of Abner Louima, the deadly FBI raid in Waco, the sniper fire in Ruby Ridge, and, most recently, the alleged rough treatment of Occupy Wall Street protestors. From these examples, people may extrapolate not only the incidence of official violence but also the law governing the use of force. This entry provides some background on the police use of force and a critical summary of the relevant law. The question remains as to whether the jurisprudence is sufficiently clear, consistent, and coherent in order to guide law enforcement, protect individual rights, and inform the citizenry of the legal boundaries.

Force, Police, and the Law

Definitions, Contexts, and Types of Force

For present purposes, the *use of force* may be defined as “any physical strike or instrumental contact with a person; any intentional attempted physical strike or instrumental contact that does not take effect; or any significant physical contact that restricts the movement of a person” (IACP, 116). Although some works on the topic provide a transnational perspective (Chevigny, 145–248), this entry focuses solely on the law of police use of force in the United States. The term *police* refers to any government agency empowered to enforce the criminal law of a given jurisdiction, including police departments, sheriff’s offices, highway patrol, and the Federal Bureau of Investigation. The *law* of police use of force comprises the legal justifications and limitations for the use of force, as well as the remedies for the use of excessive force. The resulting framework addresses the issues of when the police may use force and what types of force may be used in terms of the amount of force and the method employed.

In general, the police use of force may be justified to prevent the commission of a crime, to implement the criminal justice process, or to preserve public order. Many jurisdictions and the American Law Institute’s Model Penal Code specifically provide for the use of force in law enforcement (MPC, § 3.07). In certain contexts delineated by statute, police officers are said to possess a privilege to use force. As a constitutional matter, the police use of force is typically analyzed as a seizure of persons subject to the constraints of the Fourth Amendment. Over the years, the US Supreme Court has defined the term *seizure* in various ways. As used here, a seizure occurs when official force is intentionally applied to terminate or restrain an individual’s freedom of movement (*Brendlin v. California*, 551 U.S. 249, 254 (2007)).

The rubric of crime prevention comprises the police use of force to protect persons and property. For instance, the US Supreme Court has held that a police officer may temporarily detain an individual based on a reasonable suspicion that “criminal activity may be afoot” (*Terry v. Ohio*, 392 U.S. 1, 50 (1968)). If the officer also reasonably suspects that the individual is armed and dangerous, he may conduct a frisk for weapons to ensure his own safety and the security of others. Recently, the Supreme Court upheld the use of force to detain occupants during a home search due to “the risk of harm to both officers and occupants” (*Muehler v. Mena*, 544 U.S. 93, 100 (2005)).

The use of force to effect an arrest or otherwise seize a suspected criminal is the most obvious example of force employed to implement the legal process. Law enforcement may conduct an arrest – that is, taking an individual into custody to answer for a criminal charge – based on "probable cause," which is defined as sufficient facts and circumstances to warrant an officer of reasonable caution to believe that a crime has been committed and the person to be arrested committed it (*Brinegar v. United States*, 338 U.S. 160, 175–76 (1949)). Likewise, the police may use force to prevent the escape of a suspected criminal or to prevent the destruction of evidence. As for preserving public order, the paradigmatic example is the police use of force to suppress a riot after the rioters have been ordered to disperse and warned that force will be used if they do not obey.

Traditionally, the police use of force has been divided into two categories: *deadly force* (or lethal force) and *non-deadly force* (or nonlethal or less-lethal force). Deadly force is commonly defined as force that is likely to cause death or serious physical injury. Most prominently, this category encompasses discharging firearms at other individuals. But it also includes, for instance, the use of a police cruiser against another occupied vehicle, as when law enforcement performs a "Precision Intervention Technique" (PIT) maneuver – hitting another vehicle with the goal of causing it to spin to a stop. Non-deadly force comprises the use of all other types of force, including physical contact (e.g., tackling and punching), restraining devices (e.g., handcuffs), impact weapons (e.g., batons and flashlights), chemical weapons (e.g., pepper spray and mace), electronic weapons (e.g., stun guns), kinetic energy weapons (e.g., beanbag guns), explosive devices (e.g., flash-bang grenades), and police dogs.

Constitutional Limitations on Police Use of Force

At common law, government agents and private citizens were allowed to use both lethal and nonlethal force to apprehend a felon or prevent the commission of a felony. Nonlethal force could be used to prevent the commission of a misdemeanor amounting to a breach of the peace, but force could not be used to prevent the commission of any other misdemeanor. These standards were carried over to the American colonies and subsequently adopted in judicial opinions or codified by statute in the post-revolutionary states. Certainly, the common-law rules made some sense in an era when all felonies were punishable by death and private citizens often served as the community's law enforcers, dutifully answering the "hue and cry" to help apprehend criminals (Perkins & Boyce, § 10.1).

In modern times, however, this justification was undermined by the near monopoly of force exercised by the police, the proliferation of felony offenses in penal codes, and the reservation of capital punishment for the crime of murder. Nonetheless, some states maintained the so-called "fleeing felon" rule of the common law, which allowed the police to use whatever force was necessary, including deadly force, to prevent the escape of a felon. In its 1985 decision in *Tennessee v. Garner*, the US Supreme Court found that applications of this rule could violate the Fourth Amendment's ban on unreasonable seizures. "It is not better that all felony suspects die than that they escape," the Court opined, declaring that a "police officer may not seize an unarmed, nondangerous suspect by shooting him dead" (*Tennessee v. Garner*, 471 U.S. 1, 11 (1985)). The *Garner* Court then announced a constitutional standard for the use of deadly force:

> "Where the officer has probable cause to believe that the suspect poses a threat of serious physical harm, either to the officer or to others, it is not constitutionally unreasonable to prevent escape by using deadly force. Thus, if the suspect threatens the officer with a weapon or there is probable cause to believe that he has committed a crime involving the infliction or threatened infliction of serious physical harm, deadly force may be used if necessary to prevent escape, and if, where feasible, some warning has been given." (*ibid.*, 11–12)

Subsequent decisions have both expanded upon *Garner* and limited its categorical prohibition on deadly force to the basic fact pattern presented by the case. In 1989, the Supreme Court in *Graham v. Connor* made clear that excessive force claims arising from arrests, investigatory stops, and other seizures are properly characterized as invocations of the Fourth Amendment. Other constitutional provisions apply to individuals already in lawful custody, with pretrial detainees and convicted prisoners protected from excessive force by the Due Process Clause and the Eighth Amendment, respectively. Most importantly, the *Graham* Court held that all Fourth Amendment claims of excessive force, both deadly and non-deadly, should be evaluated for "reasonableness." This standard balances the nature and quality of the police intrusion against the governmental interests at stake, "including the severity of the crime at issue, whether the suspect poses an immediate threat to the safety of the officers or others, and whether he is actively resisting arrest or attempting to evade arrest by flight" (*Graham v. Connor*, 490 U.S. 386, 396 (1989)).

The *Graham* Court emphasized that the evaluation must not employ the "20/20 vision of hindsight." Instead, the proper perspective is that of a reasonable officer who is on the scene and may be "forced to make split-second judgments – in circumstances that are tense, uncertain, and rapidly evolving – about the amount of force that is necessary in a particular situation" (*ibid.*, 396–97). Moreover, the inquiry is one of "objective reasonableness," that is, whether the use of force was reasonable in light of the facts and circumstances confronting the police officer but without regard to his underlying intent or motive. An officer's corrupt intentions, even those that are "malicious and sadistic," do not transform an objectively reasonable use of force into a Fourth Amendment violation, just as an officer's good intentions do not render constitutional an objectively unreasonable use of force.

Most recently, the Supreme Court's decision in *Scott v. Harris* considered a specific fact pattern involving the use of police vehicles to seize a fleeing motorist. Although the use of a police cruiser to ram the motorist's vehicle did amount to deadly force, the Court rejected the idea that its earlier decision in *Garner* established "a magical on/off switch" (*Scott v. Harris*, 550 U.S. 372, 382 (2007)). The ultimate test is not whether the police used deadly force but whether the use of such force was objectively reasonable under the circumstances. In terms of the danger to others, the present case was quite unlike the escape on foot of an unarmed felony suspect in *Garner*. Pointing to a videotape of the chase, the *Scott* Court weighed the risks of the PIT maneuver versus the fleeing motorist's endangerment of pedestrians, other civilian motorists, and officers involved in the chase. According to the Court, the test of reasonableness can take into consideration the number of people imperiled by the fleeing motorist, as well as the relative culpability of that motorist versus those he placed in harm's way.

Means of Evaluating the Police Use of Force

In theory, the police use of force might be assessed through a number of legal paths. For instance, statutory schemes and departmental regulations on the use of force might be challenged on their face as constitutionally unreasonable. However, this option is largely foreclosed by legal and practical barriers to bringing facial challenges under the Fourth Amendment (*Sibron v. New York*, 392 U.S. 40, 59–60 (1968)), which might explain the persistence of statutes of dubious constitutionality in light of *Garner* (McCauley and Claus, 3). Moreover, the internal rules of an executive agency are often non-justiciable (*United States v. Caceres*, 440 U.S. 741 (1979)).

Another option would be to evaluate the police use of force in criminal proceedings. Defendants claiming to be victims of excessive force might seek, inter alia, the suppression of incriminating evidence at trial. But the courts have refused to apply the exclusionary rule absent a causal connection between the excessive force alleged by the defendant and the evidence he seeks to suppress (*United States v. Watson*, 558 F.3d 701 (7th Cir. 2009)). State prosecutors can bring charges against police officers whose use of force constitutes a criminal offense, and federal prosecutors can indict officers for uses of force that amount to deprivations of constitutional rights (18 U.S.C. § 242). Although beyond the scope of this entry, various legal requirements and practical impediments limit the viability of criminal prosecutions as a method to assess the use of force and check police abuses (Harris, 55–64).

Instead, civil suits have proven to be the most feasible means to contest the use of force. Purported victims of excessive force can bring state tort law actions against offending police officers, although claims based on simple negligence may be barred by sovereign immunity for the discretionary acts of government officials made in the course of duty. Alternatively, a 1994 federal law empowers the US Department of Justice to investigate and bring suit against police departments that have a "pattern or practice" of conduct violating the civil rights of people within their jurisdictions (42 U.S.C. § 14141). Since its enactment, the law has been used to investigate dozens of police departments, including those exhibiting patterns of excessive force. Typically, the cases result in a settlement where the department in question agrees to implement a slate of reforms. However, the law is not designed to investigate a specific case or to institute a civil action for a particular use of force.

Today, most use of force litigation is brought in federal court under a provision of the Civil Rights Act of 1871 (42 U.S.C. § 1983) which imposes liability on persons who, while acting under color of law, deprive others of their civil rights. Section 1983 itself is not a source of rights but instead provides a cause of action to vindicate established federal rights. As discussed, the relevant right in excessive force cases is the Fourth Amendment prohibition against unreasonable seizures. Although § 1983 only applies to state officials, the Supreme Court has ruled that an implied cause of action exists against federal officials for civil rights violations (*Bivens v. Six Unknown Federal Narcotics Agents*, 403 U.S. 388 (1971)).

Before trial, § 1983 cases can be stymied, or at least complicated, by the threshold issue of qualified immunity. This doctrine shields government officials from liability so long as his or her conduct does not violate clearly established rights that would have been known to a reasonable officer. The US Supreme Court has held that the first step in qualified immunity analysis is determining whether the police officer's conduct violated a constitutional right. At times, "a court might find it necessary to set forth principles which will become the basis for a holding that a right is clearly established," which, in turn, "serves to advance understanding of the law and to allow officers to avoid the burden of trial if qualified immunity is applicable" (*Saucier v. Katz*, 533 U.S. 194, 201 (2001)).

Over the past half century, thousands of federal lawsuits have raised claims of excessive force under § 1983, thereby providing the principal means for shaping the law of police use of force (Harmon, 1126). Indeed, *Garner*, *Graham*, and *Scott* were all cases brought under this provision. A number of reasons help explain the dominance § 1983 litigation, including the potential for successful plaintiffs to obtain attorney fees and costs (which, somewhat ironically, can be greater than the damages awarded to plaintiffs), as well as the fact that federal cases tend to come to trial much faster than state cases.

Controversies

The Supreme Court opinions on the use of force are often "cast at a high level of generality" and "[t]he test of reasonableness under the Fourth Amendment is not capable of precise definition or mechanical application" (*Brosseau v. Haugen*, 543 U.S. 194, 199 (2004)). Or as one federal judge put it, "There is no such thing as a per se violation of the Fourth Amendment" (*Cox v. Treadway*, 75 F.3d 230, 241 (6th Cir. 1996) (Ryan, J., concurring in part)). However, the idea that there are no per se rules in this area is belied by the fact that *Garner* did, in fact, adopt a bright-line rule regarding the use of lethal force. The same can be said of *Scott*, despite claims to the contrary in the majority opinion. Specifically, the *Scott* Court delivered the following conclusion: "A police officer's attempt to terminate a dangerous high-speed car chase that threatens the lives of innocent bystanders does not violate the Fourth Amendment, even when it places the fleeing motorist at risk of serious injury or death" (*Scott*, 550 U.S. at 386). This rule may be "sensible," as the *Scott* Court believed, but it certainly appears to be "absolute" (*ibid.*, 389 (Breyer, J., concurring)).

Objections to a per se approach might be tempered by reading *Scott* as creating a special rule regarding deadly force, as some lower court opinions have done with *Garner* (*Quintanilla v. City of Downey*, 84 F.3d 353, 357 (9th Cir.1996)). Yet the distinction between deadly and non-deadly force is not always clear. For instance, striking an individual in the head with a baton or other hard object may properly be viewed as deadly force, and some police departments classify the use of chokeholds and the firing of warning shots as deadly force. Moreover, the use of ostensibly non-deadly instruments can still produce lethal consequences, such as when a flash-bang grenade – an explosive device that creates a disorienting light and sound – ignites flammable accelerants contained in a building. Rather than relying solely on the Supreme Court's rough dichotomy between deadly and non-deadly force, most law enforcement agencies employ far more discerning methodologies to guide their officers. For instance, use-of-force continuums incorporate multiple levels of force, which typically begin with officer presence and verbal communication and end with the use of deadly force.

The totality of the circumstances approach espoused by *Graham* presents its own difficulties. As then-Judge (now-Stanford Law Professor) Michael McConnell opined: "[B]ecause excessive force jurisprudence requires an all-things-considered inquiry with 'careful attention to the facts and circumstances of each particular case,' there will almost never be a previously published opinion involving exactly the same circumstances" (*Casey v. City of Federal Heights*, 509 F.3d 1278, 1284 (10th Cir. 2007) (quoting *Graham*)). To reiterate, the Supreme Court in *Graham* listed three non-exclusive factors that may be relevant when considering the objective reasonableness of police use of force: the severity of the crime, whether the suspect poses an immediate threat to the safety of the officers or others, and whether the suspect is actively resisting arrest or attempting to evade arrest by flight. In *Scott*, the Court referenced the number of people endangered by the suspect and the relative culpability of that suspect versus those he placed in harm's way. The lower courts have cited additional considerations in assessing reasonableness, including:

- the type and amount of force used by the police
- the extent of injuries inflicted upon the suspect
- the amount of time and any changing circumstances during which the officer had to determine the type and amount of force that appeared necessary
- the relative physical characteristics of the officer and the suspect (e.g., height, weight, age, gender, and strength)
- the nature of the arrest charges
- the availability of alternative methods of capturing or subduing the suspect
- whether a warrant was used
- whether the suspect resisted or was armed
- whether more than one suspect or officer was involved
- whether a warning was given before the use of force
- whether the suspect was sober
- whether it was apparent that the suspect was emotionally disturbed
- whether the officer harbored ill will toward the suspect

Any number of other circumstances might be added to this list, either explicitly or by use of a catch-all phrase, such as "whether other dangerous or exigent circumstances existed at the time of the arrest" (*Chew v. Gates*, 27 F.3d 1432, 1440 n.5 (9th Cir. 1994)). Without constraints on the relevant circumstances or at least some guidance as to the hierarchy or relative weight of factors, the reasonableness standard can have the semblance of a Rorschach test. Along these lines, Professor Rachel Harmon has argued that "the reasoning in these cases is ad hoc, often inconsistent, and sometimes ill-considered," meaning that "the outcomes of future cases are largely unpredictable, even by the Supreme Court's own measures" (Harmon, 1123).

As noted above, some cases have taken into consideration the type and amount of force used and the availability of alternative methods of capturing or subduing a suspect. Other cases, however, have held that police officers need not use the least intrusive means of responding to an exigent situation (*Scott v. Henrich*, 39 F.3d 912 (9th Cir. 1994)). Likewise, officers are not required to use, and their departments are not required to provide, particular types of weapons (*Plakas v. Drinski*, 19 F.3d 1143 (7th Cir. 1994)). And as a matter of law, officers might not have a duty to retreat before using deadly force (*Penley v. Eslinger*, 605 F.3d 843, 855 (11th Cir. 2010)). Although several cases emphasized the communication of warnings before using force, other cases have found it objectively reasonable for an officer to forego a warning (*Colston v. Barnhart*, 102 F.3d 85 (3d Cir. 1997)). More generally, the police are not required to make any announcement when carrying out an arrest in a public place (*Catlin v. City of Wheaton*, 574 F.3d 361 (7th Cir. 2009)).

Another subject of debate in excessive force cases relates to the level of force used and the kind of injury inflicted. In passing, the *Graham* Court stated that "[n]ot every push or shove, even if it may later seem unnecessary in the peace of a judge's chambers, violates the Fourth Amendment" (*Graham v. Connor*, 490 U.S. 386, 397 (1989)). Along these lines, some courts have held that a Fourth Amendment violation only occurs when the police use more than a de minimis amount of force (*Cook v. City of Bella Villa*, 582 F.3d 840 (5th Cir. 2009)) and that the suspect must suffer an actual or non-de minimis injury (*Fisher v. City of Las Cruces*, 584 F.3d 888 (10th Cir. 2009)). But other courts have held that excessive force claims do not require more than a de minimis injury ((*Chambers v. Pennycook*, 641 F.3d 898 (8th Cir. 2011)), which is consistent with the Supreme Court's jurisprudence on inmate claims of excessive force under the Eighth Amendment (*Wilkins v. Gaddy*, 130 S. Ct. 1175 (2010)).

Additional areas of tension in the case law include the significance of verbal or physical threats by the police, particularly in the absence of physical injury; the pertinence of an officer's ill will toward a suspect in a regime premised on objective reasonableness; and the relevance of department policies given that a violation of such policies is not a basis for an excessive force claim. But perhaps the most glaring inconsistency in the jurisprudence, and the clearest split among the federal circuit courts, concerns the appropriate time frame for analyzing the reasonableness of police use of force (Avery, 267–89). Some decisions have focused on the Supreme Court's language of "immediate flight," "on the scene," "reasonableness at the moment," and "split-second judgments," all of which connote short time spans and temporal proximity (*Graham v. Connor*, 490 U.S. 386, 396 (1989)).

With these phrases in mind, the Second, Fourth, Fifth, Eighth, and Eleventh Circuits have limited the assessment to those circumstances existing at the time of the seizure. For instance, the Second Circuit concluded that an officer's

> "actions leading up to the shooting are irrelevant to the objective reasonableness of his conduct at the moment he decided to employ deadly force. The reasonableness inquiry depends only upon the officer's knowledge of circumstances immediately prior to and at the moment that he made the split-second decision to employ deadly force." (*Salim v. Proulx*, 93 F.3d 86, 92 (2d Cir. 1996))

By contrast, the First, Third, Ninth, and Tenth Circuits have held that proper analysis of excessive force claims must take into consideration the actions leading up to a seizure. In rejecting decisions espousing a narrow time frame, the Third Circuit could

> "not see how these cases can reconcile the Supreme Court's rule requiring examination of the 'totality of the circumstances' with a rigid rule that excludes all context and causes prior to the moment the seizure is finally accomplished. 'Totality' is an encompassing word. It implies that reasonableness should be sensitive to all of the factors bearing on the officer's use of force." (*Abraham v. Raso*, 183 F.3d 279, 291 (3d Cir. 1999))

Still another approach has been employed by the Sixth and Seventh Circuits, which divide use of force incidents into separate, sequential parts for analysis. As explained by the Seventh Circuit, "we carve up the incident into segments and judge each on its own terms to see if the officer was reasonable at each stage," but without returning to prior segments to reconsider the event "in light of hindsight" (*Plakas v. Drinski*, 19 F.3d 1143, 1150 (7th Cir. 1994)).

Conclusion

Given the above, it is not surprising that scholars have criticized the current law of police use of force. Professor Harmon has described the Supreme Court's jurisprudence as "profoundly impoverished," with the "paucity of reasoned analysis in this area" undermining "the evolution of a principled case law defining clear requirements for the legitimate use of police force" (Harmon, 1119, 1183). Another commentator claims that "[a]s brutality remains a problem and law enforcement challenges continue to grow, there has never been a better time to add flesh to the skeletal understandings of force found in the text of the Fourth Amendment" (Note, 2009, 1721–22). Arguably, the problem is not just the quantity of law on the use of force or the appropriate choice (or mix) of bright-line rules and flexible standards. Rather, there appears to be a disconnect between the case law on the one hand and people's perceptions on the other.

Consider, for example, the "added wrinkle" in the Supreme Court's decision in *Scott v. Harris*: "existence in the record of a videotape capturing the events in question" (*Scott v. Harris*, 550 U.S. 372, 378 (2007)). Based on its review of the tape, the *Scott* Court concluded that the fleeing motorist's "version of events is so utterly discredited by the record that no reasonable jury could have believed him," deriding the lower courts for having "relied on such visible fiction" when "it should have viewed the facts in the light depicted by the videotape" (*ibid.*, 380–81). In dissent, Justice John Paul Stevens believed that "the tape actually confirms, rather than contradicts, the lower courts' appraisal of the factual questions at issue" (*ibid.*, 389–90 (Stevens, J., dissenting)). Along the way, Justice Stevens panned "eight of the jurors on this Court" for reaching a different verdict than the lower court judges, "who are surely more familiar with the hazards of driving on Georgia roads than we are" (*ibid.*, 390). Nonetheless, the majority was "happy to allow the videotape to speak for itself" (*ibid.*, 378 n.5 (majority opinion)). Since *Scott*, the lower courts appear to have taken the cue, relying on videotapes in ruling on summary judgment motions in use of force cases (*Dunn v. Matatall*, 549 F.3d 348 (6th Cir. 2008)).

As it turns out, however, "what [a videotape] says depends on to whom it is speaking," as demonstrated by an empirical study conducted by Professors Dan Kahan, David Hoffman, and Donald Braman. The video in *Scott* was shown to a diverse sample of more than 1,300 Americans, who were then asked to describe what they saw and to provide their opinions on key issues identified by the Supreme Court. The authors found that a substantial majority of study participants had viewpoints consistent with those expressed by the eight-member majority of the Supreme Court. This perspective was hardly uniform, however. "Whites and African Americans, high-wage earners and low-wage earners, Northeasterners and Southerners and Westerners, liberals and conservatives, Republicans and Democrats – all varied significantly in their perceptions of the risk that [the fleeing motorist] posed, of the risk the police created by deciding to pursue him, and of the need to use deadly force against [the motorist] in the interest of reducing public risk" (Kahan et al., 903). As such, the vice of *Scott* was not necessarily the outcome but the way in which the Court reached it, namely, by asserting that no reasonable jury could have come to a different conclusion regarding the reasonableness of the police use of force.

The authors suggested several alternative rationales – for instance, the need for uniform, predictable rules – by which the *Scott* Court could have rendered the same judgment without dismissing other coherent viewpoints as unreasonable. To these suggestions, one might add the larger project identified by Professor Harmon: the need for "an accessible and transparent framework that the public may use to analyze highly publicized uses of police force" (Harmon, 1183). It may well be true that only a small percentage of police-citizen contacts involve the use of physical force (Adams et al., 3). But as mentioned at the beginning of this entry, the use of force tends to be understood through the lens of mass-media portrayals, which can distort popular perceptions or at least focus attention on extreme circumstances, at times fostering distrust of the police and disrespect for the legal system (Luna, 1112–19). Finding the means to educate the citizenry about the jurisprudence of force and to inform legal decision-makers about perceptions of police-citizen interactions might provide the first step toward an understanding of the police use of force that goes beyond the "Hollywood-style car chase of the most frightening sort" (*Scott v. Harris*, 550 U.S. 372, 379 (2007)).

Covert policing; Infiltration; Sting operations

Overview

Undercover policing is an investigative technique that is largely unregulated by constitutional criminal procedure in the United States, though the European Court of Human Rights has proven more willing to regulate the impact of undercover tactics on fundamental rights. American criminal law regulates undercover policing primarily through the entrapment defense, of which there are different variants. Current tests rest on empirical assumptions about the ways in which police investigations influence their target environment. Current versions of the entrapment defense do not take account of the varieties of undercover investigations and the different types of influences undercover agents may exert on their targets.

Key Issues and Controversies Surrounding the Choice of Regulatory Framework

Undercover policing is proactive an investigative tactic that allows police officers and informants to infiltrate criminal organizations or to test the criminal resolve of suspected offenders by disguising their true identities and orchestrating criminal opportunities. Undercover tactics have been examined through a rich variety of regulatory prisms, each of which captures a different feature that makes such operations vulnerable to abuse. Criminal law scholars worry about entrapment, which is an affirmative defense for targets of undercover stings who can show that government agents convinced them to commit a crime when they were not predisposed to engage in such criminal activity. Criminal law scholars also consider the potential criminal liability of undercover agents and informants who participate in the crimes they investigate. Criminal procedure scholars examine the impact of undercover investigations on the constitutional rights of criminal defendants, including their legitimate expectations of privacy under the Fourth Amendment and the ways in which undercover operations can compromise the privilege against compelled self-incrimination under the Fifth Amendment and the Sixth Amendment right to counsel.

Many civil libertarians look beyond the rights of criminal defendants to the First and Fourth Amendment interests of ordinary citizens. These concerns center on covert operations that pursue intelligence rather than evidence, since such investigations are likely to affect not only criminals but anyone who belongs to religious and political organizations that the government seeks to infiltrate. Because such investigations may not be predicated on concrete suspicion of wrongdoing, they may cast a wider net, yielding information whose validity may never be tested in court; covert scrutiny of this sort may burden the exercise of freedom of speech, assembly, and religion and may compromise the privacy of confidential communications between members of targeted organizations. Finally, state bar associations and courts that interpret state ethics codes have from time to time become concerned that prosecutors who supervise undercover operations might infringe disciplinary rules that prohibit attorneys from sanctioning acts of deception, or from sponsoring direct or indirect contact with represented parties, outside the presence of their lawyers.

Among this multiplicity of regulatory options, the entrapment defense remains the most significant, if only because most of the other types of challenges have proven either legally ineffectual or limited in scope. Appeals to civil liberties, in particular, have been notably less successful in the United States than in the European Union, where the European Court of Human Rights (ECtHR) has interpreted the Convention on Human Rights (ECHR) to protect the fair trial rights of criminal defendants whose convictions rest on evidence obtained undercover. Within the European Union, many national legislatures have understood the Convention's protections for privacy (set forth in Article Eight) as requiring statutory regulation of undercover operations and the enactment of a warrant procedure that ensures prior approval and continuing oversight by judicial officers. The Convention's privacy protections have been interpreted to limit the use of undercover tactics primarily to the pursuit of serious crimes, after showing that other, less intrusive investigative tactics seem unlikely to yield evidence against highly secretive offender groups. Accordingly, European legal systems authorize undercover operations primarily for the investigation of organized crime. Statutory constraints limit both the types of crimes undercover agents can investigate and the tactics they can use, as undercover agents in many European countries risk criminal sanctions for facilitating or taking part in crimes for which undercover tactics are not authorized by law – even when such assistance or participation serves exclusively investigative purposes. The European Court of Human Rights has also sustained challenges to undercover operations on grounds of entrapment, or because of the use of secret evidence, without adequate opportunity to question undercover agents and informants at trial. Both types of challenges invoked the right to a fair trial, as guaranteed by Article Six of the ECHR.

By contrast, undercover operations in the United States are not authorized by statute and may be initiated without obtaining a warrant or establishing probable cause or even reasonable suspicion that a crime is being committed. In *Hoffa v. United States*, 385 U.S. 293 (1966), the Supreme Court held that the use of undercover agents and informants does not tantamount to a search, within the meaning of Fourth Amendment, as targets waive their expectations of privacy in the information they voluntarily impart to others; in essence, suspects assume the risk of betrayal by their associates, or the risk that those with whom they commit crimes may turn out to be undercover agents. While listening in on a target's telephone conversation is a search that infringes on a protected expectation of privacy, eliciting such a target's confidences through undercover agents or informants does not count as a search within the meaning of the Fourth Amendment. Accordingly, resort to undercover tactics, unlike the use of electronic surveillance, requires no showing that less intrusive investigative methods have been tried or are likely to fail and no showing that the crimes being investigated are sufficiently serious to warrant the use of the undercover technique. In *Illinois v. Perkins*, 496 U.S. 292 (1990), the Supreme Court also rejected claims that undercover questioning of a custodial defendant violates his Fifth Amendment right to silence, even if he has already indicated his unwillingness to speak to the police, because the Fifth Amendment protects defendants only from compelled self-incrimination; if the defendant does not realize he is speaking to a representative of the police, the Court has reasoned, he cannot experience the conversation as an exertion of pressure by the government. Defendants have had more success challenging undercover questioning of defendants who have invoked their right to counsel. In *Massiah v. United States*, 377 U.S. 201 (1964), the Supreme Court held that once formal charges are in place, undercover questioning can violate a criminal defendant's Sixth Amendment right to counsel – but only if the questioning concerns the crimes with which he is charged and only if he has already invoked his right to counsel. Finally, sufficiently outrageous sting operations can violate defendants' substantive Due Process rights under the Fifth and Fourteenth Amendments. But this remains largely a theoretical possibility, as very few convictions have been vacated on that basis.

In recent years, US courts have also rebuffed claims that undercover policing invades their First Amendment rights of freedom of speech and assembly, though similar claims made in the 1970s and 1980s resulted in consent decrees under the terms of which police departments for cities like New York and Chicago agreed to refrain from surveillance of political and religious organizations absent any concrete evidence of ongoing or incipient criminal conduct. These consent decrees were quietly abandoned in the wake of the September 11 attacks, and the FBI, too, has modified the internal guidelines that restricted domestic intelligence agencies absent evidence of a criminal threat.

If American courts have rarely sustained legal challenges that are framed in the language of rights, and if American legislatures have never enacted a statutory warrant requirement, they have also avoided the regulatory path taken by most European legal systems before undercover tactics came to be regulated by a statutory warrant requirement: that of restraining undercover tactics through the threat of criminal sanctions for undercover agents or informants who take part in the crimes they investigate. Courts have taken the position that "[c]riminal prohibitions do not generally apply to reasonable enforcement actions by officers of the law" (*Brogan v. United States*, 522 U.S. 398 (1998)). And state legislatures have enacted broad immunities for undercover agents, through the so-called "public authority" defense, which protects law enforcement officers generally from criminal liability for enforcement actions that were duly authorized by their superiors. Unlike French and Italian immunities, which spell out the undercover tactics in which undercover agents and informants may lawfully engage, the American defense makes no effort to enumerate the enforcement actions – undercover or otherwise – for which the defense is designed.

The Dominant Framework: Entrapment

Accordingly, the entrapment defense remains the primary regulatory constraint on the criteria by which targets of undercover operations are selected and on the ways in which undercover investigations are planned and carried out. But there is an ambiguity at the heart of the entrapment defense, which accounts for the divergent ways in which it has been codified and discussed. Does the rationale for the defense rest on the view that targets do not deserve to be punished if they would have been unlikely to commit the charged offense without the criminal opportunity they were offered by government? Or does the entrapment defense exist primarily to reorient investigators away from targets of opportunity to "real" criminals, to whom the government merely tenders a convenient occasion to commit acts in which they would otherwise engage undetected?

The so-called objective test accords with the latter rationale, as it concerns itself with the nature and strength of the inducement employed by the government instead of the predisposition of offenders. While a particular defendant may well have been predisposed to commit the crime with which he is charged, an excessively appealing inducement may nonetheless amount to entrapment if it has a tendency to overcome the resistance of the average law-abiding citizen. Only a minority of jurisdictions, such as California and Oregon, have embraced this version of the entrapment defense. By contrast, the subjective variant of the entrapment defense accords with the former rationale, as it makes the defense available only to those offenders who were not predisposed to commit the crime they were eventually encouraged or persuaded to commit. A third, hybrid variant makes the defense available only if the defendant can establish both that he was not predisposed to commit the crime *and* that the government's tactics were unfair, meaning that the pressures and inducements it used were excessive. This is the most restrictive variant of the entrapment defense, as a purely subjective test would sustain a defense of entrapment even when the government offered a target otherwise reasonable inducements, so long as the targeted offender could establish a lack of predisposition.

In *Sherman v. United States*, 356 U.S. 369, 372 (1958), the Supreme Court embraced this hybrid version of the test by asking whether the inducement was objectively excessive and whether the government's tactics in fact implanted the idea for the crime in the mind of an "unwary innocent," reasoning that the legislature that defined the criminal offense could not have intended the criminal prohibition to apply to those who would not have committed such a crime without encouragement by undercover agents or informants. Critics of the subjective entrapment defense and its hybrid variant have pointed out that any claim that targets who lack predisposition do not deserve criminal punishment must explain the unavailability of any similar defense to those "unwary innocents" who were led astray by their friends rather than government agents or informants.

Critics of all three variants of the entrapment defense point out that all current versions of the test make the assumption that one can meaningfully distinguish "true criminals" from "unwary innocents." Commentators argue that almost anyone can be induced to commit a crime if the "criminal offer" is sufficiently tempting, so that the distinction between deserving and undeserving targets is at best a fluid one. The true question, for many reformers, is what level of inducement is considered reasonable, with some commentators using a market framework to argue that so-called above-market offers should be prohibited, because they may ensnare at least some targets who would be unlikely to commit crimes under "normal market conditions," meaning that they would be unlikely to take advantage of the ordinary of criminal opportunities they are likely to encounter in their normal surroundings.

Legal scholars who would prohibit the government from offering targets more than the "market price" as inducements to commit a crime have often been vague about what constitutes an excessive inducement, as they have generally not examined or systematized the variety of government sting operations that might give rise to a defense of entrapment. In the realm of sociology, however, Gary Marx's path breaking study, *Undercover: Police Surveillance in America* (1988), has identified a wide range of ways in which infiltration can alter a target's conduct or environment, along with a large number of factors that can distort the "naturalism" of an undercover operation. Marx points out that undercover operations can alter not only the opportunity structure for criminal conduct but also the motives, rewards, markets, or resources that shape targets' decisions about whether to offend and how. And among types of undercover operations, those in which an operative investigates past crimes are less likely to shape criminal conduct than anticipatory investigations that seek to prevent or facilitate future offenses. Investigations that offer criminal opportunities randomly will pose different risks of abuse than sting operations undertaken in response to prior intelligence about specific targets. Even if efforts to avoid concerns about entrapment lead investigators to emulate the natural criminal environment in their design of a criminal opportunity, too much realism may also overbear a target's autonomy, since "[i]n genuine criminal encounters, one party may coerce or threaten another party into participating" or may offer sex or drugs as an inducement.

Applicability of Entrapment Defense to the Varieties of Undercover Policing

The distortions that can be created by undercover operations may be compared to those inherent in either cognitive science or anthropology. In cognitive science, an experimental design may not correlate well with the real-life setting it seeks to emulate, if the experimental scenario is overly artificial. In the same way, an undercover agent may, perhaps unwittingly, offer a target a criminal opportunity that may be a poor substitute, or proxy, for the types of offenses that a target commits on his own, independently of the government. This may be a particularly salient risk for transactional undercover investigations, in which the undercover agent may agree to buy a much larger quantity of contraband from a suspected dealer than the target ordinarily sells to others. (American courts call this phenomenon "sentencing entrapment," if the investigator's aim is to increase the level of offending for the purpose of triggering a mandatory minimum prison term, or some other sentence enhancement.)

But some undercover investigations may more profitably be compared to ethnography, anthropology, or undercover sociology rather than the experimental designs of cognitive science. If an undercover agent infiltrates a criminal organization, learning about kinship patterns and power hierarchies, his presence as a facilitator or coconspirator can reshape some of the internal dynamics of the organization or help the organization to branch out into new territories or to take advantage of emerging criminal opportunities. In this, agents may resemble anthropologists, ethnographers, or sociologists, who become part of a community they are studying, and in the process may influence and alter the social environment, for example, by bringing with them weapons and tools that lead natives to abandon their own technologies or by helping native communities patent their knowledge of the therapeutic effects of local plants and herbs. If undercover agents participate in the organization's crimes, instead of proffering criminal opportunities that the government can control, the agents may not only help reshuffle established hierarchies but may shape at least some of the organization's criminal activities. Agents may also become entangled with and perhaps complicitous in the commission of crimes against innocent third parties or in retaliatory violence against unwitting informants (who may vouch for undercover agents without knowing their true identity.)

Most American undercover investigations can be grouped along a continuum, one end of which resembles the artificial, experimental scenarios through which cognitive scientists seek to reproduce natural occurrences under controlled conditions, while the other end of the spectrum features true infiltration of a natural environment which may, however, be altered by the presence of an outside observer. If undercover narcotics buys are closest to controlled experiments, other analogues to cognitive science experiments include the whole range of "honeypot" operations in which the police offer a criminal opportunity to targets who self-select by taking agents up on their criminal offers. Such investigations include random integrity testing of bank tellers, the establishment of storefront fencing operations, the positioning of bait cars filled with tempting merchandise, or the deployment of decoy officers posing as prostitutes on the street or as underage girls on the Internet. At the other end of the spectrum, undercover agents, sociologists, and journalists have infiltrated mental hospitals, supermarket chains, and extremist political parties, much as long-term moles have infiltrated the Cosa Nostra, the Hell's Angels, and the Klu Klux Klan.

To be sure, all undercover operations allow the government secretly to influence the crimes it investigates. But the concerns such influence might raise will be different when the government orchestrates an offense as a provable proxy for other, secret criminal activity, than when it allows its agents to take part in and perhaps even steer offenses that are orchestrated by others, in settings and with consequences that the government may either not be able to control or may be able to steer only at the cost of making the organization's true ambitions and capabilities difficult to disentangle from the government's own contribution.

Neither objective nor subjective tests for entrapment are currently able to distinguish among these types of influence in assessing targets' criminal responsibility for crimes to which government operatives contribute in an undercover capacity. That the entrapment doctrine functions as an affirmative defense makes it difficult to treat government influences as a matter of degree. By contrast, Italy and Germany treat entrapment as a scalar concept by making the doctrine available as a mitigating factor at sentencing. (The American doctrine of sentencing entrapment is rarely successful in reducing punishment to reflect government influence on the severity of a target's offense, as it is invoked only in truly exceptional cases.) This allows targets' penalties to be adjusted for the degree of government influence on targets' criminal activities, so that punishment may correspond to the nature and severity of the offenses that targets would have committed on their own. Compared with many of the member states of the European Union, the United States remains unusual in resisting both statutory regulation and warrant requirements, which would compel advance scrutiny of undercover operations, while making much less use of doctrines such as sentencing entrapment to adjust for distorting government influences in their aftermath.

Law, Diversion and Community Sanctions in Juvenile Justice

Ineke Pruin
Department of Criminology, University of Greifswald, Greifswald, Germany

Overview

Most criminal justice systems today have introduced alternatives to imprisonment. The general idea behind diversion and alternative sanctions is to keep the offender within society and to save him from the socially detrimental outcomes of imprisonment. This entry aims to give an overview about diversion strategies and alternative sanctions in juvenile justice systems which can in many countries be seen as pioneers for law reforms in the adult criminal justice systems.

Fundamentals of Juvenile Justice Systems

Generally speaking, the common idea of juvenile justice systems is that minors or juveniles should be dealt with differently than adults. According to criminological research results worldwide, juvenile delinquency and crime are episodic and regularly disappear in early adulthood. Consequently – and in line with Art. 40 (4) of the United Nations' Convention on the Rights of the Child (CRC) and many subsequent international instruments – justice systems have introduced special regulations for juvenile offenders which provide educational measures and sanctions instead of imprisonment as responses to youth criminality. The intention is to avoid compromising the developmental process of young persons in the transitional stage from youthfulness to adulthood. This development and the many international recommendations and conventions in the field of juvenile justice can be seen as the major achievement in modern juvenile criminal policy worldwide.

Justice systems differ in their approaches to youth offending. Parts of the juvenile justice systems are more justice oriented, which can mean that they sentence young offenders based on notions of punishment and accountability but also on the idea of proportionality, thus limiting interventions in order to avoid disproportionate sanctions. The idea of education and rehabilitation which is inherent also to justice-oriented juvenile justice systems is implemented by giving priority to diversion and community sanctions ("subsidiarity" of punishment or "education instead of punishment"). Therefore, in justice systems like in *Canada* or some *European states*, we find justice-oriented criminal procedural laws for juvenile offenders, oftentimes with extensive modifications compared to those for adults but by nature based on criminal law. Those are regularly focused on the offender rather than the offence, and the aim of rehabilitation plays a special role. Other juvenile justice systems are more oriented at family or youth welfare law. This includes that the offence is rather seen as a sign for the "need of help" of the juvenile and therefore leads to welfare or family law measures (e.g., in *Poland* or *Bulgaria*), and in some countries, family conferences play an important role in the practice of juvenile justice (e.g., *New Zealand*, *Northern Ireland*, or *Canada*). As more or less pure welfare-oriented systems do not provide for criminal sentences they allow for sometimes far-reaching transfers of juvenile offenders to adult criminal courts as in the *United States*.

Nowadays, as a result of manifold developments, we can hardly find a pure welfare or justice approach in one country. Systems that combine welfare as well as justice elements and that have introduced even more and different approaches to responding to young offenders are more common (Winterdyk 2002; Doob and Tonry 2004; Cavadino and Dignan 2006; Goldson and Muncie 2006; Junger-Tas and Decker 2006; Hartjen 2008; UNICEF 2008; Dünkel et al. 2011a). They differ in their scope concerning the age groups or the behavior they encompass (e.g., in many systems status, offences can open the door to juvenile justice, in others only "criminal" behavior can lead to reactions from the youth court; see for an overview Doob and Tonry 2004; Pruin 2011). However, due to the requirements of the CRC and their subsequent international instruments, many juvenile justice systems have managed to introduce procedural safeguards to make sure that the state reactions remain proportional to the seriousness of the offence.

Diversion

Definition and Functions of Diversion

One state reaction which is usually used more extensively in juvenile justice compared to adult criminal justice systems is the possibility of diverting young offenders from trial.

In the context of criminal justice, diversion is seen as a headword for decisions, measures, and strategies which aim to avoid formal penal prosecution, trial, and sentences (Koffmann and Dingwall 2007). A more concrete definition of diversion can be as follows: Diversion is the dismissal of the case when the offence is of minor gravity and if formal proceedings do not seem to be appropriate. Diversion follows the procedural principle of "expediency" (in contrast to a strict principle of "legality" which obligatorily requires formal proceedings and court decisions in any case) and its main aim is to avoid stigmatization through formal court proceedings (Dünkel et al. 2011b, p. 1651). In the juvenile justice systems, different forms of diversion are to be found: Diversion can be unconditional or conditional; furthermore, it often means the referral of juvenile offenders to health or social services or to mediation schemes instead of judging them in criminal court proceedings.

Diversion is regularly a decision of the prosecutor at a pre-court level. In many countries diversion can also be adjudicated by the judge, if after an accusation the case seems to be appropriate for a dismissal (e.g., because of reparation efforts by the offender that have been performed in the meantime). In some countries even the police are competent to divert juvenile offenders and therefore to avoid criminal proceedings more or less completely (e.g., police cautionings or warnings in Anglo-Saxon countries).

Particularly in the field of juvenile justice, since the mid-1980s many international recommendations have emphasized that diversion should be given priority as an appropriate and effective strategy of juvenile crime policy (e.g., Convention on the Rights of the Child of 1989, Article 40 (3) b), emphasized by Comment No. ten on Children's Rights in Juvenile Justice from 25 April 2007; the United Nations Standard Minimum Rules for the Administration of Juvenile Justice [Beijing Rules] of 1985, Rules No. 11.1–11.4; the United Nations Guidelines for the Prevention of Juvenile Delinquency [Riyadh Guidelines] of 1990, Rules No. 5 and 6; the United Nations Standard Minimum Rules for Non-custodial Measures [Tokyo Rules], Rule No. 5 and on the European level; the Council of Europe's Recommendation on "New ways of dealing with juvenile delinquency and the role of juvenile justice" of 2003 [Rec 2003 (20)], Rules 7, 8, and 10; and the European Rules for Juvenile Offenders Subject to Sanctions or Measures [ERJOSSM, Rec (2008) 11], Rules 5, 10, and 12).

The concept of nonintervention (or better avoiding formal prosecution) was developed in combination with decriminalization (particularly of so-called status offences) and deinstitutionalization (from youth custody and residential homes). Since the 1960s particularly in North America and across Europe, tendencies in juvenile criminal policy have emerged that are based on the notions of the principles of "subsidiarity" and "proportionality" of state interventions against juvenile offenders (Dünkel 2009). More specifically, these developments also involve the expansion of procedural safeguards on the one hand and the limitation or reduction of the intensity of interventions in the field of sentencing on the other. One major element of this philosophy was the idea of diversion, i.e., to avoid possibly stigmatizing state interventions in favor of a more lenient and – with regard to future social integration – more appropriate approach.

In spite of heavy criticism in the early 1980s, blaming "net-widening" effects and informal social control that would even surpass formal social control of the youth courts (Austin and Krisberg 1982), diversion has continued its "triumphant" expansion due to national and international developments in juvenile crime policy in the 1980s. Nowadays, apart from the aim to avoid (unnecessary) stigmatization, diversion in juvenile justice is based on the idea that education should be prioritized over punishment. From the perspective of sociology of law, the advantage of nonintervention or less severe punishment (e.g., probation instead of imprisonment) lies in the increased expectations of future norm conformity, which are expressed by the competent punishing authority to the offenders in question. The violator of the norm is under the pressure of a special (informal) obligation as he has been given a "social credit" which contributes to better compliance with the norm (see Dünkel et al. 2011b, p. 1628 with further references.).

Furthermore, the use of diversion is oftentimes related to the pragmatic consideration of reducing or limiting the courts' caseload (see in general Jehle and Wade 2006). It can be shown that an increase of cases in the criminal justice system needs to be compensated by diversionary or other bureaucratic strategies that make the "input" manageable.

Types of Diversion

Types of diversion can be distinguished by the different authorities who are competent to decide on the dismissal of the case (diversion). Diversion can be initiated by the police, the prosecutor, or the judge.

A young offender's first contact with the justice system is mostly the police. This is why police diversion is generally recommended by the international instruments (see, e.g., No. 11.2 of the Beijing Rules or No. 5.1 of the Tokyo Rules). The advantage of diversion at this early stage of the procedure is that the police can react promptly, so that there is immediacy between committing the offence and the justice system's response. On the one hand, a swift reaction is seen positively from a pedagogic point of view (if the police act cautiously and with respect). On the other hand, the amount of time during which the offender could be stigmatized is reduced. The police have a lot of discretional power in such a system. The resulting dangers could be prevented through the condition that the police have to undergo specific training on contact with young offenders.

Consequently, many juvenile justice systems, mostly in countries where the role of the public prosecution service is not very strong, introduced the possibility of "police diversion." "Police diversion" can mean that the police, to whose attention an offence committed by juveniles has come, is competent to simply take no further action because the behavior in question is viewed as being very minor, petty, and unimportant (e.g., *Cyprus, England/Wales*). In other systems the police can issue informal or formal warnings or can refer the juvenile to special diversion schemes in close cooperation with the Social Services (e.g., *Northern Ireland, Ireland, the Netherlands*).

Other countries strictly follow the procedural principle of "legality." Originally the principle of legality means that a human conduct must be declared as a crime by a specific statute or law before it can be considered as a criminal act. The strict consequence from this principle is that a special prosecution service must bring a charge against any criminal offender. If the laws in these countries provide for any form of pre-court diversion, usually the prosecution services, consisting of lawyers, are competent to decide about dismissing the case or to refer it to a special diversion scheme. Usually the decisions of the prosecution services are conditional. This means that the prosecution service offers to close the criminal proceedings when the offender has fulfilled special obligations like repairing the damage or participating at anti-aggression trainings.

In some countries, diversionary decisions can also be made by a judge at the court level. Such court diversion makes sense particularly in cases when the juvenile has paid reparation or has otherwise resolved the conflict with the victim after the prosecutor has submitted the indictment to the court, which gives the judge the impression that further prosecution would not be appropriate or necessary. Especially the countries following the traditional welfare model have facilitated diversionary strategies on a court level because of the wide discretionary power of the juvenile judge.

In consideration of the different competent authorities, juvenile justice systems generally introduced a way to divert a case and combine the conditional dismissal of the case with educational measures or interventions. The systems for this kind of "interventionalist diversion" vary.

In many countries, minor offences can be dismissed after educational measures have taken place (e.g., mediation, victim-offender reconciliation, reparation, apology to the victim). The idea is that if the conflict is already solved within the society, there is no need to further stigmatize the offender or to spend much money on cost-intensive criminal procedures. So, for example, if in *Germany* at the time of the beginning of the prosecution the offender has already apologized and paid for the damage he produced, the public prosecutor can dismiss the case without any further conditions (the German Juvenile Justice Act even encourages the prosecutor to regularly do so; see Sect. 45 al. 2 JJA).

A similar approach is followed in countries where diversion in combination with (minimum) educational interventions is seen as a possible option. One alternative is that the prosecutor or the judge can suspend the case for a certain period of time. The case will be dismissed after the offender has fulfilled special obligations, like community work or reparation of the damage or participation at certain "training courses." A comparable approach is quite common in Eastern European countries with the so-called release from criminal liability, which can be combined with educational measures.

In some countries, diversion can be combined with a referral to the Social Services (*Sweden*) or special administrative authorities/bodies, like the "Children's Hearings System" (*Scotland*) or the "Juvenile Commissions" in *Bulgaria*, *Estonia*, or *Russia*. These bodies can partly issue and partly negotiate the fulfillment of special educational obligation. The transfer of responsibility and sanctioning power to administrative bodies makes it important to guarantee that juvenile justice standards are respected on this level as well. According to the international recommendations, these kinds of administrative authorities likewise have to avoid each form of deprivation of liberty as a reaction to criminal behavior. Questionable is if "Juvenile Commissions" as they can be found in Eastern and Central Europe constitute an appropriate way of diversion. Not always the commission's decisions are subject to judicial review, even if they may include the placement of a juvenile in a closed institution (UNICEF 2008, p. 25). An interesting approach in this sense is the idea of introducing conferences to divert juvenile offenders from criminal proceedings which is apparently most developed in *New Zealand*: The police have to refer all juvenile offenders who have not been arrested and charged to a family group conference. If the conference can resolve the matter, there will be no further public reaction. The youth court is required to refer all cases coming to it for a family group conference as well (Maxwell and Morris 2006, the European approaches for the introduction of family conferences are described by Doak and O'Mahony 2011).

Efficiency of Diversion

Measuring the efficiency of sanctions is one of the most complicated issues in criminological research. Usually different sanctions are applied for different kinds of offences and offenders. This leads in practice regularly to a selection bias which makes it almost impossible to ascribe recidivism (or legal behavior) to the inefficiency (or efficiency) or the sanction (validity). Reducing a desired behavior to a special sanction is only possible with the help of studies using random assignment or quasi-experimental design (standards for evaluations were developed by Sherman et al. 1998; see also the chapters of MacKenzie and Shapland in this volume). Most study designs do not follow these standards, as it is in a criminal justice system difficult to allocate one or another sanction randomly.

With regard to diversion, there are at an international level study results which indeed used random assignment or quasi-experimental design which predominantly arrived at the conclusion that recidivism rates after diversion are lower, or at least not higher, than after formal court procedures and convictions. According to German studies, the strategy of expanding informal sanctions has insofar proved to be an effective means, not only to limit the juvenile court's workload, but also with respect to special prevention (see Heinz 2005; Dünkel 2011).

According to German data, reconviction rates of offenders who were "diverted" instead of being formally sanctioned are significantly lower (reoffending rates after a risk period of 3 years were 27 % vs. 36 %, see Dünkel 2011). Even for repeat offenders the reoffending rates after informal sanctions were not higher than after formal sanctions (see Heinz 2005, p. 306). Another study demonstrates that the increase in the use of diversion in Germany during the 1980s and 1990s does not correspond to an increase of juvenile delinquency rates. On the contrary, the recidivism rates of comparable delinquents (for different typical juvenile delinquent acts) were significantly lower when diverted as compared to those formally sanctioned by the youth court (see Dünkel et al. 2011b, p. 1639 with further references). The evident methodological problems of comparing different sanctions (concerning the seriousness of different crimes, previous convictions, etc.) were addressed by British empirical research which strictly controlled the different "sanction groups" for key variables such as age, sex, and previous criminal history. The research results demonstrate that conditionally discharged offenders had lower reconviction rates (39 %) than those sentenced to fines (43 %), probation (55 %), or community service (48 %, see Moxon 1998, p. 91). The meta-analysis of *Whitehead* and *Lab* supports the findings that diversion has the best prognosis with regard to recidivism. As far as can be seen, only the study of Morton and West (1983) could not find any reduction in recidivism from the use of youth diversion as opposed to youth courts (in *Canada*).

Looking at the costs and the impact of different sentences and interventions, it is evident that informal warnings and cautions are the least expensive measures. Further research on "what works, with whom under which circumstances" including serious control of the selection bias needs to be continued in this context.

Community Sanctions

Definition and Functions of Community Sanctions

If a case is not diverted but reaches the level of the court, many juvenile justice systems provide a lot of different dispositions as well. The so-called community sanctions define all sanctions and measures which do not lead to deprivation of liberty in any form (see Beijing Rules, No. 18). They are important as a basis to comply with the principle that no child shall be deprived of liberty except as a "last resort," as required by Article 37(b) of the Convention on the Rights of the Child. The reform movement to widen the scope of community or alternative sanctions started in the 1970s in the *United States* and *England* and later developed in the 1980s in many other juvenile (and adult criminal) justice systems. The base for the introduction of community sanctions is seen as twofold: On the one side a shift in people's attitude towards punishment emerged which tried to make criminal justice more humane (Junger-Tas 1994, p. 1). On the other hand, there was the problem of overcrowded prisons in many countries which forced to find and to use alternatives (e.g., Bala and Roberts 2006, S. 37). If we look at today's different juvenile justice systems, we do find many differences regarding the extent and types of community sanctions.

Types of Community Sanctions

As a general rule, the applicable sanctions and measures follow a certain hierarchy that is based on the order in which priority shall be given to the most educational, most appropriate sanction. This regularly opens up the possibility to combine several educational measures or sanctions with each other. We can find the following levels of sanctioning, ordered from the least to the most intrusive:

1. Warnings, reprimands, conviction without sentence, educational "directives"
2. (Day) fines, community service, reparation orders, mediation
3. Social training courses and other more intensive educational or supervision sanctions
4. Mixed sentences, combination orders (which can be characterized as a more "repressive" (intrusive) way of dealing with juvenile offenders)
5. Suspended sentences without supervision by the Probation Service
6. Probation
7. Suspended sentences with supervision by the Probation Service, electronic monitoring
8. Educational residential care, youth imprisonment, and similar forms of deprivation of liberty

The least invasive sanctions are warnings or reprimands (verbal sanctions) and followed by a wide range of alternative sanctions that exert more or less influence on the life of the offender. Many sanction systems provide educational measures (such as educational "directives" in *Austria* and *Germany*) either as independent sanctions or as complementary elements of other sanctions like probation or suspended prison sentences (e.g., *Denmark*). The aim of such educational directives is always to improve the educational impact on the one hand and to reduce the impact of risk factors in the juvenile's daily life on the other. The laws should confer a certain degree of discretionary power on the judge to enable him or her to find the most appropriate directive. In between we find the possibility to impose a day fine on juvenile offenders which is theoretically possible in many, albeit not all juvenile justice systems. Indeed, one may question if fines could be seen as educational sanctions, facing the fact that juveniles will often be unable to pay for fines with their own money.

Restorative justice elements like victim-offender mediation for juveniles do often play a special role in juvenile justice. Yet, in some (European) countries, mediation is never or only seldom practiced due to a lack of organizational infrastructure at the local level, as reported by the *Czech Republic*, *Poland*, *Romania*, and *Serbia* (Dünkel et al. 2011a). Such kinds of "restorative justice orders" can be manifold and creative in aiming at compensating the victim.

In many countries, community service combines slight "punishment" with reparative and rehabilitative elements. The offender shall offer "a 'payback' to the community via unpaid work" (Goldson 2008, p. 78). Some countries have special age limits for the imposition of community service: For example, in *England* and *Wales*, *Ireland*, and *Northern Ireland*, community service can only be imposed on juveniles aged 16 or older. Huge differences can be observed with respect to the maximum number of hours: The limit lies between 30 h in *Belgium* and 250 h in *Canada*, 300 h in Denmark, or even 400 h in New Zealand (see Dünkel and Lappi-Seppälä in this volume). The differences in legislation are partly due to different approaches and settings for community service orders: For example, in *Finland* a high number of hours (regularly only for young adults aged 18–20) will replace a sentence of up to 8 months of unconditional imprisonment (Dünkel et al. 2011a, p. 1647).

Different from community service is the sentence of "corrective labor," which can be found primarily in Central and Eastern Europe. Corrective labor may be imposed on a juvenile offender at the place of his/her regular employment for a particular length of time. In the course of corrective labor, deductions from the offender's earnings shall be made in favor of the state in the amount specified in the court ruling within a certain limit (UNICEF 2008, p. 30).

Many countries have successfully implemented creative and constructive measures such as social training courses (*Germany*) or so-called labor and learning sanctions or projects (the *Netherlands*), where the juveniles can learn to deal with their aggressive potential or where they can be trained according to their personal skills.

Some countries have introduced high intensive supervision or educational orders, e.g., special "centers" to which juvenile offenders can be sent for a few hours a day. In *England* and *Wales*, the attendance center order requires a young person to be present at a (usually) police-run institution on Saturday afternoons, where juveniles engage in physical education and other activities designed to inculcate a sense of discipline or social skills, for sessions up to a maximum of 36 h. In *Kosovo*, the court can commit a minor to a disciplinary center for a maximum of 1 month (for up to 4 h per day) or for a maximum of 4 days of a school or public holiday (for up to 8 h per day). In *France*, the law of 5 March 2007 created a new educational measure, *activities during the day* (*mesure d'activités de jour*), in which the juvenile is involved in vocational or school insertion activities at a public or qualified private institution or agency. In *Italy*, the magistrate can order the minor to carry out study or work activities in special working groups. Looking at the strict definition above it may be questionable if these measures fall into the scope of "community sanctions." However, because they are used in practice to avoid imprisonment or comparable forms of deprivation of liberty in predominant closed institutions, they deserve to be listed within this category. This is not the case for short-detention centers, where juveniles can be sent to for some days or weeks with the aim to deter the offender via a "short sharp shock." Even if some jurisdictions try to avoid "real" imprisonment with the introduction of this short-term incarceration, this however falls within the definition of deprivation of liberty as it takes the juvenile out of his social surroundings and endangers him with the negative aspects of stigmatization and other negative outcomes of imprisonment.

In many countries, supervision or surveillance orders play a special role as alternatives to imprisonment. In most countries, the Social Service or the Probation Service is responsible for the execution of these measures, but in some countries, juvenile offenders are usually supervised by the legal representative, normally the parents (e.g., "house arrest" in *Italy*). The aim is to avoid isolating the minor from his/her familiar and social surroundings in order to prevent disturbances to his/her personal development.

In *Finland* the Juvenile Punishment Order consists of work programs, supervision, and activity programs that aim to promote social adjustment, the person's sense of responsibility, and his/her social relations. There is a strict requirement that this sentence can only be issued in high-risk cases. This requirement may prevent net-widening effects as the Juvenile Punishment Order is definitively only applied in cases of repeat offenders who have already been sentenced to conditional imprisonment.

Contrarily, in *England and Wales* the introduction of the so-called referral order could well be having a net-widening effect, since it is more invasive and rigorous than the conditional discharge that it has essentially replaced in practice. "Action plans" or "referral orders" in contrast to the *Finnish* "Juvenile Punishment Order" follow a more punitive approach (Dünkel et al. 2011a, p. 1651 with further references).

In some juvenile justice systems, it is possible to confiscate a person's driver's license or to issue a prohibition from driving a vehicle as independent sanction or measure. In these cases the courts have to consider a certain susceptibility to unequal treatment, because there are special groups of juveniles or young adults who are more dependent on driving a car than others (due to work obligations, poor local infrastructure, etc.). There are serious reservations against the temporary withdrawal of a driver's license as a standalone sanction, especially if it is used for other than only traffic-related offences. The future integration of juveniles is often more difficult when their mobility is hampered. Therefore, educational efforts should be made to allow juveniles to participate in traffic in a responsible manner.

Social traffic training courses seem to be the appropriate answer, rather than excluding juveniles from mobility – particularly when they live in rural areas (Dünkel et al. 2011a).

Many juvenile justice systems provide suspended juvenile prison sentences that frequently go hand in hand with supervision by the Probation Service or a similar service with a social work approach. The "Continental European Model" of suspended sentences implies the imposition of a youth prison sentence, the execution of which is not immediate. Should an offender fail to meet the conditions of probation, suspension (as a last resort) can be revoked and the juvenile serves the term of imprisonment set at the first trial (e.g., in *Austria*, *Bulgaria, Germany*, or *Spain*). Other criminal systems like in the *United States* or the states of the *United Kingdom* introduced probation as a special sanction. This sanction is – as its name indicates – always connected with support from and control by the Probation Service. Contrary to the "Continental European Model," in these countries no term of detention is fixed. Therefore, where an offender fails to comply with his or her probationary requirements, the term of imprisonment is determined in a second sentencing trial. Here one finds another explicit example for how the same terms can mean different things in international comparative analyses: Many countries use the term "probation" to describe the "Continental European" approach of "suspended sentences with supervision."

Apparently no juvenile justice system has managed to totally avoid imprisonment or detention for juveniles. Many different forms of deprivation of liberty with corresponding institutions can be found worldwide, like youth prisons, detention centers, closed educational care, or schools "for juveniles with special needs" (see Dünkel and Stańdo-Kawecka 2011).

Especially researchers and practitioners from Central and Eastern European countries claim that oftentimes the laws in their countries do provide a lot of alternative sanctions, but the judges or prosecutors do not apply them. The reason mostly lies in the lack of infrastructure. The law might allow for victim-offender mediation – but if no organization or no service is available to offer mediation, this promising new approach will gain no importance in practice. Another problem related to the implementation of alternative sanctions is oftentimes that the question of funding is not responded or clear.

Efficiency of Alternative Sanctions

Research results on the efficiency of alternative sanctions are not as clear as for diversion (see above) and share the same problems with respect to the selection bias. However, there is some evidence that alternative sentences "work" better than liberty-depriving sentences with regard to recidivism, but the results request for differentiations: For example, Latimer et al. (2001) or Sherman and Strang 2007 showed that restorative justice programs can reduce recidivism, but there is a wide variation in their effects (see also the chapters of MacKenzie and Shapland in this volume). In general, international results show that positive effects rather are to be expected from programs comprising behavior therapy, oriented towards social learning, and tailored to the needs of the offender than from punitive sentencing and/or imprisonment (e.g., Murphy et al. 2010 with further references; MacKenzie in this volume). In contrast, programs focusing on discipline or deterrence through fear of consequences showed negative or minimal positive effects (Lipsey and Howell 2012, p. 517 with further references). Not surprisingly alternative sanctions have proven to be cost-effective compared to the immediate and belated costs of imprisonment (Aos 2006; UNODC 2007).

The Relevance of Diversion and Community Sanctions in Practice
