Oftentimes the country's "law in the book" does not correspond to the "law in practice." To investigate whether the countries use their manifold possibilities in sentencing juvenile offenders is not always an easy task: Apart from the general problems that arise when working with statistical data about crime and reactions to crime in a large number of countries (e.g., offences are in some countries registered in relation to the offence, in other countries in relation to the offender), the collection of data about sentencing in a juvenile justice system varies a lot. Sometimes an absence of reliable statistical records can be observed (see Goldson and Muncie 2006, p. 2), and even where statistical records do exist, practice of how crimes (and clear-ups) are recorded varies greatly (see Cavadino and Dignan 2006, p. 4). Thus, comparability can only be achieved through lots of interpretation. This makes an international comparison of statistical data difficult enough. The above-described wide variety of alternative sanctions in the different juvenile justice systems complicates matters further, and the different age groups that are covered by the different juvenile justice systems all over Europe additionally hinder comparability. With regard to the use of alternative sanctions in practice, it is possible to present some structural tendencies (for Europe see Dünkel et al. 2011b). Diversion has experienced a triumphant expansion in many European countries such as *Austria*, *Germany*, *Ireland*, the *Netherlands*, *Northern Ireland*, *Romania*, *Slovenia*, *Spain*, and *Sweden*, where more than 50 % and up to 70 % (Germany) or even about 80 % (*Northern Ireland*) of cases involving juvenile offenders are diverted. Other countries like *New Zealand*, *Scotland*, or *Sweden* regularly refer juvenile offenders to special institutions, conferences, or social services.

Many of those countries who do not make extensive use of diversion, primarily apply court-based community sanctions, e.g., in the *Czech Republic*, *Spain* (Catalonia), and *Switzerland*. *Slovenia* is an extreme case as in 98 % of court decisions educational measures are applied. The same is true for *Serbia* (95 %). In many Central and Eastern European countries, the suspended prison sentence is still the predominant community sanction, often because of a lack of infrastructure for other, more educational alternatives (e.g., in the *Czech Republic*, *Hungary*, *Latvia*, *Russia*, and *Slovakia*). The *United States* are infamous to sentence young offenders rather based on notions of punishment and accountability than rehabilitation, but alternative sanctions are still seen on the rise (Bishop and Decker 2006, p. 29).

Still there are countries where custodial sentencing is obviously seen as a promising answer to juvenile offending and of considerable importance in practice. *Bulgaria*, *Lithuania*, *Romania*, *Russia*, and *Spain* (particularly Catalonia) could be classified as belonging to this group. In *Bulgaria* traditionally 80–90 % of court disposals had been sentences to imprisonment, but after the law reform of 1999, the proportion of prison sentences for juvenile offenders dropped to “only” 47 % (2005). In *Romania* and *Russia*, however, compared to the Soviet time, decreasing proportions of custodial sanctions are evident. In *Spain* increasing numbers of custodial sanctions have been imposed only recently. As indicated above, some countries, mainly from Central and Eastern Europe, report that they have introduced a wide variety of alternative sanctions which are not in use to a greater extent in practice due to the missing infrastructure and unclear funding.

Conclusion

Juvenile justice systems reveal numerous possibilities to divert juvenile offenders from the criminal justice system or to offer them alternative sanctions. In many countries lawmakers and practitioners seem to be convinced that juveniles shall be saved from the socially detrimental outcomes of imprisonment, and the international recommendations which request the use of custodial sanctions only as a last resort demand the criminal justice systems to seek for effective alternatives.

As available research results allow for the gently conclusion that diversion “works” in means of the reduction of recidivism, data records on the efficiency of alternative sanctions do not allow for entirely clear positive conclusions. However, is it the correct way to ask the alternatives to imprisonment to proof their efficiency when we definitely know that imprisonment or comparable ways of custodial sanctions/measures are not at all adequate to reduce recidivism? Alternative sanctions violate human rights less than imprisonment does and are to be preferred due to the minimum intervention principle (UNODC 2007; see, however, to human rights issues in this area the chapter of Morgenstern and van Zyl Smit in this volume). And even if research shows that the cost-effective sanctions are not always superior in preventing reoffending, it is true that it is attractive for criminal justice systems to make a wide use of alternative sanctions from an economic point of view as well. This is why diversion and alternative sanctions should be extended or, where available, used more frequently in practice. Further research with random assignment or quasi-experimental design would be desirable to support the triumphal procession of alternatives to imprisonment in juvenile justice systems.

Overview

Homicide is frequently used as an indicator of violence. Its statistical superiority originates from the seriousness of this crime and from a broad availability of relevant data from law enforcement and criminal justice sources. Definitions of homicide for statistical purposes tend to focus on the intentionality and premeditation of death inflicted on a person by another person and exclude unintentional acts (non-culpable – manslaughter). Nevertheless, definitions of homicide across countries show marked differences, depending on penal codes and what is considered unlawful. Indeed, different cultures tend to criminalize different acts and behaviors.

A cross-country comparison of data based on "homicide," therefore, should take into account that the indicator includes the elements which are criminalized in each country and may exclude others, which are not.

Behaviors defined in this entry as "lawful killings" are acts with lethal consequences which are tolerated by some cultures and therefore do not appear in some homicide statistics. This is the case with "honor" killings, which are not criminalized in several countries.

The term "lawful killings" is used throughout the entry to indicate many different types of killings which in some contexts are considered "justified," or less serious from a legal point of view than plain killings. This may happen because of cultural, ethical, political, or legal reasons. Depending on countries and cultures, this could be the case with any of the following: killing in self-defense; killing in revenge or retaliation; killing as a result of provocation; killing to eliminate the pains of incurable patients; killing to defend the "honor" of a person or a family. In some cases, States take in their hands the authority to kill to defend the public order (legal interventions) or to punish someone for having killed someone else (death penalty).

This entry focuses on some specific forms of killings, namely, "honor" killings, dowry deaths, killing of persons accused of witchcraft, and mob killings, and how they relate with homicide concepts and categories. The current debate highlights two sides of the problem: on the one hand, in some countries/contexts these acts still fail to be recognized as forms of violence, sometimes even as crimes, depending on specific traditions and beliefs. Perpetrators of these killings frequently get away with committing these crimes, or enjoy more lenient investigations and sentences. On the other hand, in the countries where these killings are part of the homicide category, the seriousness of these acts may be insufficiently emphasized, and some advocate for perpetrators to be subject to sanctions harsher than those inflicted for homicides.

The entry also considers some examples of data collection or specific studies aimed at capturing relevant data to measure the extent of these phenomena.

What Is in a Label: "Homicide," Criminalization, Culture, and Human Rights

Criminalization

The United Nations Survey of Crime Trends and the Operations of Criminal Justice Systems (UN-CTS), through which UN Member States exchange crime and criminal justice statistical information, defines homicide as "unlawful death inflicted on a person by another person," which could be intentional or not.

What is considered "unlawful" depends on the definition of homicide in domestic criminal law and procedure, as well as the specific legal classification of homicide in each country. The degree of "unlawfulness" and the type of sanction foreseen for specific forms of killing vary across societies "to the extent to which different countries deem that a killing could be classified as such" (United Nations Office on Drugs and Crime 2011, p. 10).

According to Waters (2007, pp. xiii–xiv), "a murder is a social act that involves not only killing, but also judgment and evaluation by society at large" but, still, "[e]ach society has a process through which killings are described as legal justifiable homicide, illegal unjustified homicide (i.e. murder), or just plain killings. The process varies not only with a technical or legal capacity to assign blame but also with the capacity of a particular society to respond in a manner it defines as decisive and appropriate."

The process of defining a particular killing as "unlawful" involves the social context where the act is committed as well as the traditional and cultural codes of the victim and the perpetrator. Some killings may be considered as "lawful," mitigating circumstances invoked and, in some cases, impunity granted to the perpetrators, because the society at large does not consider they have committed any illegal acts. It can therefore happen that killings which are criminalized in some countries may not be in others. Boundaries for such considerations are represented by the cultural and sociological perception of specific issues such as honor, status distinctions, culpability, innocence and blame, as well as the state's approach to legitimate use of force.

In some societies, perpetrators of killings in the name of "honor" or "morality" still get reduced penalties and/or may be exculpated. This happens because the killing is "publicly justified" according "to a social order claimed to require the preservation of a concept of honor vested in male (family and/or conjugal) control over woman" (Welchman and Hossain 2006, p. 4). As sustained by Wolfgang and Ferracuti's "subculture of violence theory," within some specific ethnic groups and when the values of "honor" and "morality" are strongly perceived and shared in the society, one's capacity for violence may not only be admired but also perceived as an indispensable trait of personality.

Culture

The ecological approach to human development has been applied to criminology to explain the roots of violent crimes across different societies. It highlights the influence of community contexts in which social relationships are embedded and of the larger societal factors, such as cultural norms and attitudes, in explaining the level and dynamics of some specific forms of lethal violence.

Following this approach, homicide can be seen as a social and cultural construct in which the level of "seriousness" and "unlawfulness" can vary not only across different countries but also across different communities within the same country. Because of the way countries are composed and as a result of migration processes, most countries include a variety of ethnic and religious groups, even where a majority of the population shares the same culture.

The influence of culture is crucial to determine which behaviors are criminalized and which are not, reflecting majoritarian cultural values at the time when legislation is passed. Changes in culture and social acceptance of specific values could influence the consideration of specific behaviors as unlawful or not.

Analysis of the World Values Survey (WVS) results (a worldwide investigation of sociocultural and political change, conducted by a network of social scientists at leading universities on national samples of at least 1,000 people in 97 societies in all 6 continents) reveals that many of the basic cultural values closely relate with each other and can be grouped along two major cross-cultural dimensions, namely, one going from "Traditional" to "Secular-rational" values and one from "Survival" to "Self-expression" values.

Moving from "Traditional" to "Secular-rational" values reflects the shift from traditional religious values to secular-rational attitudes. Moving from "Survival" values to "Self-expression" reflects the shift of individual focus from personal and economic security to personal self-expression and quality of life.

Self-expression values, which focus on subjective well-being, freedom to express oneself, and quality of life, may give high priority to environmental protection, promotion of gender equality, tolerance of different characteristics and behaviors (such as migrants, foreigners, gays, and lesbians), and rising demands for participation in decision-making in economic and political life. Moreover, societies that rank high on self-expression values also tend to rank high on interpersonal trust. These types of society may therefore be much less tolerant with regard to any form of deprivation of life and crimes against the individual. Traditional and survival values stress the importance of parent–child ties and traditional family values and reject divorce, abortion, euthanasia, and suicide.

Many of these factors could have a strong influence on some types of lethal violence perpetrated within families. Societies and communities based on strong traditional values could also show higher levels of tolerance with regard to specific types of killings committed in the name of the family's respect and honor (Luopa 2010).

Nevertheless, as a result of globalization, there may be no clear-cut attribution of specific cultural values to specific countries. Therefore, different communities based on very different cultural values and norms may coexist within the same country.

Some types of killings could be "justified," or even considered "necessary" under specific circumstances, by some types of cultural values. More in-depth knowledge of causes and reasons for such considerations may allow preventing and contrasting these forms of lethal violence by focusing on their cultural roots.

Citizens of Western countries still tend to believe that "honor crimes" are a prerogative of Asian and African cultures, while this phenomenon is visibly increasing also in Europe (particularly in France, Sweden, the Netherlands, Germany, UK, and Turkey) and in the US (Council of Europe Parliamentary Assembly 2009, p. 6;

Chesler 2010, p. 3). For example, a recent study found a correlation between higher homicide rates observed in the US South and "culture of honor" as a heritage of herding carried out by early settlers, indicating that "the Southern propensity for homicide stems largely from the cultural background of the early Southern settlers alone and, in any case, is fully accounted for by the cultural background of early settlers together with current economic conditions and demographic characteristics" (Grosjean 2010, p. 20).

Indeed "honor" crimes disappeared from criminal codes in Europe (especially Western Europe) and in the US a long time ago and events of similar nature may be currently registered under the label of "domestic violence." However, their characteristics, motivations, and evolution are completely different. For example, "unlikely domestic violence, honor killings often involve multiple family members as perpetrators" (Chesler 2010, p. 3).

A proper assessment of the extent and distribution of "lawful" killings across different countries is necessary in order to properly prevent, contrast, and sanction them. In this respect, proper recognition of different cultural settings and understanding of how such data would be contributing in terms of policy relevance are necessary. For example, the proposal for an international classification of crime for statistical purposes currently discussed at the UN level considers the categories of *infanticide* and *euthanasia* separately as specific types of intentional homicide (UNODC/UNECE Task Force on Crime Classification 2011, p. 25).

Human Rights Perspective

It is important to place the present subject within the human rights law discourse. Human rights are universal and belong to every human being in every society. Therefore, human rights are generally regarded as neutral.

The issue of homicide has found its corollary in the discussion on "right to life." For human rights law, it is taken for granted that States are not only required to refrain from directly violating the right to life, but are also obliged to take positive measures to protect the individual from abuses committed by other individuals, that is to prevent such crimes and prosecute and punish the perpetrators. If initially, the right to life was envisaged as a protection from direct violations by the state, it has developed to impose on states obligations of prevention in relation to acts perpetrated by private persons.

Under human rights law, impunity for a homicide may constitute a violation of the right to life. Within the international human rights law system, only the regional legal framework, namely, the European Convention on Human Rights, specifies in a detailed way limitations on the right to life. In particular, it allows limitations of a right to life under certain conditions resulting from the use of force among others in self-defense from unlawful violence, "which is no more than absolutely necessary" (Article 2). Thus, domestic legal order may allow self-defense under conditions specified by the relevant human rights treaty. In reality, however, the debate on self-defense is much more complex.

Human rights consequences of the types of killings discussed here do not concern exclusively the right to life. Indeed, many of them involve different forms of discrimination, particularly on the basis of gender and age. A concrete case in point is "honor" killing, where discrimination can be dissected in the fact that laws applicable to this crime envisage an unequal treatment of men and women. Other potential human rights issues at stake may include nondiscrimination and equality as well as violations related to violence against women.

In practice a number of measures have been undertaken to address these issues. The human rights Treaty Bodies and Special Procedures of the United Nation's Human Rights Council have accumulated a considerable practice generally on the right to life but also as a result of the work of the treaty bodies in the context of protection of women and children against violence. General Assembly Resolution 59/165 of 10 February 2005 recalls the obligation of all States to use legislation to prevent and combat crimes in the name of honor with a view to their elimination. It also reminds the duty of states to investigate, prosecute effectively, and document cases of crimes against women and girls committed in the name of honor and punish perpetrators. Similar recommendations have been put forward in relation to the phenomenon of witchcraft. It is clear that human rights consequences of the "lawful killings" are expansive. International legal framework tends to prohibit all the practices falling under this classification by virtue of guarantees of the right to life and nondiscrimination both at universal and regional levels. States are therefore saddled with a duty to criminalize homicide and homicide-related practices.

Measuring the Extent of "Lawful Killings"

Measuring "lawful killings" requires broadening the perspective beyond criminalization to include the social and cultural aspects related to crime definition and reporting/recording behaviors and procedures. Available homicide statistics may be an adequate tool to measure the incidence of "lawful killings," depending on two levels of challenges to be considered. The first level is related to the general difficulty in comparing crime statistics across countries. The quality of statistics depends indeed on the efficiency of national reporting systems, so that discrepancies in homicide rates across countries may originate from different degrees of efficiency and/or from national-level underreporting or nonreporting issues rather than real differences in violence incidence. Moreover, homicide cases are recorded according to counting rules for statistical classification by using different units (persons, cases, victims) and time of registration (at the time of reporting/discovery of a case, at different point in time during investigation, etc.) so that direct cross-national comparison should be pondered over methodological limitations to avoid misleading interpretations of data.

The second level of challenges depends on operative definitions of crime for data collection and how they affect the classification of homicide data for statistical purposes. The general heading "homicide" may cover substantial differences in the patterns of violence. In general, definitions for unlawful killings vary depending on the involvement of legal concepts related to the perpetrator, such as motivation, involvement, responsibility, and planning. A recent study on European homicide research (Liem and Pridemore 2012) has identified two main elements in national definitions of homicide: intent and premeditation. The role of both intent and premeditation (and/or other aggravating circumstances) determines the criteria for statistical classification of unlawful killings. Differences in homicide statistics across countries, thus, depend also on whether premeditation, intent, and aggravating circumstances are defined by autonomous provisions (Liem and Pridemore 2012, p. 10).

Even when the characteristics of homicide appear clearly defined by criminal law, there are cases that may fit the definition but "there is less consensus on whether or not they should be comprised under the label homicide" (Liem and Pridemore 2012, p. 12). This refers in particular to the categories of attempted homicide, assault leading to death, euthanasia, and infanticide, which in some countries are not considered elements of homicide. Analysis carried out by the European Sourcebook of Crime and Criminal Justice Statistics about the compliance of European countries to the operative definition of homicide ("intentional killing of a person; where possible it should include assault leading to death, euthanasia, infanticide, attempts; but exclude assistance in suicide") based on inclusion/exclusion of such elements in national definitions of homicide demonstrates that only 13 countries out of 36 fully comply with the definition (Aebi et al. 2010, pp. 343–344). Liem and Pridemore (2012, p. 16) have reviewed elements included in national statistics on homicide in 34 countries also in relation to causing death by dangerous driving (which is included by 13), justified killing (10 countries), and nonintentional killings (17 countries). Altogether these findings help in understanding the impact of cross-national differences in defining homicide on the comparison of homicide rates across countries.

Consensus on what is to be considered homicide and what may be excluded, thus "excusable," depends on a wide range of cultural influences, which may go back to ancient customs incorporated in many countries. This includes a shared acceptance of which circumstances can be considered as mitigating the offense, and the concept of provocation.

While there may be a large consensus in considering mitigating circumstances for killings that occur on duty or to defend life, some cultures may consider legitimate or justifiable the killing of an unfaithful wife or of a child suspected of witchcraft. This generates several types of "lawful killings," for example, mob killings, witchcraft/ritual killings, "honor" killings, and dowry killings, for which some patchy statistics are available.

Table 1 provides some examples of available data and related sources on selected types of "lawful killings", without the ambition to provide a complete picture of their incidence and distribution. Data presented in the table are commented in the relevant sections below.

Mob Killings

The UN Special Rapporteur on extrajudicial killings and summary or arbitrary executions has described mob killings as "those undertaken by individuals or groups who take the law into their own hands. They are killings carried out in violation of the law by private individuals with the purported aim of crime control, or the control of perceived deviant or immoral behavior. Specific incidents of vigilante killings can most usefully be categorized along various axes – such as spontaneity, organization, and level of State involvement – and can be considered in relation to various characteristics – including the precise motivation for the killing, the identity of the victim and the identity of perpetrators" (United Nations 2009, para 51).

These forms of killing have been reported from all around the world to the extent that they do not represent an issue limited to any particular region but they should be considered a potential concern for all States (the report refers to cases recorded in Australia, Brazil, Benin, Burundi, Cambodia, the Central African Republic, Democratic Republic of Congo, Ghana, Guatemala, Guinea, Haiti, Hungary, Indonesia, Jamaica, Kenya, Liberia, Mexico, Nepal, Nigeria, Papua New Guinea, the Philippines, South Africa, Tanzania, Uganda). Victims are most frequently young males, who are often suspected of having committed theft, robbery, or murder, or being accused of witchcraft. The modalities of these killings vary from stoning to burning to lynching by the use of canes, machetes, or any type of weapon (Ng'walal and Kitinya 2006). For example, the Uganda Police provides statistics for *death by mob action*. Data refer to the number of investigations. Since each episode could involve more than a victim, the actual number of persons killed is probably largely underestimated (see Table 2). The increase observed in 2011 was commented by the police as "attributed to thefts, robbery, suspected witchcraft, and dissatisfaction with delayed/omission of justice" (Uganda Police Force 2011, p. 9).

Literature suggests that mob killings are likely to occur where the judicial system is weak and affected by corruption (United Nations 2009; HRW 2010). The summary executions of suspects by angry crowds would then be a response to the limited presence of the State which is perceived as lacking or delaying proceeding against criminals, causing public distrust towards justice and law enforcement institutions. Others point to inefficacy of formal and informal dispute resolution systems and the conflict between the cultural and the legal frameworks. Witchcraft is the typical example of a behavior frequently not recognized by courts, but strongly felt by the traditional culture of society. In these cases, the lynching of alleged witches is perceived by communities as an acceptable alternative form of administration of justice.

Killing of Witches

Another form of "lawful killings" related to belief systems is related to killing of persons accused of witchcraft. This practice is found mainly among tribal communities in Africa, Asia, and Pacific Islands and appears to target mainly women, elders, and children (United Nations 2012). Victims of witchcraft accusations are likely to belong to the most vulnerable

Lawful Killings, Table 1 Examples of data reported in literature on “lawful” killings (mob killings, witchcraft/ritual killings, “honor” killings, dowry killings)

Region	Country	Mob killings	Witchcraft/ ritual killings	“Honor” killings	Dowry killings	Source
Africa	Burundi	75 cases (2009)				Human Rights Watch 2010
	South Africa		132 plus unreported cases (2000)			Petrus 2009

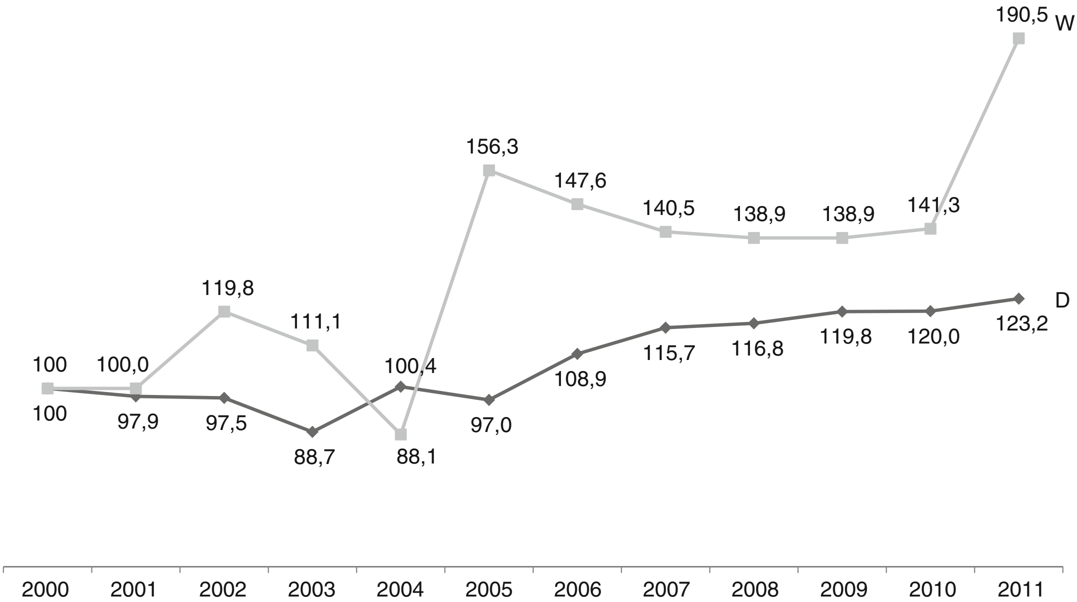
positions in society: elders and people with some form of disability or unique characteristics, such as albinos, for which they are discriminated (Dave-Odigie 2010). These killings often take place in post-conflict and post-disaster settings, or regions burdened by public-health crises. These phenomena are still frequent and rooted in lack of education and opportunities for protection of the weakest elements of the society. Such killings are captured by official statistics in India; according to the NCRB, 240 cases of witchcraft killings were reported in India in 2011. Reports of witchcraft killings have almost doubled over the last decade, with sharp increases between 2004 and 2005 and again between 2010 and 2011 (see Fig. 1). Figure 1 also shows an increase in reports of dowry deaths, the characteristics of which are described below.

Available statistics on ritual killings published by the Uganda Police Force account for 29, 14, and 8 ritual killings for 2009, 2010, and 2011, respectively (Uganda Police Force 2010, 2011). According to the Uganda Police, the remarkable decline in ritual killings was achieved against some serious challenges, including that many people still believe in witchcraft and practice rituals and some quack healers demand human body parts for their rituals (Uganda Police Force 2011, p. 10). Given the above-mentioned impact of underreporting and deficiencies in the recording systems, it may be estimated that the incidence of such killings is actually higher.

The most recent Report of the Special Rapporteur on violence against women notes the occurrence of 42 cases of killings of women due to accusations of witchcraft in Zimbabwe and other 500 in Papua New Guinea (United Nations 2012, p. 11).

"Honor" Killings

"Honor killings can be understood as an extreme result of the combination of patriarchal dominance over women and their sexuality, rigid behavioral norms, and the importance of honor for social relations in economically and socially backward, agrarian societies" (Oberwittler and Kasselt 2011). "Honor" killings exist as a mitigating circumstance in many countries/territories. For example, in 6 Mexican States out of 32 (Michoacán, Baja California Sur, Chiapas, Jalisco, Yucatán, and Zacatecas) "femicide for honor reasons" is sanctioned with sentences between 3 days and 5 years imprisonment (Chouza 2012). The perpetrators of such killings are convinced they act to safeguard the "honor" of men and families to remedy inappropriate behaviors or shameful incidents, most frequently committed by women and girls. The reasons behind killings include adultery, the choice of



Lawful Killings, Fig. 1 Trends of selected forms of "lawful" killings in India: dowry and witchcraft-related killings, 2000–2011 (index: 2000 = 100) (Source: NCRB 2000–2011)

a partner, seeking divorce, and also homosexuality, bisexuality, and transsexuality. In some cultures, when a woman is the victim of rape, this is considered to bring shame to the family and victims may be killed in the belief that this will restore the lost "honor."

The clash between different cultural values within the same country or the adaption of some members of one specific community to the "new" cultural context could be one reason for "honor" killings. These issues have been analyzed by Chesler (2010, pp. 4–5) in her study on 230 victims of honor killings in North America, Europe, and 14 countries in the Muslim world (Afghanistan, Bangladesh, Egypt, Gaza Strip, India, Iran, Iraq, Israel, Jordan, Pakistan, Russia, Saudi Arabia, Syria, Turkey) between 1989 and 2009. The results of this study demonstrated that "worldwide 58 % of the victims were murdered for behaving 'too Western' and/or for resisting or disobeying cultural and religious expectations." Indeed, since the process of adaptation to different cultures can be perceived as dishonorable by the victim's family, immigrant communities seem to be vulnerable to the problem of "honor" killings to the extent that the risk of being killed in the name of "honor" is higher among immigrant communities in the "Western world" than it is in the countries those immigrants come from (Luopa 2010, p. 7).

However, there is no specific cultural or local connotation for "honor" killings. For example, a study on 78 cases in Germany showed that "in 80 % of the cases an unwanted love affair by a woman, outside or after marriage, was the main reason for the homicide, whereas a desire to live an autonomous 'Western' lifestyle was the only central factor in very few cases." This study also demonstrated that "honor killings frequently occur in the context of 'arranged marriages', either when young women violate the norm that their partner will be chosen by the family or when married women want to escape from an unbearable relationship which is the consequence of an arranged marriage." Moreover, two-thirds of these homicides were committed in families of Turkish or Kurds origins, by first-generation immigrants, without Germany citizenship (Oberwittler and Kasselt 2011, pp. 2–3).

A recent study shows that in Italy, 127 women were killed by an intimate partner or former partner during 2010. Of these 70 % of victims and

76 % of offenders were Italians and the motives of killings included conflict in the relationship, men's unemployment, and "honor" (United Nations 2012, p. 8, Karadole and Pramstrahler 2011). The occurrence of "honor" killings in countries where "honor" crimes are not supposed to exist implies that these killings are likely to be recorded as domestic violence, thus limiting the knowledge on the real nature and extent of the phenomenon (see Table 1). The Council of Europe has expressed concern about the increase in the frequency of "honor" crimes and the insufficiency of adequate recording of their occurrence (Council of Europe 2003), which lead to progressive raising of awareness of the scale and the dynamics of the problem and reviewing cases (for example, a national review of nearly 120 cases of murder in the UK lead to the identification of at least 13 cases of suspected "honor" killings).

Reliable data are lacking. In 2003 the UN Population Fund estimated that approximately 5,000 women and girls are killed in "honor killings" every year in the world. According to the last report by the UN Special Rapporteur on violence against women, "honor killings take many forms, including direct murder; stoning; women and young girls being forced to commit suicide after public denunciations of their behavior; and women being disfigured by acid burns, leading to death" (United Nations 2012, p. 12;).

Dowry Deaths

Dowry-related killing is a practice related to religious and cultural traditions of South Asian countries; antidowry laws have been enacted in India (1961), Pakistan (1976), Bangladesh (1980), and Nepal (2009) (United Nations 2012). Indian criminal law describes dowry deaths as follows: "where the death of a woman is caused by any burns or bodily injury or occurs otherwise than under normal circumstances within 7 years of her marriage and it is shown that soon before her death she was subjected to cruelty or harassment by her husband or any relative of her husband for, or in connection with, any demand for dowry, such death shall be called 'dowry death', and such husband or relative shall be deemed to have caused her death" (304b IPC). The payment of dowry for marriages was abolished in 1961 with the Dowry Prohibition Act; however, the incidence of killings related to dowry is still problematic (see Table 2 and Fig. 1). According to the statistics provided by the NCRB, dowry-related killings have increased by 23 % over the last decade (2000–2011) and dowry represents the fifth motive for murder in India (see Fig. 1 and Table 2). According to official statistics, dowry is the fifth cause of murder. The distribution of these types of killings within India appears patchy as no cases have been reported in 10 regions, while dowry is the main motive for killings in Orissa and West Bengal, accounting for, respectively, 48 and 45 % of identified cases for which a cause was identified in 2011. Despite attempts towards criminalization of "honor" and dowry-related crimes, and removing the right to pledge for mitigating circumstances, these killings are still very frequently considered as "lawful." States responses to these forms of violence often fail in eradicating traditional customs, which frequently also involve police officers and judges who might use a discriminatory and gender-biased approach in applying the law (Luopa 2010).

Conclusions

In conclusion, "lawful" killings represent a hidden form of lethal violence, supported by some consensus and even by law in some cultures, which mostly affects women and other vulnerable groups in the society. A large portion of this violence goes undocumented, a part is recorded but fails to prominently feature in official statistics, which struggle in describing the extent of such phenomena. Beyond violence caused by the hand of husbands to wives, parents to daughters, relatives and community members to persons who are perceived as "different" or having infringed some (frequently unwritten) community laws, there are also many cases of suicides of women who are unable to find a way out from the psychological and physical abuses suffered.

Capturing the extent of these forms of violence faces both technical and cultural obstacles, as regards general limitations of comparative crime statistics and different understanding on what is to be considered "unlawful" death. In order to enhance the understanding of lethal violence patterns, more efforts should be paid in the recording and classification of the circumstances related to killings, such as, for example, a detailed description of the act/event, the alleged motives for the act, the characteristics of the perpetrator and the victim. The accuracy in the collection of this information is crucial in terms of analysis and policy making at both national and international levels.

Indeed, as stated by the UNODC/UNECE Task Force on Crime Classification (2011, p. 12), "a crime classification at international level, under the principle of exhaustiveness, should cover all possible acts or events that could carry criminal responsibility and sanctions anywhere in the world." Therefore, it would be challenging to understand how to provide an unique interpretation of "honor" killings, dowry deaths, or killing of witches, which in some parts of the world do not imply criminal responsibility and do not carry sanctions.

Left Realism

Walter S. DeKeseredy[1] and Martin D. Schwartz[2]
[1]Institute of Technology, University of Ontario, ON, Canada
[2]George Washington University, Washington, DC, USA

Overview

Left realism began in the 1980s in Great Britain partially as a reaction to those on the left who felt that talk about street crime was just a racist-fueled media scare. It was an attempt to take back the crime issue from conservatives with progressive socialist analyses and short-term solutions. Left realists felt that lower or working class members were not only the primary victimization targets of street criminals, but were being attacked from above by white collar, corporate and state crime. Rather than automatically rejecting all mainstream analysis, left realists have adopted elements of strain theory and subcultural theories to make their point that absolute poverty is not a cause of crime. Rather, relative deprivation that leads to dissatisfaction with the social order is the criminogenic factor. When such dissatisfied people lack the legitimate means to attain socially approved goals, they may join together in patriarchal, pro-violent subcultures that support their members in criminal activities and in actions to buttress their masculinities (e.g., respect, status) that have been battered by the economic policies of modern governments. The most recent left realist theories, then, which have spread from Great Britain to the United States, Canada and Australia, have added feminist and male peer support elements to concerns for progressive short term solutions.

Introduction

Left Realism can be located on a political map in comparison with so-called "right realism" and "left idealism." Right realism is a neo-conservative doctrine that attacks mainstream criminological theory, blames the working class for crime, and calls for extensive harsh measures to conduct a war on crime. It has been extremely influential in providing for massive increases in imprisonment at the same time that crime has gone down, and in convincing many police departments to engage in zero tolerance policing that targets minor annoying behaviors on the theory that this will reduce serious crime in its wake. Left idealism was a reaction to such policies on the political left that protested the implicit racism in discussions of street crime and crime statistics. Complaints about working class crime, they argued, as a media and conservative politician-induced scare tactic designed to create a moral panic that would justify oppressive actions against the poor. Rather, these theorists turned their attention on the horrific and harmful practices of corporations, the wealthy and the state.

Left realism, while actually agreeing with these varied claims of the idealists, felt that the primary focus on crimes of the powerful meant rather explicitly that crimes of the powerless or less powerful were being ignored. While idealists often argued that a concern with burglary, robbery and rape was a thinly disguised form of racism, the left realists instead argued that the predatory crimes of the underclass and the predatory crimes of the upper class squeezed the working class in the middle. As primary targets both from above and below, the working class suffers enormous victimization.

Background Description

Left realism had its beginnings in the United Kingdom in the 1980s, among theorists with extensive experience in decrying the power and actions of the law and the state, but partially as a reaction to various theorists on the political left. Jock Young, John Lea and Roger Matthews were upset that the debate over interpersonal and street crime only had two sides. The larger voice consisted of conservatives had no problem playing off racial fears to convince voters to fund a massive war on crime and an extraordinary increase in the use of imprisonment. The only other major voice came from the left, where many were arguing that any concern for street crime was a racist reaction against inner city and minority group members. After all, these people claimed (quite correctly) most of the money stolen in the world was obtained by white collar and corporate criminals, and much of the injury from illegal activities also tended to be caused by these same people through illegal code violations, lack of safety practices in manufacturing and agriculture, and substantial health threatening industrial pollution.

However, limiting the debate to only these two sides, left realists felt, meant that there remained a major problem. City people were hiding behind locked doors, giving up sitting on park benches or their front stoops to meet with their neighbors, not because they were scared that General Electric or Halliburton would rig bids to steal millions in public construction projects. Older people were dying in heat waves after nailing their windows shut despite not having air conditioning, because of a major fear, but certain not because they were afraid that a company like Union Carbide might release poison gas into the atmosphere, as they did in India in 1984. Rather, the crime problems that people in the working class are most worried about are a variety of acts committed by people at the lowest end of the socioeconomic ladder. They were afraid of rape, robbery, break-ins and burglary, assault and murder. In opposition to the left idealist notion that crime fear was a social construction based on racist and anti-minority thought, left realism took the position that working class people were being attacked both from above and below. While at the mercy of white collar and corporate criminals for a wide variety of crimes, they were also the primary victims of street criminals such as rapists, car thieves, purse snatchers and armed robbers. Thus, one of the most important early arguments of the left realists was that complaints that the justice system was racially biased (which it was), and that the legal system was put into effect to serve the interests of the upper classes (which it was), still masked the fact that the primary victims of both violent and economic crimes were lower class and working class people.

Worse, people in the general public had little respect for theorists of the left who belittled the problem of rape or robbery, the object of great fears on their part. Over 20 years ago, American left realist Elliott Currie laid out a crucial concern that completely ignoring intra-class street crime serves to "help perpetuate an image of progressives as being both fuzzy-minded and, much worse, unconcerned about the realities of life for those ordinary Americans who are understandably frightened and enraged" (1992: 91). Ignoring or belittling a concern for street crime and victimization meant handing over the entire issue of street crime to conservative politicians, who had no problem using it to their benefit first to elect their candidates, and then to implement a series of progressively harsher criminal justice policies, such as longer sentences, mandatory sentences, increased imprisonment, reduced defendant rights, and reduced services for rehabilitation or treatment.

These were not the only places where left realism diverged from common positions taken by other theorists of the left. In the first place, left realists made it clear that they did not feel any necessity to be constrained by the dictates of Marxist theory (Hayward 2010). This was not unique on the left, it was still controversial in some quarters when it became an essential element in left realist theory. While explicitly remaining on the left politically, they borrowed any ideas from mainstream criminology that they believed had merit or explanatory power that would advance or help their explanations of criminal behavior. It was much more common then (and to some degree today also) for left-leaning criminologists to reject wholesale any theories that originated in mainstream criminology, for no other reason than the place of their origin. Thus, it was a major divergence from the norm for left realism to adopt some mainstream ideas just because they seemed valuable or had explanatory power. For example, Lea and Young (1984) borrowed extensively from concepts brought into criminology by Robert K. Merton (strain theory) and Albert K. Cohen (subcultural theory). Lea and Young argued that although criminologists have commonly claimed that crime was caused by poverty, one cannot attribute or explain crime solely through absolute deprivation or extreme poverty. There are many cultures where people were much poorer than the poor of the United State or Great Britain on some objective scale (income, standard of living, purchasing power), but these poor people in other cultures as a group committed much less of what is usually termed street crime (e.g., burglary, robbery, rape, assault). Thus, just the state of having a small amount of money – poverty – was not a sufficient explanation for criminal activity. Rather, the left realists said, crime has its roots in "relative deprivation," or the extreme differences between rich and poor that leads to discontent with the political structure. This was particularly true in a context where such people do not see any hope of a political solution. Such people who are frustrated and disempowered by relative deprivation tend to band together – to come into contact with other disenfranchised people, and eventually form subcultures that in many cases encourage or legitimate criminal behavior.

State of the Art

There have been a number of more current left realist perspectives. For example, DeKeseredy and Schwartz (2010) have more recently argued that criminological subcultural development has been strongly influenced in recent years by the destructive consequences of conservative Chicago School economic policies, and by marginalized men's attempts to live up to the principles of hegemonic masculinity in an environment that offers few constructive outlets for men concerned with masculinity to act out this gendered behavior. Without jobs, social structures, organized sports or educational support, marginalized men sometimes find that crime provides one of the few bases of support available to them for gendered behavior. As newer conservative economic models predominate, jobs continue to be eliminated or exported and salaries for those that remain often cut drastically. Deindustrialization and the drastic decline in family owned farms provide more challenges to young men's masculine identity than ever before, and the addition of the effects of institutionalized racism no doubt contributes to the mushrooming presence of criminal gangs in the United States.

Although many or even most men who are economically marginalized engage in male to male violence as a form of compensatory masculinity, DeKeseredy and Schwartz (2010) argue that others, including those influenced by a patriarchal culture, engage in a variety of forms of male-to-female victimization as an effective means of repairing damaged masculinity (Messerschmidt 1993). Women abuse has become in many violent subcultures a legitimate way of maintaining patriarchal authority and control.

Other left realist perspectives have attempted to explain other problematics. For example, Gibbs (2010) argues that left realist theory is useful in attempts to explain terrorist acts. Economically disenfranchised men not only are a pool from which street criminals are drawn, but they also under certain circumstances join terrorist-supporting subcultures. Thus, she argues, current political "get tough" policies are likely to be just as unsuccessful in fighting terrorist acts as they have been in fighting street crime.

If there is one thing that separates left realist theory from other theoretical perspectives, and particularly mainstream criminology, but also a substantial portion of critical criminology, it is the importance to any theoretical discussion of short-term, anti-crime policies and practices. British left realism has been centrally concerned with criminal justice reform. In the early formulations, it received extensive attention for proposals dealing with the democratic control of policing. The goal was to implement a pattern of minimal policing in areas where local communities were opposed to a heavy police presence, and to oppose such policies as zero tolerance policing. The goal was to locate and implement police reforms that people in a district actually want.

Further, left realists understood that limiting policing suggestions to issues related to the criminal justice system would doom them to failure. To some degree, the criminal justice system is asked to clean up society's messes, caused by problems in low employment, bad housing, poor schools, and cuts in other city services. Left realists have argued that many of these issues are related to crime, and included in their short-term proposals for solutions things that might deal directly with these problems, such as an increase in the minimum wage, and affordable day care. To curb crimes of the powerful, left realists have called for such policies as the democratization of corporations, representative citizen patrols to study complaints of corporate crime, and enforcement of regulatory procedures and mechanisms. Still, this area has not been a major strength for left realists.

Controversies

One of the most potent critiques of left realism, especially in Great Britain, has been the attack that it does not offer a coherent theory of the state (Coleman et al. 2009). For the most part, this has been an attack on the 1980s concept of the Square of Crime, which focused on four interacting elements that can be visualized at the corners of the square: the victim, the offender, state agencies such as the police, and the public. Jock Young explained the relationship (1992: 27):

> It is the relationship between the police and the public which determines the efficacy of policing, the relationship between the victim and the offender which determines the impact of the crime, the relationship between the state and the offender which is a major factor in recidivism.

This conceptualization, it was often argued, was most relevant to inner-city street crime, and less relevant to a broader understanding of various societies and crimes being studied today. Further, the development of the state, while inherent in the square of crime, was not fleshed out in significant detail.

One recent attempt to deal with this problem came from Roger Matthews (2009) who published a refashioned left realist theory that prioritizes the state and views it as one of the "fundamental organizing concepts that provide the conceptual frameworks through which we make sense of the social world" (2009: 346). Matthews developed an extensive call for linking theory, method and intervention in his re-energized left realist theory. However, this is a single author, and certainly much more extensive work on this subject needs to be done.

As mentioned, one of the central features of left realism is that the main architects did not feel constrained by traditional leftist theory, and in fact took their influences from any source they felt advanced explanatory power or knowledge. Unsurprisingly, then, there has been considerable controversy on the left among those people who are in fact bound to traditional Marxist or other leftist structures, and find that any incorporation, integration or use of theories developed by mainstream theorists to be a sign of right-wing tendencies. Thus, to give just one example, Jock Young's use of such mainstream concepts as strain and subculture to attempt to harness a left realist explanation earned him what Yar and Penna (2004) no doubt viewed as their ultimate insult: he was labeled a "positivist" for using a politically incorrect theory. Others on the left have similarly attacked left realism for being politically incorrect, rejecting the claim of the left realists that they are engaged in socialist analysis. Similar attacks were made on left realists for their use of social science data collection such as victimization surveys to develop information to inform their theories.

Another strong controversy in England was the series of attacks from the left from people who believed that short-term solutions that fix problems with the police only plays into the hands of the state. After all, critical changes that make people happy with the police are proposed and implemented, then they will turn their attention away from other issues that might fuel their discontent. This improvement of such things as the police ultimately will only strengthen the existing power structure (e.g., Jamieson and Yates 2009). An alternative formulation of this notion is that the state, the legal system and the criminal justice system are all part of an overarching system that makes any efforts at reform end up as mere tinkering with the inside structures and ultimately meaningless. Left realists, on the other hand, have always believed that ignoring street crime and policing problems while waiting for the outcome of the eventual revolution means ignoring and condemning the women and men who are the victims of both street criminals and also the overzealous activities of some police forces. Any delay in making reforms just means that more lives will be destroyed by criminal or police action. Thus, one of the major contributions of left realists was to argue that it was possible to be a complete realist while at the same time pushing for left-oriented progressive solutions to crime. They argued that it is a legitimate goal to "chip away" at the capitalist patriarchal order, rather than holding off to await the success of some policy to overthrow all of society's structures. Of course, there are many who see this lack of support for the revolution as a serious flaw in left realism.

There have been sharp attacks on left realism for ignoring crimes of the capitalist order. Of course, those criminologists that were called left idealists here were heavily focused on corporate and state crime, and they obviously felt that such a focus was important. However, as also made plain in this essay, from the beginning one of the central tenets of left realist thought was that members of the working class were victimized from above (white collar, state and corporate crime) as well as below (street crime). Further, there were a series of important works those arose from left realist theory on corporate crime in the 1980s and 1990s. Yet, there is no question that the primary focus of left realists was to correct the imbalance of looking only at state and corporate crime, and ignoring the victimization of people by street criminals.

The other area of major attack on left realism has been the argument that some of the theorists have been gender blind. There is some truth to the argument made by some feminist critics that the earlier left realists, and even some of the more recent formulations, are not particularly sensitive to the unique problems of women, although certainly much left realist analysis affected men and women equally. It is not unfair to call them gender blind, as they were indeed more directed toward issues that were of major import to men, such as bar fights and police harassment of young men. Still, left realists were some of the first to recognize the importance of gendered issues. One of their most famous tools, the local victimization survey such as the Islington Crime Survey, was developed specifically to look at measures often seen as gendered, but ignored by most victimologists, such as fear of crime, avoidance behaviors on the streets, sexual harassment, and injury from rape or domestic violence. Still, early left realism was not strong on issues related to how patriarchal structures affected not only women's victimization but women's criminal patterns. More recently, left realists have begun to look at some of these issues, such as violence against women in a global perspective (Currie 2008), and a gendered subcultural theory that deals with violence against women (DeKeseredy and Schwartz 2010).

Although there are numerous places where left realist theories were used to study violence against women, one fertile area has been the study of male peer support as a form of subcultural behavior. In particular, men who use violence against women as a method of repairing damaged masculinities, or in an attempt to maintain and uphold patriarchal structures, often have subcultural male peer support for their actions. A variety of studies have found a relationship between the extent of male violence against women, and the amount of time that such men spend with their male friends, and indeed the amount of commitment these men have toward maintaining these male peer support structures. In particular, drinking alcohol with such friends seems to be related to such male violence. In a national representative sample of men, Schwartz, et al. (2001) found that men who went out drinking two or more times a week, had male friends who offered them support for the emotional abuse of women, and offered support for the physical abuse of women, were ten times as likely to sexually abuse women as men who did not have such friends or drinking patterns.

Another recent left realist approach was developed by Dragiewicz (2010), who attempted a left realist explanation for the existence of the anti-feminist fathers' rights group activism. Such groups have been active in arguing that women are as violent as men, and are politically active in fighting any legislation proposed to reduce violence against women, and in fighting attempts to make men responsible for child support payments. Dragiewicz argues that which such group members are not socioeconomically marginalized by the usual standards, but that they experience divorce and child support as socially and economically marginalizing. She argues that "These marginalized men seek out like-minded peers in person and online, drawing upon and adapting mainstream discourses around families, violence, and gender to reassert patriarchal masculinity in the face of challenges" (Dragiewicz 2010: 205).

Conclusion

Criminal justice policy and government policy in general have been trending further and further to the right over the past 30 years. Even in the United States when Democrats have been elected to the presidency during that time, they have engaged in policies that incorporated a great deal of the current conservative thinking, in what Elliott Currie has termed "progressive retreatism." In general, the entire fight against crime has been ceded to the right, and many observers on the left have limited themselves over the past 30 years to sitting on the sidelines and carping.

DeKeseredy and Schwartz (2012) have issued a call for left realists to do even more to publicize solutions, form alliances with progressive community agencies, and in general to translate left realist ideas into action steps. Currie (2008: 117) suggested that: "the choice is stark and simple: We can either let the process continue and fortify outselves against it, with more gated communities and more prisons, or we can decide that it is not tolerable and work to change it. What we cannot do is pretend we don't know it's happening."

Legal Control of the Police

Rachel Harmon
University of Virginia School of Law,
Charlottesville, VA, USA

Overview

Police officers are granted immense authority by the state to impose harm. They walk into houses and take property. They stop and detain individuals on the street. They arrest. Sometimes they kill. The problem of policing the police is how to regulate police officers and departments to protect individual liberty and minimize the social costs the police impose while allowing them to do what is necessary to achieve the ends of policing: reducing fear, promoting civil order, and pursuing criminal justice. Constitutional law as interpreted by the United States Supreme Court provides the most well-known check on police conduct. In addition, many other federal, state, and local statutes, constitutional provisions, court decisions, and administrative regulations also govern the police. Since federal constitutional law cannot alone ensure that the benefits of policing are worth the harms it imposes, this participation by other government actors is essential to ensure adequate regulation of the police. However, the laws that presently govern the police are not tailored to balance the individual and societal interests at stake when police officers act, they lack coordination, and responsibility for regulating the police is haphazardly allocated. As a result, the present array of laws that polices American policing does not promote law enforcement that is maximally effective and protective of civil rights.

Policing the Police Through the Courts and Constitution

Constitutional law has long been a central component of legal efforts to police the police. In the early 1960s, under the leadership of Chief Justice Earl Warren, the United States Supreme Court authorized broad new remedies for violations of federal constitutional rights by local police. First, in 1961, in *Monroe v. Pape*, the Court interpreted 42 U.S.C. § 1983, a long-standing civil rights statute, to permit civil liability for police officers who violated federal rights even if those officials also violated state law. Later the same year, in *Mapp v. Ohio*, the Court imposed the exclusionary rule on states, mandating that state courts – like federal courts – exclude from state criminal trials evidence obtained in violation of the US Constitution's Fourth Amendment ban on unreasonable searches and seizures. These decisions gave victims the incentive and means to challenge police conduct, the courts the opportunity to refine constitutional doctrine, and the police new reasons to comply with constitutional norms.

A few years after the Court broadened remedies for constitutional violations by the police, it expanded the constitutional standards that set limits on police conduct. In *Katz v. United States* and opinions following it, the Supreme Court eliminated technical requirements that previously limited the scope of the Fourth Amendment, reframed Fourth Amendment analysis to bring a broader array of police practices within the Amendment's ambit, and emphasized the importance of warrants issued by neutral magistrates as a means of ensuring the constitutionality of police activity. In *Miranda v. Arizona* and its progeny, the Court applied the Fifth Amendment privilege against self-incrimination to police interrogations and imposed prophylactic rules and an exclusionary remedy to protect suspects during those interrogations. Like *Katz*, *Miranda* subjected additional police activity to judicial review, and, like *Mapp*, the case increased incentives for litigation and police compliance. Through these cases, the Court firmly established constitutional law as an important mechanism for regulating the police.

While the Supreme Court's doctrines have changed over time, its enterprise has not. Since 1968, the Court has considerably loosened the constraints on the investigation and detection of crime imposed by the Fourth and Fifth Amendments, substantially narrowed the scope of the exclusionary rule, and, after expanding § 1983 liability significantly in the 1970s, contracted liability in more recent decades. Even so, the paradigm arising from the Warren Court doctrines remains largely intact. Courts continue to apply the Fourth Amendment and the *Miranda* doctrine to impose detailed regulations governing police searches of homes, cars, and people and defining the procedural protections defendants are entitled to during custodial interrogations. Moreover, courts continue to require exclusion of evidence and to permit civil liability to remedy civil rights violations by the police. Thus, courts continue to delimit and protect constitutional rights through criminal cases and civil suits.

Although the judicial enterprise of defining and enforcing constitutional rights is and has been for many decades an important means to regulate the police, the judiciary cannot alone effectively prevent police misconduct, and the policy problem policing presents is not limited to constitutional rights. Courts suffer systematic limitations that inhibit them from undertaking the complex analysis of policing that effective regulation of the police demands, and constitutional rights are structurally unable to balance fully the harm police conduct imposes against its beneficial effects. Consequently, while courts and the Constitution play an important role in regulating the police, the judiciary and the Constitution can never successfully address the problem of policing without assistance.

Fourth Amendment doctrine makes apparent some of the limitations of courts. When courts evaluate whether a police search or seizure is "unreasonable" and therefore unconstitutional, courts frequently must appraise the nature of the intrusion on the individual, the strength of the government's interest in the intrusion, and the consequences for law enforcement of various possible rules and then balance these interests against each other. Assessing these considerations requires courts to draw factual conclusions about matters beyond the circumstances of the particular case, such as whether law enforcement can achieve its ends by alternate means. Similarly, when courts seek to interpret the exclusionary rule and civil remedies to prevent future constitutional violations by police officers, they do so based entirely on the likely effects of doctrines on police behavior. Thus, in order to tailor remedies to encourage lawful police behavior, courts must make correct judgments about what police officers value and how particular legal decisions are likely translate into incentives for them.

Although courts can define and vindicate constitutional rights only if they are capable of these kinds of empirical assessments and predictive analyses, they are notoriously ill suited to these tasks. For one thing, courts act with grossly inadequate data. Most Fourth Amendment questions are contested in state criminal cases in which neither party is likely to have adequate resources or incentives to effectively litigate significant empirical questions, and even a civil plaintiff hoping for compensation after a violent arrest cannot cost-effectively litigate many matters. As a result, courts deciding constitutional criminal procedure matters have no effective mechanism to obtain evidence about policing and incorporate it into their normative judgments. Even when courts are able to engage in effective empirical analysis, they have little opportunity or ability to adjust a doctrine as the facts and social science underlying it evolve, since they are bound by precedent and limited to deciding questions presented by the cases before them. As a result, courts have systematic difficulty formulating effective rules for the police and structuring remedies to prevent constitutional violations.

Even if courts could overcome these barriers, a major objective of police regulation would still remain beyond their reach. Ideal regulation of the police would take into account considerations such as how harmful any police action is to individuals and communities, as well as how it compares to other means of producing law and order in terms of cost, harm, effectiveness, and officer safety, in order to specify the conditions under which the police should harm individual interests for the greater good. If courts regulate the police, then the legal problem of policing is limited to constitutional violations. Constitutional rights are, however, ill suited to balance societal interests in law enforcement and individual freedom.

While constitutional rights accommodate both individual and societal interests, the well-known process by which constitutional rights are articulated and enforced dictates that rights provide only a limited tool for shaping police conduct. First, rights establish only minimum standards for law enforcement. Because individuals assert rights against the police rather than the other way around, constitutional criminal procedure rights are always framed as a ceiling on government action. They thus cannot reflect a full analysis of how to balance competing interests when the police enforce the law and individuals are harmed. Constitutional criminal procedure rights are therefore commands about what the police *cannot* do, not standards for what they *should* do. Second, because constitutional criminal procedure rights set unbreakable rules for police officers in advance, the rights themselves must be defined to permit law enforcement flexibility in pursuing societal aims even if this produces societally undesirable results in individual cases. That is, the "ceiling" set by constitutional rights must be higher – more generous to law enforcement – than would result from a full balancing of the interests at stake. Third, because rights are held and enforced by individuals, usually with respect to specific actions, they do a poor job of measuring aggregate costs and benefits of law enforcement activity. Intrusions by the police, such as stopping and frisking pedestrians to investigate crimes, may be constitutionally justified, and yet when multiplied thousands or hundreds of thousands of times, those intrusions may impose total costs that substantially undermine the quality of life in a community in a manner the Constitution cannot check.

Because of these characteristics, constitutional rights are structurally incapable of encouraging law enforcement to impose only necessary, fair, and efficient harms on legitimate interests in privacy, equality, autonomy, and the like. Instead, the Constitution provides only a rough measure of whether police conduct is justified. Adequately protecting individual and communal interests therefore requires nonconstitutional regulation of the police.

The Law of the Police

Government actors other than the courts, using legal tools other than the Fourth and Fifth Amendment, already create, empower, influence, and constrain the police and those that supervise them. There exists a vast web of law regulating the police, which can be divided into four categories: (1) law that authorizes or restricts the conduct in which police may engage; (2) law that remedies, punishes, or disincentivizes violations of the first category of law; (3) law that governs the hiring, management, and organization of police officers and departments; and (4) law that governs the availability of information about police activities.

Laws Authorizing and Restricting Conduct

Laws that regulate police conduct come from sources ranging from the Vienna Conventions on Consular and Diplomatic Relations, which limit police power to engage in searches, seizures of property, and arrests involving diplomats, to a San Francisco ordinance that prohibits police officers from questioning people about immigration status. Federal law, for example, contains more than a dozen statutes that regulate police searches, electronic surveillance, and access to private information. These statutes range from Title III, which governs federal wiretaps, to the Health Insurance Portability and Accountability Act, which restricts law enforcement access to and use of medical records. And federal law concerning the police is not limited to statutes governing searches and seizures. For instance, the Illegal Immigration Reform and Immigrant Responsibility Act provides for local police enforcement of federal immigration law, and the Law Enforcement Officers Safety Act allows qualified active and retired law enforcement officers to carry a concealed firearm anywhere in the United States, even if forbidden by state law. In addition to federal statutes, federal constitutional doctrines outside of the Fourth Amendment and *Miranda* also affect the police. Most notable among these, the First Amendment limits the conditions under which police officers may make arrests for breach of the peace, disorderly conduct, and resisting arrest. As these examples suggest, federal regulation of police conduct beyond constitutional criminal procedure doctrine is considerable.

State constitutions, statutes, and regulations regulate police conduct even more extensively. Local police officers are created by state law, which both grants power to police officers and restricts its exercise. Thus, state statutes permit police officers to engage in community caretaking and criminal law enforcement, allow officers to use force, require police to aid citizens in limited circumstances, mandate that officers arrest suspects in domestic violence cases, and forbid the police from asking questions unrelated to the subject of a traffic stop, for example. State constitutional law frequently mirrors federal law, regulating searches, seizures, and interrogations, but it is often interpreted more expansively to control police behavior that is beyond federal constitutional protection. Local ordinances further restrict police conduct, limiting the use of race in police actions, for example. Finally, departmental administrative rules – often known as general orders – provide the most important and extensive guidance to police officers about what they must, may, and may not do.

Laws to Remedy and Punish Violations

The second category, laws that provide remedies for violations of rules governing police conduct, includes federal constitutional decisions mandating that evidence illegally obtained by the police be excluded from federal criminal trials, as well as federal statutes that authorize criminal prosecution and private civil suits against local officers, departments, and municipalities. States provide similar remedies that supplement federal law, including statutes authorizing criminal prosecution, evidentiary exclusion, civil suits for damages and other relief, and sometimes, structural reform of departments. States, municipalities, and departments themselves often also provide other remedies, without analogs in federal law, for police conduct that is unconstitutional, illegal, or merely against administrative regulations. For example, most states authorize revocation of police officer certification for some kinds of misconduct, which prevents officers from reentering law enforcement in the same state. Municipalities frequently provide for civilian review of citizen complaints concerning police misconduct. And internal administrative rules within police departments establish procedures for taking, investigating, and resolving complaints and impose punishments for misconduct, often through an internal affairs unit. These internal administrative processes provide the most commonly used remedy for misconduct and, in many jurisdictions, are also subject by local ordinance, charter amendment, or public referendum to external review by an auditor or civilian oversight agency.

Laws Governing Hiring, Management, and Organizational Requirements

Some of the most important rules and laws governing the police are laws that set standards for hiring, training, and managing police officers. Policing is usually organized as a function of municipal or county government. Municipal ordinances, city charters, and other local laws dictate matters such as who hires and fires the police chief and thus often who ultimately controls policy in the police department. Although local governments largely oversee policing, federal and state laws check local political control of the police.

For example, every state has a peace officer standards and training commission (“POST”) that establishes minimum qualifications and training requirements for police officers as well as a process for licensing them. These commissions control how old and how educated police officers must be and what kind of criminal record they can have, factors that may affect whether officers are likely to engage in misconduct. They regulate the hiring process for officers, including whether officers must pass psychological or medical screening. Finally, they are the primary determinant of what kind and how much training police officers receive.

Other statutes affecting the police may impose less direct standards of police qualifications. The Lautenberg Amendment to the Gun Control Act of 1968, for example, changed federal gun laws to prohibit individuals convicted of misdemeanor domestic violence crimes from possessing a firearm. The Gun Control Act also applies the prohibition to those subject to a restraining order or dishonorably discharged from the military. As a result of this law, individuals in these categories cannot serve as sworn police officers in most jurisdictions, even if state law would otherwise allow them to serve. These federal requirements also affect the size of the pool of potential officers as well as who becomes an officer and therefore constitute one more piece of the web of laws that governs American policing.

In addition to laws mandating qualifications and training for police officers, federal and state laws constrain the organization of police departments and management of police officers. Federal law imposes constraints on how police officers are hired and fired through statutes and constitutional doctrines that prohibit employment discrimination. In addition, federal laws influence how officers are managed: The Fair Labor Standards Act, for example, influences when police work, including how shifts are structured to address overtime thresholds, a major financial and administrative issue for police departments. And the Fifth Amendment privilege against self-incrimination has a distinctive application to government employees that frequently restricts the use of statements compelled in administrative investigations of police officers against them in criminal prosecutions. State law is even more significant. State laws and regulations do everything from authorizing the existence of police departments to setting qualifications for the police chief. And state employment and labor laws, including civil service law, collective bargaining law, employment discrimination law, and law enforcement officer bills of rights, constrain most employment decisions by police departments and local governments.

Laws Governing Information About the Police

Finally, a variety of state and federal laws govern the production and distribution of information about the police. Most of the information that exists about policing is collected by police officers themselves pursuant to internal administrative policies demanding that officers complete form reports about arrests, uses of force, responses to citizen calls, and other interactions with the public. Other information is produced by departmental practices, such as installing video cameras in police cars or recording interrogations that occur at the station house. While these local practices are driven in significant part by departmental concerns, external legal constraints on departments influence them substantially. Thus, a department may collect data about the race of those targeted in traffic stops to fulfill the terms of a lawsuit settlement over racial profiling or in response to a local ordinance or state law. Of course, internal policies and state and local law can inhibit as well as facilitate the production of information about policing. Some departments collect little information on daily police activities, a practice that makes scrutinizing those activities difficult. And some states have applied laws governing recorded communications to prohibit private citizens from videotaping or audiotaping their interactions with the police.

Access to information about police conduct is often similarly shaped by a combination of departmental practice, state law, and civil settlements. State statutes and rules of civil and criminal procedure mandate government disclosure of some kinds of information about police conduct and departmental policies to civil plaintiffs and criminal defendants. Open records laws permit the broader public to obtain some information about police departments and their management, and some states expressly require departments to collect and disclose data about policing. But many states restrict public access to data about police misconduct, either through generally applicable statutory exemptions, such as exemptions for personnel records or for criminal investigations, or through specific exceptions for law enforcement. As a result, for example, internal disciplinary records and citizen complaints against an officer can be unavailable to the public, limiting political accountability for police practices.

Weaknesses of the Law Governing the Police

As this description suggests, local, state, and federal actors use a range of legal mechanisms to influence policing. Although this participation by institutions other than courts and regulation outside constitutional law is essential to effective governance of the police, the existing web of laws governing the police has arisen organically, the product of institutional arrangements and historical contingencies that have little to do with policing. As a result, these laws are often not tailored to serve the end of making law enforcement worth its costs, they are inadequately coordinated to promote efficient police practices, and responsibility for generating and enforcing them is haphazardly allocated among governmental institutions. As result, American policing does not fully ensure that police effectively control crime, fear, and disorder without imposing unjustifiable and avoidable costs on individuals and communities, despite extensive legal regulation.

First, existing law is not well designed to promote harm-efficient policing and cannot easily be made to do so. Legal regulation of the police should promote harm-efficient policing – that is, policing that imposes harms only when, all things considered, the benefits for law, order, fear reduction, and officer safety outweigh the costs of those harms. Presently, harm efficiency is largely left to the local political process, and police departments and local and state governments already take it into account in governing policing, at least to some degree. Some departments adopt, for example, internal regulations forbidding consent searches without reasonable suspicion of criminal activity, even though constitutional law demands no individualized suspicion before requesting consent to search. Nevertheless, public debates about police practices often focus on whether their conduct is constitutional or effective, not whether it is harm efficient, distracting political actors from this central question. Moreover, in order for regulatory actors to promote harm-efficient means of policing, they must have a basis for doing so, including an account of what the relevant harms and benefits of policing practices are and empirical work measuring and comparing harms and policing efficacy. Presently, however, insufficient data is collected about policing to provide the basis for harm analysis, and no substantial academic literature exists that can be used to compare policing techniques with respect to both effectiveness and harm. Until regulators mandate the necessary data production and collection, and scholars lay the conceptual and empirical groundwork for understanding harm efficiency, institutional actors will be stymied in their efforts to regulate the police toward this end.

Second, existing laws regulating the police interact in ways that may undermine the goal of ensuring that policing practices adequately protect individuals and communities. For example, courts have tailored civil remedies for unconstitutional policing to encourage departmental reforms likely to reduce misconduct, such as careful hiring practices and adequate training and supervision of police officers, but these judicial efforts cannot achieve their aim because state collective bargaining and civil service laws create countervailing incentives discouraging departments from implementing the same reforms. In a majority of states, civil service laws heavily regulate the treatment of public employees, including police officers. These laws allow costly legal battles when police departments demote, transfer, or fire an officer and thus impose significant additional costs on police departments trying to manage officers who commit misconduct. They therefore disincentivize precisely the same conduct that civil remedies are intended to encourage. Collective bargaining rights similarly deter department-wide changes intended to prevent constitutional violations. In states that mandate collective bargaining before a department changes its disciplinary process or promotion standards, departments face significant additional costs for increasing internal accountability for police officers, a key means of preventing police misconduct.

As these examples suggest, departments enter a legal minefield whenever they take employee action or make new policies. This is not to say that we should eliminate civil service laws or collective bargaining: These laws have complicated goals and effects that go beyond facilitating harm-efficient policing. Nor does it mean that civil remedies should not be used to incentivize reform. But until courts and legislatures consider the interactions among the myriad laws governing the police, legal efforts to regulate the police may not promote effective reform.

Third, although police departments, local governments, states, and the federal government all influence police conduct, as the example of the courts suggests, government institutions are not equally well suited for the tasks governing the police demands. Courts cannot, for example, determine the consequences of the real-world trade-offs between effective policing and individual freedoms that policing puts at stake. Regulating policing effectively therefore requires allocating institutional responsibility for regulating the police and choosing the best legal mechanisms for influencing police conduct. The existing allocation of responsibility and existing choice of mechanisms are unlikely to serve the goal of effectively regulating the police because they reflect historical and political contingencies rather than a considered choice about the best institutional approaches to regulation of the police. Unfortunately, reassigning responsibility for regulation to institutional actors with adequate capacity and incentive to ensure that the communal benefits of policing are worth its costs to individuals and communities cannot be done easily.

Police departments have enormous influence over the conduct of police officers, but they are nevertheless imperfect regulators of policing. Departments have difficulty engaging in broader causal analysis about how effective and harmful alternative law enforcement practices are. Moreover, police chiefs and local political actors lack sufficient incentive to ensure that individual interests are adequately vindicated in policing, because they are usually better rewarded for maintaining order and reducing crime than for protecting civil rights of the minority of residents targeted by police activities. Thus, police departments and local governments cannot be counted on to produce consistently harm-efficient policing.

Although states are critical in shaping police conduct, much of state regulation governing the police is aimed solely at ensuring law enforcement effectiveness rather than balancing effectiveness and civil rights. In addition, state law provides numerous mechanisms for remedying misconduct, but they seem uniformly weak. This state of affairs suggests that state actors have inadequate incentives to promote harm-efficient policing.

Thus, while local and state actors already promote civil rights to some degree and they could do so more, they likely cannot be expected to take adequate account of individual constitutional rights and constitutional interests that extend beyond them: They cannot and do not have sufficient reason to reach the appropriate trade-offs between effective policing and individual freedoms.

By contrast, federal actors can engage in thorough analysis about how to reduce harms to constitutional interests while engaging in effective law enforcement and may be able to encourage local and state action toward these ends. Congress already plays an active role in regulating the police. It has long regulated some police uses of private information deferentially regulated by the Court. It funds the Department of Justice's significant civil rights efforts, including criminal prosecution of abuses by local law enforcement, funding for nonprofits that promote civil rights in law enforcement, and technical assistance to police departments. And it is responsive to change: After court decisions restricted federal civil suits for injunctive relief against police departments, Congress passed 42 U.S.C. § 14141 authorizing the Department of Justice to bring suits for equitable remedies against police departments that engage in a pattern or practice of unconstitutional misconduct.

Though federal actors are capable of regulating the police, congressional attention to civil rights is piecemeal and irregular, and federal intervention in policing has long been politically controversial. Congress has not yet required even mandatory data reporting for local police departments, though the need for such data as a foundation for the regulation of the police is obvious, and though this could easily be carried out by existing Department of Justice components. More comprehensive regulation of the police, including the administrative analysis of the consequences of alternative law enforcement practices for individual and societal interests, is therefore unlikely and in any case may not justify its costs. As this analysis suggests, reaching a combination of government institutions with both the ability and the motive to regulate police officers and police departments effectively represents an ongoing challenge to efforts to ensure that police practices are carried out to promote law and order while minimizing harm.

Conclusion

The police have always represented both hope and harm. They contribute to social order but also threaten it. Though courts can judge the moral and historical imperatives that underlie constitutional rights, they cannot assess conditions on the ground or predict the consequences of legal rulings on civil rights and law enforcement. The project of defining and protecting constitutional rights inevitably requires input from other institutional actors. Although other government institutions have long participated in regulating the police, these efforts cannot approach ideal regulation of the police. First, political actors lack sufficient incentive and an adequate basis for determining when law enforcement should harm individual interests for societal ends, given the risks to human dignity and the costs and benefits of law enforcement activity. Second, because existing efforts to regulate the police operate without coordination, the multiple efforts to govern policing sometimes conflict and undermine rather than reinforce the policy goals of balancing the costs and benefits of law enforcement. Finally, various political institutions face structural limitations and incentives that may be incompatible with effective regulation of the police. Future efforts to improve law governing the police must address these substantial challenges.

Overview

Public police are now one part of a network of law enforcement that includes private police and security, regulatory agencies, businesses, schools, and private individuals. Police have always formed partnerships to help them in responding to, and preventing crime, but increasingly these partnerships are moving beyond joint approaches to solving community problems. Third-party policing is an approach that rests on the use of legal levers available to non-offending third parties under regulatory and private law frameworks. There has been a blurring of these frameworks in recent times, so that many noncriminal levers are available for police and their partners to use for crime reduction purposes. The types of levers commonly used in third-party policing are discussed, along with the types of crime and disorder problems which they have been used to address. Challenges to the broader use of regulatory frameworks are overviewed, and future directions and especially the need for further research, are suggested.

Introduction

Third-party policing (TPP) occurs when police form crime control or prevention partnerships or networks with non-offending third parties (Mazerolle and Ransley 2005; Buerger and Mazerolle 1998). Police partner with a range of state and non-state agencies, private organizations, and individuals to focus on crime reduction or prevention goals. Typical partners include housing agencies, property owners, rental agents, health and building inspectors, private businesses and professionals, parents, schools, and private security providers. Typical crime problems at which TPP has been directed include illicit drugs, alcohol-related violence and disorder, young offenders, and property offenses.

The distinctive feature of TPP, compared with other innovative and proactive policing strategies such as problem-oriented policing (POP), is its placement within a legal and regulatory framework. This framework enables police to use the authority and powers of their voluntary, co-opted, or coerced partners to help control crime problems. In particular, police gain access through their partners to a range of criminal and noncriminal legal mechanisms or levers. These levers include civil regulation and remedies, along with contractual and tortious rights, which can greatly extend the reach of police (Mazerolle and Ransley 2005, 2006). Unlike POP, TPP goes beyond merely "harnessing the crime control capacities of third parties" (Cherney 2008: 631) in identifying and developing responses to crime problems. It draws on developments in regulatory theory and practice that allow police to use new techniques, institutions, and mentalities of control. Police become part of the trend to regulatory justice (Crawford 2003, 2009) that can extend and improve upon traditional criminal justice responses. In its focus on problem places, people, and activities, TPP also brings together opportunity and place-based theories of crime and crime prevention with innovative policing strategies, and gives police a new role as regulators of crime (Eck and Eck 2012; Mazerolle and Ransley 2012).

One appeal of TPP for governments and law enforcement is that non-offending third parties assume, or are made to assume, some of the responsibility and costs of controlling and preventing crime. Especially in times of fiscal restraint this has economic advantages (Eck and Eck 2012), as well as giving police access to new levers and remedies, such as civil orders and injunctions, property closures, parental responsibility contracts, and asset forfeiture schemes. These levers can be directed at the underlying causes and supports of crime, and can have a preventive and intelligence-based focus rather than the purely reactive responses of most traditional policing practices. A second appeal of TPP is that by relying on noncriminal measures, some of the restrictions and protections of the criminal justice system such as high evidentiary standards and burdens of proof, can be avoided (Mazerolle and Ransley 2005; Crawford 2009).

The discussion below canvasses these issues, beginning with an analysis of the regulatory and legal context of TPP. It compares TPP with traditional approaches to crime control and prevention, and then discusses in detail the legal frameworks most used in TPP. The discussion moves on to some of the key issues and debates arising from the topic, including the potential impact of TPP on increased criminalization and net-widening, and for inequitable and discriminatory policing. The final comments address future directions for TPP and the need for more evidence-based research on what levers work best and when, and why this is so.

Fundamentals

Context: Regulatory Approaches to Criminal Justice

Third-party policing approaches are part of a broader shift in regulation and governance which has occurred in many societies over the past 40 years, and which has led to new responses to crime along with many other social and economic problems (Feeley and Simon 1992; Ericson and Haggerty 1997; Garland 2001; Ericson 2007). The new approaches to governance have involved a move away from state sovereignty and control to networks of power (Braithwaite 2000), a diffusion of responsibility (Garland 2001), and an expectation that non-state actors and individuals must contribute to responses and solutions. Regulatory theorists see this as a shift from state-centered command and control to new modes of pluralistic, networked, or nodal regulation (Burris et al. 2005).

Central to this shift has been the rise of risk as an organizing concept, so that the new forms of regulation rely on notions of risk assessment, identification, and analysis, rather than on general rules applied equally to all regulated individuals (Sparrow 2012). Feeley and Simon (1992) applied this concept to criminal justice, arguing that it has seen a shift from a focus on individual offenders, the assignment of blame and responsibility, and goals of treatment and rehabilitation. In their "new penology," the focus instead is on actuarial classifications of risk and dangerousness and reliance on selective surveillance and incapacitation to reduce crime opportunities (Willis and Mastrofski 2012). The shift from old to new penology is also a shift from seeing crime as deviance to crime as normalized, and from ideas of treatment and rehabilitation to the management of risk (Garland 2001).

At the same time, the development of the new regulatory state (Braithwaite 2000) has led to a "proliferation of new administrative agencies as well as an enormous expansion in private policing. Regulatory and private policing entities are part of a new division of policing labour with the public police" (Ericson 2007: 387). Regulatory styles have also shifted, from a focus on command and control and detailed prescriptions and inspectorate models, to new forms of responsive and smart regulation tailored to particular industries and contexts, and in which risk identification and management again plays a central role (Mazerolle and Ransley 2005).

As a result of these trends to risk, regulation, and pluralization, public police have now been joined by regulatory agencies with many police-like powers, and private policing organizations, in overlapping networks of security. Policing is now provided by "a growing plethora of governmental and non-governmental providers" (Stenning 2009: 22; Jones and Newburn 2006). Contemporary policing is marked by diversity, complexity, and a "messy reality" where rather than smart and responsive regulation playing a less coercive role than traditional law enforcement, tools of intervention have become increasingly interchangeable and overlapping (Crawford 2006: 469). In this environment the role of public police has changed, so that policing services are increasingly provided by networks of public, private, and welfare agencies, with public police as one node of the network (Ransley and Mazerolle 2009), albeit a coordinating or anchoring node (Ericson and Haggerty 1997; Crawford 2006).

In addition to these new regulatory approaches to criminal justice and policing, new theories have been developed about crime control and prevention. The rise of crime opportunity theory and its focus on places, patterns, routine activities, and rational choice has led to recognition that regulation and regulatory measures or instruments have a central role to play in criminal justice and crime control (Eck and Eck 2012; Ayling et al. 2008; Mazerolle and Ransley 2012). TPP provides an organizing framework for how this occurs, and highlights the role of police in developing and implementing new regulatory approaches to crime control and prevention.

As discussed earlier, TPP occurs when police persuade or coerce non-offending partners into assuming crime reduction or prevention responsibilities. As such, police form formal or informal partnerships directed at specific crime problems. The development of police partnerships is not new – as Smith and Alpert (2011) point out, Sir Robert Peel's eighteenth-century "new police" rested on a community partnership model. Contemporary versions of community policing also rely heavily on policing as a series of collaborative partnerships (Willis and Mastrofski 2011; Skogan 2011) focused on identifying and solving community problems. The "joint policing" model involves "collaborative, proactive, preventive actions to reduce or remove crime and to protect and secure spaces and places in lieu of traditional reactive models" (Smith and Alpert 2011: 136). Similarly, problem-oriented policing approaches often focus on police working with community members to identify problems and their solutions. What sets third-party policing apart from these other strategies is the way in which it involves police harnessing not just partners but their formal and informal legal powers over offenders or potential offenders. These partnerships occur within a context of changing legal frameworks.

Changing Legal Frameworks

The messy reality of policing now draws on a range of legal frameworks, in addition to traditional criminal justice models. The major distinction between these frameworks has been in their goals and targets – traditionally criminal law has focused on detecting and prosecuting those who commit morally wrong offenses, while regulatory and private law measures have focused on governing legal business and private activities (Mazerolle and Ransley 2012), mainly using negotiation, inspection, and administrative and civil sanctions, as shown in Table 1. As an organizing and analytical mechanism, the different categories of law are described by reference to their goals, attributes, targets, methods, outcomes, actors, and styles (see Mazerolle and Ransley 2005: 67–69; Cheh 1998).

In the context described above, where trends in governance, risk, and pluralization have broken down traditional categories, there has been a blurring of legal frameworks. As shown in Table 2, criminal law now draws on regulatory and civil law mechanisms, and vice versa. Mazerolle and Ransley (2005: 67) refer to this as a convergence of legal frameworks. In this environment, criminal law makes use of civil processes and remedies, while in both regulatory and private law serious misbehaviors are criminalized. The major implication of this convergence in legal frameworks has been to facilitate the use in criminal law enforcement of a large range of sanctions and processes outside the traditional criminal justice system, such as civil remedies and administrative sanctions. The principal facilitator of this convergence has been the concept of risk. Proactive policing strategies have focused on risky places (i.e., hotspots of crime) and people (i.e., repeat offenders, particular groups), while regulators have adopted self-regulation approaches based on risk assessment (Sparrow 2012). The main effect of this convergence can be seen in Table 2 in that there has been a blurring of targets, methods, outcomes, actors, and styles across the different categories of law, in contrast to the relatively clear-cut divisions shown in Table 1.

The rise of TPP is a reflection of this convergence, in that it enables police to draw on a much wider variety of legal levers than was previously available to them. The next section discusses some of those levers.

Legal Levers for Third-Party Policing

Despite this convergence of legal frameworks, it is important to understand the source of law that underpins each legal lever used in TPP, because this source affects the nature, extent, and limitations of the lever. Table 3 summarizes the levers commonly used in TPP and their main features. For each type of lever, there is a description of the source of authority (whether legislation, regulation, contract, or tort), the extent to which the lever applies (i.e., generally or targeted), and the types of legal outcomes that can arise. The final column indicates the range of non-offending third parties who are utilized by each lever to achieve crime control or reduction benefits, through the co-option of their legal authority.

Table 3 is not a comprehensive list of legal levers available, but it does illustrate the range and breadth of measures, and of potential third parties, that can be used in TPP. Mazerolle and Ransley (2005) give comprehensive examples of the ways in which each of these levers has been used across different jurisdictions, in the two broad areas of controlling and prevent drug problems, and other forms of crime. For drug problems, laws and regulations focused on premises (e.g., crack houses, methamphetamine laboratories, derelict buildings), and accompanying nuisance abatement civil suits, have been used in many places in the United States and Australia. These strategies involve police partnering with city and state inspectors and sometimes neighbors, to require property owners to become more responsible for controlling activities on their premises that lead to drug problems. A range of civil sanctions can be used (fines, injunctions, rectification orders, loss of license or permit, forfeiture) to persuade or coerce these third parties to assume crime control responsibilities. This not only shares responsibility but shifts some of the costs associated with crime reduction to third parties. The use of civil levers removes the need

Legal Frameworks for Third-Party Policing, Table 1 Traditional categories of law

Focus	Criminal	Regulatory	Private
Goal	Detection, prosecution, punishment, rehabilitation of offenders	Orderly conduct of economically desirable activities	Dispute resolution in private financial and family activities
Activities	Morally repugnant offenses	Business activities	Commercial and domestic interactions
Targets	Individual offenders	Businesses	Private individuals and groups in dispute
Methods	Investigation, arrest, criminal trial	Conciliation, negotiation, self-regulation, inspection, limited prosecution	Private court action to enforce rights under contracts and tort
Outcomes	Fines, incarceration	Penalties, rectification orders, license revocation	Damages, injunctions, specific performance
Actors	Police, prosecutors, courts, correctional staff	Regulatory agencies, local governments, industry associations	Individuals in private relationships, civil courts
Style	Guilt and punishment for individual offenses	Creation of business obligations, consequences enforced by sanctions	Creation of private obligations, consequences enforced by sanctions

for police to gather evidence to a criminal standard of proof, to prove individual responsibility for breaches, and often also involves a reversal of the burden of proof, so that property owners must show they were not aware of criminal activities to avoid responsibility. Other drug problem-related forms of TPP include monitoring and reporting schemes, such as when doctors, pharmacists

Legal Frameworks for Third-Party Policing, Table 3 Legal frameworks for third-party policing

Extent of application	Legal outcomes	Types of TPP levers and interventions	Third parties targeted by the intervention
Statutes			
General or a specified population, e.g., liquor retailers, parents, gangs	Criminal or civil action leading to criminal or civil penalties, or administrative measures	*Orders to control behavior*, e.g., antisocial behavior orders; truancy and gang orders, child welfare and domestic violence orders, mental health and vagrancy laws	Parents, schools, non-offending gang members, institutions and shelters, housing authorities
		Movement and association limits, e.g., curfews; traffic, move-on, and crowd control powers; probation and community corrections conditions limiting criminal contacts	Parents, local councils, probations/corrections staff
		Conduct licensing, e.g., alcohol, firearms and prostitution licensing, pawn/second-hand shops and dealers	Retailers, service providers
		Formalized surveillance, e.g., offender notification, probation and community corrections reporting conditions	Probations/corrections staff
		Property controls, e.g., drug house and rave site limits	Property owners, rental agents local councils
		Mandatory reporting, e.g., methadone prescribing, cash transactions, chemical sales, child and spousal abuse	Doctors, pharmacists, health funds, banks, retailers, schools
		Civil forfeiture, e.g., assets gained through crime, "hoon" cars	Banks, vehicle licensers
Regulation/subordinate legislation			
General, within a specified area, e.g., local council or housing authority area	Criminal or civil action leading to criminal or civil penalties, refusal of consent, eviction, rectification orders, property forfeiture or confiscation	*Orders under regulatory codes*, e.g., building, fire, health, safety, noise, animals, liquor licensing, environmental, public housing, parking, venue by-laws and codes requiring closure, rectification, removal of hazards, or restrictions on use	Property and business owners, local councils, housing authorities, regulatory agencies
		Product and service standards, e.g., requiring vehicle immobilizers	Manufacturers and service providers, standards associations
		Controlled zones, e.g., begging, busking, drug and alcohol free areas, limits on street prostitution	Local councils, retailers and business owners, prostitutes
Contract			
Specific – parties to a contract	Civil action for specific performance, damages or injunction, non-renewal of contract, eviction, loss of bond	*Enforcement of conditions*, e.g., property use and maintenance in private housing and commercial leases; crime reduction measures in service provision contracts, e.g., lighting and security	Property and business owners and associations, housing authorities

(*continued*)

Legal Frameworks for Third-Party Policing, Table 3 (continued)

Extent of application	Legal outcomes	Types of TPP levers and interventions	Third parties targeted by the intervention
		standards in commercial car parks	
		Incentives, e.g., insurance bonuses and rebates for crime prevention measures	Landlords, insurers
Tort			
Specific – duty of care owed	Civil action for damages or injunction	*Actions for nuisance, trespass, or negligence*, e.g., against noise, physical disorder, pets, physical access, breach of duty of care, misfeasance	Landlords, local councils, housing authorities, liquor retailers, licensed venues

or chemical manufacturers, wholesalers and retailers are required to record and report transactions involving drug precursors. Such schemes co-opt these third parties into systems of surveillance and sources of intelligence for proactive policing.

For other nondrug crimes, the most widespread use of TPP has been in schemes designed to reduce or prevent antisocial behavior and disorder. The most comprehensive of these schemes is the antisocial behavior agenda introduced in Britain from 1998 onward, which featured a range of civil orders and contracts imposed to control offending and pre-offending activities. Crawford (2009: 817) identifies 18 new tools used in this scheme, including civil orders (e.g., antisocial behavior, drug intervention, parenting, individual support, child curfew, dispersal, drink banning orders) and contracts (e.g., acceptable behavior, parenting, tenancy contracts). All of the measures are civil, involving a mix of regulatory and contractual techniques, but breach of most leads to a criminal sanction. The scheme has been much criticized, and while the new government elected in 2010 announced its intention of withdrawing the system, its most recent proposals suggest that many of the new tools will be rebranded and retained (see The Independent, 23/5/2012). While the British antisocial behavior scheme is comprehensive, many of its individual components are seen in other jurisdictions. In particular, measures directed at parental responsibility for juveniles, such as truancy and curfew orders, are common in Australia and some parts of the United States (see Mazerolle and Ransley 2005). Most jurisdictions have anti-vagrancy and begging regulations, and several Australian states have introduced civil measures directed at alcohol-related violence (see Mazerolle et al. 2012). These types of levers induce third parties, whether parents, schools, club-owners, or city administrators, to accept responsibility for reducing crime and disorder using civil or private law measures available to them.

As discussed above, increasingly, this type of approach is coupled with crime opportunity approaches that seek to identify and reduce facilitating environments for crime. As Eck and Eck (2012: 308) note, “rather than viewing crime as simply a matter between offenders and police, a place focus requires consideration of the morality of crime facilitation by third parties.” They suggest that such approaches can not only reduce crime, but also reduce the economic demands on police and policing, by sharing responsibility and costs. However, the extension of responsibility in this way, and the increased use of TPP and regulatory strategies, is not without problems and controversies, and the next section examines some of these.

Key Issues and Controversies

A threshold problem for TPP approaches is that, typically, police agencies are different to regulators and other third parties. Police do not view themselves as regulators, have different systems of training and organization, and a different culture. Sparrow (2012: 347) refers to this as the "divide" between police and regulators and attributes it to police unfamiliarity with the role of regulations, the distinctive police culture and domain, and the special risks they face. These differences can impede police from recognizing opportunities for TPP, and identifying regulators and legal levers that can be used to respond to particular crime problems. However, Sparrow (2012) also sees similarities between the shift in regulatory approach to risk-based strategies and the rise of POP and other innovative policing strategies which are similarly based on risk. He argues that POP has become single-dimensional, focused almost entirely on place-based interventions, and that increased use of a toolbox of regulatory strategies can expand the reach of innovative policing. But Sparrow (2012: 354) concedes a significant barrier to this occurring – how can police and regulators agree on who does what to deal with particular problems? Tilley (2012) goes further to ask who should pay for what and who should bear the costs of crime prevention efforts? This is particularly important when crime and its prevention is not the core business or concern of most third parties identified in the discussion above.

Tilley (2012) and Eck and Eck (2012) identify other potential problems with regulatory approaches to crime control and prevention. Spreading responsibility to non-offending third parties can create costs for the blameless, as well as those who facilitate crime, for example, when all bar owners are required to upgrade security in response to violence that occurs only at a few sites. Some strategies can be seen as too interventionist, such as the requirement for bars to use plastic glasses or serve low-alcohol drinks (Mazerolle et al. 2012). Such measures can add to the cost of doing business and favor those traders who cut corners rather than those doing the right thing.

Mazerolle and Ransley (2005) grouped the disadvantages of TPP as unintended side effects: the disproportionate allocation of policing and regulatory resources creating either over- or under-policing; the displacement of crime problems; the intensification of crime and disorder in already disadvantaged areas; the co-option of regulatory resources and agendas away from their core concerns, such as public health and safety; and the dilution of criminal law protections and restraints. Additionally, there is a danger of regulatory creep that extends the acceptable limits of government intervention in the lives of citizens and businesses. Crawford (2009: 818–819), discussing the British antisocial behavior agenda, notes similar concerns including: the use of civil measures to evade criminal justice process; the introduction of new forms of hybrid liability that potentially lead to increased criminalization and net-widening; the reliance on subjective perceptions of risk in place of objective assessments of past conduct; the privileging of public anxieties, fears, and concerns as triggers for formal action (as in dispersal orders); the trends to preemption and individualized rather than generally applied controls; and the substitution or supplementation of judicial decision making by police and regulatory discretion.

Many of these concerns and issues remain unexamined in any systematic way, with the possible exception of the British antisocial behavior system. How TPP affects the communities in which it is practiced, whether it does so equitably and with accountability are empirical questions that remain largely unanswered. Also insufficiently examined is the effectiveness of TPP – does it work, and if so, when and in what forms? Mazerolle and Ransley (2005) conducted an extensive review of the evaluation literature, identifying 80 studies of TPP strategies. They found that business owners are the third parties most often targeted to share crime control or reduction responsibility, in dealing with problem bars, property crime in unsecured car parks, drunks and disorderly behavior in public places, and street prostitution. Other third parties included parents, schools, liquor licensing authorities, car manufacturers, local councils and public housing authorities. Overall, the use of these third parties and their legal levers was found to be an effective tactic for crime control.

Future Directions/Conclusion

The use of TPP is part of a shift to regulatory justice that positions police at the center of crime control and prevention networks. Most TPP currently occurs in an ad hoc and variable way, apart from the British antisocial behavior agenda. In times of financial constraint, TPP will become increasingly attractive to governments wanting to share costs with business and individuals, and with police agencies wanting to draw on the resources and expertise of other regulatory bodies.

While there is some evidence that TPP is effective (see Mazerolle and Ransley 2005; Eck and Eck 2012), there is a clear need for more research that encompasses at least the following:

- The full range of legal levers for TPP that already exist and the contexts in which they are available for use in TPP strategies
- The effectiveness and limits of various levers in various situations – what works, when, and why
- The full costs of financial burdens shifted to others through TPP, and the impact on their private or regulatory functions and concerns that results
- The extent to which TPP is used differentially in different communities – are disadvantaged neighborhoods over-targeted or neglected?
- The extent to which TPP is used differentially against different social and demographic groups – to their advantage or disadvantage
- The extent to which TPP has resulted in expanded criminalization, leading to new offenses and criminalizing conduct previously seen as disorder or nuisance
- The extent to which TPP has resulted in net-widening, particularly by criminalizing noncompliance with regulatory and civil sanctions
- The extent to which TPP has diluted criminal justice processes, by criminalizing those against whom noncriminal justice processes have been used
- The impact of TPP on regulators and the extent to which their agenda has become co-opted by crime reduction concerns

There seems little doubt that the trend to regulatory justice, and the accompanying rise of TPP strategies, is occurring. The challenge for police is to manage this trend in a thoughtful and useful way. The challenge for researchers is to study the features, utility, and costs of the trend and to suggest ways of better harnessing its advantages while minimizing the potential costs and disadvantages.

Legal Interventions

► Lawful Killings

Legal Rules, Forensic Science and Wrongful Convictions

Carole McCartney
School of Law, University of Leeds, Leeds, UK

Synonyms

Junk science; Miscarriages of justice

Overview

Law and science have long had a strained relationship although their tendency to "clash" may have been exaggerated over the years. The source of their disharmony has most often been seen as the result of the two domains having both dissimilar methods and goals. Regardless of the extent to which this is true, there remain apposite and acute concerns regarding the status of science utilized by the law, in particular forensic science and its interplay with criminal law. Without delving into the philosophy of science or law, or the psychology of the courtroom, it is considered here whether legal rules have, and can, prevent flawed scientific evidence from entering the courtroom by empowering judges to rule questioned scientific evidence inadmissible. It concludes that where evidential hurdles for forensic science exist, decisions to permit forensic science into evidence may still appear arbitrary, as well as inconsistent between and within jurisdictions. In addition, such hurdles may come too late in the criminal process to prevent all injustices. Current attempts to regulate forensic science are welcome but do not yet go far enough to ensure that wrongful convictions will not continue to occur, with forensic science and scientists playing a significant role in these miscarriages of justice and judges unable to execute their gatekeeper role effectively and consistently.

Fundamentals

The prefix "forensic" simply means the use of science in legal fora: applying science to answer a legal question. Efforts have been made to circumscribe the field of "forensic science," with the UK's (now defunct) Forensic Science Service stating that the task of forensic science is "to serve the interests of justice by providing scientifically based evidence relating to criminal activity," and the definition given in the US Congress Forensic Science and Standards Bill of 2012 3(a): "'forensic science' means the basic and applied scientific research applicable to the collection, evaluation and analysis of physical evidence, including digital evidence, for use in investigations and legal proceedings, including all tests, methods, measurements and procedures."

Most often, forensic science is a subdiscipline of a larger scientific body, such as pathology, toxicology, archaeology, or genetics. There are also a variety of "experts" who may be called upon to testify on matters in issue at trial (e.g., forged documents, firearms), each being a "forensic specialist" for the purposes of a criminal trial. There is potentially no limit to the scope of physical evidence (or "trace" evidence) that can be utilized, from the smallest fragment of glass, the most obscured fingerprint, or the tiniest swab of human tissue to the entire scene of a major disaster or the realms of cyberspace. There are, therefore, potentially no limits on the number of disciplines that may be utilized in a forensic investigation. Herein lies one of the pivotal difficulties with forensic science: the multiplicity of techniques, technologies, and disciplines, which can sit under the "forensic science" umbrella, risks over-inclusion. It is this over-inclusion that lies at the crux of some of the frustrations with forensic science. While some forensic technologies are born of rigorous scientific testing and experimentation (the oft-used example being DNA profiling), many others have no, or a minimal, scientific basis or grounding in experimentation and testing.

This variety of disciplines and techniques and their great variances in reliability and validity create an issue for users of forensic science: how to discern between those reliable and valid techniques that can assist, and those that may be insufficiently reliable and valid, and can mislead. So, while on first blush it would appear contradictory to discuss forensic science and judicial oversight alongside wrongful convictions, this question occupies the minds of legal professionals, researchers, practitioners, and forensic experts alike: how can courts ensure that valid and reliable scientific evidence, and *only* valid and reliable scientific evidence, is adduced during trials, thereby using forensic science to *prevent* wrongful convictions?

Ruling potentially unreliable or invalid forensic evidence inadmissible at trial, while clearly having an impact on that specific trial, may also have important wider ramifications. If a particular expert, expertise, or evidence type is regularly deemed inadmissible, then police or legal professionals will lose confidence in them and stakeholders may insist upon greater controls or regulation. It may be that, as we have seen in the USA, Canada, and the UK in recent years, political demands are made for changes to the forensic science community. Public confidence in the operation of the criminal justice system is an essential prerequisite of any legitimate legal system, and if forensic science brings that system into disrepute or diminishes public confidence, then the forensic science community should not be surprised if their reputation en masse is tarnished and stricter regulation is insisted upon.

Key Issues/Controversies

The forensic scientist (or rough equivalent) has been popularly portrayed in both factual and fictional media as a heroic figure in the fight against crime. In the twenty-first century, that portrayal has had to become more nuanced as forensic science has been pinpointed as playing a role in causing wrongful convictions while failing to prevent others. Forensic scientists have been accused of inter alia: negligence, corruption, and perhaps most critically, of not being "scientists" at all.

The growing international "innocence movement" has paradoxically utilized modern forensic techniques and technologies to free innocent prisoners, simultaneously demonstrating the flaws of many forensic techniques that were used to convict those prisoners and the failure of the courts to prevent misrepresented or misinterpreted forensic evidence from being relied upon at trial. Yet wrongful convictions most often result not from a single error but a composite of failures that can include, but are clearly not limited to, the gathering, interpretation, and communication of forensic evidence. It is most often human fallibility that lies at the heart of wrongful convictions. Forensic science can then overcome the failings of many other, unreliable, and often highly questionable evidence types, regularly relied upon at court. For this reason, forensic science cannot fairly be portrayed as the cause of wrongful convictions, as it plays probably a more significant role in prevention and cure; these three roles are considered, before turning to the place of forensic science in the courtroom.

During police investigations, the gathering of scientific evidence cannot prove any one theory of events, or conclusively prove anyone guilty of a criminal offense in isolation of other evidence, but it can be incredibly valuable in explaining events and implicating individuals involved in criminality. Most often, its value can lie in supporting, or refuting, a version of events provided by those deemed to be involved (or by the police, prosecution, or defense). Indeed, forensic science is now considered integral to many criminal investigations, particularly serious offenses, but also "volume" (mostly property) crimes. Forensic science as neutral, objective, evidence is perhaps of most value at the outset of police investigations, where erroneous judgements or false assumptions can send investigators down a blind alley. A piece of scientific evidence gained early in an investigation can ensure that the wrong suspects do not continue to be the center of investigators attentions, thus preventing a wrongful conviction.

Some traditional police "practices," hopefully now becoming obsolete, have not always leant themselves to ensuring that only the guilty are ever convicted. Many suspects in the past have been "persuaded" to confess, and not only the guilty succumbed to such pressure. Informants were also heavily relied upon, and written police statements were not always entirely accurate. However, police practices were not always to blame. Police relied – and still do to a greater extent – on witnesses. These may be eyewitnesses, which are considered highly valuable in securing a conviction. However, as psychologists have demonstrated for many years, people can be highly unreliable at the same time as highly persuasive, especially when they truly believe themselves to be telling the truth. There is a wealth of research on how poor human memory is, how bad we are at identifying people (particularly people we don't know or who are different from us ethnically or in terms of age), how easily we can be persuaded of something or change our recollections to match them with expectations, etc. In short, relying on humans to assist in the detection and prosecution of offenses can be highly problematic, even when those humans are not deliberately lying.

In light of such unreliability, scientific evidence would seem to avoid these "human" problems. There is no need to rely on a person testifying that they saw the defendant at the scene of the crime, if we also have their fingerprints found at the scene. There have been numerous cases where eyewitnesses – victims even – have identified with 100 % certainty their attacker, and yet later DNA evidence has proven that they are mistaken. It would seem far safer to rely upon a DNA match of a rapist than the testimony of the victim (certainly if they don't know their attacker before the crime). Furthermore, the popular (and populist) perception of an almost continuous increase in crime, coupled with a perceived inability on the part of the police to detect criminals or convict them, raises the hope that scientists will be able to tip the justice scales back in favor of the police and prosecution. The growth in forensic science is then based upon the assumption of science as capable of being a neutral, objective, "arbiter of truth" (Dreyfuss and Nelkin 1992: 339). However, uncritical faith can be misplaced, and as scientists themselves warn, "the general public often has an unrealistic expectation of what forensic science can achieve" (Ross 1998: 41).

Yet, forensic science has come to the aid of many wrongfully convicted, most clearly in DNA exonerations, of which there have been over 300 in the USA alone since 1989, with undoubtedly many more to come. The discovery and proliferation of DNA profiling has had a dramatic impact because it has come to be trusted as almost indisputable evidence. The strength of DNA evidence has meant many convictions have been overturned that would have been impossible to overturn otherwise. In some of these cases, DNA has subsequently been used to locate the real perpetrators, sometimes many years after the crime. In just one example, Sean Hodgson spent 27 years in an English prison for a murder that he had confessed to but had not committed. Blood type matching had been used at trial to support Hodgson's confession, but after DNA testing of the evidence 27 years later, it was proven that he was not the killer and freed. There have now been numerous cases around the world where innocent people have called for evidence to be tested or retested in their cases, in the hope that DNA will finally see justice in their case.

It is not hard when reading of famous miscarriages of justice to find instances of flawed scientific evidence being used to convict the innocent, from terrorist bombers found to have nitroglycerine on their hands, which it later transpired could have been a number of harmless chemicals from many household items, to mothers convicted of killing their babies when they had died of unknown, but entirely natural causes. Such cases exemplify the risks of relying upon techniques or "theories" that are erroneous. While experts in these cases were often castigated after the conviction is overturned, many had continued working and testifying before their mistakes were brought to light. The experts were also singled out as isolated "mavericks" in many instances, providing a scapegoat for the wider scientific community. Many other cases however, have relied upon valid scientific principles, but the expert has provided misleading testimony, often overstating the probative value of their evidence or its reliability.

The Innocence Project in New York has of February 2013 exonerated over 302 people wrongly convicted using DNA testing. In 50 % of those cases, the DNA testing has identified the true perpetrator. An early analysis of the first 86 of those exonerations found that faulty forensic evidence had played a role in two-thirds of the convictions. Latest analysis demonstrates that unvalidated or improper forensic science played a role in approximately 50 % of wrongful convictions later overturned (Innocence Project 2009). In such cases, if available evidence had been subjected to DNA testing, then the suspect would have been excluded and most often, another suspect indicated.

The US National Registry of Exoneration, launched in May 2012 by the University of Michigan Law School and the Center for Wrongful Convictions at Northwestern University, is an online database containing a list of exonerations in the United States since 1989. The registry lists more than 1066 wrongfully convicted individuals and is growing. In an analysis of 873 of these cases, 24 % featured false or misleading forensic evidence (Gross and Shaffer 2012). These figures are slightly lower than found by Neufeld and Garrett (2009) in their analysis of 137 trial transcripts of convictions later overturned by DNA. They found experts in 60 % of the cases to have given invalid testimony that overstated the evidence, was unscientific, or contrary to empirical data. They gave instances of erroneous or unsupported testimony about the accuracy and results of forensic techniques including hair comparison, bite-mark comparison, serology, fingerprint comparison, and even DNA testing.

While the work of a forensic expert can take place in any number of environments, particularly when examining crime scenes, for instance, the laboratory is most often the typical workplace of a forensic scientist. However, for forensic evidence to be of utility, it must be able to make the transition from crime scene, via the laboratory, to the courtroom, where it is ultimately used. While much forensic testing will not produce any positive results, or may simply be retained as "intelligence" for possible future use, if test results are not able to be admitted at court as relevant evidence, then the resources used to obtain that evidence will have been wasted. This transition to admissible evidence at trial is then essential if forensic evidence is to be able to play a role in criminal justice.

Experts have been permitted to give evidence in courts for centuries, and their word and expertise have been rarely questioned. Medical men of the middle ages, for example, were often called upon to testify as to their opinion on questions such as cause of death or the sanity of the defendant. Fingerprint experts have, for the last century, been testifying that the prints found at the scene of a crime, for example, “matched” the defendant to the exclusion of all others. However, it has been the massive expansion in forensic science in the last couple of decades, and the increasing incidence of DNA exonerations, that has led to the current paradox being brought into sharp relief. While it has compelling value in preventing and overturning wrongful convictions, forensic science can still also lie at the heart of flawed investigations and trials. In fact, forensic science is introduced to reduce uncertainty and bring objectivity to legal disputes, yet it is increasingly under fire for obfuscation, the introduction of partiality and partisanship, and creating new sites of dispute, that is, for *increasing* uncertainty rather than alleviating it.

One of the perennial predicaments is that while a technique may have a valid scientific basis and prove reliable in its application, how can it be ascertained that it was correctly applied in this case? What are the error rates associated with the technique that may mean that the testing could be wrong in this particular instance? Furthermore, are there any pertinent factors that could jeopardize the reliability or validity (or both) of the testing in the particular instance? For example, the operator (scientist) is incompetent or unqualified, the technique is novel and untested, contamination has occurred, the provenance of the exhibits or results cannot be attested to, and the results have been misinterpreted. As one can quickly see, the use of forensic science can be a complex and complicating factor in any legal dispute.

As the omnipotent umpire, the judge has the task of ensuring the legality and fairness of a trial, and for as long as experts have been allowed to give evidence, there have been rules regarding the expert’s remit and the special allowances afforded them. In light of the powerful influence of science at trial, efforts have been made to bolster the role of the judge in ensuring that science is only used at trial when relevant and reliable and is represented impartially and accurately for the assistance of the fact finders. This has led to the common representation of judges as “gatekeepers,” guarding the doors of the courts to ensure that invalid or unreliable science cannot enter. This could be argued to be the most obvious way to keep “junk” or bad science from admission at trial, but there are complicating factors. These are not limited to the fact that judges themselves are fallible, not always as impartial as one might hope, and rarely have a scientific grounding upon which to rely when ruling. The ability of judges to interpret and apply “correctly” (assuming there is a “correct” decision) complex exclusionary rules is further complicated by the difficulty of the task itself and the clarity, or otherwise, of the rules.

In a survey of 400 judges on their understanding and acceptance of their role as “gatekeeper,” Gatowski et al. (2001: 443) found that 91 % believed the role was appropriate. Those doubting believed that judges had insufficient scientific training, making the role “‘difficult, untenable, or inappropriate’” (Gatowski et al. 2001: 444). Indeed, the researchers found judges equally divided on whether their education adequately prepared them to deal with scientific evidence, many stating that the extent to which judges could properly apply criteria to judge scientific evidence was “questionable at best” (Gatowski et al. 2001: 451–452). The authors concluded that the lack of scientific literacy among trial judiciary, and the increasingly complex nature of the science coming before courts, demonstrates a need for more science-based judicial education (Gatowski et al. 2001: 455). While a laudable aim, the exclusionary rules themselves have been widely criticized (there is a substantial literature but, e.g., see Edmond (2000); Risinger (2000–2001); Danaher (2011)). These differ between jurisdictions with the USA, Canada, Australia, and the English courts all making attempts to improve the exclusionary rules applying to expert evidence, some meeting with more success than others. Some of the important cases are discussed below.

International Perspectives

The USA, perhaps unduly, has earned a reputation as both a highly litigious nation and one that has most utilized "junk" science to ensure a favorable legal outcome for clients, in particular in multimillion dollar "toxic tort" civil cases. Indeed, in the decades leading up to one particular toxic tort case, that of *Daubert v Merrell Dow Pharmaceuticals* 509 U.S. 579 (1993), there was a great deal of controversy over the perceived "flood of 'junk' science that, according to some popular critics, threatened to inundate the courts" (Beecher-Monas 1998: 58). The so-called *Daubert* case was the progenitor of two further cases which have come to be known as the "*Daubert* trilogy" (the other two being *General Electric Co. v Joiner, 522 U.S. 136, 118 S Ct. 512* (*1997*) and *Kumho Tire Co. Lts v Carmichael, 119 S Ct. 1167* (*1999*)). Prior to these, the standard for evaluating expert testimony was the "Frye" standard, from *Frye v. United States*, 293 F. 1013 (D.C. Cir. 1923). At the core of Frye was the contention that judges should refer to scientists, admitting evidence when the method utilized was "sufficiently established to have gained general acceptance in the particular field in which it belongs"(1014). This came to be known as the "general acceptance" rule and was reinforced by the Federal Rules of Evidence adopted in 1976, of which Rule 702 stated that "if scientific, technical, or other specialized knowledge will assist the trier of fact to understand the evidence or to determine a fact in issue, a witness qualified as an expert by knowledge, skill, experience, training, or education, may testify thereto in the form of an opinion or otherwise."

Many states continued to utilize the Frye standard, but the "general acceptance" rule gave rise to problems and two primary concerns: (1) it required the establishment of an "orthodoxy," but such an orthodoxy may be indulgent, in that it is based upon a body of work that has no scientific validity or has any checks or objective standards, and (2) waiting for "general acceptance" may stifle innovation or deprive courts of novel techniques or scientific breakthroughs. "Acceptance" within the scientific community can be misleading, in that some methods or theories are "accepted" almost by faith, and are not proven flawed for many years, perhaps refuted by people on the periphery who lack "acceptance" by the wider scientific community. The Frye standard and Federal Rules were then proving inadequate. A more stringent standard was therefore outlined in *Daubert*, where general acceptance was just one of five criteria by which to "test" scientific evidence:

1. Whether the theory or technique in question can be (and has been) tested
2. Whether it has been subjected to peer review and publication
3. Its known or potential error rate
4. The existence and maintenance of standards controlling its operation
5. Whether it has attracted widespread acceptance within a relevant scientific community

Most states have adopted the *Daubert* standard, some still work with the *Frye* test, and a few have their own tests they adopt on a case-by-case basis. *Daubert* explicitly placed judges in the role of gatekeeper who must evaluate the scientific validity and reliability of scientific evidence. It also switched the focus from whether there was a scientific consensus upon which to base the evidence given, to whether the techniques and methodology used were valid. The *Kumho Tire* case clarified that the *Daubert* analysis applies to scientific, technical, and otherwise specialized knowledge, and not exclusively to scientific evidence (so applying to engineers, etc.) (at 1175). *Kumho* also strengthened trial judge's discretion in noting that the judge had "considerable leeway" and "broad latitude" in flexibly applying the criteria set out in *Daubert* (at 1176).

Daubert has provided a useful checklist but is by no means uncontroversial. In his judgement in *General Electric Co. v Joiner*, 522 U.S. 136 (1997), Justice Stephen Breyer alluded to the difficulties that judges faced: "scientific evidence often requires judges to make subtle but sophisticated determinations," (p. 1) and "those duties often must be exercised with special care" (p. 2). Scholars have produced many theoretical, quantitative, and qualitative analyses of the operationalization of *Daubert*, debating the relative merits of each of the criteria; considering how judges are deciding on admission, the extent to which judges are able to apply the criteria; as well as assessing various forensic methods using the *Daubert* criteria. Many have found the *Daubert* criteria wanting, as well as doubting the ability, or willingness of judges to apply them strictly. Moriarty and Saks (2005: 29) concluded that "some forensic sciences have been with us for so long, and judges have developed such faith in them, that they are admitted even if they fail to meet minimum standards under *Daubert*. Faith, not science, has informed this gatekeeping." In their major report "Strengthening Forensic Science: The Path Forward," the National Academy of Sciences was pessimistic about the contribution that could be made by judges and their gatekeeper role in preventing "junk science," concluding that "*Daubert* has done little to improve the use of forensic science evidence in criminal cases" (NRC 2009: 106). Their research found that US appellate courts were too deferential to admissibility decisions made by trial judges and were simultaneously being too generous in admitting prosecution expert evidence while generally excluding expert evidence for the defense (NRC 2009: 96).

Both Canadian and Australian State and federal legal jurisdictions have seen expert evidence and forensic science playing a role in wrongful convictions. In both countries, public inquiries and Royal Commissions following exonerations have driven forensic science policy and reform. In Canada, the case of *Mohan* [*1994*] *2 SCR 9* established a four-part test for expert evidence, requiring that it be (1) relevant, (2) necessary in assisting the trier of fact, (3) not otherwise subject to an exclusionary rule, and (4) given by a properly qualified expert. The subsequent Canadian Supreme Court cases of *R v J-LJ* [2000] 2 SCR 600 & *Trochym* [2007] 1 SCR 239 affirmed that there are enhanced tests of reliability for expert evidence and courts must particularly scrutinize novel science or methodologies, similar to the approach in *Daubert*.

The 2008 Inquiry into Pediatric Forensic Pathology in Ontario (the Goudge Report) inquired into a series of wrongful convictions relating to the pathologist Charles Smith. The report affirmed that judges play "an important role in protecting the legal system from the effects of flawed scientific evidence" and that "judges bear the heavy burden of being the ultimate gatekeeper in protecting the system from unreliable expert evidence" (Goudge Report 2012: 470). Goudge asserts that "trial judges should be vigilant in exercising their gatekeeping role" and that a test of reliability is embedded within the *Mohan* test. Evidence must thus be excluded by judges if not satisfying standards of threshold reliability, whether or not the science is novel (Recommendation No. 130). The report stressed that judges needed to pay close attention to the methodological and reliability issues identified in *Daubert* (pp. 483–484). Enhanced judicial education was also recommended to enable judges to undertake their gatekeeping role competently.

Similarly, Australia has suffered wrongful convictions that have led to Royal Commission reports highly critical of scientific evidence. In 1987, Judge Morling released a report into the Azaria Chamberlain conviction that dismissed the majority of the prosecution's scientific evidence and saw the conviction overturned. Previously, in 1984, the Shannon Royal Commission into the conviction of Edward Charles Splatt had implicated flawed scientific evidence which led to his release and pardoning. Such Royal Commissions have seen improvements in forensic science provision across Australia. However, legal reforms have been more fitful and uneven across the continent.

Australian courts follow a variety of state, federal, and common law, with many adhering to uniform evidence legislation which admits opinion evidence under s. 79, where the opinion must be (1) relevant; (2) from a person who has specialized knowledge; (3) the specialized knowledge is based upon the person's training, study, or experience; and (4) the opinion is wholly or substantially based on that specialized knowledge. However, the legislation does not define "specialized knowledge" or require certain criteria for the "field of expertise" to be met. This has given rise to debate about the role of reliability. In *HG v The Queen* (1999) 197 CLR 414, the common law is cited as requiring an expert's knowledge or experience to be in an area "sufficiently organized or recognized to be accepted as a reliable body of knowledge or experience" (at 58). However, the New South Wales Court of Criminal Appeal has said that evidentiary reliability is not a consideration under s79 (*R v Tang* (2006) 161 A Crim R 377; [2006] NSWCCA 167). The focus of attention must be on "specialized knowledge," not on the introduction of "an extraneous idea such as reliability" (at 137). For a country that has seen wrongful convictions based upon unreliable expert evidence, this is a worrying judgement indeed.

Presently the English and Wales legal system operates a "case-by-case" assessment of experts (their evidence tested via cross-examination), which has on occasion proved flawed. Expert opinion evidence is admissible under *R v Turner* [1975] QB 834, where "an expert's opinion is admissible to furnish the court with scientific information which is likely to be outside the experience and knowledge of a judge or jury...." In recent years, judges have approved and adopted the South Australian case of *Bonython* [1984] 38 SASR 45, which requires consideration of the subject matter of the expert's opinion, considering whether it "forms part of a body of knowledge or experience which is sufficiently organized or recognized to be accepted as a reliable body of knowledge or experience"(at 47). This still stops short of an explicit or stringent gatekeeping role for English and Welsh judges, an omission that the Law Commission of England and Wales in their 2011 report on expert evidence is hoping to fill. Their Draft Bill seeks to introduce a statutory reliability test for expert evidence, requiring the party wishing to rely on the evidence to demonstrate that it is sufficiently reliable to be admitted. It is intended that this will be an enhanced test of admissibility, with a suggested list of criteria for judges to consider.

Future Directions

Given the difficulties highlighted with the gatekeeping role of the judge and the vagaries of expert evidence admissibility at trial, it may be more prudent to ensure the reliability and validity of scientific evidence *prior* to admission at trial. Indeed, given that most wrongful convictions have at their core defective investigative decision making, it is vital that forensic evidence utilized by investigators is reliable to ensure decisions made at this stage are based upon sound evidence. If forensic evidence is flawed at the investigative stage, it is often too late, and the damage irreversible at trial. Given then that it is essential that all forensic evidence is reliable and valid, whether used at trial, during an investigation, or held as "intelligence" by law enforcement agencies, there must be systems in place to ensure the quality of forensic evidence from the outset of the criminal process. This requires regulation and oversight of forensic science from the crime scene to the courtroom and quality assurance standards for the education, training, and operation of forensic scientists and the quality assurance and accreditation of their working environments and practices.

During the massive expansion of forensic science provision in the late twentieth and early twenty-first centuries, there have been a series of reports commenting upon forensic services. In England and Wales, the Royal Commission on Criminal Justice of 1993 (The Runciman Report) made 13 recommendations specific to forensic science. Of these, the establishment of an oversight body was deemed a priority. A subsequent report into serious contamination at a military forensic explosives laboratory by Professor Caddy in 1996 recommended the creation of an "Inspectorate of Forensic Sciences" and advocated the registration of individuals as forensic practitioners, a call repeated by the House of Commons Science and Technology Committee (2005), when it proposed greater regulation of forensic science. In 1999 the establishment of the Council for the Registration of Forensic Practitioners (CRFP) sought to register "competent" forensic practitioners. However, the CRFP stopped far short of bringing rigorous scrutiny to bear upon forensic science and in 2009 was closed in the light of financial difficulties, lack of stakeholder support, and the newly created Forensic Regulator role.

The role of the UK Forensic Regulator was created in 2007 and was tasked with establishing and monitoring quality standards and oversees accreditation via the UK Accreditation Service (UKAS) using the international laboratory testing ISO17025 standard, necessitating UKAS establish supplementary standards and modifications to tailor the standard to forensic science. However, there remain questions over whether regulation reforms are being applied equally to all aspects of forensic science. On the one hand, the introduction of the regulator was presented as creating a generic standard for forensic science providers in the UK and “a light touch” in steering service providers. However, there remain concerns about a perceived lack of teeth and gaps in regulation, with a fear that accreditation may prove to be superficial. The regulator also faces serious resource restrictions.

There is increased recognition in the USA for the need for proper regulation and oversight of forensic science. The New York State Commission on Forensic Science which accredits and monitors forensic laboratories was established in 1994 and in Texas in 2005; the legislature established an independent oversight body for forensic laboratories to identify and oversee rectification of problems that have blighted forensic science in that state. Despite such innovations, in February 2009, the National Academy of Sciences report, *Strengthening Forensic Science in the United States: A Path Forward*, is almost unremittingly condemnatory. This critical tone was not unexpected, given that the committee had been established in the wake of high-profile failings and against a backdrop of the ongoing exoneration of innocent people, convicted often with the aid of flawed or misrepresented forensic science. In addition, the USA was still struggling to make inroads into significant backlogs in forensic laboratories despite increases in federal funding. The report unsurprisingly found serious issues facing forensic science and concluded that any remedy would have to be national in scope and demands both leadership and funding.

In July 2012 legislation was introduced to the US Congress to help prevent wrongful convictions by bringing reliable, science-based standards to forensic evidence. The Forensic Science and Standards Act of 2012 seeks to strengthen forensic science and standards: “yielding evidence that judges, prosecutors, defendants, and juries can fully trust.” The Forensic Science and Standards Act of 2012 would require the National Institute of Standards and Technology (NIST) to develop forensic science standards while a Forensic Science Advisory Committee ensure the implementation of standards. Further, a National Forensic Science Coordinating Office, housed at the National Science Foundation (NSF), would also develop a strategy to support a forensic science grant program to promote research.

With international forensic data exchange increasingly common, quality standards for forensic science have become ever more important. The requirement that forensic science providers have demonstrable quality standards and accreditation has now been mandated with EU Council Framework Decision 15905/09. Accreditation of laboratories to the ISO17025 standard was viewed as providing “mutual trust in the validity of the basic analytic methods used,” although it does not mandate particular methods to be used, only that the method be suitable for its purpose. This decision only covers laboratories, omitting any quality oversight of the retrieval of forensic information, whether at crime scenes or in police stations, for example, its scope restricted to the results of laboratory activities.

It is unlikely that any standard can regulate every aspect of a forensic practitioner’s work. The lack of oversight of crime scene examination and evidence retrieval will be very difficult to overcome, particularly where police personnel are working in their domains without external supervision or oversight. Well over half of forensic science services (measured by cash value) in England and Wales are delivered within police forces’ own scenes of crime operations and scientific support services, with this set to increase. These services are not yet subject to the same quality standards regimes as apply to commercial providers. Yet differential standards operate against the public interest, increasing the risk of flawed results being relied upon, or challenged in the courts. In many countries, all forensic science services come under the auspices of the police, with their accreditation status and quality assurance regimes unknown. The use of personnel directly employed by the police has been roundly criticized by all reports looking into forensic science. Indeed, high-profile wrongful convictions in England and Wales were tainted by the suspicion that scientists had been too easily influenced by the police when undertaking testing and reporting results. The US National Research Council (2009) report specifically recommends that all forensic laboratories be removed from law enforcement premises and/or their administrative authority.

Despite the overwhelming support for a stronger and more regulated range of forensic services, difficulties persist. There remains the ever-present problem of funding: to oversee all forensic science provision to a standard which some would still view as inadequate has required considerable investment. It is also dangerous to implement quality standards and operating procedures that are not underpinned by rigorous scientific research, yet it is this lack of underlying "science" that has been most strongly criticized. Significant investment in research is still required prior to regulation. Further, the proper extent of the reforms in the forensic area, as opposed to their direction, remains largely unconsidered. For example, it might be asked why fingerprints are currently collected and analyzed by the police without reference in the vast majority of cases to scientists or independent laboratories. The answer seems in the main to be historical; fingerprinting was developed by the police themselves two or three decades before the establishment of formal laboratories. Thus, forensic science should be defined in wide terms and regulators given a wide remit if the quality of justice is to be improved.

Another problem concerns how forensic evidence is handled and the particular danger that tests adverse to the contentions of the prosecution will be disregarded and suppressed. This leads to the observation that acceptable forensic detection ultimately depends not only on the imposition by society of training, rules, sanctions, and supervision but also on the internalization by scientists of the ethics behind that training. As has been found to be indispensable in relation to police interrogation practices, it is necessary to impact upon the whole culture with which the police approach investigations. A corresponding approach to forensic evidence should spark further debate as to qualifications and training.

Despite almost comprehensive favorable media representation, forensic science has not eradicated the potential for factual errors in legal investigations and criminal trials resulting in wrongful convictions. While the realization of the extent of human unreliability has grown at the same time as scientific and technological power and knowledge have increased, undoubtedly preventing many wrongful convictions, they may still flourish in a culture which fails to properly scrutinize and question forensic evidence. Research into the causes of wrongful convictions clearly demonstrates that while the utilization of forensic evidence can assist the pursuit of justice, it can also seriously hamper fact finders and triers of fact in criminal cases.

One attempt to prevent wrongful convictions has been in the development of evidentiary rules to prevent flawed scientific evidence from entering the courtroom, empowering judges to rule questioned scientific evidence inadmissible. However, such admissibility standards have also been criticized, with commentators concluding that there remains a "conspicuous need for further refinement and greater vigilance to make these standards effective" (Edmond and Roach 2011).

While forensic scientists have joined calls over the years for better regulation, to provide assurance to the courts that experts before them will be qualified, and their evidence valid and reliable, there remain serious limitations to current regulation that means that the gatekeeping role of judges in courtrooms remains as vital as ever. The task cannot be left to judges alone however. Without "good" forensic science, authorities run the risk not only of wrongful convictions but also a loss of public confidence in the criminal justice system. It is critical that attention be paid to the delivery of forensic services: how scientists are trained and standards are set, monitored, and maintained across the forensic science sector. If this were to be done to a high standard, then the burden upon judges in their role as gatekeeper and the opportunities for error would be lessened.

Legal Status of Abortion

Gilbert Geis
School of Social Ecology, University of
California, Irvine, Irvine, CA, USA

Overview

The moral issues in regard to the proper legal status of abortion do not involve a dispute over fundamental demonstrable facts but rather concern a myriad of considerations that lie beyond empirical verification or dismissal. It is this ambiguity that allows the dispute to be so contentious and continuous. There also is considerable argument but few facts concerning the consequences of the triumph of either the pro-choice position favoring legal abortions or the pro-life position that advocates that there be no government-accorded right to an abortion. Some pro-lifers, although by no means all, qualify this last view by granting the right to an abortion when a conception is the result of rape or incest or if the abortion seems necessary to save the life of the pregnant woman. When the "health" of the women becomes a proabortion criterion – especially her mental health – pro-life forces tend to object on the ground that pro-choice proponents define "health" so loosely that it would allow abortions almost at will. The incest exception also can be controversial. Most incest likely occurs between teenage and somewhat older brothers and sisters: should abortions be allowed in these instances if they are otherwise banned?

Key Issues

Some people note that permissible abortions detract from the population growth, although there is no agreement whether this is a good or an undesirable consequence. There also are those who insist that if legal abortions were not available, nearly as many women who now have them would choose illegal ways to get rid of the embryo growing inside them. Disputes can become highly emotional with the pro-choice advocates publishing frightening scenarios depicting poor and desperate women resorting to back-alley quacks or to dangerous folk remedies to deal with what they regard as an intolerable situation. Botched amateur abortion procedures can prove fatal; the pro-choice forces point out that the death rate from legal abortions, which increases with the length of the pregnancy, is about 0.7 per 100,000 operations (Bartlett et al. 2004). Depending on the source you rely upon, the death rate for legal abortions may or may not be higher than that in which pregnancies are carried to term. The pro-choice forces, for their part, often employ grisly pictures of aborted matter, particularly in regard to late-stage abortions when the images bear obvious humanlike features.

There is among the pro-life advocates a belief that permissible abortions are evidence of the trend toward more degeneracy in the United States, part of a burgeoning spirit that favors self-interest over social and moral imperatives. Others believe that permitting legal abortions demonstrates the freedom that should characterize a democratic society.

In terms of empirical evidence, some scholars have reported that the number of what they label "marginal children" is decreased by the availability of legal abortion. They maintain that cohorts of children born after legalized abortion have experienced a significant reduction in the number of adverse outcomes compared to the average child and that the "marginal child [who was aborted] would have been 40–60 % more likely to live in a single-parent family, to live in poverty, to receive welfare, and to die as an infant" (Gruber et al. 1999, p. 269). Others maintain that abortion has contributed to a decline in the rate of juvenile delinquency and crime (Donahuse and Levitt 2001). That finding, if accurate – it is disputed by Joyce (2003) – would have to be considered with a research conclusion that having a baby significantly decreases the likelihood of delinquency among adolescent girls (Hope et al. 2003). Pro-lifers generally find such studies unpersuasive, declaring that alternative explanations are just as plausible for the reported results, and, besides, the outcomes, even if accurate, do not make what they consider to be fetal homicide either justifiable or excusable.

For the pro-life group, a fundamental moral consideration is that for them at the moment of conception the embryo becomes a human being and has the right to have his or her life sustained. Some regard this as a sacred right and rely on biblical sources to make their case; others see the issue as one of secular morality. Carried to its logical extreme, this position regards abortion as murder, though only extremely rarely do pro-life people maintain that women who have abortions ought to be tried in criminal courts for homicide.

For the pro-choice camp, the decision whether to carry the fertilized embryo to term should be the woman's because her body is deemed to be her personal domain. They maintain that the state has no right to demand that a woman give birth to what is now in her womb. Those adopting this position have to grant that the state often intrudes to dictate what they must do with their body, such as put it inside a classroom in their early years.

Some in both the pro-life and pro-choice camps believe that the father of the child should have a voice in the decision about whether or not an abortion ought to be elected. If the couple is not married, nor a pair, advocates of this position typically agree that the responsibility to raise the child should be totally on the man who objects to an abortion. The subtitle of a law review article illustrates how some women feel about any involvement of a putative father-to-be: "A Women's Womb is not a Man's Castle" the subtitle reads; the text of the article notes that in law the unwed father has no rights and to afford him any would make a woman's right to an abortion "virtually meaningless" (Preshiran 1990, p. 1365).

Roe v. Wade

The clash between opposing views about abortion began most dramatically after a Supreme Court opinion – *Roe v. Wade*, handed down in 1973 – decreed that under the umbrella of the judicially decreed doctrine of privacy abortions must be legally available to women in the first trimester of pregnancy. During the decades, since the *Roe* decision, pro-choice advocates have whittled away at the Supreme Court opinion, hedging it with requirements that make access to abortions more burdensome.

A major pro-life group goal is to have the Supreme Court, if it is reluctant to overturn *Roe v. Wade*, to alter its ruling by declaring that abortion is not a federal matter but that individual states should be allowed to adopt whatever rules they desire in regard to abortion. Justice Antonin Scalia, who strongly supports this view, has declared that the Court should repudiate *Roe*, which he sees as the Court's "self-awarded sovereignty over a field in which it has little proper business" (*Webster v. Reproductive Health Services* 1989, p. 532). A result of state control of abortions obviously would be that persons living in a state such as Utah who desired an abortion would have to travel to a state such as California to undergo the procedure. Obviously, the less affluent would be most affected if the states were to determine their position on abortion.

The pro-choice advocates, since they continue to retain the right to a legal abortion, have largely been relegated to a defensive position, trying to erect barricades against the incremental advance of the agenda of the pro-life forces who have benefited by having a Supreme Court with a conservative majority that recently had the very unlikely arrangement of six Roman Catholic justices (all but one a conservative) and three Jews (all liberals) sitting on the nine-person bench.

South Dakota and Abortion

In 2011, as illustrative of the whittling away process, the South Dakota legislature, with a three-to-one majority of Republicans, enacted the first statute in the nation that requires women seeking abortions to undergo a consultation at a "pregnancy help center" where they are to be informed what assistance is available "to help the mother keep and care for her child." The statute also established the nation's longest waiting period – 3 days – after an initial visit with an abortion provider before the procedure can be done. About half of the states in America have a 24-h waiting period – none, until South Dakota's action, any longer than that. It is presumed that the waiting period, the extra trip to the sites for counseling, and the cost of overnight stays will deter some South Dakota women from seeking abortions. Since no doctors in South Dakota will perform abortions, women in the state who desire abortions are dependent upon physicians who once a week fly into South Dakota from Minnesota.

When signing the legislation into law, South Dakota's governor wrote that he hoped that women considering abortion will use the 3-day waiting period to become "as fully aware as possible of the implications of the grave decision to terminate the most sacred gift of life." The governor praised the law as promoting "voluntary, uncoerced, and informed" decision-making in regard to abortion. He presumably had in mind husbands, family, friends, or others who might encourage an abortion when he employed the word "uncoerced," but opponents found the usage ironic in view of the fact that the required counseling would be by individuals without accreditation who are personally committed to the pro-choice ideology. One of the counseling sites, the Alpha Center in Sioux City, for example, had declared that abortions increase the risk of breast cancer, infertility, and depression, a conclusion decried by the most reputable scientific studies (see, e.g., Varmos 2003).

A Democrat member of the South Dakota legislature expressed the basis for her opposition to the new law, stating that "South Dakota women should not need any in-person lecture from an unqualified, uncertified faith-based counselor or volunteer at an anti-choice clinic" (Sulzberger 2011).

In 2011, the eighth circuit of the federal appellate court upheld the constitutionality of the major elements of the South Dakota law, including the fact that the person seeking an abortion must be told that what she was contemplating would "terminate the life of a whole. separate, unique human being." At the same time, the court ruled against the requirement that the woman should be informed that her behavior increased the risk of "suicide ideation" and suicide itself. The court maintained that there was no satisfactory evidence to support this conclusion. Critics would argue that the same was true of the "unique human being" message. In 2012, the legislature mandated that abortion counselors must be certified but rejected a proposal that the doctor and the proposed patient could conduct their business on the telephone, thereby avoiding the possible expenses of an extra trip to the abortion site.

The Personhood Movement

The boldest drive by the pro-life forces has involved an effort by a group called Personhood USA to sponsor referendums that seek to alter state constitutions so that a fetus at the moment of fertilization is deemed to be a human being and its destruction therefore becomes a grave criminal offense. The proposed amendment makes no exception for fertilizations that were the consequence of rape or incest or that were found to be likely to produce seriously deformed children. An egg fertilized in a test tube was also to be regarded as a person.

A Personhood initiative in November 2011 appeared on the ballot in Mississippi, arguably the most conservative state in the nation. Proponents thought its passage would be a slam dunk and were stung when it went down to defeat by a 58–42 % vote. Many persons who opposed legal abortion voted against the measure because they believed it was too broad and overly ambiguous. Some pro-lifers also thought that the measure was certain to be struck down by the courts and thus would set their movement back in the minds of the public. There also was voter concern that the measure would have implications for the legality of some birth control procedures such as the use of intrauterine devices that allow egg fertilization but prevent the embryo from attaching to the uterine wall. Supporters of the initiative maintained that many of the views of opponents were scare tactics and not realistic assessments of the proposed measure (Markoe 2001, December 13).

The Mississippi legislature responded to the Personhood proposal's defeat by placing particularly cumbersome restrictions on which doctors could do abortions and where they must be granted permission to do so. A temporary injunction against the law was granted in mid-2012 (*Jackson Women's Health Organization v. Currier* 2012), but the case is likely to be under legal review for a considerable time. About 2,200 abortions were performed in 2010 in Jackson, the site of the only clinic in Mississippi offering the service.

Religion and Abortion

Catholicism

The hierarchy and communicants of the Roman Catholic Church constitute major supporters of the pro-life movement. Catholics, the country's largest religious group, make up 24 % of the population of the United States. Clearly, not all Catholics follow every church doctrine literally, and a large number of individuals with other religious affiliations and many with no such allegiances are part of the pro-life camp.

The historical record shows that in earlier times the core issue for Roman Catholic theologians regarding abortion was the question of "ensoulment," that is, when the soul unites with the body to produce an actual human being. For some time, Catholic authorities held that abortion during the initial stages of pregnancy did not constitute a religious sin because the soul had not yet entered the fetus. St. Augustine in his fourth-century writings declared that the amalgamation of body and soul did not take place until the time of fetal quickening, which usually occurs during the fifth month of pregnancy with the development of the spinal cord. Pope Innocent III, the church leader from 1198 to 1216, set the dividing line for when abortion became a mortal sin at 40 days after conception for a male fetus and 80 days for a female fetus, numbers based on the time when it became possible to determine genital development in spontaneously aborted fetuses. In practice, since the gender of the gestating fetus was unknowable at the time, 80 days became the sanctioned time for a legal abortion (Asma 1994). The problem the church faced was that in regard to ensoulment, the task of sustaining its legitimacy was made significantly more difficult by virtue of the fact that religious conceptions of the soul are often hybrids of fundamentally inconsistent notions.

The current position of the Catholic Church regarding abortion was forcefully enunciated by Pope Benedict XVI in 2010:

> From the moment of its conception life must be guarded with the greatest care. With regard to the embryo in the mother's womb science itself highlights its autonomy, its capacity for interaction with the mother, the coordination of biological processes, the continuity of development, the growing complexity of the organism.
>
> It is not an accumulation of biological material but rather of a new living being, dynamic and marvelously ordered, a new individual of the human species. This is what Jesus was in Mary's womb; this is what we all were in our mother's womb. We may say with Tertullian, an ancient Christian writer, "the one who will be a man is one already"[Bindley 1890, ch. 9], there is no reason not to consider him a person from conception. (Benedict 2010)

The Pope's statement represents a departure from the Church's earliest emphasis on allowing abortions until ensoulment. That criterion, obviously lying beyond any possibility of demonstration, was open to being scorned by nonbelievers as no more than folklore. To declare that humanity begins at birth is a much less vulnerable position. The best that skeptics can say is "Maybe so, maybe not." Pro-choice advocates might add that they resent having the church's arguable interpretation determine their personal behavior in regard to whether or not to undergo an abortion.

Abortion in Brazil

The United States has the fourth largest number of Roman Catholics of any country in the world. As the largest religious group in the United States, the Church is able to influence to some extent the alignment between its doctrines and secular law. In Brazil, which has the largest number of Catholics of any country, the Church, home to 75 % of the country's population, inevitably exerts a great deal more power over daily affairs than it does in the United States.

Brazilian law permits abortion in cases of rape and in circumstances in which giving birth could cause the death of the pregnant women. To perform an abortion on oneself or another person carries the possibility of a 3-year prison term.

The status of abortion was vaulted into the limelight in Brazil in 2009 when it became known that a 9-year-old girl had undergone a medical abortion in the city of Recife after she was made pregnant with twins by her 23-year-old stepfather. The doctors claimed that the girl's 80-lb body was not mature enough to give birth safely. Church authorities retorted that the doctors could have resorted to a Caesarian section to bring the twins into the world.

The rift between church and state came into play when the Church excommunicated the girl's mother (but declared there was no theological doctrine to allow it to do so in regard to the stepfather) as well as all members of the medical team that had participated in the abortion. The President of Brazil deplored this action. The Archbishop replied that the President ought to study up on his theology. "We know people have other ideas," the Archbishop declared, "but if they do they are not Catholics. We want people who adhere to God's word." The Archbishop later added: "Abortion is much more serous than killing an adult. An adult may or may not be innocent, but an unborn child is most definitely innocent. Taking that life cannot be ignored" (Downie 2009).

The statistics concerning aspects of the abortion phenomenon in Brazil portray a situation difficult to interpret. There were 3,093 legal abortions performed in the country from January to November of 2008. The Ministry of Health indicates that 200,000 women, almost all of them Catholics, appear at hospitals or medical clinics each year for treatment for errant illegal abortions. It is estimated that there are about 14 million clandestine abortions performed in Brazil annually. Yet, 67 % of the population responding in a national poll indicated that their preference is to leave the law as it is (Downie 2009).

Abortion and Other Religions

Protestants

Protestant religions run a gamut in regard to abortion, although the most prominent tendency is to echo the Catholic Church's position but less categorically, lest the ministers offend too many communicants. A policy statement by the Evangelical Lutheran Church in America, for instance, reads as follows:

> …the number of induced abortions is of deep concern to this church. We mourn the loss of life that God has created. Abortion ought to be an option only of last resort. Therefore, as a church we seek to reduce the need to turn to abortion as the answer to unintended pregnancies. (Baker and Ehlke 2011, p. 122)

The "ought" in statement is somewhat equivocal, and the words "we seek" do not suggest as vigorous a condemnation of abortion as that promulgated by Catholic theologians.

Mormons

The Church of Latter-Day Saints (Mormons) allows abortions under limited circumstances (rape, for instance) but advises that those contemplating the procedure first consult with the local presiding church authority and then go ahead only after receiving divine conformation of their decision through prayer (Hunter 1990).

Judaism

We can examine the theological position of Jews as an interesting example of an approach that, depending on which segment of the religion a communicant adheres to, comes close to or differs notably from Catholic doctrine.

In terms of theology, Jews divide into three major subgroups: Orthodox, Conservative, and Reform. The issue of Jews and abortion is more complex than with Catholics because there is no one person, such as the Pope, who can put forward a position that would represent the official stance for all the observant.

Orthodox Jews oppose abortion except under very limited circumstances, while some conservative and reform rabbis take the position that a fetus is not a person until some segment of the birthing baby moves outside the mother's body. Theology aside, Jewish authorities find themselves faced with a survival problem that tilts them away from endorsing abortion. In the United States, about half of the Jews marry outside their religion, and their children may or may not be raised in the Jewish faith. Besides, the Jewish birth rate is not sufficiently high to reach replacement levels.

Orthodox Jewish theology takes a position opposite to that of the Catholic Church on the priority of mother and fetus in instances when a decision has to be made which of the two is to be sacrificed to save the other. A one scholar has enunciated Jewish doctrine: "If a woman suffered hard labor in travail, the child must be cut up in her womb and brought out piecemeal, for her life takes precedence over its life; if the greatest part already has come forth, it must not be touched, for the claim of one life can not supersede that of another" (Zoloth 2003, pp. 40–41).

Attitudes Toward Abortion

A comprehensive analysis of the views regarding abortion among white and black men and women from the 1970s date demonstrated shifts over four decades. Factors said to have had an impact on these swings include the increase in female participation in the labor force, the alterations in the extent of nonmarital sexual activity (a dramatic upward move followed by a decline after the appearance of the AIDS epidemic), the further secularization of the society, the increase in educational attainments, the decreasing vitality of the feminist movement, and the growing vigor of the antiabortion movement (Carter et al. 2009, p. 3).

The trend analysis is based on the results of the General Social Survey that questions a representative sample of noninstitutionalized English-speaking adults in the United States. Abortion attitudes were determined by a composite score based on answers to seven questions, asking the respondent if he or she favored allowing abortion under each of the following conditions:

1. If there is a strong chance of a defect in the baby?
2. If she is married and does not want any more children?
3. If the woman's own health is seriously jeopardized by the pregnancy?
4. If the family has a very low income and cannot afford any more children?
5. If she becomes pregnant as a result of rape?
6. If she is not married and does not want to marry the man?
7. The woman wants it for any reason?

The was a slight decrease in support for abortion during the 1980s compared to the period between 1973, when *Roe v. Wade* was decided, and the following decade. That decline has been tied to the influence of President Reagan's antiabortion views but, of course, could have been a cause for his election. White males have been and remain the most liberal of the demographic groups studied when it comes to abortion attitudes. White females are the second most liberal group followed closely by black females and black males. The striking decline in support for abortion among black females from the 1980s to 2008 brings their score close to the point at which it stood in the 1970s before a dramatic rise from the 1980s to the 1990s. It is black males who show the greatest increase in support for abortion between the 1970s and current times (Carter et al. 2009).

Abortion and the Law

Frederick J. Tausig, a leading authority on abortion, observed of the pre-*Roe* days that he knew of "no other instances in which there had been such frank and universal disregard for a criminal law" (Taussig 1936, p. 422). There are greatly varying estimates of the number of illegal abortions in the United States that set the annual figure for the years right before the *Roe* decision at about 200,000–1.2 million. If all women who underwent illegal abortions then were included in the crime statistics, the female crime rate would have far exceeded that for males. In practice, sanctions were not applied to women who had abortions but to those who performed them. Most often, this happened when the aftereffects of the procedure brought the woman to a hospital. There she sometimes offered or was persuaded to testify against the abortionist (Regan 1997).

As with many highly controversial issues in the United States, such as racial desegregation, it was the judiciary that took the lead in endorsing the dramatic national shift in abortion practices. Part of the reason for this is that federal judges are appointed for life and need not be unduly concerned about public disfavor with their decisions. Presidents, governors, and legislators, if they want to remain in office, cannot afford to alienate too significant a portion of their constituency and often decide to stay on the sidelines in regard to actions that might split the public.

Fifteen states had already relaxed restrictions on abortion by 1973. In tandem with *Roe v. Wade*, the 7–2 Supreme Court decision that allowed abortions to be performed legally throughout the nation during the first trimester of pregnancy, the *Doe v. Bolton* (1973) opinion delivered the same day declared unconstitutional a Georgia law requiring that a doctor's decision regarding abortion had to be confirmed by another doctor or a committee and had to be performed in a hospital. Among the forces that appeared to underlie the *Roe* decision was the power of the feminist movement, particularly in terms of the considerable number of women moving into the work force. Birth control pills (replacing more cumbersome and less employed means of contraception) and the growing use of condoms called into question the inviolability of the birth process, since it could readily have been prevented before it began. Condoms became available in college campus restrooms, and birth control pills often sit on the kitchen counter, waiting to be swallowed with orange juice at breakfast.

Parental Notification

The matter of parental notification became the first major abortion battleground. In *Planned Parenthood of Kansas City, Missouri v. Ashcroft* (1983), the US Supreme Court ruled that it was constitutionally acceptable to demand that minors inform their parents of the intention to have an abortion; in some instances, telling a judge could substitute for parental notification. By 2012, in 22 states a parent had to consent to the procedure and in three of these, both parents. In 11 states, a parent only had to be notified and in one of these, both parents. In seven states, the parental notification had to be notarized. In the remaining states, an abortion could be had by a minor without parental involvement.

The irony in the success of the campaign to incorporate parental notification by underage women in the requirement for an abortion surfaced in a later study that indicated that the ruling appeared to have produced only a scant effect on teenage abortions. In Tennessee, for instance, the abortion rate went down after a federal court put a parental notification law on hold but increased when the requirement was reinstated. The rate of abortions fell in Texas after parental notification was mandatory but not nearly as much as it had dropped before then. All told, the study found "no evidence that the laws had a significant impact on the number of minors who got pregnant, and, once pregnant, the number who had abortions" (Lehren and Leland 2006, p. A1).

The *Webster* Case

An important victory for pro-lifers came 16 years after *Roe* when the Supreme Court in *Webster v. Reproductive Health Services* (1989) upheld the constitutionality of a Missouri law that prohibited the use of public facilities, such as municipally owned hospitals, to perform abortions, except when necessary to save a woman's life. The Missouri law also disallowed public funding for programs that included proabortion counseling. The court further agreed that a doctor could be required to inform a pregnant woman seeking an abortion whether her fetus was viable and might possibly survive if delivered prematurely.

The *Casey* Case

The Supreme Court's ruling in *Planned Parenthood v. Casey* (1992) found the justices deciding by a five to four vote to uphold a Pennsylvania law that required a woman seeking an abortion to listen to a lecture or watch a film about fetal development and then wait a day before undergoing the procedure. The doctor was obligated to provide information about alternatives to abortion, its medical risks, and the probable gestational age of the fetus. The doctor also had to inform the patient regarding medical benefits for prenatal care, childbirth, and neonatal assistance, among other matters. The Court, however, refused to endorse the segment of the Pennsylvania law that required the woman, unless she had compelling reasons for not doing so, to sign a statement that she had informed her husband that she was going to have an abortion.

The *Casey* decision was something of a disappointment for the pro-life camp which had thought there was a good chance that the Court would totally jettison *Roe v. Wade*. It led the antiabortion forces to decide to take a lesson from the civil rights movement and to incrementally pick away at elements of *Roe* until it had been so weakened that it would virtually fall of its own accord. They took particular heart from the clause in *Casey* that stated that the Court would be hospitable to abortion arrangements so long as they did inflict an "undue burden" upon women seeking an abortion. Pro-lifers anticipated that "undue burden" was so vague a criterion that it left a great deal of room for them to chip away at the guidelines for abortions.

Late-Term Abortions

The controversy between supporters of legal abortion and their opponents, like many campaigns for the minds of the public, has relied upon the manner in which disputed matters are worded. In the overall denotation of the two sides, those opposing abortion enjoy the verbal high ground. Pro-life is a more appealing slogan than pro-choice. Who can declare that they are not in favor of life, especially when considering its alternative? Pro-choice, on the other hand, sounds self-indulgent. Choices are always limited and where would its adherents draw the line? The unequal appeal of the way the sides have designated themselves has been noted elsewhere: "Perhaps 'pro-choice' once was good enough shorthand for liberty, human dignity, individualism, pluralism, self-government and woman's equality," writes Nancy Cohen (2010, p. A20), who then adds: "But anyone who thinks it still is sufficient as we enter our fifth decades of the cultural wars [over abortion], hasn't been paying attention." By the last, she means attention to the growing strength of the pro-life movement.

The same kind of verbal warfare was prominent in regard to what here is being called "late-term abortions." Pro-life forces defined the matter as "partial-birth abortion" and described the procedure in repellent terms. Pro-choice advocates tended to rely on the terms "dilation and extraction" (d & x) or "dilation and evacuation" (d & e), the medical designations for the procedure. These were abortions generally performed during the fifth to the sixth month of pregnancy. Estimates placed their number at somewhere between 2,000 and 5,000 a year.

The procedure was banned by the federal Congress in 2003. Signing the measure into law, President Bush noted that "for years a terrible form of violence has been directed against children who are inches from birth." The constitutionality of the measure was upheld by a 5-4 vote in the US Supreme Court (*Gonzalez v. Carhart* 2007). The law decreed a fine of not more than $250,000 and/or 2 years imprisonment for "any physician who, in or affecting interstate commerce, knowingly performs a partial birth abortion and thereby kills a human fetus." The Court's opinion noted, rather oddly, that "while we find no reliable data on the phenomenon it seems unexceptional to conclude some women come to regret their decision to abort the infant they once created and sustained" (*Gonzales v. Carhart* 2007, p. 159). This piece of obiter dicta (off-the-cuff musings not directly relevant to the case) is undoubtedly accurate, but the same can be said, perhaps more tellingly, about births – or, for that matter, about people who marry and Supreme Court judges who render decisions they come to regret.

Pro-choice groups had little leverage against the groundswell of public support in opposition to late-term abortions. The view of the liberal wing of the medical profession was expressed in an article in the prestigious *New England Journal of Medicine*:

> This is the first time the Court has ever held that physicians can be prohibited from using a medical procedure deemed necessary by the physician to benefit the patient's health. (Annas 2007, p. 2201)

Subsequent Developments

For a time thereafter, the abortion issue was confined to the periphery of social concerns in the face of America's involvement in wars in Iraq and Afghanistan and the drastic economic meltdown in late 2008. Then abortion recaptured in headlines in March 2011 when the Republicans in Congress held up to almost the very last moment passage of a budget bill that would keep the government functioning. It was not monetary concerns that were being fought over but the Republican's demand to end all funding for Planned Parenthood, a national agency that devotes a small portion of its work to abortion. The Republicans also wanted to stop funding for abortions in the District of Columbia, which is ruled by Congress, and to end the distribution of funds to any overseas government that reallocates some part of the money to agencies encouraging or performing abortions. The dispute over these matters finally was postponed at the last moment in order to keep the government running. But the fact that abortion again has become a political issue is indicated by the fact 944 bills were introduced intro state legislatures during the first 3 months of 2012 seeking to rein in abortions (about 3 % of these bill make it into law).

The Demographics of Abortion

The most reliable statistics on abortion in the United States are those gathered by the Alan Guttmacher Institute, a nonprofit organization that conducts research on human reproduction and performs policy analyses and sponsors public education programs.

The Institute notes that there have been about 50 million abortions since the procedure was authorized by the *Roe* decision in 1973 and 2008 (2008 was the latest year for which US figures were available as late as mid-2012.4 That figure represents a decrease from the highest levels of 1.6 million in the 1980s, despite a growing population. Part of the decrease is due to the appearance of the so-called morning-after abortion pills (RU-486 or Mifepristone) that were sold over the counter to women over 18 and by prescription to those younger.

The legal abortion rates by 4-year periods are presented in Table 1.

Nearly half of the pregnancies in the United States are reported to be unintended, and 40 % of these pregnancies are terminated by abortion. Eight percent of the abortions are performed on teenagers. The figures for other age groups are 20–24 years old (33 %) and 25–29 (24 %). Women who have never married and are not currently cohabiting accounted for 45 % of all abortions, while 61 % are performed on women who already have one or more children. Twenty-eight percent of the women who obtain abortions report that they are Catholics (Jones et al. 2010).

Four of the 13 possibilities were the median number offered by the 1,160 women questioned about the reason they chose to undergo an abortion. Three-fourths cited concern for or responsibility to other individuals; three-fourths said that they could not afford a child; three-fourths said that having a baby would interfere with work, school, or the ability to care for dependents; and half indicated that they did not want to be a single parent or were having problems with their husband or partner (Finer et al. 2005).

For and Against Legal Abortion

Most of the positions taken by pro-choice advocates and those favoring the pro-life positions are summarized below.

The Pro-life Claims

1. It is argued by pro-lifers that to allow legal abortion represents a wedge into more drastic reinterpretations of life and its value. They maintain that since the elderly tend to be a drain on the economy, especially in terms

Legal Status of Abortion, Table 1 Abortion rate per 100,000 women, 1973–2008

Year	Rate
1973	16.3
1977	26.4
1981	29.9
1985	28.0
1989	26.8
1993	25.0
1997	21.9
2001	21.1
2005	19.4
2008	19.48

Source: Alan Guttmacher Institute

of their pensions and medical costs, attitudes favoring abortion could readily be expanded to form a basis for a program of euthanasia directed against old people.

2. Legal abortion is said to make fetal experimentation and human cloning more acceptable, actions most pro-lifers deplore.
3. Pro-lifers maintain that many women who undergo abortions later come to deeply regret that irreversible action; therefore, all reasonable means ought to be allowed to keep them from doing something they subsequently would wish they had not done.
4. Relatively few persons, pro-lifers point out, no matter how wretched their situation may be, choose to end their lives. Nor do many people wish they had never been born. The argument is offered that the fetus being aborted has no way of registering his or her view on the matter and that pro-lifers must defend the fetus.
5. Pro-lifers believe that abortion encourages immoral behavior, such as premarital or extramarital sexual intercourse.
6. The term "genocide" is sometimes used by pro-lifers to describe what they view as the slaughter of millions of unborn human lives.
7. Pro-lifers often insist that the Supreme Court put its nose (and votes) into business that is far removed from its judicial concerns and competence.
8. In regard to *Doe v. Bolton*, pro-lifers maintain that the definition of a pregnant woman's health was overbroad and ill defined since it includes emotional, familial, and other conditions that can be employed as excuses for a self-indulgent act.
9. With ultrasound techniques now able to determine the gender of the fetus, pro-lifers note that abortion will be used to discriminate against female fetuses, skewing the population ratio and in time having far-reaching detrimental consequences for social life.
10. Pro-lifers argue that the loss of manpower and womanpower because of legal abortions creates a necessity for the United States to rely upon foreigners to maintain an adequate workforce. This necessity, they argue, has led to a considerable influx of illegal aliens who are claimed to be a drain on the economy.
11. Pro-lifers say that as a nation that largely derives its moral principles from biblical writings, we should be obligated to follow Christian theological doctrines that preach divine objections to abortion.

The Pro-choice Claims

1. Pro-choice advocates emphasize that making abortion illegal has racist implications. They point out that when abortion was against the law, fatalities from outlawed procedures were found primarily among poor minority group women.
2. Pro-choicers believe that if women bear children they do not want, they are very likely to severely undermine the quality of life in store for those children and, as a result, impose social costs upon others.
3. Pro-choicers dispute the claim that there exists biblical justification for the crusade against legal abortions and that, even if there are such doctrines, they should not be used to interfere with options available to those who do not accept them as guidelines for their own conduct.
4. While granting that it was a Supreme Court of males that enunciated the *Roe v. Wade* doctrine, pro-choicers point out that it has been only males who have allowed inroads against

the unfettered application of the original ruling. None of the women who are or have been on the court have ever voted in favor of an abortion restriction.

5. The pro-choice forces find the ideologies of pro-lifers illogical and contradictory if not hypocritical. They point out that pro-lifers tend to argue that they want the government to get off their backs, yet at the same time, they advocate that the government intrude into people's freedom by forbidding them to undergo abortions.

Conclusion

The fight (battle may be the better term) over abortion shows few signs of abating. It is difficult to think of a resolution that would appease and subdue both sides. Perhaps the best shorthand summary of the situation is that of Laurence Tribe, an eminent constitutional law professor: "What we have here," Tribe (1991, p. 6) has observed, "is a clash of absolutes."

Criminal thinking model; Lifestyle theory of crime

Overview

Lifestyle theory holds that crime is a developmental process guided by an ongoing interaction between three variables (incentive, opportunity, and choice). During each phase of the criminal lifestyle (initiation, transition, maintenance, burnout/maturity), incentive, opportunity, and choice take on different values and meanings. Existential fear serves as the incentive for the initiation phase of a criminal lifestyle. Once initiated, the incentive for continued lifestyle involvement becomes a fear of losing out on the benefits of crime. By the time the individual enters the third (maintenance) phase of a criminal lifestyle, incentive has changed once again, this time to a fear of change. With the advent of the burnout/maturity phase of the criminal lifestyle, incentive has changed yet again, this time to a fear of death, disability, or incarceration. Comparable transformations take place in opportunity and choice. Current controversies include (1) generalizing results obtained from research on male prison inmates to that on female inmates and nonincarcerated offenders, (2) documenting the clinical predictive efficacy of assessment procedures designed to measure key lifestyle constructs, and (3) examining the possibility of an allegiance effect for much of the research on lifestyle theory. Open questions requiring further study include (1) investigating the hierarchical model of criminal thinking proposed by lifestyle theory, (2) exploring the role of criminal thinking and other quasi-time-stable cognitive factors in mediating and clarifying important crime relationships, and (3) ascertaining whether the lifestyle approach to intervention qualifies as evidence based.

Introduction

The lifestyle theory of crime has its roots in Bandura's (1986) social cognitive model, Sykes and Matza's (1957) techniques of neutralization, and Yochelson and Samenow's (1976) work on the criminal personality. As such, it is designed to explain habitual criminal activity by focusing on the cognitive factors that support antisocial behavior. The cognitive-behavioral proclivities of lifestyle theory are obvious given its emphasis on cognition, behavior, and the cognition-behavior relationship. Less obvious, perhaps, is how lifestyle theory integrates cognition and behavior. This entry, in addition to describing the lifestyle theory of crime, is designed to provide the reader with an understanding of exactly how cognition and behavior interact to increase or decrease a person's risk for future criminal involvement.

Background

For much of its history, criminology has restricted itself to a small portion of the relevant data, resulting in the simplistic single-variable theories that now dominate the field. Biology and psychology have been largely ignored by criminologists and while biology and psychology are no more capable of providing a complete explanation of crime than criminology, a complete explanation necessitates their inclusion. The lifestyle theory of crime attempts to highlight psychological variables that may be helpful in explaining certain well-known crime relationships. In this vein, lifestyle theory seeks to integrate constructs from divergent conceptual models rather than perpetuate the artificial dichotomies that seem to have limited theory development in the field of criminology (i.e., classicism vs. positivism, propensity vs. development, continuity vs. change). How lifestyle theory integrates these artificial dichotomies is discussed next.

Early criminological theory emphasized the classical perspective that humans are rationale decision makers who engage in behaviors they believe will provide them with the greatest amount of pleasure and the least amount of pain. The criminal justice system still relies heavily on the classical notion that people choose to commit crime. Theoretical criminology, however, has largely rejected the notion of choice in favor of a deterministic model of criminal behavior in which crime is seen as a function of sociological and environmental factors over which the actor has no control. Lifestyle theory integrates these opposing points of view into a single perspective in which incentive (pushes from within), opportunity (pulls from without), and choice (the decision-making apparatus) are equally important in the development of criminal behavior.

Some criminological theories view offenders as *exhibiting a* propensity for crime; other criminological theories postulate that crime follows a developmental sequence or pattern. The first approach underlies the career criminal paradigm and the second approach lays the foundation for the criminal career paradigm. Lifestyle theory asserts that crime is both a propensity and developmental process and that the career criminal and criminal career paradigms, rather than being diametrically opposed, are actually complementary. Integration of the career criminal and criminal career paradigms gives rise to four overlapping but sequential phases of lifestyle development: initiation, transition, maintenance, and burnout/maturity. Certain propensities lead some individuals to drop out of the sequence during an early phase (initiation, transition) and others to avoid the sequence altogether. Alternate propensities lead some individuals to remain in the sequence or in a particular phase of the sequence longer than most people.

Continuity versus change is another dichotomy that has preoccupied the field of criminology. Some theorists conceptualize crime as a time-stable characteristic that is largely impervious to change, whereas other theorists conceptualize crime as an unstable developmental pattern that is subject to regular and dramatic periods of change. Crime continuity, whereby past offending serves as one of the best predictors of future offending across multiple studies, is often used to support the stability argument. The age-crime relationship, in which crime peaks during mid-adolescence and then drops off sharply in late adolescence regardless of whether crime is measured with official, self-report, or victimization data, is often used to support the instability argument. Lifestyle theory agrees with both positions and integrates stability and instability into its framework by proposing the existence of quasi-time-stable cognitive and behavioral variables that give the lifestyle the appearance of being both stable and changeable.

Another dichotomy that has helped shape the lifestyle theory of crime is whether individual differences in criminality are categorical (difference in kind) or dimensional (difference in degree). This time, however, one side of the controversy (i.e., dimensional latent structure) rather than an integration of the two sides receives the bulk of empirical research support. In a recent review of the taxometric literature on antisocial personality, psychopathy, and criminal lifestyle, Haslam (2011) concludes that these crime-related constructs are dimensional rather than categorical in nature and that individual differences in these crime-related psychological constructs are quantitative (people can be ordered along one or more dimensions) rather than qualitative (people can be grouped into types or categories). Based on taxometric and confirmatory factor analytic research (Walters 2009), lifestyle theory proposes that a criminal lifestyle is composed of two overlapping dimensions: proactive criminality and reactive criminality.

State of the Art

The lifestyle theory of crime, as described in Walters (1990), has undergone several revisions and elaborations. This section on the state of the art of lifestyle theory provides a summary of the most recent version or iteration of lifestyle theory as applied to habitual criminal conduct (Walters 2012a).

Precursors to a Criminal Lifestyle

Prior to entering the initial phase of a criminal lifestyle, certain conditions are already in place. Two commonly observed precursors of a criminal lifestyle are templates and trial runs. A template consists of cultural and subcultural factors that provide a context for subsequent development of a criminal lifestyle. Sundry environmental and familial factors help shape an individual's attitudes and thinking toward antisociality and crime, which, in turn, increase or decrease the person's susceptibility to future criminogenic influences. The child's interactions with the interpersonal environment consequently form a template that makes it more or less likely that he or she will pursue criminal opportunities present in that environment. Trial runs are the individual's initial attempts to employ antisocial solutions to solve interpersonal problems (e.g., acquiring a toy they want, avoiding punishment for stealing a treat from the proverbial cookie jar). The reaction the child receives from his or her interpersonal environment will go a long way toward shaping his or her thinking with respect to future criminal opportunities.

Phase I: Initiation

The first phase of a criminal lifestyle is referred to as initiation. This phase begins with commission of the first arrestable crime and ends when the individual either adopts a conventional lifestyle or moves into the next phase of a criminal lifestyle. Each phase of a criminal lifestyle is a function of specific incentives, opportunities, and choices, around which the current discussion is organized.

Incentive: Existential Fear

Existential fear is a fear of nonbeing combined with a sense of separation and alienation from the environment. Although it is a fear shared by all humans, it is shaped and molded by a person's experiences in the survival-relevant areas of affiliation, control/predictability, and status.

Those whose fears have been shaped by affiliative concerns might experience existential fear as a fear of fitting in or being rejected. Those whose fears have been shaped by control concerns might experience existential fear as a fear of losing control. Those whose fears have been shaped by status concerns may perceive existential fear as a fear of being anonymous or unsuccessful. Existential fear serves as an incentive for behavior in that it motivates, pushes, or encourages the individual to engage in behaviors designed to reduce or alleviate the fear. The degree to which a criminal lifestyle promises the individual relief from existential fear is the degree to which the individual is motivated to enter a criminal lifestyle.

Initially, existential fear is tied to one's physical survival. It is, in effect, a manifestation of the person's survival instinct. This can become distorted over time, however, to where the individual paradoxically favors psychological survival of the lifestyle over physical survival of the organism. This is particularly true of a criminal lifestyle. Research indicates that criminality is often associated with low anxiety or fearlessness (Newman and Schmitt 1998). Lifestyle theory conceptualizes fearlessness as a relatively weak bond between existential fear and physical survival, keeping in mind that lifestyle theory is a dimensional model and that bond strength is a matter of degree rather than an all-or-nothing proposition. Because existential fear needs to be attached to something, the individual with low fearlessness will often attach their existential fear to a lifestyle. Under the proper conditions, this lifestyle could turn out to be a criminal lifestyle.

Opportunity: Early Risk Factors

Opportunity factors increase or decrease a person's risk of entering a lifestyle. In line with the criminal lifestyle's dimensional structure, no single risk factor determines a person's position on the proactive and reactive dimensions of the lifestyle; rather, it is the total number of relevant risk factors that is important (additive etiology). Some risk factors have a greater impact than other risk factors, certain risk factors interact with one another, and some risk effects are moderated by a third variable. Childhood temperament is considered a particularly salient risk factor for the purpose of initiating a criminal lifestyle. Novelty seeking, negative emotionality, and physical activity are three temperament dimensions likely to be elevated in someone at risk for future antisociality. Because childhood temperament is a function of both genetics and early environment, it demonstrates the complex interaction that exists between biological and developmental factors in the formation of a criminal lifestyle. Other risk (opportunity) factors vital during the initiation phase of a criminal lifestyle include stress, weak socialization to conventional groups, strong socialization to deviant groups, and the availability of criminal opportunities in the current environment.

Choice

Lifestyle theory rejects the hard determinism of the positivistic tradition. Even though incentive drives behavior and opportunity shapes it further, the individual still makes choices. The active decision-making that gives rise to choice is a two-stage process: generation and evaluation. The goal of the generation stage of the decision-making process is to come up with as many alternative solutions to a problem as possible. The goal of the evaluation stage of the decision-making process is to systematically and effectively evaluate the pros and cons of each alternative option. For a variety of reasons, from intelligence to experience to poor integration of decisional economics (rational choice) and emotion (empathy), the crime-prone individual often has trouble generating alternatives, properly evaluating alternatives, or both. This is a problem during all four phases of a criminal lifestyle, but during the initiation phase the issue often is resisting the powerful effects of actual and anticipated positive reinforcement for criminality (excitement, curiosity, peer acceptance). Lifestyle theory rejects traditional rational choice and deterrence theory in favor of a model that encompasses both rational and irrational choice.

Phase II: Transition

The transitional phase of lifestyle development is characterized by increased involvement in, commitment to, and identification with the criminal lifestyle. In contrast to the experimentation of the initiation phase, the transitional phase is marked by a growing sense of comfort with the lifestyle accompanied by the belief that certain basic needs will be satisfied by the lifestyle.

Incentive: Fear of Lost Benefits

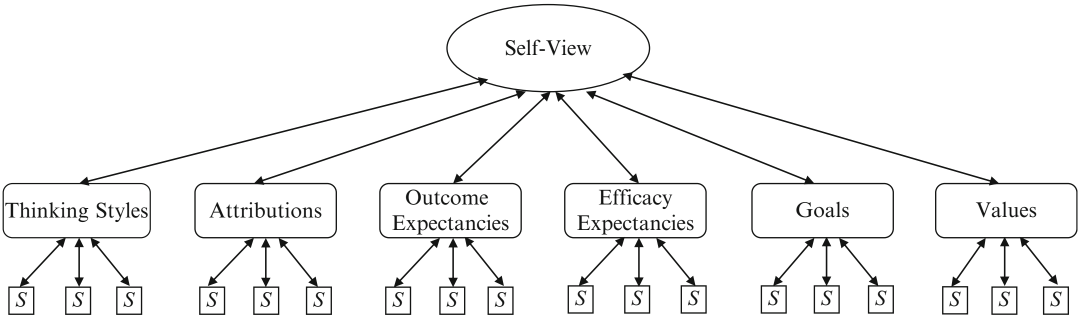
It is during the initiation phase of a criminal lifestyle that the individual comes to realize the material and psychological benefits that can be derived from being involved in a regular pattern of criminality. Existential fear facilitates the transition to a higher level of lifestyle involvement by stimulating a person's fear of losing the material (money, excitement, power) and psychological (affiliation, control, status) benefits of a criminal lifestyle. This transformation of existential fear into a fear of losing the material and psychological profits of a criminal lifestyle is instrumental in transitioning the individual to the next phase of the lifestyle whereby commitment to the lifestyle and certain corollaries (initial incarceration, labeling, rejection of conventional values) take precedence.

Opportunity: Schematic Subnetworks

With increased internalization of the criminal lifestyle, opportunity transitions from behavioral to cognitive. This is another way of saying that a person starts acting like a criminal before he or she starts thinking like one. Once the individual starts thinking like a criminal, his or her opportunities are shaped primarily by six cognitive factors known as schematic subnetworks. Lifestyle theory proposes that criminal cognition is hierarchically organized; with belief systems (self-view, worldview, past view, present view, future view) at the top of the hierarchy, individual criminal thoughts are the bottom of the hierarchy, and several layers of schematic subnetwork in between (see Fig. 1). The six primary schematic subnetworks in the lifestyle model are thinking styles, attributions, outcome expectancies, efficacy expectancies, goals, and values (see Table 1 for more details).

Choice

Decision-making tends to narrow as the individual's commitment to a criminal lifestyle grows. Many people who enter the transitional phase of a criminal lifestyle never possessed good problem-solving skills to begin with. Of those who enter this phase with adequate problem-solving skills, it is the generation stage of the problem-solving process that is most adversely affected by the individual's growing commitment to a criminal lifestyle. As the person begins narrowing the focus of his or her problem-solving deliberations to criminal options, he or she starts a process, facilitated, in part, by criminal thought patterns and other schematic subnetworks (which can be considered purveyors of irrational choice), of discarding and denigrating the noncriminal options available to him or her. Near the end



Lifestyle Theory, Fig. 1 The hierarchical organization of criminal cognition (Note. S = individual criminal thoughts or schemes)

Lifestyle Theory, Table 1 The six quasi-time-stable cognitive variables in lifestyle theory

Cognitive factor	Description
Criminal thinking	Thinking styles that support criminal behavior. The criminal thinking hierarchy is organized, from top to bottom, into a superordinate factor (general criminal thinking), two higher-order factors (proactive and reactive criminal thinking), and eight individual thinking styles (mollification, entitlement, power orientation, and superoptimism under proactive; cutoff, cognitive indolence, and discontinuity under reactive; sentimentality by itself)
Attributions	Beliefs about the causes of one's own or others' action; self-labeling and hostile attribution biases, whereby the individual perceives an unintentional act on the part of another person as a deliberate and hostile act, are two ways attributions help maintain a criminal lifestyle
Outcome expectancies	Beliefs about the anticipated consequences of crime and other behaviors; the criminal lifestyle is characterized by strong positive outcome expectancies for crime (money, power, acceptance) and weak negative outcome expectancies for crime (death, injury, incarceration)
Efficacy expectancies	Beliefs about one's chances of successfully engaging in a behavior or completing a task; the criminal lifestyle is associated with strong self-efficacy for crime and weak self-efficacy for conventional behavior
Goals	Objectives one pursues; the goals that direct a criminal lifestyle tend to be of short (reactive) to intermediate (proactive) range rather than long term
Values	Priorities that govern one's actions; a criminal lifestyle tends to be driven by physical (reactive) and mental (proactive) hedonistic values

of the transition phase, it is not uncommon to find the proactive (scheming, cold-blooded, e.g., "what's in it for me?") and reactive (impulsive, hot-blooded, e.g., "I'll get you for that!") dimensions of decision-making exerting independent, simultaneous, and poorly modulated effects on behavior.

Phase III: Maintenance

Whereas the majority of those who enter the initiation phase of a criminal lifestyle never progress to the transitional phase and a sizeable minority of persons who move into the transitional phase drop out before entering the maintenance phase, there is virtually no attrition from the maintenance phase. This is because the maintenance phase of a criminal lifestyle is a period of maximum lifestyle involvement, commitment, and identification.

Incentive: Fear of Change

As scary as a criminal lifestyle and its consequences (injury, death, and incarceration) may be, they are often not as frightening as the prospect of change. Fear of change consequently becomes the primary incentive for remaining in a criminal lifestyle long after it has stopped being fun. The individual feels compelled to remain in the lifestyle even though the benefits no longer seem to outweigh the costs, and it is a fear of change or better yet, a fear of the unknown, that is behind the individual's inactivity and apparent immobility. Things may not be as the person would like them to be but there is comfort to be found in the familiar, even when the familiar is no longer as comfortable as it once was. Giving up crime may be interpreted as symbolic death by someone in the maintenance phase or at least tacit acceptance that the years spent in a lifestyle were a waste of time and a poor decision on his or her part.

Opportunity: Psychological Inertia

Psychological inertia is based on Newton's first law of motion, which states that a body at rest will remain at rest and a body in motion will remain in motion unless acted upon by an outside force. Once a criminal lifestyle is in motion, it will maintain itself until acted upon by an outside force for change. The progenitors of psychological inertia are the six schematic subnetworks mentioned in the previous section on transition. Each of these quasi-time-stable cognitive factors gives rise to continuity in criminal behavior. Criminal thinking, for instance, provides offenders with a way of understanding the world that is consistent from one situation to the next and helps rationale their ongoing criminal behavior. Attributions like self-labeling, outcome expectancies of unlimited power and control, high self-efficacy for crime and low self-efficacy for conventional behavior, short-term goals, and hedonistic values all keep the individual locked in chronic pattern of offending by way of psychological inertia.

Choice

During the maintenance phase of a criminal lifestyle, the individual may truly believe that he or she has no choice other than to remain in the lifestyle. Given that lifestyle commitment is maximal during this phase, it is easy to see why many late phase offenders feel "stuck" in the lifestyle or view continued criminal involvement as their "fate." Hence, attitudes expressed by probation officers, correctional staff, or even counselors suggesting that offenders never change (i.e., "once a criminal, always a criminal") may serve to inhibit the natural changes process that leads to change in even the most recidivistic of offenders. The ability to generate and evaluate alternatives is almost universally weak in those who reach the maintenance phase of a criminal lifestyle. Fear of change and psychological inertia only serve to reinforce the fatalistic belief that their situation will never change. There is hope, however, and this hope arrives in the form of the fourth and final phase of a criminal lifestyle, burnout and maturity.

Phase IV: Burnout and Maturity

The combined effect of the negative long-term consequences of a life of crime and the aging process leads to the fourth and final phase of a criminal lifestyle, burnout and maturity. Whereas burnout is a decrease in physical energy and stamina that makes crime more difficult and less pleasurable, maturity is a psychological process involving a genuine change in interests, goals, values, and activities. Physical burnout is inevitable, psychological maturity is not. An individual who is physically burned out but has not yet achieved psychological maturity may switch to a less physically taxing criminal activity, like dealing in stolen property; nevertheless, he or she will remain on the outskirts of the lifestyle. Whereas the transition from the maintenance phase of a criminal lifestyle to burnout and maturity can be abrupt, it is normally a gradual and uneven process.

Incentive: Fear of Death, Disability, and Incarceration

With respect to fear, the offender has come full circle once he or she enters the burnout/maturity phase of a criminal lifestyle. One of the factors associated with initiation of the lifestyle is a weakened bond between existential fear and physical survival and the creation of a robust bond between existential fear and some activity, in this case, the criminal lifestyle. During burnout/maturity the bond between existential fear and physical survival strengthens, while the existential fear-lifestyle bond weakens. This is achieved by way of a growing fear of incarceration, a fear of dying in prison, and fears associated with the negative consequences of a criminal lifestyle, namely, death, injury, and disability.

Opportunity: Approach and Avoidance

Several factors support desistence from crime by increasing opportunities for prosocial activity and decreasing opportunities for antisocial activity. This can be accomplished by approaching goals, options, and outcomes incompatible with crime, such as marriage, parenthood, and conventional employment, or avoiding goals, options, and outcomes compatible with crime, such as drug use, criminal associates, and settings where one has committed crime in the past. As approach and avoidance opportunity factors interact, burnout and maturity increase and the risk of future criminal involvement drops dramatically.

Choice

Choice plays a vital role in crime initiation, maintenance, and desistance. During burnout and maturity, its role is to focus the individual on the rapidly accumulating negative consequences of criminal behavior, from incarceration to death. Many individuals, as they get older, become better problem solvers. Age seems to have a positive effect on a person's ability to both generate and evaluate alternatives and the negative consequences that accompany a criminal lifestyle are more difficult to accept and tolerate as the person ages. More people exit a criminal lifestyle during the initiation phase, but the greatest proportion of people exit the lifestyle during burnout and maturity. Fear of death, disability, and incarceration; approaching prosocial situations and avoiding antisocial ones; and placing greater emphasis on the negative consequences of crime than on the perceived benefits of crime are at the heart of the burnout and maturity phase.

Current Controversies

Nearly all of the research on lifestyle theory has been conducted on male inmates serving time in US federal prisons. A handful of studies have been conducted on US state prisoners and forensic patients and several studies have been done on European samples but only one study used female participants (Walters et al. 1998), and no studies have tested lifestyle theory in community corrections clients. The research base for lifestyle theory must consequently be expanded. Not only is there a need for more research on female offenders and community samples, but research on the invariance of lifestyle principles across ethnic groups and crime categories is also required. Research on juvenile samples is also needed. Whereas application of lifestyle theory to children and adolescents has been covered recently (i.e., Walters 2012a), there have been no research studies on lifestyle theory in which juveniles have served as subjects.

Assessment procedures have been developed to measure key concepts in lifestyle theory but the clinical utility of these measures remains largely untested. Thus far, the Lifestyle Criminality Screening Form (LCSF: Walters et al. 1991) has been developed to assess the behavioral dimensions of a criminal lifestyle (irresponsibility, self-indulgence, interpersonal intrusiveness, and social rule breaking), the Psychological Inventory of Criminal Thinking Styles (PICTS: Walters 1995) can be used to assess criminal thinking, and the Outcome Expectancies for Crime scales (OEC: Walters 2003) are available for assessing positive and negative outcome expectancies for crime. In the name of clinical utility, these measures should be capable of predicting important crime outcomes like recidivism with at least modest to moderate effectiveness. In addition, they should also possess incremental validity relative to easily obtained measures like age and criminal history.

Meta-analyses have been conducted on the LCSF ($k = 11$) and PICTS ($k = 7$) as predictors of recidivism, with r serving as the effect size measure and studies being combined using the random effects model. The results reveal a weighted effect size of .23 (95 % CI = .15–31) for the LCSF and .20 (95 % CI = .15–24) for the PICTS General Criminal Thinking (GCT) score. Viewing these results relative to Cohen's (1988) guidelines for small (.10), moderate (.24), and large (.37) effect sizes, we can see that the LCSF and PICTS both achieved effect sizes in the small to moderate range. Because the LCSF is a measure of criminal history, it is not possible to evaluate its ability to predict recidivism beyond the effects of age and criminal history. However, when the PICTS GCT score was entered into a regression equation behind age and criminal history, it continued to predict recidivism above and beyond the contributions of age and criminal history (Walters 2012b). A meta-analysis or incremental validity analysis could not be performed on the OEC because of a lack of recidivism data.

Theoretical articles and research reports on lifestyle theory have been published largely by one individual, the author of lifestyle theory. An allegiance effect can arise any time an author is evaluating his or her own theory and is most commonly observed in studies where an assessment device or therapeutic modality is being evaluated. Eight of the eleven LCSF studies and five of the seven PICTS studies included in the previously mentioned meta-analyses were performed by the author of lifestyle theory (Walters). A small difference was observed when the 13 effect sizes obtained in studies by Walters ($r = 0.23$, 95 % CI = 0.17–0.28) were compared with the five effect sizes obtained in studies conducted by outside researchers ($r = 0.18$, 95 % CI = 0.09–0.26); however, the difference disappeared when a single outlying study was removed from the outside researcher group ($r = 0.22$, 95 % CI = 0.14–0.29). Only two empirical studies have evaluated the lifestyle approach to intervention and both were published by Walters (1999; 2005). Until outside researchers conduct more studies on lifestyle theory, the possibility of an allegiance effect for research on lifestyle theory remains an open question.

Open Questions

Besides investigating whether an allegiance effect accounts for some of the positive results obtained in research on lifestyle theory, there are three other open questions that demand attention. First, there is a need for more research on the hierarchical structure of criminal thinking. This hierarchy fits into the criminal thinking schematic subnetwork box found in Fig. 1, with general criminal thinking at the top, proactive and reactive criminal thinking in the middle, and the eight individual criminal thinking styles at the bottom. Applying item response theory (IRT) principles and confirmatory factor analysis to a sample of nearly 3,000 incarcerated male offenders, Walters, Hagman, and Cohn (2011) determined that the sentimentality scale did not load onto either of the two higher-order factors (proactive, reactive) or the superordinate general criminal thinking factor. Based on these results, it has been recommended that instead of calculating the GCT score by combining the raw scores of the eight thinking style scales, the seven thinking style scales other than sentimentality be used to calculate the GCT. Further research is nonetheless required to cross-validate these results in a noninstitutionalized sample.

A second open question is whether the cognitive factors in lifestyle theory mediate important crime relationships. In the first of several studies, Walters (2011) discovered that the PICTS GCT score partially mediated the relationship between a history of serious mental health problems and subsequent institutional violence in a group of federal prison inmates. A second study found that the GCT score partially mediated the relationship between race and recidivism (Walters in press b) and a third study revealed that the PICTS Reactive Criminal Thinking score partially mediated the relationship between prior substance abuse and subsequent recidivism (Walters 2012c). In a fourth study, Walters (in press a) determined that the GCT score and weak self-efficacy to avoid future police contact both mediated the relationship between past and future criminal conduct. It would appear that at least some of the quasi-time-stable cognitive factors in lifestyle theory are capable of mediating crime-relevant relationships, although further research is required to ascertain the extent to which the effect applies to all six factors.

A third open question is whether lifestyle intervention can be considered evidence based. Given that there have been only two empirical studies on lifestyle intervention to date (Walters 1999; 2005), there is insufficient evidence at this time to conclude that lifestyle intervention is evidence based. Nevertheless, the approach is manualized and has been adapted for use in an outpatient substance abuse program in Denmark (Thylstrup and Morten Hesse in press). One of the founding principles of lifestyle intervention is that while behavior proceeds cognition in the development of a lifestyle (i.e., a person starts acting like a criminal before he or she starts thinking like one), cognition proceeds behavior in lifestyle change (i.e., a person stops thinking like a criminal before he or she stops acting like one). Although cognition and behavior cannot be meaningfully separated, the early stages of lifestyle intervention focus primarily on challenging criminal thinking patterns and other cognitive mediators of criminal behavior, with the behavioral interventions becoming more prominent at latter stages of the treatment process. Research is required, however, to determine whether the progression proposed by lifestyle theory (i.e., start by focusing on cognition and then move into behavior) is justified.

Conclusion

The lifestyle theory of crime is presented for the purpose of illustrating how psychological factors are capable of furthering our understanding of criminal behavior. Lifestyle theory seeks to reconcile popular dichotomies in the field of criminology (classicism vs. positivism, propensity vs. development, continuity vs. change) by incorporating features of criminality that have been largely ignored by traditional criminological theories. After reviewing the developmental progression vital in initiating and maintaining a criminal lifestyle, controversial topics and open questions concerning the theory are discussed. The future of lifestyle theory depends on its ability to attract the attention of outside researchers and clinicians so that the model's potential can be tested and its limitations delineated.

Overview

Police investigators must often determine whether multiple crimes have been committed by the same offender. In ideal situations, this decision is based on an analysis of physical evidence left at crime scenes, such as DNA, fabric fibers, and/or fingerprints. However, despite what is portrayed in the popular media, such evidence is not always available to be processed (Davies 1991). Given this, the police have had to establish alternative methods for linking serial crimes. One of the most commonly used approaches is behavioral linkage analysis.

When using this form of analysis, an attempt is made to link crimes based on the behaviors that offenders engage in while committing their offenses. Specifically, the goal is to identify patterns of behavior across an offender's crimes that meet two criteria: behavioral stability and behavioral distinctiveness (Canter 1995). Behavioral stability exists when offenders behave in the same or similar way across their crime series (i.e., high levels of within-series similarity). Behavioral distinctiveness exists when the behaviors exhibited by one serial offender are different from those exhibited by other offenders committing similar types of crimes (i.e., low levels of between-series similarity). When offenders behave in a relatively stable and distinct fashion, it may be possible to link them to their crimes and to differentiate between crimes committed by different offenders (Bennell et al. 2009).

In the investigative setting, linkage analysis is most often carried out by crime analysts or police officers who have specialized training. Generally speaking, there are two ways that the linking task is approached (Woodhams et al. 2007). Proactive linking involves attempts to determine whether a new crime series can be identified by examining the similarities and differences that exist between unsolved crimes archived in a large database. In contrast, reactive linking typically involves attempts to determine whether unsolved crimes can be linked to a particular offense of interest to the police (it may also involve attempts to determine whether a specified set of crimes are the work of a common offender). In some cases, the perpetrator of an index crime may already be known to the police, and the task is to determine whether any unsolved crimes are the responsibility of that particular offender.

Although there is no one method for conducting behavioral linkage analysis, many approaches consist of the following steps: (1) searching for crimes that share similar behavioral features; (2) isolating all the similarities and differences between the crimes that are identified; (3) evaluating the importance of those similarities and differences by, for example, considering the base rates of the behaviors within larger samples of offenses (given that frequently occurring behaviors are unlikely to be useful for distinguishing between crimes committed by different offenders); (4) determining the likelihood of actual crime linkages; and (5) reporting the results of the analysis to investigators (Woodhams et al. 2007).

Historical Developments

The idea that an offender's behavior can be useful for linking crimes is not new. In Gross's (1906) classic book, *Criminal Investigation*, he highlighted the potential value in using an offender's modus operandi, or MO, to link his crimes. Even before this, police agencies in England and Wales had begun developing sophisticated systems for categorizing MOs for the specific purpose of linking crimes (Fosdick 1915). For example, around the turn of the century, Chief Constable William Atcherley of the West Riding Yorkshire Constabulary developed a coding scheme for burglary MOs that increased the ease with which these crimes could be compared to one another. This system was further refined in North America to allow for more detailed comparisons (Vollmer 1919).

Such coding systems, which were used throughout the early 1900s, assumed that offenders exhibit behavior in a highly stable fashion across their crimes. However, thinking around this issue gradually changed. Investigators began to realize that an offender's MO can vary across his crimes for a number of reasons, including learning, maturation, and situational factors (Douglas and Munn 1992). This led to a search for crime features that would remain more stable over time. Law enforcement professionals began to distinguish between three related but distinct constructs: MO, ritual, and signatures (Hazelwood and Warren 2003). MO refers to functional behaviors that are required to successfully commit a crime. Ritual refers to fantasy-based behaviors, which are symbolic in nature and reflect the psychological needs of an offender. Finally, signatures refer to combinations of behaviors (MO or ritual) that are assumed to be relatively stable and unique to each offender. Despite the lack of empirical research to support their use, by the 1990s, linking crimes based on behavioral signatures became a popular approach (e.g., Keppel 1995).

In order to systematize the analysis of an offender's crimes, including their MO and ritual behaviors, police professionals have historically used charts that allow them to compare common and distinctive features exhibited across a set of crimes. While such charts are still commonly used today (Burrell and Bull 2011), sophisticated computer databases are also sometimes relied upon to track and analyze the behaviors of offenders (Collins et al. 1998). One of the first systems designed for this purpose was the Violent Crime Apprehension Program (ViCAP), which was developed by the Federal Bureau of Investigation for the purpose of enabling cross-jurisdiction crime linkages (Howlett et al. 1986). With the cooperation of police investigators from across the country who provide ViCAP with detailed information about the crimes they are investigating, this system allows the ViCAP team to organize, search, and analyze offense-related data in an attempt to identify patterns across crimes that may indicate the presence of serial offenders. Since the development of ViCAP, other systems have also been developed. Most notable among these is the Violent Crime Linkage Analysis System (ViCLAS). Constructed by the Royal Canadian Mounted Police in the mid-1990s (Collins et al. 1998), ViCLAS is currently being used by police forces around the world in an attempt to link serial crimes and is generally considered the gold standard for linkage systems.

Current Research

With the advent of standardized data collection protocols came the possibility of conducting empirical research to examine the degree to which behavioral information can be used to reliably link crimes to the same offender. While this field of research is still relatively new, the number of studies in this area has grown rapidly over the last decade. Existing studies examine a wide range of issues.

Tests of the Linking Assumptions

The majority of linking research conducted to date has attempted to determine whether the assumptions of behavioral stability and distinctiveness (and thus linking) are empirically supported. Many studies in this area use the same basic procedure: (1) the researcher categorizes crime scene behaviors into domains based on their particular function (e.g., wearing a mask is assigned to a "planning" domain in cases of robbery); (2) behavioral similarity scores are calculated for each domain for pairs of crimes that have either been committed by the same offender (linked pairs) or different offenders (unlinked pairs); (3) a statistical procedure, such as logistic regression analysis, is then used to determine the degree to which these similarity scores discriminate between the two types of crime pairs; and (4) linking accuracy is quantified using a measure known as the area under the curve (*AUC*), derived from receiver operating characteristic analysis, which typically varies from 0.50 (chance accuracy) to 1.00 (perfect accuracy). In general, research of this type provides support for the assumptions underlying linkage analysis in crimes ranging from serial burglary (e.g., Bennell and Canter 2002) to serial homicide (e.g., Melnyk et al. 2011), with *AUC* values in the range of .60–.90 being frequently reported. Evidence is even emerging that it is possible to use certain types of behavioral information (e.g., spatial and temporal information) to accurately link offenses that fall into different crime categories (e.g., a residential burglary and a sexual assault committed by the same offender; Tonkin et al. 2011).

Using Behavioral Themes to Link Crimes

Rather than assigning behaviors to domains based on their particular function, other researchers have examined the linking assumptions by using clustering procedures (e.g., multidimensional scaling) to group crime scene behaviors into psychological themes (e.g., hostility). These themes then form the basis for further analysis. For example, Santtila et al. (2008) used Mokken scaling, which is similar to factor analysis, to derive behavioral themes (or dimensions) from the crime scene behaviors of Italian murderers. Using scores derived from seven dimensions as independent variables, and the series an offense belonged to as the dependent variable, they were able to use discriminant function analysis to correctly assign 62.9 % of crimes to the correct series. While lower accuracy rates have been reported for other types of crimes (e.g., serial arson; Santtila et al. 2004a), even these studies suggest that linkage accuracy exceeds levels that would be expected by chance.

Identifying Factors That Influence Linkage Accuracy

Many studies have also focused on identifying factors that might influence the accuracy with which crime linkages can be identified. While a range of factors have been explored (e.g., the type of similarity coefficient used to measure across-crime similarity; Melnyk et al. 2011), most research has examined whether certain crime scene behaviors (or themes) are more useful for linking purposes. Recent findings suggest that this is the case. For example, crime scene behaviors which are “offender-driven” appear to be exhibited in a more stable and distinct fashion by offenders (and are thus better predictors of whether crimes are linked) than behaviors that are more “situation-driven.” In cases of serial burglary, for instance, the distance between crime site locations (which is obviously determined by where an offender decides to commit their crimes) can be a very effective linking cue, whereas the type of property stolen by an offender (which depends on what is available to be stolen) tends to lack high levels of predictive accuracy (Bennell and Canter 2002). Similar conclusions can be reached from studies of linkage analysis that have used the thematic approach. In Grubin et al. (2001) study of serial sexual assaults, for instance, behaviors related to a “control” theme (e.g., having a weapon, which would appear to be planned in advance of the crime) were exhibited more consistently than behaviors related to a “style” theme (e.g., taking money from the victim, which depends on situational factors).

Understanding the Complexities of Linking Decisions

Another body of research has investigated some of the complexities involved in linkage analysis by examining how decision-makers perform on laboratory-based linking tasks. For example, Santtila et al. (2004b) examined the performance of experienced car crime investigators, experienced general investigators, novice general investigators, and naive participants on a mock linking task using car crime data. They found that, while investigators were significantly more accurate than naive participants, there were no differences between the different types of investigators in terms of their linking accuracy, with each group identifying about half of all possible links (although experienced car crime investigators did rely on significantly less information than every other group to make their decisions). The reasons why participants in these types of studies experience problems with identifying crime linkages are still not well understood, but they likely have to do with difficulties in selecting appropriate linking cues and in adequately processing this information (Bennell et al. 2010). It may also be the case that participants who have been examined in these types of studies lacked the necessary training or experience in linkage analysis to perform well on the tasks or that the tasks themselves were inappropriately designed.

The Development of Computerized Linking Algorithms

In contrast to the research just described, studies have also explored whether more "mechanical" approaches can be used to identify crime linkages, which is potentially important given the problems that people seem to encounter when faced with this task. In addition to various statistical approaches that have been examined (e.g., Bennell and Canter 2002), a variety of computer algorithms have also been tested (e.g., Yokota and Watanabe 2002). Studies indicate that these algorithms have the potential to automatically link crimes, sometimes with a high degree of accuracy, and that these procedures are associated with a number of advantages over other, more subjective, procedures. For example, some of the tested algorithms can weight behavioral similarity scores between crimes, such that information which is more prone to errors is given less weight (Brown and Hagen 2002). While it is still too early to make recommendations for how these computer algorithms (or similar tools) should be used in investigative settings, they may be able to effectively support the decisions currently being made by linkage analysts.

Examining Design Decisions from Previous Linking Studies

Finally, much of the research being conducted recently examines the impact of potentially problematic design decisions that have been made in previous studies. For example, most studies conducted on linkage analysis have relied on samples of solved serial crimes because, in order to determine linking accuracy, researchers need to know which crimes in their sample are actually linked. While this makes sense, designing studies in this way can bias results if the sampled crimes were originally linked and solved because they were characterized by highly similar or distinct MOs (Bennell and Canter 2002). If that were the case, levels of accuracy reported in these studies may overestimate what is actually possible when linkage analysis is applied to unsolved crimes. Fortunately, recent research that has examined linking accuracy for crimes first linked by MO versus DNA has indicated that similar levels of accuracy are observed, suggesting that there may be no need to worry about previous results (Woodhams and Labuschagne 2012). Similar attempts have been made to explore the impact of other design decisions, such as the common but questionable practice in most linking studies of excluding non-serial offenses from samples.

Remaining Challenges

Despite the growth in studies that has occurred over the last decade, challenges still remain, both for researchers working in this area and for practitioners who conduct linkage analysis.

Dealing with Problematic Data

Some of the most difficult challenges faced by both researchers and practitioners relate to issues around data quality (Burrell and Bull 2011; Woodhams et al. 2007). In both research and practice, linking decisions tend to be based on certain sources of data – typically victim statements or crime reports – that can be highly problematic. For example, with respect to victim statements, victims can forget what occurred during a crime, they can be reluctant to talk about certain events, and reports of what they say can be distorted by the police (Alison et al. 2001). Crime reports, on the other hand, are often plagued with missing data, and certain pieces of information contained within them can be highly unreliable (e.g., the time that a burglary occurred). Any research results that emerge from such data sources, or any linkage decisions that are based on them, must obviously be viewed with caution, though improvements to data coding and recording protocols can improve the situation.

This type of data can also be very limited with respect to what it reveals about offenders and the crimes they commit, which can prevent, or at least hinder, useful lines of research or inquiry. For example, in other research contexts where high-quality data can be collected, it has been discovered that individual differences in noncriminal behavior are more stable across "psychologically similar" situations (e.g., Shoda et al. 1994). This is clearly an important finding that might have relevance to the linking context. Unfortunately, despite the efforts by some (e.g., Woodhams et al. 2008), it is difficult to examine these issues within the investigative context. It is typically not possible to observe crimes taking place, and data sources like victim statements do not tend to include detailed information about situational factors. This prevents researchers from examining potentially interesting (and useful) issues. For the linkage analyst, such problems limit their ability to understand how situations influence offenders and to interpret the meaning or significance of specific behaviors, which is often necessary to accurately link crimes.

Conducting (and Getting Access to) Valid Research

A related challenge for researchers in this area is to conduct studies which produce results that generalize to real investigations (i.e., externally valid studies). The challenge for practitioners is to make sound linking decisions in the absence of externally valid linking research. The primary issue for researchers is that attempts to improve the external validity of their studies can sometimes make the research more challenging to conduct. For example, in order to increase the validity of studies concerned with linking accuracy, researchers might want to include serial and non-serial crimes in their samples, rely on serial crimes that have been linked initially by DNA, and include every crime from each offender's series. The problem is that it is difficult, though not impossible (e.g., Woodhams and Labuschagne 2012), to get access to such data. Unfortunately, the further studies stray away from these sorts of samples, the more the generalizability of results will become a serious concern.

Given these issues, practitioners often face challenges in applying existing research to linking tasks. While the sorts of sampling issues described above are certainly part of the problem, there are additional (potentially more serious) issues that need to be addressed. Indeed, some practitioners argue that much of what is studied by researchers in this area is largely irrelevant for decisions that analysts routinely have to make, leading to calls for research that is more pragmatic in nature (Alison and Rainbow 2011). For example, most research to date has examined proactive linking, where large samples are searched, crime linkages are established, and accuracy is determined. However, analysts often encounter reactive tasks where they are asked to determine whether a set of offenses, thought to be connected by an investigator, are likely to be linked (Rainbow in press). At best, research on proactive linking tasks is relevant here and researchers have simply not made this clear. At worst, a large body of research that has been conducted is of little use in assisting analysts on common tasks that they encounter.

Withstanding Legal Scrutiny

Increasingly, linkage analysis is finding its way into court when questions are raised about whether a defendant is responsible for multiple crimes (Labuschagne 2006). This presents challenges for both researchers and practitioners. While practitioners will likely be the ones presenting at trial, for their testimony to be admitted in many jurisdictions good linking studies will be required. Indeed, although standards of admissibility differ across jurisdictions, at least some rely on criteria that relate directly to research. For example, beyond having to establish expertise and demonstrate that testimony is relevant and useful (i.e., goes beyond the common understanding of the judge or juror), if one were to apply the *Daubert* criteria from the USA to any sort of linkage analysis, issues related to its reliability would also come up (Woodhams et al. 2007). Questions about the testability of the linking assumptions would likely be asked, in addition to other research-related questions pertinent to this issue (e.g., have the assumptions been tested, have the results of those tests been adequately published). It is doubtful that all the *Daubert* criteria would be met at the moment (Woodhams et al. 2007). Whether they are in the future will depend, to some extent, on the type of research that is conducted and published. In this way, researchers have a role to play in developing research that can allow linkage analysis to withstand legal scrutiny.

For practitioners, there are two issues they could potentially speak to at trial – behavioral similarities that exist across the crimes in question and/or how peculiar (distinct) the similar behaviors actually are (Ormerod 1999). As just discussed, the primary challenge for practitioners will be getting their evidence admitted. Usefulness might prove to be a controversial issue. Despite evidence to the contrary in some jurisdictions (e.g., Labuschagne 2006), it is debatable whether testimony related to similarities would be commonly heard by the courts given that jurors and judges can arguably perceive similarity for themselves (Ormerod 1999). However, evidence related to distinctiveness might be viewed as more useful. Issues of reliability could also be contentious. The practitioner will have to clearly demonstrate that distinctiveness exists and convince the court that their testimony is sound. Currently, there appears to be no standard (i.e., commonly accepted) protocol for measuring distinctiveness, and there is insufficient published research on this particular topic, especially as it relates to reactive linking tasks. While the increased use of crime linkage systems, such as ViCLAS, will assist in establishing base rates of behavior, the reliability of the data contained within these systems will have to be confirmed.

Overview

The role of space and place has a long tradition in American criminology largely germinating from the ground-breaking research of Shaw and McKay (1942). Yet by the 1960s and 1970s, criminological attention had turned almost wholly to individual-level causes of crime. Over the past three decades, however, researchers have rediscovered the central role of communities in the causation and control of crime. Like people, communities have a criminal history or “criminal career”; they experience relatively more or less criminal activity than both other places in the city and compared to their own levels at earlier periods in time. To the extent that the natural history of a community affects its current crime rates, its reputation for violence, and its projected levels and patterns of crime and violence in the future, the idea that a community may follow a specific type of trajectory, or “career” may be more theoretically useful to criminologists than are cross-sectional or static patterns across space. This entry describes the theoretical foundations of the literature on longitudinal crime trends at places, provides an abbreviated overview of various methodological approaches to modeling community crime trajectories, elaborates on some key findings, considers the conceptual implications of the unit-of-analysis (or what is meant by “place”), and ends with a discussion of both thorny issues and future directions for research.

Introduction

If it is true that the whole is greater than the sum of its parts, then a key to the success of any social group is its ability to build and sustain a sense of community – to generate a capacity for realizing the shared interests, actions, and fortunes of its members (Sampson and Groves 1989). The criminological literature on space and place primarily is concerned with investigating how one’s residential environment either creates vulnerabilities to risk of victimization or provides conditions conducive to offending among the already predisposed. Much scholarly work has identified the risk factors associated with crime in space, including: (1) the social and economic characteristics related to social disorganization such as poverty, family structure, residential mobility, ethnic and racial heterogeneity, and urbanization (Shaw and McKay 1942; Sampson and Groves 1989); (2) private, parochial, and public social controls (Bursik and Grasmick 1993; Carr 2003); (3) risky terrains rife with concentrated public housing, bus stops, liquor stores, leisure establishments, bars, and other entertainment venues (Caplan et al. 2011; Felson 1998; Griffiths and Tita 2009); and (4) gang territory or drug market locales (Tita and Ridgeway 2007), among others. These features affect the likelihood of criminal events occurring within neighborhoods.

Until recently, however, the neighborhood-effects literature treated local characteristics as if they were relatively static or fixed. That is, the presence, absence or level of various population and land use features were used to predict the distribution of crime across urban space. Despite having much success in explaining cross-sectional aggregate crime patterns, this approach fundamentally ignores one of the basic lessons of the early disorganization scholars: communities change over time, either as a consequence or independently of the outcome under study. For this reason, it is important to consider the joint spatial and temporal aspects of communities or, said differently, longitudinal crime trends at places.

In 1986, Reiss and Tonry edited a volume of *Crime and Justice: A Review of Research* entitled *Communities and Crime*. This volume emerged prior to what would become a plethora of studies on social disorganization and neighborhood effects over the succeeding decades. In anticipation of this scholarly interest, the authors of *Communities and Crime* prepared thoughtful and important essays on the dynamics of crime across urban space, focusing on issues of stability, change, and community careers in delinquency, crime, and violence (Reiss and Tonry 1986). Unfortunately, their call for attention to the dynamics of community crime trends went largely unheralded. While the neighborhood-effects literature mushroomed (Sampson et al. 2002), it remained predominantly targeted at difference in crime across space rather than changes in crime at places over time. Criminologists are certainly much better prepared to discuss the role of communities in crime causation as a consequence of the neighborhood-effects literature, but our understanding of how crime changes over time across place remains in its infancy.

The remainder of this entry is organized as follows. The first section describes the central theoretical arguments for explaining the dynamics of crime in space. In the second section, three common methodologies that have been employed to capture crime trends in empirical models are briefly outlined. The third section provides a short review of the literature on community trends in delinquency, crime, and violence. This is followed by a section that problematizes the plethora of “places” operationalized by researchers. Finally, the entry ends with a consideration of a number of data problems confronting scholars of neighborhoods and crime and touches upon anticipated directions of future research.

Theoretical Fundamentals

It was at the Chicago School that Clifford Shaw and Henry D. McKay first studied the distribution of delinquency across the city and pioneered one of the most important ideas in criminology of the twentieth century. In brief, Shaw and McKay (1942) observed that neighborhoods in the transitional zone – or in neighborhoods contiguous to but immediately outside of the central city – repeatedly represented the highest rates of juvenile delinquency over more than three decades (1900–1933), irrespective of the particular ethnic group residing in these places at any given period. In effect, then, rates of delinquency must be explained as a consequence of the conditions of the community rather than the personal characteristics of the persons who reside there. This finding, which undermines the premise that specific individuals or groups have an inherent predisposition toward antisocial behavior, was possible precisely because Shaw and McKay (1942) found stability in delinquency rates over a period in which extensive population change took place. It was the longitudinal nature of their research, in particular, that set the stage for this key theoretical breakthrough.

Despite its import, the heyday of social disorganization gave way as scholars turned toward individual-level explanations for offending behavior by the late 1950s and certainly the 1960s. A quarter of a century later, however, interest in places and crime trends reemerged. For example, Scheuerman and Kobrin (1986) explored the concept of stability and change in the crime rates of dangerous communities in Los Angeles and, in doing so, introduced the idea that communities have "careers" in crime in much the same way that individuals do. Specifically, they found that high-crime neighborhoods followed three distinct trends over two decades: emerging, transitional, and enduring. Moreover, the relationship between neighborhood deterioration and crime is a reciprocal one, with deterioration preceding initial spikes in crime but prompting additional deterioration once crime rates have reached high and stable levels. Scheuerman and Kobrin were focused on changes in social, economic, and family population characteristics of communities whereas both Wilson and Kelling (1982) and Skogan (1990) considered the potential reciprocity between crime and signs of neighborhood incivilities including social (panhandling, public intoxication, etc.) and physical (graffiti, broken windows, etc.) forms of disorder. According to this logic, places that appear to be uncared for by neighborhood residents and places that are void of private, parochial, and public controls are vulnerable to criminal invasion. The "spiral of decline" that ensues is inherently a temporal process (Skogan 1990).

While not focused specifically on the communities and crime question at its inception, it is noteworthy that Cohen and Felson's (1979) Routine Activity theory also centers on how large-scale social changes influence the dynamics of crime over time. The routine activities of everyday life, including the work and home activities that shape the tempo, timing, and guardianship capabilities of communities, help to explain aggregate crime trends. At its core, then, place-based crime trends are a reflection of broad social and economic transformations that can be tracked and modeled over time. Like social disorganization theory, the central premise of routine activities theory is rooted in an examination of crime rate trends in places, rather than static or cross-sectional levels.

Methodological Diversity

A series of methodological innovations make examining crime trends at places possible. Some of the first studies focused on stability and volatility in community crime relied on cross-lagged correlations or residual change scores to decompose the degree of change between *t* and *t*-1 that could not have been predicted on the basis of levels at time *t*-1 (Bursik 1986). For example, Bursik (1986) compares change score models to cross-sectional models predicting community delinquency rates in Chicago at each decade between 1930 and 1970. These comparisons lead him to conclude that, "without testing the assumption of stability, ecological models will not only have a limited degree of theoretical power, but they will have an interpretive framework that is generally unrelated to the dynamics of modern urban areas" (Bursik 1986, p. 59). That is, static models ignore both expected and unexpected ecological changes that are entirely consistent with dominant theoretical explanations for community crime rates. A key limitation of these early methodological approaches is that they are "relatively cumbersome when multiple waves of data are analyzed and, for this reason, applications of such techniques have generally focused on a series of two-wave trends, providing a truncated sense of neighborhood change" (Kubrin and Herting 2003, p. 332).

More recent approaches to modeling neighborhood change and associated trends in crime rates utilize growth-curve modeling and/or semi-parametric group-based trajectory procedures. Growth-curve regression models take advantage of information about the individual slopes of each geographical unit-of-analysis under study to predict how various independent variables affect changes or trends in the dependent variable (Kubrin and Herting 2003; Braga et al. 2010, 2011). The advantage of such an approach is related to the fact that no trend information is lost in the estimation of the models. Alternatively, some scholars have exploited the capacity of Nagin's (1999) semi-parametric group-based trajectory procedure to reduce the temporal homicide rates of *N* census tracts, street segments, or other places into a smaller number of latent classes or groups exhibiting similar violence levels and following like-trends over some period of time (Griffiths and Chavez 2004; Groff et al. 2010; Weisburd et al. 2004). The resulting number and shapes of place-based homicide trajectories ostensibly capture the various types of place-based "criminal careers."

Key Findings

This section provides a brief (and, of necessity, incomplete) overview of a few of the key findings in the longitudinal crime trends at places literature. Much of the research focused on crime trends across place has modeled longitudinal homicide rates – sometimes disaggregating by victim-offender relationship, motive, or weapon type – in part due to data availability and quality issues (Griffiths and Chavez 2004; Jennings and Piquero 2008; Kubrin and Herting 2003; Stults 2010). For example, in using growth-curve models to capture-distinctive trends in general altercation, felony, and domestic homicide trends in St. Louis neighborhoods, Kubrin and Herting (2003) find that disaggregation of homicide type is imperative as neighborhoods vary in temporal trends by homicide type. In particular, various aspects of neighborhood structure are related to both the amount but also the nature of neighborhood homicide. Griffiths and Chavez (2004) likewise demonstrate that Chicago neighborhoods exhibiting a high and increasing gun homicide trend between 1980 and 1995 have marked unobserved heterogeneity in their criminal careers (i.e., in their total homicide trajectories). Some of these neighborhoods are characterized by a high and unstable homicide trajectory driving citywide trends over the period, as one might expect. Yet four times as many neighborhoods following a high and increasing gun homicide trend are characterized by a moderate and relatively stable total homicide career over the same period, relative to other neighborhoods in the city. Cumulatively, these studies provide substantial evidence that place-based patterns in homicide type reveal considerable variability and instability both over time and across space.

Research at the county-level also illustrates the importance of place in understanding temporal homicide patterns. Jennings and Piquero (2008) show, for example, that rural counties are significantly more likely to exhibit non-declining intimate-partner homicide trends between 1980 and 1999, compared to their urban counterparts. And McCall et al. (2011) have recently extended this literature to examine temporal changes in the homicide rates of US cities over 30 years. Not only are cities distinguished by multiple and varied homicide trajectories, but disadvantage and other characteristics associated with social disorganization more generally (McCall et al. 2011; see also Land et al. 1990) predict membership in the consistently more violent city groupings compared to those cities that are members of the lower and more stable latent classes.

The literature on longitudinal crime trends at places is not limited to homicide research. For example, Weisburd et al. (2004) find that a very small group of street segments in Seattle are responsible for generating volatility in the city-wide pattern of total criminal incident reports to police, as the vast majority of street segments follow relatively stable trends between 1989 and 2002. Studies employing trajectory or growth-curve models for crime trends at places have also measured juvenile arrests (Weisburd et al. 2009), robbery rates (Braga et al. 2011), and disorder (Yang 2010), among others. The bulk of the literature on trends in all types of criminal events at most aggregate micro (e.g., street segment, face block, intersection, etc.) and macro (e.g., census tracts, cities, counties, etc.) units-of-analysis has repeatedly shown that very few places are responsible for high rates of crime and violence, that these places tend toward volatility rather than stability in trends over time, and that the nature of the events under study (e.g., gun violence, intimate versus non-partner victim-offender relationship, age of offender, etc.) affect levels, trends, and the distribution of incidents both across places and over time.

A Plethora of "Places"

The neighborhood-effects literature is rightfully concerned with what geographers call the Modifiable Areal Unit Problem – or the extent to which the unit-of-analysis used by the researcher as an operationalization of neighborhoods influences the findings of the study (Openshaw and Taylor 1979). Scholars interested in understanding neighborhood levels and changes in violence have tended to use census tracts as an approximation of neighborhoods (Griffiths and Chavez 2004; Hipp 2007; see Fagan 2008) while those focused on the emergence and stability of hot spots in micro-places have elected to use even smaller aggregates, such as street segments or block faces (Braga et al. 2010; Weisburd et al. 2004, 2010). Any unit-of-analysis is associated with both advantages and disadvantages, some of which are related to data availability (particularly over time), the spatial units at which policing agencies release information on criminal incidents within their jurisdictions, census units required to access structural characteristics of place, and size of the residential population or daily population flows into and out of the physical space.

One consideration in selecting the geographical unit of analysis is the extent to which the findings at one level are either robust across levels of analyses or almost wholly dependent upon the researchers' definition of place (Hipp 2007). The problem is this: while findings that can be replicated at multiple aggregate units are arguably more robust than findings which vary across aggregations, robustness across units that bear little relation to one another or to what we mean by "neighborhood" suggests that the concept of neighborhood is relatively unimportant. It is not the extent to which the same findings can be replicated at different operationalizations that should matter, so much as the fit between the operationalization of neighborhoods in empirical research and neighborhoods on-the-ground, as identified and understood by residents.

The longitudinal crime trends at places literature is among the most open to the use of extremely varied aggregate units. This is, in part, because not all research in this area is concerned with neighborhood crime trends. Specifically, Braga and Weisburd (2010, p. 2) note that "micro-places" are "specific locations within the larger environments of communities and neighborhoods…[] sometimes defined as buildings or addresses, sometimes as block faces or street segments, and sometimes as clusters of addresses, block faces, or street segments." It is in these micro-units that crime "hot spots" emerge. St. Jean (2007) makes the same point in his ethnographic study of a high-crime neighborhood in Chicago. He finds that very few streets within this community are the sites of crime and violence. The same result is found by Groff and colleagues (2010) in their quantitative study of street segments in Seattle, Washington.

In this case, Groff et al. (2010) establish that there is considerable variability in the 16-year crime trajectories of street segments that are adjacent to one another; consequently, they argue that this heterogeneity in the criminal careers of very small geographic units which are situated in close spatial proximity reflects "the importance of looking at the micro level" (Groff et al. 2010, p. 26).

The openness of scholars in the longitudinal crime trends at places literature to using various different spatial aggregation of the unit-of-analysis generates a great deal of information about how crime is situated both in space and over time. Both the hot spots and the neighborhood crime literatures have benefitted from consideration of the size and shape of "places.' At the same time, the opportunity to cherry-pick the size of the unit under study may necessitate careful theoretical unpacking. For example, how many street segments comprise a neighborhood? How is living beside a street segment following a high-crime trajectory different from living far away from one or any? Are any of the census classifications (e.g., tracts, blocks, etc.) reasonable proxies for neighborhoods? Does the concept of neighborhood really matter? What do we mean by "place" and how do places of varying sizes, shapes, and histories change the empirical picture?

Methodological Considerations and Future Directions

The longitudinal-crime-trends-at-places literature is an exciting field of study that remains largely in its infancy. As a consequence, scholars who study crime trends at places face difficulties related not only to the theoretical issues associated with defining places but also to methodological complications. A continual challenge is the availability of appropriate spatial and longitudinal data. For example, to predict changes in crime trends at places, scholars require data capturing changes in the various independent variables that are associated with aggregate levels of crime. The most widely accessible and most commonly used data on the social and economic conditions of place are compiled by the United States Census, which are available only on a decennial basis for most areas of the country. Land use and other characteristics of place not drawn from the Census can be coded to more fully specify quantitative models predicting crime trends. The problem these scholars face, however, is in explaining *changes* in crime as a consequence of risk factors in the setting (e.g., bars, leisure establishments, public housing) that remain relatively static over 5, 7, or even 10 years. In essence, researchers need to distinguish the "vulnerability" to crime created by these relatively stable criminogenic environmental conditions from "exposure" to crime, captured in unstable local crime trends (Caplan and Kennedy 2011).

In order for researchers to better model and specify how vulnerabilities in the form of local criminogenic conditions can result in different rates of exposure (or changes in crime over time), the gap between theory and data must be addressed. In particular, future researchers need to develop and collect more dynamic indicators of place-based crime and associated behaviors, social and demographic characteristics, land use, and other temporal aspects of place. Researchers need to consider innovative sources of data and more refined measures of key characteristics of places.

Greater attention should also be focused on measuring the intervening mechanisms which link risk and place, and which underlie the process of change in crime at places. Recent research on crime and place has identified a number of potential avenues to consider, such as social capital, collective efficacy, formal and informal social control, culture, and social isolation, among others. A renewed focus on intervening mechanisms requires that researchers integrate spatial and temporal data on these dynamics as a function of place. While developing innovative ways of substantively measuring intervening mechanisms is important, future research must also better specify the proper time lags for capturing change over time, as well as the reciprocal effects of patterns of crime, place-based characteristics, and intervening mechanisms.

Finally, future research needs to consider how the unique spatial characteristics of place create important considerations for change over time. While much of the focus on the dynamics of longitudinal trends in crime at places has centered on temporal change, we must not forget about space. A focus on space means that researchers must aim for a substantive understanding of the environment which surrounds a place, both socially and physically. Researchers need to consider how external factors may influence trajectories of crime and other place-based characteristics. The characteristics of proximate places may directly and indirectly influence levels and changes in crime. Future research should assess the interrelationship between internal rates and changes in both crime and place-based characteristics as well as external (environmental) factors. External influences include, but are not limited to, the structural and demographic characteristics of proximate places, as well as larger economic and political factors. Places may be influenced by their immediate neighbors, local law enforcement, political and economic policies, and decisions which occur well beyond the boundaries of a particular place. Focused attention toward these theoretical and methodological issues will further develop our collective understanding of the meaning of space, place, and time in the criminological literature.

Longitudinal Studies in Criminology

Holly Nguyen and Thomas A. Loughran
Department of Criminology and Criminal Justice, University of Maryland, College Park, MD, USA

Overview

The purpose of this entry is to "take stock" of the important contributions of longitudinal studies in the field of criminology. First, classic longitudinal studies in criminology are reviewed. Second, the authors review key findings from the major contemporary longitudinal studies that focus on the development of crime and delinquency. Third, there are numerous longitudinal studies that have a broader focus but have important provided important insight into crime and delinquency; thus, some of the contributions of these studies are examined. To conclude, potential avenues for future research are suggested.

Introduction

Core issues that capture the imagination of criminologists, such as identifying the antecedents of criminal behavior or why some individuals desist from crime while others continue criminal lifestyles, are issues which require longitudinal data to disentangle. Sheldon and Eleanor Glueck conducted a series of seminal studies (1950) that demonstrated that long-term follow-ups studies were both feasible and valuable to the study of crime and delinquency. Since then, there have been specific calls for more longitudinal studies (e.g., Farrington et al. 1986) and recently, there has been considerable growth in both number and quality of longitudinal studies of crime and delinquency. These studies are integral in shaping how the study of crime has been advanced.

Longitudinal, or panel, data consists of repeated observations on the same units of analysis over time, offering many advantages over cross-sectional data. Some of these advantages include having a better precision of the sequence of events timing and measurement; studying intra-individual change; and disentangling direct and indirect causal chains of analyses (Thornberry and Krohn 2003). Despite the vast potential, many early researchers who had access to longitudinal data did not take advantage of this potential and analyzed their data as though it were cross sectional (Farrington et al. 1986). The growth in the number of studies that use longitudinal data in recent years can be attributed to a number of factors including methodological and analytical advances especially developed for panel data. Further, many of the contemporary studies in criminology were initiated in the 1980s with cohorts born in the 1970s. Thus, these data are just now coming to into fruition. Undoubtedly, the use of longitudinal data has advanced the field of criminology both in terms of theory and policy (this, however, is not without controversy).

The purpose of this entry is to "take stock" of the important contributions of longitudinal studies in the field of criminology. Given the abundance of studies, however, this is not a straightforward task. Past reviews of longitudinal research have broadly consisted of two approaches. Some reviews of the literature have discussed key findings of each study (e.g., Thornberry and Krohn 2003), while other reviews choose key topics and summarize the findings across studies (e.g., Farrington 2003). The authors approach the topic by using both approaches. First, the classic longitudinal studies in criminology are reviewed. These studies are important in that they provided a springboard both methodologically and theoretically in which contemporary researchers could be inspired. Second, the key findings from the major contemporary longitudinal studies (that focus on the development of crime and delinquency) are examined. Some of these studies are still ongoing and scholars are just beginning to witness the returns to these data. Third, there are numerous longitudinal studies that have a broader focus, such as the *National Longitudinal Survey of Youth*, but include crime and delinquency measures. The contributions of these studies are reviewed. Finally, this entry concludes by suggesting potential avenues for future research.

Classic Longitudinal Studies

Classic longitudinal studies are characterized by the following of one cohort over time. Information was often collected through official records on a number of important factors such as family life, school, employment, police contacts, and court dispositions. Records would be collected over a number of times. By following one cohort however, potential problems such age, period, and cohort effects can arise (see Farrington et al. 1986). Another criticism is that early researchers did not pay attention to the exact timing of specific events so that causal mechanisms can be established (see Farrington 1988). Although single cohort designs are criticized, it is important to spend some time looking at some of the seminal works in the study of the development of crime and delinquency.

Sheldon and Eleanor Glueck are considered the pioneers of longitudinal research in crime and delinquency. The Gluecks' study consisted of 500 delinquent boys (recruited at ages 7–11) living in the Boston area. Each delinquent was matched with a nondelinquent by age, family background, general intelligence, ethnicity, and residence in an under-privileged neighborhood (Glueck and Glueck 1950). The Gluecks' inquiry fell into five main categories: family and personal background, body types, health, intelligence, and temperament and character. The major contribution of the Gluecks' was their discovery that factors relating to temperament and family characteristics played an important role in later delinquency, and emphasized early detection and prevention.

Another reason why the Gluecks' study is one of the most important longitudinal inquiries is because of the highly influential work of Robert Sampson and John Laub (1993). Sampson and Laub reanalyzed the Glueck data using modern analytic techniques and formulated their age-graded theory of informal social control, which posits that informal social bonds can be an important factor in continuity in and desistance from crime. In 2003, Laub and Sampson conducted a follow-up study of the original participants of the study. In addition to following up with official records of all the original participants, they conducted in-depth interviews with 50 of the men who were in their 70s at the time of follow-up. This makes their study the longest follow-up study in criminology. A number of important contributions have stemmed from Sampson and Laub's work including insight into the mechanisms of desistance and turning points, which include importance of marriage, work, and military service.

The Cambridge Study in Delinquency Development is a prospective study composed of a sample of 411 boys from South London who were aged 8 or 9 between 1961 and 1962. The goal of the original Cambridge study was to test several hypotheses about delinquency: first was to describe development of delinquent and criminal behavior; to assess the efficacy of prediction; and to explain why or why not it continued to adulthood. The investigators examined socioeconomic conditions, schooling, friendship, parent–child relationships, extracurricular activities, school records, and criminal records. They also performed psychological tests to determine the causes of crime and delinquency. The importance of this study is that there have since been follow-up studies of the men up to the age of 48. Few studies have followed as many subjects for as long as the Cambridge study. Researchers are still analyzing data from the Cambridge Study to assess important criminological puzzles.

Another seminal longitudinal study is the Philadelphia Birth Cohort, collected by Wolfgang et al. (1972), which has been described as "one of the turning points in criminological research in the United States" (Laub 2004). The study is composed of two birth cohorts, 1945 and 1958. The 1945 cohort consisted of males who resided in Philadelphia from 10 years (most from birth) to at least 18 years old, and contains almost 10,000 cases. Information contained in school records, police records, and dispositions from juvenile and criminal court records was used to provide important descriptive information and also to allow the researchers to predict offending behavior. Since 1968, Wolfgang et al. were able to follow up and conduct interviews with 567 of the original sample from 1945. The follow-up consisted of questions pertaining to offenses in which the participants were not arrested for. The 1958 cohort study was a replication of the 1945 study to assess whether there were any cohort effects. The 1958 cohort was much larger, over 28,000 subjects and resulted in substantively comparable findings.

The most important contribution of Wolfgang et al.'s study is their identification of the "chronic offender," which they identified as boys with four or more offenses. They found that the chronic offenders consisted of 18 % of the delinquents but were responsible for over half of all the offenses. Further, the Wolfgang et al. (1972) study found that the probability of committing an offense increased with each successive offense committed. That is, the probability of committing a second offense after the first was about 50 %, the third after the second was about 79 %, and about 80 % thereafter. In fact, Wolfgang et al. (1972) have been credited as being the seed of the criminal career paradigm (Piquero et al. 2007). The notion of the chronic offender and methods to prospectively identify such individuals still captures the interest of scholars today.

Other classic studies have also provided a foundation for the study of criminal careers. For example, Blumstein et al. (1985) were able to prospectively identify chronic offenders based on low IQ, poor parent–child rearing, convicted parents, conduct, and other behavioral problems among a London cohort. Other scholars have also argued that factors such as parent–child rearing and early signs of aggression can be predictive of later delinquency. Robins (1978) showed that there is continuity in antisocial behavior and offending. These studies support the famous "Robin's Paradox," which argues that "antisocial behavior virtually requires childhood antisocial behavior; yet most antisocial children do not become antisocial adults" (p. 611). Horney and Marshall (1991) focused on the reliability of life event calendars and emphasized the importance of short-term within-individual variability. Other issues such as work and crime have been made possible through longitudinal studies such as the National Supported Demonstration Work Project. Lyle Shannon also added to criminal career work by following three cohorts from Racine, Wisconsin.

The authors have spent time on some detail reviewing several classic longitudinal studies in the hopes of illustrating the innovative and creative nature of early longitudinal research. These studies provide a foundation in which contemporary researchers are able to refine research designs and move toward a better understanding of the development of crime and delinquency. Indeed, scholars today are still using classic longitudinal studies to provide commentary on new questions (e.g., the next section turns to contemporary longitudinal studies. In reviewing these studies, the authors take a slightly different approach and use the key findings from the past 20 years of longitudinal research as a guide.

Contemporary Longitudinal Studies

The contemporary longitudinal studies reviewed in this entry are more eclectic than the classic studies. They are, however, often larger-scale studies with various methodological improvements over classic studies. For example, rather than one cohort, many of them employ "accelerated cohort" designs, which tracks several cohorts over a shorter period of time while others follow subjects who are closely clustered in age. Many are also conducted at multiple sites. Krohn and Thornberry (2008) identify three main purposes of contemporary longitudinal studies. The primary purpose is to describe delinquent and criminal careers. The second purpose is to identify causal mechanisms of delinquent behavior. The third purpose is to identify the consequences of delinquent/criminal behavior. To be sure, different longitudinal studies have different emphases. For example, some may focus on structural characteristics while others focus on biological factors. There are dozens of studies that can be considered contemporary longitudinal studies, with many still ongoing. These studies have been conducted across various samples and throughout numerous countries. The burgeoning of information makes the task of reviewing contemporary longitudinal studies challenging. Thus, as an organizing framework, the authors identified five key findings gleaned from longitudinal studies in criminology over the past several decades. The five findings include: problem behavior begins early; parents, school, peers, and social structure remain consistent risk factors; there is often co-occurrence of problem behaviors and delinquency; there is a substantial amount of continuity in crime and delinquency; and there is also a considerable amount of change. Each will be reviewed in succession.

1. *Problem behavior begins early*

Since Wolfgang et al.'s finding of the chronic offender, there has been great interest in identifying individuals who are at high risk of becoming chronic or life-course persistent individuals. Several longitudinal studies focus on identifying early signs of risk factors. Risk factors can be identified prenatally or when children are very young (before the age of 6). Scholars have found that prenatal complications, such as exposure to substances like cigarettes, alcohol, and other drugs, interact with psychosocial and environmental factors, such as maternal rejection, poor parenting, neighborhood disadvantage, and low-income, to produce a heightened risk of later antisocial behavior.

Early childhood signs include disruptive behavior like aggression and negative emotionality (Tremblay et al. 2003). Researchers have found that there is a moderately stable relationship between early disruptive behavior and other similar behaviors (heterotypic). Important findings such as those from the Pitt-Mother and Child Project show that very few children have an onset of conduct behavior before the age of 5 or 6. Further studies suggest that the earlier a child is identified and treated, the higher is the likelihood of prevention. Several longitudinal studies have been central to our understanding of early childhood risk factors on later delinquency. This group of studies would include the Montreal Longitudinal and Experimental Study (Tremblay et al. 2003), which tracks subjects from kindergarten to high school and has a special focus on parent–child relationships. The Dunedin Study is a multidisciplinary study that follows 1,000 individuals for almost 40 years and the Longitudinal Study of Biosocial Factors Related to Crime and Delinquency which studies the prenatal and child-related health of a high-risk sample of boys.

2. *Important factors: parents, schools, peers, and social structure*

The previous section discussed how early childhood risk factors can set a child on to a path to later delinquency. Similarly, there are factors in later childhood and adolescence that are also indicative of persistent delinquent behavior. In 1986, the Office of Juvenile Justice and Delinquency Prevention funded a large-scale project entitled the Program of Research on the Causes and Correlates of Delinquency. These projects consisted of: the Denver Youth Study, the Pittsburgh Youth Study, and the Rochester Youth Development study. In a review of the findings of these and four other large-scale longitudinal studies, Thornberry and Krohn (2003) identified parenting, schools, peers, and social structure as consistent factors that can affect children's lives. These predictors can be taken as part of a risk factor approach or guided by criminological theory. Nevertheless, examining these factors provides a useful approach to reviewing longitudinal studies.

Various indicators of poor parenting have been consistently found to be positively related to delinquent or problem behavior. Using the Rochester Youth Development Study, childhood and adolescent maltreatment is linked with later antisocial behavior. Sampson and Laub (1993) found that parent–child attachment mediated the relationship between poverty and delinquency. Similarly, findings from the Montreal Longitudinal Study suggest that healthy child-rearing practices and supervision are crucial protective factors against future antisocial behavior (Tremblay et al. 2003). Using data from the Cambridge Study, scholars investigated childhood neglect and juvenile delinquency and found that the odds of juvenile conviction were over four times higher for subjects who were exposed to childhood neglect than subjects who were not.

Children spend vast amounts of time in school, and thus, experiences in school are an important factor to consider in the development of delinquency. Low levels of intellectual ability and academic achievement are a consistent predictor of delinquency and other problem behaviors (Thornberry and Krohn 2003). For example, Raine et al. (2002) found that life-course persistent offenders had lower visuomotor functioning than other subjects. A birth cohort from Kuai was followed and results suggest that individuals who had below average intellectual skills had a greater likelihood of antisocial behavior.

The relationships between delinquent peers and one's own delinquency have been a part of many longitudinal studies. There is strong support for the causal role that deviant peers play. For example, research suggests that deviant peers provide support and opportunity for delinquent behavior which in turn has an effect on the patterns of associations an individual has. Moreover, in mid-adolescence, selection and socialization are important whereas in late adolescence, socialization is more important. New longitudinal methods have been developed to assess the impact of delinquent peers. Longitudinal social network data gathered by the Netherlands Institute for the Study of Crime and Law Enforcement's School Study, a study that focuses on social networks and the role of peers in delinquency. Scholars have used Simulation Investigation for Empirical Network Analyses, a method that can estimate the effects on individual changes in network ties as well as effects on changes in individual behavior, and found that the average delinquency of an individual's friends has a significant causal effect on the individual's behavior.

The idea of delinquent peers has extended to inquiry into the causes and consequences of gang membership. Krohn and Thornberry (2008) commented that longitudinal studies are an “ideal design for investigating the impact of gang membership on life-course development” (p. 130). For example, the Seattle Social Development Project is an example of a longitudinal study that looks at the development of both positive and problem behaviors among adolescents and young adults. Researchers using data from the study found that youth who are gang members more often commit property and violent offenses.

Since Shaw’s work on juvenile delinquency prevention in the 1930s in Chicago and the founding of the Chicago Area Project, structural factors have been an important part in investigating the development of delinquent behavior. Shaw and McKay’s (1942) seminal work on social disorganization pointed to community factors such as poverty, population mobility, and population heterogeneity as correlates of delinquency. Several contemporary studies have also incorporated structural factors in their design. For example, the Project on Human Development in Chicago Neighborhoods (PHDCN) is an interdisciplinary study which assesses families, schools, and neighborhoods affect child and adolescent development. The PHDCN has two components: a neighborhood level component and an individual level component. Researchers using the PHDCN have provided important insight into the dynamics of the mediating effects of social control on neighborhood disadvantage (Sampson and Morenoff 2006). The Denver Youth Study also integrated high-risk neighborhoods as an integral part of the study.

3. *Co-occurrence of problem behaviors and delinquency*

There have been calls by prominent criminologists for the discipline to consider a broader set of behaviors beyond crime (Sampson and Laub 1993), with the rationale that there may be an underlying dispositional trait between crime and other risky behaviors. Important questions such as whether all problem behaviors, such as substance abuse, delinquency, school problems, aggression, promiscuity, and violence, represent one underlying syndrome and to what extent risk factors are the same for all problem behaviors are of central concern for developmental researchers. Results to date suggest that this is the case. Huizinga et al. (2000) found that individuals with serious delinquency also are more likely to have mental health problems. Similarly, data from the Denver Youth Study show that there is overlap between violent behavior and mental health problems. Using data from the Cambridge study, Piquero and colleagues (2011) found that chronic offenders were more often hospitalized and have a registered disability. Loeber et al. (1998) looked at eight problem behaviors, including substance use, conduct problems, physical aggression, and depression, and found that they were interrelated. Thus, how extensive the overlap between offending behavior and other problem behavior is unclear but commentary on this topic has been consistently positive.

4. *There is a significant amount of continuity*

According to Farrington (2005), one of the most widely accepted conclusions about the development of offending is that there is a marked continuity in antisocial behavior. That is, there is a relative stable ordering of individuals on some level of antisocial tendency. This important finding has motivated scholars to investigate what the mechanisms behind continuity are. Two divergent explanations have dominated criminology: state dependence and population heterogeneity. State dependence argues that the effects of earlier offending have an effect on later offending whereas population heterogeneity offers persistent individual differences as an explanation to continuity. Blokland and Nieuwbeerta (2010) use data from the Criminal Career and Life-course Study, which follows 4,684 Dutch offenders for the better part of their lives, and found that both population heterogeneity and state dependence partially explain continuity in offending. The more an individual offends, however, the effect of state dependence weakens. Violent and aggressive behavior also appears to have continuity. Farrington (1993) suggests that there is continuity in bullying behavior – both within and between generations. Individuals who self-report bullying at 14 were more likely to report bullying at age 32. Their children were also more likely to be bullies.

5. *There is also change*

Thus far, the authors have not portrayed an optimistic view of the development of offending. While there is a marked continuity in offending and other problem behaviors, there is also a great deal of change. Investigation into change was sparked by Sampson and Laub's (1993) study. The scholars found that there are multiple pathways to desistance and identified four major factors associated with change: marriage, the military, reform school, and neighborhood change (Laub and Sampson 2003). The study of desistance remains a challenge however, because measuring desistance is not straightforward. For example, there is debate regarding the definition of what constitutes cessation from crime and the data are ultimately right censored. Moreover, the methodological advancement developed has allowed scholars to study population heterogeneity in developmental offending trajectories by identifying groups of distinct trajectories. Piquero (2008) reports over 60 studies that have employed such group-based trajectory modeling to study change over time.

The idea of change provides researchers with incentive to explore the factors and mechanisms that contribute to desistance. For example, Hawkins et al. (1992) advocate for a risk factor preventive approach whereby risk factors are identified and then addressed to promote desistance. The idea of change was the impetus behind The Pathways to Desistance project. The Pathways study is a large collaborative, multidisciplinary project that followed 1,354 serious juvenile offenders aged 14–18 for 7 years after their adjudication. The main purpose of the study is to identify factors related to continued desistance. General findings suggest that almost all offenders greatly reduce their offending and longer stays in institutions do not reduce recidivism.

Other Important Longitudinal Studies

It is important to note that the authors have based our review primarily on panel studies that focus on the development of crime and delinquency. There are, however, many longitudinal studies that have a broader focus but also include delinquency measures. These studies are often large in scale and are of a representative population sample of adolescents. These studies are rich sources of data that provides insight into many important criminological questions that only longitudinal studies can shed light on.

A couple of the national longitudinal surveys commonly used in criminological research include: the National Longitudinal Survey of Youth (NLSY) and the National Youth Survey (NYS). The National Longitudinal Survey of Youth is a study of 9,000 individuals who were born in 1980–1984 and has been used to study issues such as education, work, and crime (Lochner 2004). The National Youth Survey began in 1976 and is ongoing. Parents and youth were interviewed about both conventional and deviant types of behavior by youths. Important studies on drug use deterrence, labeling, and peer influence have used the NYS.

Monitoring the Future is an annual nationally representative survey of American high school students. Annual follow-up questionnaires are mailed to individuals in each graduating class for a few years after their initial participation. Data from Monitoring the Future has provided insight into patterns of drug use and work and delinquency. The National Longitudinal Study of Adolescent-Health (Add-Health) is also a nationally representative sample of adolescents in grades 7–12. In addition to collecting information on neighborhood, family, social, psychological, health, and economic well-being, the Add-Health collects information on the social networks of adolescents. This has generated a number of important studies that provide commentary on the nature of delinquent peers.

Future Directions

The discipline of criminology owes much of its knowledge of the development of offending to past and current longitudinal studies. In this entry, the authors reviewed classic studies that are the foundation of longitudinal studies in criminology, key findings gleaned from contemporary panel studies, and some of the important nationally representative longitudinal studies on adolescent well-being. However, it is realized that there are other important longitudinal studies that were not included in this entry. To this end, the authors urge readers to explore previous syntheses of longitudinal studies (Blumstein et al. 1986; Delisi and Piquero 2011; Farrington 1988b; Liberman 2008; Thornberry and Krohn 2003).

Despite considerable advances made in the study of the development in crime and delinquent behavior over the last few decades, there are avenues that would benefit from greater scholarly investment. One such avenue is longitudinal experimental designs. Despite highlighting the value of longitudinal experimental studies over 20 years ago, Farrington (2006) was able to only identify four longitudinal experiments that have incorporated significant pre- and post-developmental measures, suggesting that there is a dearth of research that assesses the long-term effects of interventions.

As ongoing longitudinal studies extend into their subjects' early adulthood, it is important to investigate intergenerational study of crime and delinquency. Elder (1985) noted that one of central tenets of studying the life course is the notion of linked lives, which refers to the interaction between individuals and their social world. He argues "Each generation is bound to fateful decisions and events in the other's life course" (p. 40). Issues of central concern such as continuity and change can be extended to look at intergenerational patterns in crime and problem behaviors. Ongoing studies such as the Rochester Developmental Youth Survey and the Denver Youth Study are gathering information on the children of the participants. Preliminary results from these studies and past studies like the Ohio Life Course Study suggest that there is a clear relationship between the antisocial behaviors of parents and their children.

Finally, an important yet often neglected line of inquiry is investigation into the processes of co-offending. Co-offending has important implications for the development of criminal careers. For example, co-offenders tend to be more prolific offenders, are more likely to engage in violence, and have longer criminal careers (McGloin and Nguyen 2012). Indeed, greater insight into co-offending can be important in terms of theory and policy. In conclusion, longitudinal studies in criminology have made significant strides since the Glueck's Unraveling Delinquency study. Continued improvements in methodological designs, advancements in statistical applications, and theoretical refinements will provide scholars of crime with a number of interesting avenues for research.

Managerial Court Culture

Brian J. Ostrom and Roger A. Hanson
National Center for State Courts, Williamsburg,
VA, USA

Overview

Court culture as a concept follows from the modern management maxim that there is more than one way to get things done and done well in the workplace. Formulating an effective strategy for a particular workplace requires a good understanding of not only the formal structure and lines of authority but also the unwritten rules, unofficial networks, and underlying norms and behaviors that shape how work is accomplished. As a result, knowledge of an organization's cultural web is a crucial factor when searching for ways to improve operational effectiveness.

This entry outlines the development and current state of court managerial culture by reviewing five pertinent inquiries. All of the studies focus primarily on American felony criminal state trial courts and share a comparative approach, examining courts in several states. The first pair provides initial impetus by popularizing the concept of local legal culture as it relates to why case resolution in some courts is timelier than in others. Timeliness is an undeniable mark of performance due to the US Constitution's enshrinement of a "speedy trial" in the provisions of the Seventh Amendment. The third study extends the notion of culture by elaborating three distinct work orientations made up of different constellations of norms. The fourth study provides evidence that culture affects different behavior patterns among courts as well as in different attitudes on the part of prosecutors and defense attorneys. The fifth project draws on a broad range of research traditions, including organizational effectiveness in both the private and public sectors and

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

modern methodologies. The inquiry develops a conceptual framework, applies it, and shows how results are solid grounds for changing behavior. The conceptual framework has the dual advantage of creating a typology of culture based on a set of values appropriate to the American context and simultaneously amenable to using alternative values as might exist in other legal systems. Hence, the entry concludes with suggestions for future research, including work in other countries.

Introduction

A perennial theme in contemporary criminal court administration is that better management enables higher organizational performance benefitting all participants in the legal process. Superior administration of the legal process comes about supposedly by the actions of enlightened leaders who cultivate collegial agreement on administrative goals to resolve cases expeditiously and fairly treat litigants and others, and then put objectives into place. Yet, the nature of court organizational structure introduces notable challenges to such aspirations.

Minimal hierarchy of authority exists around which to fashion purposeful management. Professional attorneys, who by virtue of public election or legislative or executive appointment, occupy the position of state constitutional officers. Judges do not select their colleagues and thereby have limited means to control the behavior of their fellow members of the bench. As a result, a call for reaching collective decisions in a court requires an appreciation of the coequal status of judges. Even a judge in a leadership position, such as the presiding or chief judge, possesses limited formal authority to set administrative policy for the court, an equal among firsts. Compare this type of setting to an executive agency led by a chief cabinet officer that appoints assistant secretaries. If the judges are willing to share, collaborate, and follow the lead of a presiding judge, supported by a court administrator, establishing court-wide ways of doing business is a viable option. On the other hand, if individual judges seek to maintain autonomy in administrative matters, reaching agreement on standard work practices is much more difficult. As a result, voluntary commitment to collective decision making inhibits the adoption of court-wide policies and procedures – even those deemed to be best practices.

Courts are not the only institutions challenged by calls for synchronized management that seem quite natural in the bottom-line motivated private sector. They fit within a category of structures called loosely coupled systems. “In loosely coupled systems, the forces for integration—for worrying about the whole, its identity, its integrity and its future—are often weak compared to forces for specialization” (Hirschorn 1994). Coordination is difficult because the members do not think about system-wide goals, but, as in the case of courts, focus instead on their own subunit, assigned caseload, or courtroom. Recognizing the decentralized character of how decision making occurs in each court is another way of saying court culture matter.

Early Efforts

The first term to describe court culture was local legal culture. The idea of local legal culture arose in two complementary studies of delay reduction in criminal courts during the 1970s. In 1976, Nimmer (1976) observed that the “local discretionary system” is a major obstacle to criminal court reform efforts and later went on to claim that lengthy case processing times are “most directly associated with prevailing informal norms of the judicial process and with the personal motivations of participating attorneys and judges” (1978). Following this pioneering work, what caught the imagination of the field of court administration as well as law professors, judges, and social scientists was a subsequent study of both civil and criminal trial courts by Church et al. (1978): They formulated a working hypothesis that challenged the conventional wisdom that resources determined success in resolving cases expeditiously. They instead postulated

> The speed of disposition of civil and criminal litigation in a court cannot be ascribed in any simple sense to the length of its backlog, any more than court size, caseload, or trial rate can explain it. Rather, both quantitative and qualitative data generated in this research strongly suggest both speed *and* backlog are determined in large part by established expectations, practices, and informal rules of behavior of judges and attorneys. For want of a better term, we have called this cluster of related factors the "local legal culture."

Similar to Nimmer, Church et al. defined local legal culture as the "established expectations, practices and informal rules of behavior of judges and attorneys." Their interpretation of the wide variation in the timeliness of different courts attributed the speed of resolution more to the views of judges and attorneys than to structural, resource, or procedural distinctions among courts. Both sets of studies consider expectations stable implying that efforts to reduce court delay encounter strong resistance unless the expectations themselves are the subject of planned change. The concept of local legal culture enjoyed acceptance of the proposition that timely court performance is primarily governed by shared beliefs, expectations, and attitudes, although the substantive nature of the determining views lacked specificity and confirming evidence. As a result, local legal culture does not distinguish different types of cultures and does not offer a basis for putting courts into different categories.

Culture as a Working Hypothesis

Local legal culture is the subject of considerable attention and conceptual enrichment in a third inquiry by Eisenstein, Fleming, and Nardulli (Eisenstein et al. 1987). These scholars studied three criminal courts in each of three states, Illinois, Michigan, and Pennsylvania. They claim norms define how the courts should operate and that differences in norms contribute greatly to the observed variety in how courts conduct business. They extend the previous research by focusing more on what constitute the norms. By calling particular sets of norms "work orientations," they signal that norms are complex and have multiple consequences.

Work orientations "are rationalizing principles" that court leaders "use to explain why particular tasks or functions" are structured the way they are in their respective courts (Nardulli et al. 1988). These powerful forces are not the same from court to court, but they also are not unique to each court community. Indeed, the scholars see three types of distinctive work orientations in the courts they studied: (1) structural or formal, (2) efficiency, and (3) pragmatic orientations.

The first orientation emphasizes the compliance with professional norms including close adherence to rules and the rejection of expediency. The second orientation places a premium on the efficient use of resources and promotes the expeditious handling of cases, even if the achievement of smooth handling occasionally calls for deviation from rules. Finally, a pragmatic orientation is the most flexible approach because the routine is whatever the consensus is at a specific point in time. With no long-term commitment made to a particular manner of conducting business, the prevailing norm is deemed satisfactory until a problem emerges calling the existing paradigm into serious question. Then, new agreements on ways of resolving cases are necessary and appropriate and the emerging consensus guides the court until it too, ultimately proves problematic. This intriguing configuration of cultures advanced the concept of local legal culture but emerged as a working hypothesis at the conclusion of the inquiry. None of courts under study actually were placed in one of the orientation categories and no tests were conducted on the relationship between orientations and expected consequences.

Judges Nudge Attorneys to an Expeditious Culture

A fourth inquiry by B. Ostrom and Hanson (1999) provides empirical evidence pertinent to a critical aspect of managerial culture. Their study proposed that timeliness and quality are compatible. This proposition challenged the popular view that efforts to resolve cases more quickly compromise quality because delay reduction activities cut corners. This research focused on nine midsized communities: Albuquerque, Austin, Birmingham, Cincinnati, Grand Rapids, Hackensack, Oakland, Portland, and Sacramento. An initial part of the research involved dividing the courts according to their observed degrees of timeliness and placing them into one of three subgroups: very expeditious, moderately expeditious, and least expeditious. To test the study's hypothesis, frontline attorneys completed questionnaires that tapped into their views on the workings of the state trial court where they practiced and how they assessed the opposing side.

Findings from the investigation revealed that when courts act decisively to manage the litigation, they achieve both timeliness and enable attorneys for both the state and the defendant to prepare and present their arguments effectively. Attorneys have distinctive views toward the leadership role played by a court, a court's ability to communicate its expectations clearly, the degree to which the opposing side is well trained and prepared for trial, and the extent to which the opposing side operates in an adversarial manner. On the one hand, if attorneys see a court exercising firm leadership, a court stating its policies clearly, and the opposing side is equipped for trial, the court is among the most expeditious subgroup. Conversely, if the attorneys see a court as a hazy communicator, a source of weak leadership, and the opposing side as ill prepared, the court is of lesser expeditiousness. In all three subgroups, attorneys view the opposing side as a strong adversary, suggesting the timely resolution of cases does not require counsel to abandon the goals of protecting society (prosecutor) or to defend a criminal defendant's constitutional rights (defense attorney). These relationships offer strong evidence that the degree to which the Seventh Amendment is consistent with reality depends on effective management actions taken by judges and administrators and embraced by legal practitioners. However, what is missing concerns the rationale prompting judges to exercise control over the legal process in some courts to a greater degree than in other courts.

Taken together, this previous body of research does converge on the central point that court culture, norms, and beliefs held by judges, attorneys, and court administrators shape how courts operate. Moreover, these investigations document that legal practitioners are aware of court policies to the extent that judges and administrators clearly articulate when, how, and why court proceedings are going to occur. These four studies provide solid justification for further inquiry into the specific norms and values associated with different culture types. A fundamental component missing from the initial research was a methodology for measuring culture and an investigation into the consequences of possible cultural variation.

Constructing Managerial Court Culture

The earlier lines of research primarily affirm what court administrators and judges know: culture plays an important role in how courts function. Some management cultures inhibit modernization, reform, and performance. Others are more conducive to the development and adoption of better ways of doing things. In essence, the notion of local legal culture emerged as a shorthand phrase to refer to a host of norms and resulting behaviors not otherwise easily explained. Unfortunately, simply naming a phenomenon is not the same as measuring it and using it to both explain and improve court performance. Without a vocabulary and set of tools to distinguish fundamental types of cultures, courts will continue to struggle in building a management culture that supports and expects to achieve high-quality case resolution.

Building on and refining previous studies, a fifth approach by Ostrom et al. (2007) provides a more comprehensive framework, along with a set of steps and tools to assess and measure a court's current and preferred culture. Culture assessment furthers observation and measurement of the abstract concept of court culture, thereby making it an explicit part of court management and reform efforts. Because assessing court culture can yield systematic information compatible with and useful to understanding court performance and the allocation of court resources, an expository summary of this fifth link in a long line of research indicates the current state of knowledge.

B. Ostrom et al. follow the lead of managerial experts who contended culture is the glue that operates at many different levels in an organization. Schein (1999) argued that to comprehend what matters in culture, one must strive to understand the espoused values (i.e., the values that shape why an organization acts in a particular way) and basic assumptions (i.e., jointly learned values, beliefs, and assumptions that become shared and taken for granted in an organization) that shape the way work gets done in the organization. For Schein, culture is the mental representation of the work environment that members of the organization carry in their heads.

Schein's advice, applied by B. Ostrom et al. to the study of courts focused on shared mental models that judges, administrators, and staff hold and take for granted. A court's management culture manifests itself in what is valued, the norms and expectations, the leadership style, the communication patterns, the procedures and routines, and the definition of success that makes the court unique. More simply: "The way things are done around here."

B. Ostrom et al. accepted the proposition that culture evidences itself in the "accumulated shared learning of a given group" (Schein 2004). For courts, this shared learning comes from parallel experiences in meeting the aims of the judicial branch. The live and unanswered question then became for B. Ostrom et al. as, if a court's culture is the result of accumulated learning, how does one describe and catalogue the content of that learning?

Types of Managerial Court Culture. The conceptual framework developed by B. Ostrom et al. organized managerial culture into four distinct types of cultures, communal, networked, autonomous, and hierarchical, defined as follows:

- ***Communal***: Judges and managers emphasize the importance of getting along and acting collectively. Communal courts emphasize group involvement that produces mutually arrived at agreements. Procedures are open to interpretation and creativity is encouraged when it seems important to "do the right thing."
- ***Networked***: Judges and managers emphasize inclusion and coordination to establish a collaborative work environment and effective court-wide communication. Efforts to build consensus on court policies and practices extend to involving other justice system partners, groups in the community, and ideas emerging in society. Judicial expectations concerning the timing of key procedural events are developed and implemented through policy *guidelines* built on the deliberate involvement and consensus of the entire bench. Court leaders speak of courts being accountable for their performance and the outcomes they achieve.
- ***Autonomous***: Judges and managers emphasize the importance of allowing each judge wide *discretion* to conduct business. Many judges in this type of court are most comfortable with the traditional adversary model of dispute resolution. Under this traditional approach, the judge is a relatively passive party who essentially referees investigations carried out by attorneys. Individual judges exercise latitude on key procedures and policies. Limited discussion and agreement exist on court-wide performance criteria and goals.
- ***Hierarchical***: Judges and managers emphasize the importance of established *rules* and *procedures* to meet clearly stated court-wide objectives. These courts seek to achieve the advantages of order and efficiency in a world of limited resources and calls for increased accountability. Effective leaders are

good coordinators and organizers. Recognized routines and timely information reduce uncertainty, confusion, and conflict in how judges and court staff make decisions.

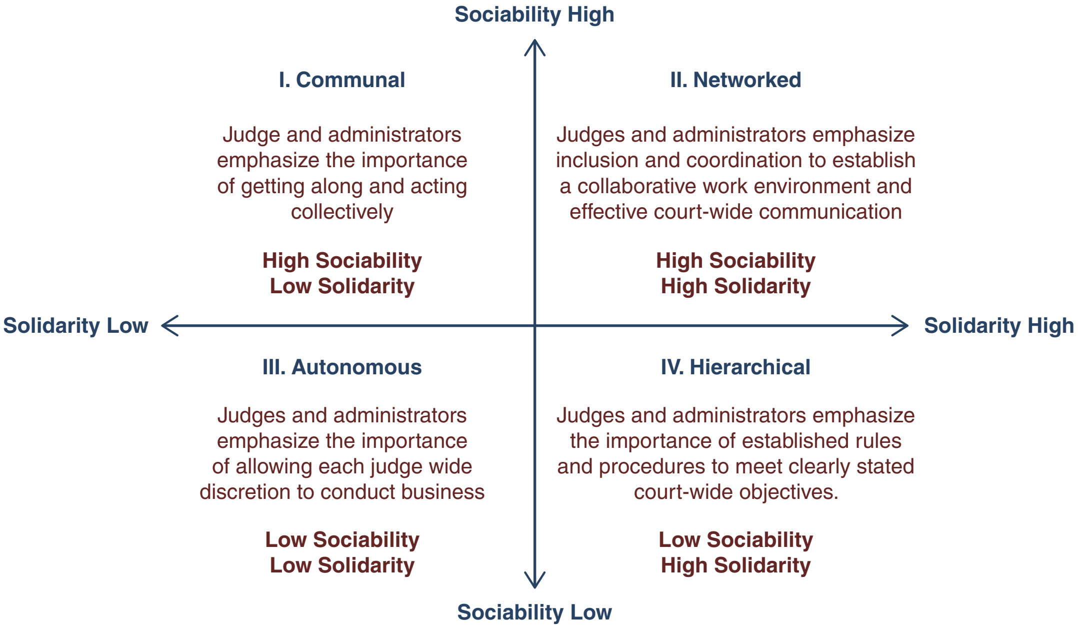
Empirical Findings. B. Ostrom et al. measured the extent that courts in the real world fit into one of these four types. Moreover, they assessed both the current culture and the type of culture that judges and administrators preferred to see in place in the future. Additionally, both prosecutors and public defenders provided evaluations of the performance of the court where they practiced on a daily basis. As a result, conclusions surfaced on what, if any, consequences flowed from the judicial embrace of a particular culture. The following synopsis highlights their essential observations.

Courts with hierarchical cultures achieve objective standards of timeliness promoted by the American Bar Association (ABA) and other groups, more closely than courts with other dominant cultures do. Interestingly, all of the courts under study exhibited awareness of this connection. Every court, according to the preferences of judges and administrators, seeks to increase its hierarchical culture in the area of case management. This common desire likely arises because none of the courts currently meet the ABA-prescribed time frames. Courts are cognizant of this situation and seek to do better by moving toward a culture more conducive to expedition and timeliness.

Like culture, court performance has multiple dimensions. Moving beyond timeliness, practicing attorneys evaluate courts on how well they achieve other important goals, such as access, fairness, and managerial effectiveness. With these criteria, the picture becomes more complex. The courts with more hierarchical cultures rated less satisfactorily on access and fairness, for example, than courts with other cultures. Prosecutors and public defenders do not see only virtue in a court's emphasis on timeliness and a move toward a more hierarchical culture to achieve that goal. Both sets of attorneys also can see greater benefits to themselves from the courtroom workgroup relations fostered by an autonomous culture's minimal emphasis on solidarity. Vested interests in established work patterns perhaps lead attorneys to view courts with autonomous cultures as also doing better when it comes to access, fairness, and managerial effectiveness. Further complexity arises because prosecutors and public defenders disagreed over the relative merits and limitations of other cultures. The former see the greatest advantage in networked cultures because of the emphasis by the court on guidelines consistent with a prosecutor's desire for some firmness in guilty plea policies. Public defenders have an opposite orientation and like a communal culture's emphasis on flexibility that they view as enhancing their role in gaining the best resolution for their clients. Managing the competing interests of prosecutors and public defenders, while maintaining an effective internal work environment for judges and court staff members, highlights the management challenges facing court leaders.

Methodology. The development of this fourfold typology follows from an analysis of how expert practitioners believe core values affect and relate to carrying out work. Sixteen values culled from the literature on court administration include such distinct values as collegiality, continuity with the past, discretion, standard operating procedures, flexibility, rule-oriented, innovation, judicial consensus, and self-managing. Using a tightly structured questionnaire, 53 seasoned practitioners, including judges, administrators, prosecutors, and defense attorneys, compared and contrasted the values. This exercise asked the practitioners to indicate how closely each of the 16 values relates to each of the other 15 values. The results of paired comparisons, using the technique of multidimensional scaling, showed four clusters of four values each.

The clusters illustrate the core values of different types of cultures and fit along two dimensions called solidarity and sociability. Solidarity refers to the degree to which a court has clearly understood shared goals, mutual interests, and common tasks and sociability refers to the degree to which people work together and cooperate in a cordial fashion. Each of the four



Sociability High
I. Communal
Judge and administrators emphasize the importance of getting along and acting collectively
High Sociability
Low Solidarity
II. Networked
Judges and administrators emphasize inclusion and coordination to establish a collaborative work environment and effective court-wide communication
High Sociability
High Solidarity
Solidarity Low
Solidarity High
III. Autonomous
Judges and administrators emphasize the importance of allowing each judge wide discretion to conduct business
Low Sociability
Low Solidarity
IV. Hierarchical
Judges and administrators emphasize the importance of established rules and procedures to meet clearly stated court-wide objectives.
Low Sociability
High Solidarity
Sociability Low

Managerial Court Culture, Fig. 1 Court culture classifications

cultures is a particular combination of solidarity and sociability, as shown in Fig. 1.

Communal culture is low on solidarity and high on sociability. Its distinctive values are flexibility, egalitarianism, negotiation, and trust. A network culture seeks both sociability and solidarity. Its values include judicial consensus, innovation, visionary thinking, and human development. An autonomous culture emphasizes neither sociability nor solidarity. Its values are self-managing, continuity, independence, and personal loyalty. A hierarchical culture stresses solidarity but not sociability. Its values are rules, modern administration, standard operating procedures, and merit-based staff promotions.

B. Ostrom et al.'s proposed concept of culture is manifested in familiar and recognizable activities called "work areas," such as the handling of cases, the responsiveness of courts to the concerns of the community, the division of labor and allocation of authority between judges and court staff members, and the manner in which court leadership is exercised. Each particular culture's way of doing things exists in four work areas as seen in the Value Matrix (Fig. 2).

B. Ostrom et al. developed a survey instrument to determine what individual judges and administrators believed about the execution of work in key areas. Because each culture was presumed to manifest itself differently, the instrument asks individuals to indicate how closely each of four ways of getting work done corresponds to what happens in their court (current culture) and what they would like to see as the work style in the future (preferred culture). An application of the framework to courts in California, Colorado, Florida, Maryland, Minnesota, Ohio, Oregon, Utah, and Washington and the Tax Court of Canada found examples of each of the four cultures, although the autonomous culture is the most frequent. This balanced distribution suggested courts are not monochromatic in their work orientations. On the other hand, regardless of the current culture, the vast majority of courts under study indicated a similar mosaic-like preference for the future. Specifically, they tend to desire hierarchical orientations to dominate in the work areas of case management and change management, networked orientations to dominate judge–staff

	Communal	*Networked*	*Autonomous*	*Hierarchical*
Case Management Style	Flexibility— Judges follow accepted principles for the timing of key procedural events, but are comfortable fashioning their own approach to "do the right thing."	Judicial Consensus— Judicial expectations concerning the timing of key procedural events are developed and implemented through policy guidelines built on the deliberate involvement and consensus of the entire bench.	Self-managing— Individual judges are relatively free to make their own determinations on when and how key procedural events are to be completed.	Rule oriented— Judges are committed to the uniform use of standard case flow management techniques (e.g., early case control, case coordination, and firm trial dates) with the support of administrative and courtroom staff. Written court rules and procedures govern what judges do.
Judge and Court Staff Relations	Egalitarian— Characterized by teamwork, cooperation, and participation. Judges, court managers, and staff work things out flexibly as they go along. Judges agree all individual staff members should obtain satisfaction from work, but no set training program applies to all staff uniformly.	People Development— Characterized by commitment to innovation, diversity of ideas, and widespread managerial and courtroom staff development. Attention is paid to developing effective court-wide communication. Regular systematic performance evaluations are encouraged.	Personal Loyalty— Characterized by personal loyalty to individual judges. Non-standardized procedures are the norm as judges have wide discretion in how they recruit, manage and reward their courtroom support staff.	Merit— Characterized by formal rules and policies, with people following clear guidelines and written instructions about work. Reasons for rewards and demerits are clear. Poor performance is dealt with quickly. Maintaining a smooth running organization is important.
Change Management	Negotiation— The change process tends to occur incrementally through negotiation and agreement. Procedures are seldom rigid so that the actual application of policy changes may reflect revision and compromise among work teams of individual judges and corresponding court managers and staff.	Innovation— The change process tends to be proactive in order to achieve desired goals. Judges and court managers are open to new challenges and acquiring new resources to support innovation. Monitoring and reacting to broad court performance targets are encouraged.	Continuity— The change process tends to occur sporadically as the court is generally content to preserve established ways of doing business. Centralized change initiatives are a challenge because each judge exercises a wide scope of latitude in the choice of practices and procedures.	Modern Administration— The change process tends to emphasize improved efficiency and using new techniques to measure the way work is done. Judges and court managers seek and use court performance information, data, and technologies to help make better business decisions.
Courthouse Leadership	Trust— Leadership in the court is generally considered to exemplify building personal relationships and confidence among all judges and court employees; and seeking to reconcile differences through informal channels.	Visionary— Leadership in the court is generally considered to exemplify innovation, inclusion, and coordination by the presiding judge and/or court management team to establish a collaborative work environment.	Independence— Leadership in the court is generally considered to exemplify preserving individual judicial discretion, allowing judges to use their own criteria in defining success, and not necessarily relying on the same indicators of achievement.	Standard Operating Procedures— Leadership in the court is generally considered to exemplify centralized control and organization to achieve administrative efficiency. A presiding judge and/or court management team typically has authority to establish a clear division of labor and set court wide expectations.

Managerial Court Culture, Fig. 2 Value matrix member relations, and a communal culture to dominate the area of courthouse leadership.

Origins and Controversy. The effort to study managerial court culture has roots in initial court research and from private sector studies and selected public organizational experts on culture. Concerning private sector management and performance, B. Ostrom et al. looked to the work of business school scholar Robert Quinn and his colleagues. They had embarked on nearly two decades of sequential studies and made clear the relevance of culture as they summarize the traits of successful private sector businesses:

> The major distinguishing feature in these companies, their most important competitive advantage, and the most powerful factor they all highlight, as a key ingredient in their success, is their organizational culture. The sustained success of these firms has had less to do with market forces than company values; less to do with competitive positioning than personal beliefs; less to do with resource advantages than vision. In fact, it is difficult to name even a single highly successful company...that does not have a distinctive, readily identifiable, organizational culture. (Cameron and Quinn 1999)

Growing awareness that culture matters to performance and long-term success in the world of business triggered the emergence of culture analysis as a definable area in the field of management and organizational studies largely beginning in the 1980s.

B. Ostrom et al. then found support in applying Quinn's ideas to courts in the views of public sector scholars, such as Wilson and Dilulio. Wilson (1989) had made the case for including organizational culture in the study of public sector organizations. Wilson opened the door for integrating work on private sector organizational culture into the study of the public sector with the following claim: "Organizations matter, even in government agencies" (1989). He argued culture is a core topic for public sector organizational analysis because organizations have a culture just as an individual has a personality. Organizational culture is a relevant and important facet of all bureaucracies – public and private.

However, when shifting the focus to public institutions, Wilson anticipated some difficulties in diagnosing a public organization's culture. Specifically, public organizations do not necessarily have a single culture. In response, B. Ostrom et al. expected courts might manifest a mosaic of complementary and competing cultures. Identifying and understanding the resulting mosaic and the relationship to performance becomes vital to public sector management.

Additional insights come from DiIulio (1993) who had suggested that the measurement of organizational culture is an important part of any public administration improvement strategy. He had proposed the following agenda for doing so:

1. To observe how members at every level of an organization "really behave"
2. To relate systematically these observations to the formal character of the organization in order to see what (if any) connections exist
3. To search systematically for the connections (if any) between organizational activities and real-world outcomes

The key research focus is to discover the relationship between "the way things are" in an organization and the ability of the organization to reach its stated ends.

Following the direction of Wilson and DiIulio's arguments, B. Ostrom et al. found three reasons to suggest private sector studies inform the specific topic of court culture. First, the concept of court culture and the parallel private sector investigations both revolve around the idea that "the way things get done" (i.e., work orientations) defines the character of the organizations. To the extent that judges and administrators in one court have particular views on how cases should be resolved, they will organize themselves differently than individuals with dissimilar views in another court. Second, work orientations shape the degree of a court's effectiveness. This linkage in the private sector made the search for a parallel relationship in public institutions, including courts, worthwhile. Third, business school scholars have shown private organizational culture is susceptible to measurement and the results are interpretable within a typology of cultures.

Of course, some scholars argue that knowledge about private organizations cannot be a basis for understanding public bodies. Wallace Sayre expressed this viewpoint in his well-known assertion that public and private organizations are "fundamentally alike in all unimportant respects." More specific assumptions underlying this argument are public agencies that, in contrast to private bodies, lack a clear bottom line (e.g., profit and market performance), have a diverse set of goals and performance criteria, and are more "open" and with greater exposure to public scrutiny, and managers of public organizations have shorter time horizons. Yet, when looking at the temperaments, skills, and techniques of judges, court managers, and court employees, the differences between public sector and private sector organizations and management are minimal. This point of view is expressed in Lynn's observation that

> [t]he two sectors are constituted to serve different kinds of societal interests, and distinctive kinds of skills and values are appropriate to serving these different interests. The distinctions may be blurred or absent, however, when analyzing particular managerial responsibilities, functions, and tasks in a particular organizations. The implication of this argument is that lesson drawing and knowledge transfer across sectors is likely to be useful and should never be rejected on ideological grounds. (2003, 3)

The ability to measure culture by borrowing the tools available in the broader organizational culture literature highlights the relevance of the methodologies to the field of court administration.

Unsettled Issues

An unresolved issue concerns the scope of the managerial court culture approach. Even in the strictly American context, the question is whether a culture framework applies to different types of disputes, such as civil, family, juvenile, or probate. For B. Ostrom et al., broadening the scope of study beyond criminal cases is possible because despite the unique set of substantive laws governing other types of disputes, they all share an essential characteristic. In every court, cases move from one key procedural event to another. To execute this common process, the activities represented by the four areas of the court culture framework occur in every type of case. As a result, case management style happens in civil cases just as in criminal cases. Judge–staff relations exist in probate cases just as in criminal cases. Courthouse leadership governs juvenile cases just as in criminal cases. Furthermore, how the work is to be done in each area reflects cultural values such as independence, discretion, inclusiveness, and efficiency more than by differences in evidentiary standards, rights of the parties, and severity and type of possible sanctions imposed on a losing party among courts.

Legal criteria specify desirable goals more than how to achieve them. In fact, appellate courts are likely to be amenable to cultural examination because the key procedural events are more definable and similar across appellate courts than trial courts (Chapper and Hanson 1990). Experts and practitioners are likely to have multiple hunches and notions to explain anticipated cultural variation. What judges and court administrators think are appropriate work orientations will likely vary by case type and differ from what criminal courts demonstrated. For example, in the area of case management style, judges with a civil docket may prefer to give greater deference to the bar. In the area of judge–staff relations, probate judges may want to grant greater independence to legally trained staff. In the area of courthouse leadership, judges handling juvenile dependency cases may seek to develop strong connections with social welfare agencies. For all these reasons, B. Ostrom et al. believe that despite variation in work orientations across areas of law, the managerial court culture framework opens up a valuable vista to future court studies.

Ongoing efforts to understand and diagnose court organization culture in American trial courts highlight the relevance of the approach to legal systems outside the borders of the United States. Without claiming that the use of those tools answers all questions, court scholars in other countries should benefit by adapting what has been set in motion. Applicability of the methods likely hinges on three conditions: (1) the opportunity for collegial discussion among judges and staff members exists, (2) judges and staff members have some say over the design and implementation of court administration policies and practices, and (3) the judge with official leadership responsibilities has an interest in organizational improvement. The more vibrant the collegial discussion, the more aware judges are that their administrative decisions have independent consequences, and the greater the interest of administrative leaders, the greater the utility of investigating managerial court culture. The use of the same methods that are free and open to inspection augurs well for truly comparative research across boundaries.

Conclusion

Culture focuses attention on variables exercising a strong, independent influence on the administration of the legal process. Reforms need to bond with cultural values to stand a chance of influencing court performance. For this reason, the effort to understand cultural values as indicators of the current state of affairs and future possibilities is as deserving of attention as any other aspect of court management, such as structure, process, or resources. Implementation of new practices becomes less difficult under a supportive culture.

Managing Innovation of Policing

Marleen Easton
Faculty of Economics and Business
Administration, Ghent University, Ghent,
Belgium

Overview

This entry seeks to address some of the main issues in relation to the management of innovation in public policing without the pretense of being exhaustive. This entry will first contextualize innovation in public policing by paying attention to evolutions in our contemporary society. Second, the entry zooms in on the content of innovations in public policing and aspects of the process of diffusion. Third, attention is focused on challenges related to the process of managing these innovations. Finally, the entry concludes by suggesting some ideas for future research, which are needed to move forward in the field of managing innovation in public policing.

Introduction

> All innovations represent change but not all changes are innovative (Etter 1995, p. 278).

Managing the innovation of public policing is a challenge for police leaders around the world. These innovations are driven by evolutions in our contemporary society, and chance events are often related to the upsurge of reforms in this field. There is significant diversity in the content of innovations taking place. Furthermore, these innovations are conceptualized, studied, and measured in different ways. It is unclear what the effects of most innovations are on public police performance. Nevertheless, they are disseminated and mimicked all over the world. Police leaders have no choice but to get up to date. Knowledge on the content of the innovations is required to get ready for the process of adoption and diffusion. Unfortunately, concepts and ideas of innovation often lack a translation to practices. There is little coherence in broader understandings of what works, in which specific context, based on which implementation strategies, or how it was supposed to work but actually failed. This hampers fundamental changes in the functioning of the police and requires more research in the field of innovation in public policing. In this entry, we address each of these aspects more in detail.

By addressing the management of innovation in public policing, we enter the crossroad of literature on innovation and change management in public organizations, on the one hand, and literature on public police studies and innovations, on the other hand.

A first observation to be made is that the definition of the word “innovation” has subtly changed since the late 1960s. It is no longer enough to introduce a new idea, to be creative, to talk about innovation. The idea has to be brought into use, be successful, before innovation can be said to have taken place. Mulgan and Albury (2003, p. 3) define innovation as “new ideas that work” and to be more precise *successful innovation is the creation and implementation of new processes*, *products*, *services and methods of delivery which result in significant improvements in outcomes efficiency*, *effectiveness or quality*. The change in the content of this concept reflects the current societal pressure on public and private organizations all over the world to be successful in dealing with societal transformations.

Since the eighties, this evolution has been known as New Public Management in the public sector, which has featured the transfer of principles from the private sector to the management of public organizations. Principles such as external orientation, service delivery, partnership, debureaucratization, performance management, accountability, efficiency, and effectiveness are at the core of the movement and were used in (inter)national public sector reforms (Pollitt and Bouckaert 2011). These principles can also be found in the philosophy of community-oriented policing, which frequently has been operationalised as external orientation, accountability, empowerment, partnership and problem-solving.

When looking at high-performing innovative organizations in the public sector, leadership is one of the key characteristics.

> These leaders, these senior managers and lead professionals are hungry, thirsty, exploring all the time the external environment. These are people who are both externally and frontline oriented in their approach to management. And they maintain a 'split screen narrative'; they are interested in innovation but not for its own sake, rather they are concerned about how to continue to improve their day-to-day operations and services and products while at the same time building innovative capacity to address present and future challenges. (Albury 2011, p. 230)

Furthermore, there is a difference being made between management and leadership, which is crucial to the management of innovation. In essence, leadership is all about inspiring, motivating, coaching, and mobilizing individuals and groups. Leaders have a vision by which they give directions for the future. Although managers can be leaders, the management process as such is more about bringing consistency within the organization by planning, organizing, budgeting, controlling, and the like (Bennis 1993). From this perspective, innovation is mainly related to the leading capacities of managers in terms of being creative and entrepreneurial and which has been described as "transformational leadership" (Bass and Avolio 1990).

Although innovation might be considered to be the new buzzword in policy documents on public organizations, it is worthwhile to transcend fads and fashions in addressing the management of innovation in public policing (Abrahamson 1991). Therefore, it is essential to use a historical approach to this subject and to contextualize it in the dynamics of our contemporary society/societies. The role of the environment of any public organization in stimulating the demand for change is inevitably and should be taken into account. It is a lesson learned based on the contingency approach and (new) institutional perspective in the change management literature (Powell and DiMaggio 1991; Scott 2001; Maguire and Uchida 2000).

Contextualizing Police Innovation

It cannot be denied that the times we are living in today are characterized by constant change. Concepts such as "*postmodern* society," "*risk* society" or "*Information* Age," and the "*Network* society" are being used to refer to the major transformations in our global world. Changes in relation to our economy, politics, ecology, technology, demography, culture, religion, values, and social interactions are at the heart of it.

The combination of economic forms of globalization (interconnectedness of world financial markets, extensions of free trades, technological standardization, and internationalization), cultural globalization (through movies, fashions, and sporting events), and social changes in the pattern of life (increased life expectancy, changes in the patterns of family life, rise in the level of unemployment and migration flows, etc.) makes the nature and pace of change today unique (Pollitt and Bouckaert 2011).

Apart from the new opportunities and chances, these driving forces influence the problems arising in our societies. The nature of threats, risks, crime, criminals, and criminal organizations is changing, and the "localized citizens' demands" for more security and protection are rising all over the world. To answer these "demands," the public police has up until now gone through a period of significant change and innovation (Mastrofski and Willis 2010). Processes, services, and methods of delivery have been revised to improve the functioning of the public police. To get accustomed to new social media such as Twitter and Facebook, mobile communication, and the need to closely work together with other (security) actors in the field are just some of the challenges the public police face today.

The current European and North American (economic) crisis is adding greater complexity to it all. Castell and his network of academics talk about "the Aftermath" referring to an era before and after the economic crisis of 2008 (www.aftermathproject.com). It is a social crisis which is bringing about a fundamental transformation of societies at large. Citizens are being challenged to become creative in dealing with this new context and so are policy makers and (leading) managers in the public sector. The time has come to produce significantly better outcomes for significantly lower costs (Albury 2011). Austerity measures generate immense pressures on all public services, including the police. Instead of doing more with less, in some countries, the police might have to find a way to do less with more (involving more people and delivering more impact). This means that a smaller (less public money is available), smarter (better use of informational and human assets), and sharper (interventions targeted to where they can make a difference) style of policing is considered to be a possible way to deal with this challenge (Innes 2011, p. 80). The way in which this context may be fertile ground for innovations is still to be seen but worthwhile to follow up as it might depend on policy choices made by politics.

It is important to note that these driving forces may provide pressure, but they do not supply the ideas for innovation, which is to be generated by (leading) managers of public policing. The question arises: "what is yet to come and what will be the content of the innovations for policing in the future?" Groups of academics and/or practitioners working on a vision on policing for the future address these questions, and most of them rely on the societal transformations mentioned above to start thinking creatively about possible future challenges for the functioning of the police. Interesting in this respect is the RAND-publication on "Moving Toward the Future of Policing" and the activities of the "Pearls of Policing" network, which bring together police leaders from around the world to think about a vision on policing the future. These networks raise questions on what the main challenges will be for police work in the next decades. In their writings and conferences ideas, knowledge and experiences are shared which can be inspiring for law enforcement leaders around the world.

Finally, chance events such as scandals, disasters, accidents, and unpredictable tragedies are quite often related (as a catalyst) to the upsurge of reforms in the public sector (Pollitt and Bouckaert 2011). For example, the Marc Dutroux scandal (serial killer and child molester) and more specifically the lack of information exchange between the existing police agencies at the time was one of the reasons for the substantial reorganization of Belgium's law enforcement sector in 1998. With the law on the integrated police force (07/12/1998) structured on a local (local police) and a federal (federal police) level, the State Police, Municipal Police, and Criminal Investigation Department, who used to be separate agencies, were integrated. During the reorganization community policing was introduced by law. This illustrates the dynamic relation between the public police and its societal environment in terms of change and innovation.

In what follows, the content of public police innovations and some aspects of the process of diffusion are considered.

The Content and Diffusion of Innovations in Public Policing

Although there might be some overlap (Scott 2009), community policing, broken windows policing, problem-oriented policing, pulling levers policing, third-party policing, hot spots policing, CompStat, evidence-based policing, intelligence-led policing, telemetric policing, restorative policing, and zero-tolerance policing are all considered to be major innovations in (American) public policing developed during the last three decades (Weisburd and Braga 2006; Scott 2009). The classification as "major" refers to the influence of these innovations on the broad array of public police tasks and on the practices and strategies that broadly affected the public policing of American communities. In the wake of the September 11, 2001, terrorist attacks on New York and Washington *terrorist-oriented public policing* can be added to this list as one of the broad and quite complicated innovations (Mastrofski and Willis 2010, p. 117).

Nevertheless, there is some discussion on whether the innovations above are cultural and/or structural; incremental or radical; strategic, administrative, technical, or programmatic; and focusing on a single service, a department, or the total organization of the police (Damanpour 1991; King 2000). In relation to innovations, the question often persists whether it is rhetoric or reality. This discussion creates a division between “believers” and “nonbelievers” on each of these innovations between and within the community of scholars and practitioners. It is reflected in the lively debate in the literature of which Weisburd and Braga (2006) present a representative sample. Currently, however, it is not clear at all where the state of the art is in research on these innovations in public policing.

The notion of a policing model is found to be useful in making the complexity of innovations comprehensible. Ponsaers (2001, p. 473) roughly discerns four police models: the military bureaucratic model, the lawful policing model, the community-oriented policing model, and the public-private divide policing model. Each of these models is considered to have an internal-logical vision which has a critical function and involves basic assumptions in itself about the role and the place of the police in society. This includes a position in relation to key questions about police discretion, the role of the law, responsibility, relationships with the population, professionalization, legitimacy, prevention, and pro-/reactive police force policy. These are the key issues being influenced by the broader societal context mentioned above. From this perspective, these police models can be considered to be important innovations in policing.

The importance of these police models for the topic of managing police innovation is threefold. First, it shows that police innovation is related to the timeframe in which it takes place. The military bureaucratic model, now considered to be the traditional model, was innovative at the time in dealing with the problem of corruption, politicization, and the lack of professionalism. The postmodern “Public-Private Divide Model” fits into the current challenges for the police in an era of economic crisis and an evolving security field in which there is an increasing degree of interaction between public and private bodies. A second reason is that this approach makes it possible to distinguish these police models from other kind of concepts and to clear up the conceptual “mess.” For example, discerning four police models makes it possible to emphasize that the broken windows theory is not a model but a theory. In this line of reasoning, problem-solving/oriented policing and reassurance policing are a variant of the community policing model, and intelligence-led policing is simply the result of an evolution in technology (Ponsaers 2001).

The third reason why police models are important to address the issue of innovation is that police models are not to be considered as sequences in time, they are not chronological episodes but logic deductions. In other words, reform processes inhibit a programmatic choice and the danger of a return to more conservative police models is always present. Importantly, a police organization can be considered as a combination of police models. The combination will vary in relation to the political consensus and integration within society. In that respect, the responsibility of police chiefs and politicians is huge (Ponsaers 2001, p. 492).

Despite the discussions, it is important to note that most of the innovations mentioned above have to varying degrees been “exported” throughout the (Western) world. Overall, there is optimism among scholars as Weisburd and Braga (2006, p. 12) observe *police agencies have become open to the idea of innovation, and that new programs and practices have been experimented with and adopted at a rapid pace over the last few decades*. Efforts are being made to “translate” some of these concepts to different contexts (see, e.g., Ponsaers and Easton 2008) and to implement the innovations, often conceptualized in the Anglo-Saxon world, to other continents where public police units, departments, and agencies have their own structure and culture. At the same time, efforts are being made to integrate some of these innovations to avoid too many new notions in the world of public policing and to try to capture the overall picture (Ponsaers and Easton 2008; Scheider et al. 2009).

Around the world, this process of “translation” and “integration” is being done by organizing seminars in which attention is being paid to new concepts and evolutions in the field of policing and which are being discussed by academics and practitioners. Networks such as the Centre for Excellence in Policing and Security in Australia, the Asian Association of Police Studies, the African Security Sector Network, the UK Police Foundation, the Scottish Institute for Policing Research, The Dutch Society, Security, and Police Foundation, and the Center for Police Studies in Belgium are explicitly investing in these exchanges. An example are the efforts to explain the concept of "reassurance policing" and the link with "community policing" in order to inform police chiefs on these new evolutions. It was done during a seminar on "Reconsidering Reassurance Policing" in May 2009 organized by the Belgian Flemish Center for Police Studies in collaboration with the Dutch Society, Security, and Police Foundation and the UK Police Foundation.

The main reason why the "export" of such innovations remains quite remarkable is that there is no clear evidence on the effect the innovations have on police performance (Weisburd and Braga 2006, p. 339). "Does it work?" often remains the question which cannot always be answered on the basis of current empirical research in the field of policing. The "contrasting perspectives" on police innovations are fueled by the finding that the success of these innovations is seldom revealed due to the complex nature of police work (complex relation between outcome and effect of police work). Studies rather indicate that the standard model of policing continues to dominate the work of most public police agencies (Skogan and Frydl 2004). In other words, the public police are more likely to follow traditional police practices and models than to choose innovative approaches. Nevertheless, not everybody is that pessimistic about the public police. According to Mastrofski and Willis (2010, p. 116), generalization about change in relation to public policing is hazardous. They refer to the existing tension in academic research between the temptation to overstate the capacity of the public police to resist change and the temptation to overstate their susceptibility to change.

There is an urgent need for more (comparative) research work in this domain. Measures of innovations and change in public policing are far less developed than that available in innovation studies of other organization types. *Innovativeness studies* which quantify the adopted innovations and aim at explaining why some organizations adopt more innovations than others are scarce. It has limited understanding of why some departments are more innovative than others. There is in fact some disagreement about the impact of environmental factors, on the one hand, and internal, departmental factors, on the other hand (King 2000, p. 306). Furthermore, there is certainly a gap in the *diffusion studies* on innovations in public policing which describe and predict the spread of an innovation or innovations across a group of adopters, over time (King 2000, pp. 303–305). In relation to public policing, these studies conclude that innovations are slowly adopted by a few departments at first, and over time, the rate of adoption increases. Larger departments tend to adopt before smaller departments (Weiss 1997).

To sum up, there is significant diversity in the content of innovations taking place. Despite this diversity and the fact that it is unclear what the effects of most innovations are on police performance, these innovations are disseminated and mimicked all over the world. Without presuming that all innovations are transferable, the question arises as to what is known about the process of managing these innovations as management is a crucial aspect of any type of dissemination. In what follows, we further elaborate on this.

The Process of Managing Innovations in Public Policing

When Pettigrew (1992) stresses the interaction between the context, content, and process of changes, (leading) police managers are at the heart of these interactions. To learn more about the process of managing police innovation, it is interesting to have a look at *process studies* being done in the field of public policing in relation to some of the innovations mentioned above. *Process studies* explain the way in which an innovation is discovered, adopted, adapted, and employed by an organization. The study of the adoption of innovation has only recently become a subject of interest for police scholars (Skolnick and Bayley 1986; Weiss 1997).

Nevertheless, there have been few systematic studies of these processes, and scholars were generally not concerned about the emergence of innovation as a research problem when these innovations were being developed (Weisburd and Braga 2006, p. 11). As a consequence, there is remarkable little research on the innovation process or how it can be facilitated or implemented (Maguire 2009). There is likewise little systematic, cross-agency research on the extent and effectiveness of organizational change strategies in policing or on the role of police leadership in relation to these strategies (Skogan and Frydl 2004, p. 9).

There are, nonetheless, some challenges related to the management of innovation in public policing that need to be addressed. The complicated nature of this management process is related to the fact that police managers do not operate in a vacuum but find themselves in an "arena" of forces. Key players are the internal police **p**ersonnel and organization, the **p**ublic or the communities being policed, the **p**oliticians and the civil servants, diverse external **p**artners of the police, and the **p**ress or media. Numerous sources of resistance and challenges are related to this "5**p**" complexity (Skogan 2008).

A big challenge is related to the competing demands and high expectations of the public towards the police. Because time and money is limited, the police are often unable to meet the "list" which different communities generate. Police managers need to respond to priorities with the available means and effectively communicate with the public to achieve the necessary legitimacy and support. This task is further complicated by the competing nature of the demands coming from different communities. However, it is important to note that societies are quite different in this respect. The public police are not the first point of reference for all citizens around the globe. For example, South African citizens are contacting their neighbors or private security agencies first when confronted with security problems. The public police over there are not at all the first to be called in emergencies.

Furthermore, managers in police innovation need to build public and political support. Police innovation might not be isolated to the police organization alone. The innovation must be supported by the (local, federal, regional) network of (community) agencies that influence the functioning of the police. The failure of (interagency) cooperation can be a substantial source of resistance in relation to the numerous external (state and non-state) partners the police are now expected to work with. These partners have their own view on security and well-being which might not fit the assumptions of the police innovation (Reiner 1992; Skogan 2008). However, external support can be crucial as it might help the change manager to respond to internal opposition to the innovation that has to be implemented. Taking this into account, it might be wise to invest time in the transition of innovation to successors in leadership, in the police organization, and within the governmental and community environment (Skogan 2008, p. 33).

In addition to these external contextual elements, managing innovations in public policing implies addressing the traditional internal resistance to change. Changes to established workplace cultures and practices in police organizations are difficult to generate. This is related to the nature of public police work and the structures and cultures that this has generated. This is a culture that has been called traditional or conservative as it holds on to established practices and symbolic representations of "discipline" (Marks and Fleming 2004). This hinders attempts at developing more participatory management techniques which are crucial to some of the innovations mentioned above. A culture based on "top-down command and control" is, for example, resistant to take into account critical reflections of police personnel on internal or external work-related procedures.

Furthermore, managers have to take into account that within this culture, police unions play a role in resisting innovations which include performance measurement and augmented accountability mechanisms (Reiner 1992). This may be understood from their attempt to preserve the professional discretion of the rank-and-file in the police organization. The fact that the core of the innovations cannot easily be translated into actual practices is fueling this kind of resistance. This may also be related to the fact that it is difficult to measure and reward all aspects of police work. It is, for example, easy to measure interventions at traffic incidents on the basis of police reports, but it is much more difficult to measure and reward the efforts of police to strengthen their relationships with local communities. This complicates the implementation of innovations such as community policing that include important activities which cannot always be measured (Skogan 2008).

A significant internal source of resistance, which must not be underestimated, is the rank-and-file officers. They are often asked to leave their traditional roles and meet new and high expectations for which they do not always have the necessary skills and training. These officers are quite often suspicious about new ideas that they easily call "fads" and put aside to deal with "real" police work. Furthermore, middle managers are not always enthusiastic. Empowerment of the lower ranks, for example, which is a key element in community-oriented policing, is challenging police power which is traditionally built on command and control and doing everything by the book. Managers are asked to have trust in the professionalism of their police officers and encourage the exercise of police discretion. For established managers, this is a radical change that is not always welcome (Skogan 2008, pp. 24–25).

Being aware of this kind of resistance to change, managers need to fine-tune their strategies to support their personnel depending on their stage in the adoption of the innovation. On a Gauss curve, the stages of each employee may vary from being part of the small group of "innovators" and "early adapters," being part of the "early majority" or "late majority" which is representing most of the group to being a member of a small group of "laggards" (Rogers 1962). Reeducation might work in relation to innovators and early adopters, but most of all, persuasion strategies will be needed to get the rest going in the desired direction. In this regard, the police is far from close to the many innovators and early adapters in the world of crime and criminal organizations they are fighting against (Treverton et al. 2011).

The ultimate challenge is to incorporate new management practices into police organizations in such a way that these changes are experienced "as unremarkable as the air they breathe" (Shearing 1992 in Marks and Fleming 2004, p. 786). According to Toch (2008), reform can get considerable credibility if officers are enlisted as change agents, encouraging them to get involved in the design and implementation of change. In this line of reasoning, police unions can be considered as change agents also (Marks and Sklansky 2011). It might help if the utility function is taken into account. Police personnel, as cultural subjects, only subscribe to a certain kind of policing and policy if they also derive an individual or social added value from this (Easton and Van Ryckeghem 2010). Financial or promoting rewards for extra investments in relation to innovations can make a difference in the motivation for change. However, it is important to not allocate the innovation to a new unit within the organization or to ask people to allocate their extra overtime to the implementation of new practices (Skogan 2008, p. 27). An innovation such as community policing should be an overall strategy for the organization as a whole.

This complexity of issues and factors requires a flexible leadership style in which attention for continuity and innovation is combined. Purely instrumental (transactional) leadership will remain important to develop a working environment in which one can work effectively and efficiently. Transformational elements will be essential as well they empower people by formulating a vision and mission for the future of the police organization.

At times managers might find themselves confronted with even contradictory requirements on the organizational, strategic, and operational level of the police organization. The community policing model asks him/her to accept decentralized decision-taking, generalization as principle for labor division, a preventive orientation, a social strategy, and an open, proactive interaction with the environment. This may conflict with the demands of the military, bureaucratic model that stresses centralization, specialization, repression, and a closed system that is reactive in the interaction with the environment. Furthermore, a high degree of fragmentation in the decision-taking, specialization, a risk calculation, and contracting with consumers may be essential to implement the public-private divide model. In relation to various task environments, different police models coexist within a single police organization (Ponsaers 2001, p. 492). Police managers might find themselves "juggling" with inherently conflicting demands. This might be considered to be one of the main challenges in managing innovation in public policing.

To sum up, the challenge for police managers and leaders in the twenty-first century is to adapt their police organization to a demanding context and translate societal changes into the functioning of their organization by implementing innovations as mentioned above. The fact that different authors conceptualize, study, and measure police innovation in different ways generates different findings and makes the field of police innovation a "morass" wherein (leading) managers try to "survive." Although managing innovations in public policing inhibits challenges that are well known in the field, there is an urgent need for more empirical research on this topic.

Conclusion and Future Research

This overview makes clear that insights on the management of public police innovations might be "lost in translation." Firstly, innovators in policing have lent insights from public sector reform and were inspired by New Public Management. The application of the concept in the world of policing might need some further attention due to the specific nature of police work reflected in its culture and structure. Secondly, innovations tend to be captured in concepts and ideas for too long and lack a translation to practices within the police organization to be able to get implemented and radically change the functioning of the police. Thirdly, different authors conceptualize study and measure police innovation in different ways which generates different findings. It makes the empirical field of police innovation a morass and fuels a constant debate on how to manage police innovation. Fourthly, it is a challenge for academics and practitioners to develop and promote future innovations in a more integrated fashion to police. It is clear that more research is needed on the management of innovations in public policing.

Most innovation studies have not concentrated sufficiently on the dynamics behind police leadership, managerial, or tactical programs to provide understanding and/or guidance as to how these changes and innovations came about, how they were designed, what processes facilitated or hindered the finalization of project or program goals and objectives, and what outcomes were produced. The context in which such outcomes produce or fail to produce is often "black-boxed." There is a general absence of a body of literature that can be used to both identify the processes employed to design or implement police strategies or tactics which are part of major innovations, and the outcomes of those efforts. Simply put, policing has an oral tradition, where learning from the successes and failures of others has not been well routinized. Rather, police leaders emerge, have success and failures, and then often fall back into obscurity, without passing their learning and experience on to future generations of police leaders. This is an important conclusion for three reasons.

First, in the absence of collective understanding of environmental and institutional dynamics in policy choices and their implementation, police leaders are left to a hit-and-miss process, ill informed by current experience and knowledge. As such police chiefs often operate with policy and tactical blind spots, often mimicking what are thought to be national trends, whether or not those trends suit the particular police agency, or community in question. Replicating the practices of larger police agencies may actually do harm to smaller agencies, where there are perhaps greater ties between the police and the community. Moreover, appearing to look innovative in mimicking larger agency practices can actually lessen police effectiveness and the legitimacy the public accords the police in smaller communities. In short, mimicking bigger is not always better. Structures and practices of small agencies remain under examined (Mastrofski and Willis 2010, p. 57).

Second, given the large gaps between academic research and police policy and decision making, police chiefs may be uninformed about "what works" and therefore must rely on institutional and programmatic myths. It may be argued that the current police research literature itself suffers from questions of validity and scientific credibility, a criticism leveled by what is known as the evidence-based policing movement. Further, it can be asserted that what are called "best practices" are often absent in police discussion and in the preparation of a new generation of police leaders. Consequently, old practices, ideologies, and routines persist. This may account for the near uniform persistence in patrol and investigative practices that have little evidence of actually working, such as general patrol and general investigations.

Third, at the tactical level, there is no body of literature that actually assesses how certain tactics were called for, designed, implemented, and which impact they generate. There are assessments of parts of these questions scattered throughout the research and program evaluation literature, but there is little coherence in broader understandings of what works, in which specific context, based on which implementation strategies (how it was made to work), or how it was supposed to work but actually failed. The exception to this statement, perhaps, is in the area of problem-solving, where there has been an attempt to provide a systematic review (see, e.g., www.popcenter.org).

This makes clear that to support the management of police innovation in the future, two kinds of investments are essential. The first is the development of "evidence-based police practices" that support leaders in managing police innovations in the implementation process and confrontation with numerous constraints related to the functioning of the public police. The second is investment in future police leaders to have the necessary attributes, skills, and knowledge to manage it all. These investments can help future leaders to play a role in managing police innovation and translate broader societal transformations (sociological, economic, political, technological, etc.) into the functioning of the police organization of tomorrow taking into account its own character.

Synonyms

Critical criminology; Radical criminology

Overview

Despite the fact that Marx did not address crime in a systematic way, criminologists have used Marxist theory to analyze laws, crime, and the criminal justice system. Over the past 40 years, Marxist criminology has become a core component of what has been broadly referred to as critical criminology. Many critical criminologists have contributed to the development of Marxist criminology, and its position within the field of critical criminology is well established. At the same time, the insights provided by Marxist criminological theory have received little interest among mainstream criminologists, despite the fact that some share with Marxist criminologists a macrolevel or structural approach to studying crime. While recent developments in Marxist criminological theory have slowed, Marxist criminologists are still able to provide a viable framework to understand law, crime, and state responses to crime.

Marx and Crime

The works of Karl Marx, Friedrich Engels, Antonio Gramsci, Emma Goldman, Willem Bonger, and a host of others who have stood on their shoulders provide what the philosopher of science T.S. Kuhn aptly named a "paradigm." A paradigm is a general theoretical perspective composed of concepts, hypotheses, and perspectives from which political, economic, and social relations can be analyzed, explained, and understood. The Marxian paradigm, which serves as a foundation for a corpus of knowledge in the social sciences generally, and criminology in particular, is thus a very general perspective from which specific (although sometimes conflicting) theories are developed. With such a large fountain of ideas, it is not surprising that no one "Marxist theory" can claim an exclusive interpretation.

Despite the fact that there are a wide variety of "Marxist theories," there are two fundamental characteristics of Marxist theories that tie them all together and differentiate Marxist theory from other paradigms. First is the belief that the material conditions of a particular time and place – not norms or values of culture – are the starting point for an analysis of why political, economic, and social relations have the shape and texture they do. Second is the assumption that social theory generally, and criminological theory in particular, is best served by approaching the subject from a *structural perspective*.

The structural perspective is of course not unique to Marxist theory. Emile Durkheim argued, in his classic text *Suicide*, that individual explanations of suicide were impossible to come by, but explanations of why suicide rates varied according to social structural characteristics were not only possible but also scientifically defensible. Durkheim, however, did *not* see the importance of material conditions in determining suicide rates (social class is never mentioned in the entire book). On the contrary, Durkheim based his analysis on the importance of norms, specifically normative integration, a paradigm that has dominated criminological theory ever since.

The Marxian paradigm stressing material conditions has influenced many theoretical paradigms in criminology, albeit often rather tentatively. Edwin Sutherland's essentially psychological theory of the cause of crime explained individual criminality by the degree of association an individual had with "attitudes favorable or unfavorable to the commission of crime." The implicit assumption was that people from the lower classes (thus material conditions) were more likely to have associations with attitudes favorable to the commission of crime. The theory was, however, basically normative in that it was attitudes and norms that were the deciding factors in the etiology of criminal behavior.

Robert Merton's strain theory is likewise a combination of Marxist materialism and Durkheimian emphasis on norms. The "strain" in Merton's theory derives from the location of groups or individuals in the social structure relative to their access to legitimate means for achieving culturally prescribed goals. It is not material conditions per se; it is material conditions as they relate to cultural norms (goals and means) that provide the impetus for crime.

Sutherland and Merton exemplify the tendency of criminological theory to emphasize the importance of norms and to give passing reference to the fact that material conditions (in particular social class) may contribute to the learning of social norms (Sutherland) or the experience of social strain (Merton).

Herein lies the most fundamental difference, then, between the Marxist paradigm and that of other criminological theories. The Marxist paradigm, with few exceptions, does not seek to explain why individuals commit crime (for exceptions, see Bonger, 1916; Colvin and Pauly, 1983) but seeks to explain why different types of crime are situated where they are in the social structure and why different economic systems (e.g., capitalism and socialism) produce different types and rates of crime. The starting point for Marxist theory is not the norms, values, and culture of the historical period. For Marxist theory the starting point for explaining any social phenomenon lies in the material conditions and the social structure of a particular historical period.

Social Order and Crime

Since Marxist criminologists look to social order when explaining crime and societal responses to it, they begin with an analysis of the existing social arrangements. For Marxist criminologists, the laws that define behaviors as crimes emerge from the existing social order. In this view, social order comes before the laws that define behaviors as crimes (Michalowski 1985). This is very different from mainstream criminological theory that assumes crime creates the need for laws, which then in turn produce social order (Michalowski 1985).

Marxist criminologists have argued that political economy is dynamic and develops in stages over time. Thus, the particular form of capitalism may change depending on historical social and political developments. For example, the emergence of the welfare state changed many capitalist economies in that politicians decided to add (or strengthen) social safety nets, such as unemployment benefits and welfare for the poor. Marxists have argued that the development of the welfare state was necessary to stem the tide of class conflict that arose from growing class inequality and labor unrest. Marxists have argued that because capitalist economies contain inherent contradictions, they must constantly undergo change to address the problems created by them. In many cases, the state intervenes to dampen the effects of particular social problems created by these contradictions. However, these attempts to dampen the effects of structural contradictions create new dilemmas which then must be resolved, thus continuing the process of reproducing capitalism Chambliss (1993).

Marxist criminologists have been careful to note that some capitalist systems are more likely to be criminogenic than others. For instance, some capitalist societies have stronger social safety nets that reduce inequality and provide basic necessities like health care to its members (e.g., Western European capitalism as opposed to the capitalism found in the United States). Capitalist countries that provide stronger social safety nets also produce different cultural values that are less likely to promote the welfare of the individual over that of the community.

Beginning the analysis of crime from a structural, material paradigm leads to different theories than does beginning from an individualistic, normative paradigm. The structural-materialist paradigm also generates very different *questions.* For example, criminological theory generally assumes what the Marxist paradigm seeks to explain: Why are acts defined as criminal? Why are some people more likely to be labeled and punished than others? What effect does the classifying of some acts as crimes have on economic, political, and social relations? How does the classification of acts and people as criminals serve to perpetuate and maintain the class structure of the society (be in capitalist, socialist, or feudal)? What interests are served by the particular criminal law system in effect at different times and places?

The Development of Marxist Criminology

Neither Marx nor his writing partner, Friedrich Engels, developed a systematic theory of crime. Rather, Marx chose to focus his attention on analyzing capitalism as one stage in the larger history of economic development. While Marx was very critical of the negative aspects of early industrial capitalism, such as the exploitation of the working class by industrialists, he also viewed capitalism as a necessary stage of development that would create the technology and industrial capacity to lay the foundation for a more just society based on mutual benefit, rather than the exploitation of one class (workers) by another (owners). Crime, for Marx, was a social problem like any other in capitalist societies.

Marx believed that capitalism is an inherently unstable system that is prone to crises. For example, capitalism needs competition between business owners, since without it, monopolies emerge that control markets and prices. However, as one company becomes powerful, it can eliminate competition by buying up competitors, or simply crushing them with vast resources (e.g., a large retailer, because of enormous purchasing power, is often able to sell its products at a much lower price than small retailers). Eventually, the state has to step in to prevent this type of monopoly capitalism, passing antitrust and other laws. Thus, Marx viewed each crisis in capitalism as the result of some underlying contradiction in the system. As contradictions give rise to crises, someone (usually the state) must intervene to save the capitalist system from its own destructive tendencies.

Subsequent Marxist theorists have argued when public policies and social institutions are created to resolve one dilemma arising from an inherent contradiction in the system, another one emerges. Because capitalist economies are crisis prone, they undergo stages of growth and decline, leading to boom cycles characterized by economic growth and prosperity, as well as bust cycles characterized by a lack of economic growth, high unemployment, and increased poverty. These cycles influence both crime and societal responses to it. As changes are made to the system to reduce the problems created by one dilemma, new problems emerge that must be dealt with.

One of the first scholars to apply Marx's theories to crime was the German criminologist Willem Bonger. Bonger (1916) argued in his book *Criminality and Economic Conditions* that crime in capitalist societies arose from egoism (self-interest). Bonger (1916) viewed capitalism as an economic system that tended to bring out the most egoistic, and least altruistic, tendencies in people. Bonger (1916) was careful to argue that egoism does not, in itself, cause people to become criminal. Rather, he argued that certain environments make people more capable of crime. Related to the egoistic tendencies of capitalism, Bonger (1916) also claimed that the capitalistic economic system of exchange, that encourages people to act primarily out of self-interest, weakens social bonds. In such systems, the interests of the individual are not balanced with the interests of the collective and create an environment of intense competition and individualism. Much crime, then, occurs because the social bonds that tie the interests of people together are weakened in favor of an ethos of individualism and self-interest.

Another important and early development in Marxist criminology was *Punishment and Social Structure*, by George Rusche and Otto Kirchheimer (1939). Rusche and Kirchheimer (1939) continued advancing a Marxist analysis of crime in their study of punishment. They argued that capitalist systems create forms of punishment that correspond to their productive systems and that large pools of surplus labor in the market are likely to lead to more severe penal policies (i.e., large pools of unemployed people are more likely to result in longer prison sentences).

The 1970s saw the emergence of a sustained interest in Marxist theory and crime by critical criminologists. One of the most significant attempts to develop a Marxian framework for studying crime was *The New Criminology*, by Taylor et al. (1973). Giving primacy to a structural approach to understanding crime, Taylor et al. (1973) challenged criminologists to avoid reductionist explanations of crime that focused on individual causes of crime while providing a strong case for developing a theory of crime that located its causes within the existing political economy.

Structuralist and Instrumentalist Marxists

Early attempts to develop Marxist criminology saw debates emerge between scholars who had differing views on the role of the state in making laws and resolving crises within the capitalist system. On one hand, those such as Quinney (1974) argued that the purpose of laws and the criminal justice system was to maintain the class interests of the powerful. In this view, the state has little autonomy from the ruling class, and laws are instruments used to advance their interests. Others, such as Greenberg (1981) and Chambliss (1993), argued that the primary purpose of the state is to preserve the system itself. Greenberg (1981) made a compelling case that the ruling class is not as cohesive as Quinney and other instrumentalists had argued, and Chambliss (1993) advanced a comprehensive analysis of contradictions, showing that at times, the state passes laws that do not directly favor the ruling class, but are nonetheless intended to stem the negative consequences of a particular crisis in the system.

While the instrumentalist perspective provided a useful starting point to analyze the role of the ruling class in law making, today most Marxist criminologists reject this view. While it is true that the interests of the ruling class are often promoted in the social policies of the state, most Marxists view the overarching goal of the law, and the law making process, as a means to preserve the capitalist system.

Who Are the Criminals?

One of the important contributions of Marxist criminology has been the ways in which it has expanded the study of crimes to include crimes of the powerful. Many early attempts to develop Marxist criminological theory focused on crimes committed by the lower classes (e.g., Bonger 1916; Rusche and Kirchheimer 1939). While the early Marxists studied street crimes within the broader context of political economy, other Marxist criminologists later turned their attention to the study of corporate, state, and state-corporate crimes (e.g., Michalowski and Kramer 2006).

Since Marxist criminologists believe that the origin of all crime can be found in the political economy, it may be tempting to view crime and other social problems arising from the inherent contradictions of capitalism as necessary and positive features that will eventually cause capitalism to collapse. The danger in this view is that street crime can become romanticized, either as a symptom of system crisis necessary for collapse or as some type of rebellion against the system. In this latter case, criminals are viewed as forces resisting capitalist domination.

As left realists and other Marxist criminologists have warned, this view of crime is counterproductive. If criminologists have learned anything over the past 100 years, it is that most victims of street crime are very similar, demographically, to those engaging in crime. Thus, poor minorities living in urban areas are likely to be victimized by other poor minorities living in their neighborhoods. Many left realists have pointed out that the most harmful effects of street crime are not realized by the ruling class – which in many cases can insulate itself from street crime – but by other members of society that are exploited by the system. In the view of left realists and many Marxist criminologists, there is nothing romantic or revolutionary about street crime.

The fact that many Marxist criminologists have examined the crimes of the powerful, combined with the fact that they do not view street crime as revolutionary, does not mean that they have ignored it (see Carlson and Michalowski 1997). In fact, Marxist criminologists have studied all different kinds of crime, from crimes on the street to crimes in the suites.

Crime in the Streets

When explaining traditional forms of street crime, Marxists look to the ways in which economic conditions foster crime. For example, some areas have much higher levels of crime than others, and a Marxist explanation for those differences would begin with an analysis of how factors like poverty, persistent unemployment, and other “structures of disadvantage” play important roles in creating a criminogenic environment in these areas (Taylor 1999).

Since capitalist systems are dynamic, the amount and type of crime may vary from one period to the next and from one country to the next. For example, some capitalist economies have relatively high unemployment rates but lower levels of serious poverty because of public assistance programs (e.g., many countries in Western Europe). Other countries, such as the United States, have persistent unemployment and poverty, with fewer public dollars spent on social welfare. In addition, these structural differences give rise to significant differences in cultural values. For example, the egoism that Bonger (1916) identified differs from one culture to the next. In the United States, serious "structures of disadvantage" are coupled with an ethos of individualism, egoism, and extreme competition for scarce resources. In many urban areas in the United States, it is common to see highly concentrated poverty and unemployment, with little or no opportunity for success in the formal economy. Therefore, it is not uncommon to find underground economies in these areas, where drugs and other illegal goods and services are exchanged.

Crime in the Suites

While the social costs of street crime are significant, the costs of corporate crime are even higher. From a Marxist perspective, the crimes of the powerful are just as important as street crimes and have the same genesis in the political economy.

If capitalism reduces the altruistic tendencies of people and increases their competitiveness, the same is even more so for corporations, since their very survival depends on competition and making as much profit as possible. For corporations, making a profit trumps all other considerations. One of the clearest ways in which this can be seen is in the harm that is caused when corporations circumvent regulatory laws in order to maximize profits. Michalowski and Kramer's (2006) anthology documents many cases where corporate crimes were committed because regulatory laws were either circumvented or simply not enforced by governmental agencies.

Profiting from Crime

The social responses to crime in the United States have resulted in the highest per capita imprisonment rate (750 per 100,000) of any advanced industrial nation (Cowling 2008). With only 5 % of the world's population, the United States imprisons 25 % of the world's prisoners (Herivel and Wright 2007).

Carlson et al. (2010) have argued that the roots of this problem can be found in the economic crisis of the 1980s. During the 1980s, many areas in the United States underwent deindustrialization, where manufacturers moved their plants overseas, in large part to save money on labor and regulation. Deindustrialization caused unemployment to rise dramatically in many industrial cities and devastated local communities. In many areas, drug markets emerged, followed by violent crime. Politicians of all stripes endorsed "get tough on crime" policies, resulting in mandatory sentencing, longer sentences, and exploding prison populations.

Furthermore, Carlson et al. (2010) argued that the net effect of the "get tough on crime" policies that emerged from the economic crisis of the 1980s resulted in increasing numbers of people from the surplus population being incarcerated. In addition, they noted that more money has been spent on the criminal justice system itself, increasing amounts of which have been channeled to private corporations that either run prisons or provide key services for them.

Politics and Crime

Marxist criminologists have long argued that politicians have profited from crime in using "get tough on crime" platforms to win elections. Beginning with the "war on crime" that began in the 1960s, there has been a successive line of presidents and politicians who have advanced policies leading to increased incarceration rates as well as increased spending on all aspects of the criminal justice system.

For example, Chambliss (2001) noted that increased expenditures for the criminal justice system compete directly with other important expenditures such as education, programs for the poor, and other social services. While not Marxist in orientation, Jonathan Simon's (2007) *Governing Through Crime* extends Chambliss' (2001) earlier work by arguing that the focus on crime has become so normative that hardly anyone questions the ways in which crime control policies have radically changed American institutions. While states have been quick to cut funding for education during tough times, they have been slow to cut expenditures on criminal justice – even when crime rates are falling.

Mass Incarceration

Criminologists have noted that one of the most obvious results of the various "wars on crime" that have been waged over the past 50 years is the enormous increase in the prison population in the United States. Poor, young, urban, minority men have disproportionately been incarcerated, leading to startling inequalities in incarceration rates between whites and other minority groups. As Western (2006) has shown, young African-American males are six to eight times more likely to be incarcerated than their white counterparts. This alarming trend has been termed "mass incarceration."

Young minority males have been systematically excluded from economic opportunities, experiencing unemployment rates and poverty rates far higher than whites. Confined to the poorest urban neighborhoods, many minority males have not had access to well-paying manufacturing jobs that disappeared during the wave of deindustrialization during the 1980s. Excluded from the legitimate economy, many of these young men have turned to the underground economy.

Rather than addressing the underlying economic realities of urban areas and their structural problems, politicians have decided to become more punitive, passing a series of "get tough on crime" bills. Aside from incarcerating large numbers of poor, minority males, these policies have resulted in strained budgets and cuts in other essential programs like education and public assistance to the poor.

From a Marxist perspective, mass incarceration is not only a matter of crime and politics but also indicative of larger economic trends. Carlson et al. (2010) have argued that the current trend of imprisonment stems from repressive policies, not necessarily linked to increased crime. For example, mass incarceration serves to reduce the surplus labor force while simultaneously increasing spending in the criminal justice system, employing more people, and increasing the need for goods and services (Carlson et al. 2010). As Carlson et al. (2010) noted, this "imprisonment binge" has "served capital accumulation indirectly by restraining large segments of the surplus population from posing public problems in the form of crime, and directly by serving as a vehicle for private profit realization" (p. 256).

Social Structures of Accumulation and the Neoliberal Project

From a Marxist perspective, the periods of growth and decay in capitalism repeat themselves because of the inherent contradictions within the system itself. Some stages of capitalism have been characterized by economic growth and relative prosperity (i.e., the years after WWII). Other periods, like the Great Depression during the 1930s, were characterized by severe problems such as mass unemployment and deep poverty. Because capitalism is crisis prone, no period of growth lasts forever. Eventually, a crisis emerges that forces a new stage of capitalist development. Each stage of capitalist development, however, relies on institutional structures to support it. In some cases, this means that institutional structures undergo significant change to support capital accumulation. In other instances, social institutions are intentionally weakened to promote capital accumulation (e.g., deregulating the financial sector that leads to the most recent economic crisis). Social Structures of Accumulation (SSA) theory, which has its roots in Marxist theory, views important social institutions – such as the criminal justice system – as playing vital roles in undergirding any sociohistoric stage of capitalist development.

For over 30 years, neoliberal politicians have sought to weaken the welfare state and the social institutions and structures that have been created to support it. While the philosophical roots of this movement have been around for a long time, the period of economic stagnation of the 1970s created a political opportunity to advance neoliberal economic theory. In the early years, champions of neoliberalism such as Ronald Reagan and

Margaret Thatcher sought to wage a war on government itself, characterizing it as the enemy of economic prosperity and personal freedom. Other important components of the neoliberal project have included efforts to reduce taxes (particularly for the rich), the deregulation of business and industry, transferring collective risk to individuals, the decline in labor rights and the power of unions, the promotion of privatization, and perpetual budget crises caused by reducing taxes while increasing spending (see Harvey 2010). The most radical version of neoliberal politics can be seen in the tea party movement in the United States, with its extreme forms of privatization, antitax, and antigovernment rhetoric.

The neoliberal movement has brought with it repressive policies of increased social control that have filtered through many social institutions, most notably the criminal justice system. Carlson et al. (2010) have argued that the criminal justice system, while not a core social institution, plays a significant role in the accumulation of capital by controlling crime and civil disorder and thereby creating a good investment climate. In addition, the growth of mass incarceration has kept significant numbers of the "surplus population" of young men behind bars (Carlson et al. 2010).

From a Marxist perspective, neoliberalism has been a significant force that has given rise to the increasing privatization of prisons, resulting in "prisons for profit." Private sector prisons, like other businesses, are not run for the collective good. Rather, the goal for privately owned prisons is to make a profit. Critics of the neoliberal project have noted that private prisons transfer public money to private stakeholders, shifting the (ostensible) purpose of prisons from protecting the public to making money (Herival and Wright 2007).

On the other end of the class spectrum, some have argued that neoliberalism has resulted in the deregulation and the weakening of regulatory agencies that were created to prevent various forms of corporate crime. In this sense, the neoliberal project has created many opportunities for corporations to engage in criminal activity, such as the financial fraud that lead to the meltdown of the housing market.

The overarching ideology of the neoliberal movement has been that invisible market forces are better at controlling the behavior of people and institutions than laws or regulations. As an extreme form of Bonger's (1916) egoism, the ideology of market forces has entered nearly every facet of human relations, resulting in the radical change of traditional forms of social control such as community norms and other social institutions, like the family and education. As Currie (2004) noted, this trend has resulted in an extreme version of social Darwinism that can be seen throughout contemporary social institutions, ranging from "sink or swim" families where adolescents are left to fend for themselves to the draconian zero tolerance policies found in schools.

The net result of neoliberalism has been an enormous transfer of wealth from the bottom of the class structure to a very small group at the top, against the backdrop of various "wars" (i.e., crime, drugs, terrorism) that have, in many significant ways, undermined democratic institutions and processes. To paraphrase Reiman and Leighton (2010), during the neoliberal era, the rich have gotten much richer, while the poor have gotten prison.

In a very paradoxical way, however, the current politics of crime do not fit with the neoliberal trend of shifting collective risk from the collective to the individual. When it comes to crime, neoliberals are very supportive of strong government intervention to provide collective security. Yet, as Simon (2007) has noted, very few politicians have questioned the fact that "neither contemporary liberal nor conservative principles extol the kind of penal state and gated civil society we are building by governing through crime." From a Marxist perspective, such paradoxical views can only be understood as ideology, the purpose of which is not to promote some principle like individualism but is rather an attempt to promote the particular interests of the ruling class (preserving a system of capital accumulation) by extolling the virtues of collective risk in one situation (crime) while ignoring them in another (e.g., attempts to privatize social programs like social security).

The Future of Marxist Criminology

The most recent and comprehensive overview of Marxist criminology is Cowling's (2008) *Marxism and Criminological Theory*: *A Critique and a Toolkit*. Cowling (2008) argued that Marxist criminology can be advanced by further refining its analysis of the ways in which capitalism reproduces itself, including both the roles that criminal justice institutions and laws play in this process. Given the recent crisis of the global capitalist system following the housing market collapse, Marxist scholars find themselves with ample opportunity to study the ways in which states attempt to respond to the inherent contradictions within capitalism and in doing so provide insight to significant social problems like class inequality and crime.

The current crisis of capitalism provides several potential areas of inquiry for Marxist criminologists. For example, Marxist criminologists might examine the enormous impact of the financialization of the US economy over the past 30 years and the ways in which the exponential growth in the financial sector has led to the current economic crisis. There is little doubt that the neoliberal policies that emerged in the 1980s eventually lead to the deregulation of the banking and finance industry, creating the opportunity for banking and finance to take tremendous risks in order to increase profits. The rewards of these risks were privatized, but as the subsequent collapse showed, the costs were socialized – in the form of a $700 billion taxpayer bailout. Given the tremendous cost and harm created by the banking industry, why is it that there has not yet been a single prosecution? In addition, a Marxist analysis could provide insight to the fact that very little legislation has been passed to curb the practices of the banking and finance industries.

Marxist criminologists can also benefit from the good analysis that is currently being provided by both general Marxist theorists and other critical criminologists. For example, few Marxist criminologists have carefully examined the ways in which current Marxist theorizing can be applied to crime (c.f., Carlson et al. 2010; Carlson and Michalowski 1997). These theoretical insights could easily be applied to the work that has been done by mainstream criminologists. Take, for example, mass incarceration that has continued, unabated, for over 10 years. The great paradox of mass incarceration is that incarceration rates have steadily increased, while crime rates have decreased. Clearly, there is amble room for Marxist criminologists to contribute to the understanding of mass incarceration by providing a structural explanation that is grounded in political economy.

Also, Marxist criminologist would do well to address the criticisms leveled at Marxist criminology by other critical criminologists who have been critical of the fact that Marxist criminologists have been slow to adequately address important issues like gender and race.

Finally, while there have been several varieties of Marxist criminology over the years, and the amount of scholarship in the area has waned in recent years, Marxist criminology still provides a useful, macrolevel approach to understanding the problem of crime. As long as capitalism and the social problems like crime that it generates exist, Marxist criminology will continue to be relevant.

Measurement of Self-Control

Chris L. Gibson
Department of Sociology and Criminology & Law, University of Florida, Gainesville, FL, USA

Overview

Gottfredson and Hirschi's concept of self-control is one criminological construct that has sparked a large amount of theoretical and empirical debate among criminologists. The interest in measuring self-control and understanding the psychometric properties of self-control measures is perhaps due to the explanatory power that Gottfredson and Hirschi (1990) attribute to self-control and the theoretical propositions they make regarding this construct. It is therefore surprising that little effort has been made to systematically examine and compile the state of criminological research on the measurement of self-control. This entry is designed to fill this void by providing a review of several issues related to the measurement of self-control and empirical studies on self-control measurement.

This review will accomplish several tasks. First, conceptual and operational definitions of self-control will be discussed. In doing so, this entry highlights the disagreements on whether the concept should be operationalized in terms of attitudes and behavior and whether it should be treated as unidimensional or multidimensional. Second, although different measures of self-control have been used by criminologists, this entry focuses extensively on Grasmick et al.'s 24-item, attitudinal scale, which is arguably the first and most commonly used measure of self-control. Finally, directions for future research are offered that cover a broad range of topics related to the conceptualization and measurement of self-control.

Self-Control Definitions

Gottfredson and Hirschi (1990, p. 89) provide a meticulous account of the six "elements of self-control." Those lacking self-control will have a "concrete here and now orientation"; "lack diligence, tenacity, or persistence in a course of action"; are "adventuresome, active, and physical, are indifferent, or insensitive to the suffering and needs of others"; and "tend to have minimal tolerance for frustration and little ability to respond to conflict through verbal rather than physical means" (Gottfredson and Hirschi 1990, pp. 89–90). They (Gottfredson and Hirschi 1990, pp. 89–90) link each element of self-control to the criminal act. First, the "here and now" orientation reflects the immediate gratification provided by crime, and those with low self-control have an inclination to respond to tangible stimuli in the immediate environment. Second, lacking diligence, tenacity, or persistence reflects the easy and simple gratification provided by crime, and those with low self-control tend to want immediate rewards without much effort. Third, being adventuresome, active, and physical are reflective of the excitement, risk, and thrill attached to the criminal act. Fourth, being insensitive or indifferent reflects the lack of relevance of the discomfort or pain the victims of criminal acts may experience. Fifth, possessing a marginal tolerance for frustration reflects relief from temporary irritation. These individuals will also possess a volatile temper indicative of their low tolerance for frustration. They note that "there is a considerable tendency for these traits to come together in the same people" (Gottfredson and Hirschi 1990, pp. 90–91).

Some criminologists have interpreted Gottfredson and Hirschi's definition of self-control as a unidimensional construct because its dimensions should coalesce in a person. According to Trochim (2001, pp. 136), unidimensionality can be thought of as a number line, meaning that one line should be used to reflect higher or lower levels of a trait. For self-control, this would mean that all elements specified by Gottfredson and Hirschi are one and the same and therefore do not represent different attributes as they can all be captured on one number line to indicate more or less self-control.

In one of the first empirical tests of Gottfredson and Hirschi's theory, Grasmick et al. (1993, pp. 9) explicitly interpreted the concept of self-control as a unidimensional construct:

> A factor analysis of valid and reliable indicators of the six components is expected to fit a one factor model, justifying the creation of a single scale called low self-control. In effect, this is a very crucial premise in Gottfredson and Hirschi's theory. A single, unidimensional personality trait is expected to predict involvement in all varieties of crime as well as academic performance, labor force outcomes, success in marriage, various "imprudent" behaviors such as smoking and drinking, and even the likelihood of being involved in accidents. Evidence that such a trait exists is the most elementary step in a research agenda to test the wealth of hypotheses Gottfredson and Hirschi have presented

Others have also pursued measurement of self-control under a conceptual framework of unidimensionality. For example, Nagin and Paternoster (1993, p. 478) note that "the construct was intended to be unidimensional." Further, Piquero and Rosay's (1998, p. 157) interpretation shows consistency with a unidimensional definition when they stated, "evidence for a solution that has more than one factor would not be consistent with Gottfredson and Hirschi's claim."

Criminologists have also interpreted Gottfredson and Hirschi's original conceptualization of self-control as a multidimensional construct, likely due to the elements that embody the concept of self-control. Unlike unidimensionality, it can be problematic to measure a multidimensional construct on a single number line (Trochim 2001, p. 135). For instance, intelligence consists of multiple dimensions such a math and verbal ability. A person may have strong verbal ability and weak math ability. Some argue the same is true for self-control. For example, some individuals may have a high level of impulsivity but also have lower levels of frustration. Various elements of self-control may indicate different, yet correlated, constructs. As such, it would be incorrect to depict a person's level of self-control using one number line.

While some criminologists suggest that evidence of multidimensionality would be damaging to Gottfredson and Hirschi's original conceptualization (Longshore et al. 1996), others interpret such evidence as support for their claim (Arneklev et al. 1999; Vazsonyi et al. 2001). Arneklev and colleagues (1999) argued that Gottfredson and Hirschi specify six dimensions of self-control, so the characteristics cannot be anything but multidimensional. What is questionable, according to Arneklev and his colleagues (1999), is whether or not these six elements account for a final, higher-order construct. Vazsonyi et al. (2001) also argued that Gottfredson and Hirschi conclusively outline self-control as a multidimensional trait. However, they also suggest that this is not in contrast to a unidimensional interpretation when they stated that "a multidimensional measure of self-control still can and does imply that these elements together form a single latent trait of self-control" (Vazsonyi et al. 2001, p. 98).

The conceptual confusion resulting from interpretations of Gottfredson and Hirschi's description of self-control complicates efforts to validate scales designed to specifically test self-control. This is largely because there is no general consensus on how to interpret their construct.

An appropriate operational definition is the second source of controversy regarding self-control as a construct (Akers 1991; Hirschi and Gottfredson 1993, 1994). The controversy surrounds two different operationalizations: attitudinal and behavioral. For Hirschi and Gottfredson (1993), behavior-based operationalizations are preferred. They (Hirschi and Gottfredson 1993, p. 49) explicitly stated, "behavioral measures of self-control seem preferable to self-reports" and "multiple measures [items] are desirable." In contrast, Akers (1991) has warned against such operationalizations due to a tautology issue of not having indicators of self-control that are independent of outcomes that it should predict. Nevertheless, Hirschi and Gottfredson argue that behavioral indicators can be identified independent of crime. They propose the following:

> With respect to crime, we would propose such items as whining, pushing and shoving (as a child); smoking and drinking and excessive television watching and accident frequency (as a teenager); difficulties in interpersonal relations, employment instability, automobile accidents, drinking, and smoking (as an adult). (Hirschi and Gottfredson 1994, p. 9)

Furthermore, Hirschi and Gottfredson (1993) prefer direct behavioral observations when operationalizing self-control, and they put less faith in self-reports. They argue that "the level of self-control itself affects survey responses. . .self-report measures, whether of dependent or independent variables, appear to be less valid the greater the delinquency of those whom they are applied" (Hirschi and Gottfredson 1993, p. 48). While they do not argue for abandoning operational definitions that employ self-report methods to test self-control theory, they do suggest that differences among respondents should be considered in measurement when testing their theory (Hirschi and Gottfredson 1993, p. 48).

Few studies have used direct behavioral observations to measure self-control. For example, Keane and colleagues (1993) used direct observations (i.e., failure to wear a seatbelt) as well as self-report behavioral items (i.e., drinking, perceived risk of being stopped by police) to predict driving under the influence. Most behavioral operationalizations of self-control, however, rely on self-reports. In operationalizing self-control, Zager (1994, p. 75) used an index consisting of "six self-report delinquency items, including alcohol use, marijuana use, making obscene phone calls, avoiding payment, strong arming students, and joyriding." Similarly, Evans and his colleagues (1997) used an operational definition of low self-control that consisted of self-reports of violating the speed limit, drunk driving, illegal gambling, and using drugs. Many of these self-report behaviors are deviant and criminal acts that Gottfredson and Hirschi (1990) would argue are predicted by low self-control, but they are used in some studies to measure low self-control as well. This can be a problem for researchers when attempting to disentangle cause and effect. Another problem with behavioral measures is the degree of measurement error they contain. For instance, Gibbs and Giever (1995) state that "crime and analogous behaviors as measures of self-control can be expected to contain substantial error because they reflect several underlying variables or constructs" (Gibbs and Giever 1995, p. 249).

The other, probably more favored, operational definition of self-control among criminologists has been attitudinal and/or personality-based self-report items (Grasmick et al. 1993; Gibbs and Giever 1995). Some argue that this method is a way to overcome the tautology problem (Stylianou 2002), while others argue that this approach implies psychological positivism and is incongruent with the self-control construct (Hirschi and Gottfredson 1993).

Gibbs and his colleagues (1998, p. 95) suggest that a variable used to explain behavior "can be most clearly grasped and tested when it is defined as something broader or different than behavior." An advantage to such an approach is that it "leaves no space for tautology" (Stylianou 2002, p. 538). Additionally, Gibbs and Giever (1995) argue that self-inventory, personality-based operational definitions have advantages over behavioral ones for two reasons: (1.) they are more useful in tapping more cognitive aspects of self-control and (2.) allow for a more comprehensive coverage of domains of self-control because items can be developed to capture typical modes of behavior that relate to everyday life (Gibbs and Giever 1995, p. 249).

Few self-report attitudinal and/or personality-based operational definitions have been developed specifically to test Gottfredson and Hirschi's construct of self-control (Gibbs and Giever 1995; Grasmick et al. 1993). While Gibbs and Giever (1995) created such a measure, its creation was intended to be relevant only to college students and has not received much empirical attention beyond their own exploratory scrutiny. Grasmick et al. (1993) created a 24-item attitudinal/personality scale based on their interpretation of Gottfredson and Hirschi's conceptual definition of self-control, and it has been used widely in tests of Gottfredson and Hirschi's (1990) theory. For instance, Pratt and Cullen (2000) show that at least 12 studies have used Grasmick et al.'s (1993) scale in examining self-control theory, and many others have used it since then (Ward et al. 2010; Gibson et al. 2010). Since Grasmick et al.'s attitudinal scale has been one of the most utilized measures of self-control, the next section provides an extensive review of studies that have been conducted to examine its reliability and validity.

In the Beginning: Creation of the Grasmick et al.'s Self-Control Scale

Grasmick and colleagues paid close attention to how Gottfredson and Hirschi (1990) conceptually defined the elements of self-control and derived an operational definition to reflect its conceptual properties. Grasmick and colleagues (1993) suggested that the six components of self-control can be interpreted as a "personality trait" that should conform to a unidimensional trait.

Grasmick and his colleagues used many items in pre-testing college students to identify the final 24 items. This resulted in four items for each of the six elements of self-control. Please see below for lists of the original items. Items were scored on a four-point Likert scale ranging from (1) strongly disagree, (2) disagree somewhat, (3) agree somewhat, and (4) strongly agree.

Grasmick et al.'s (1993) self-control items

Item
Impulsivity
I often act on the spur of the moment without stopping to think
I don't devote much thought and effort to preparing for the future (reverse coded)
I often do whatever brings me pleasure here and now, even at the cost of some distant goal
I'm more concerned with what happens to me in the short run than in the long run
Simple Tasks
I frequently try to avoid projects that I know will be difficult
When things get complicated, I tend to quit or withdraw
The things in life that are easiest to do bring me the most pleasure

(*continued*)

Item
I dislike really hard tasks that stretch my abilities to the limit
Risk Seeking
I like to test myself every now and then by doing something a little risky
Sometimes I will take a risk just for the fun of it
I sometimes find it exciting to do things for which I might get in trouble
Excitement and adventure are more important to me than security
Physical Activities
If I had a choice, I would almost always rather do something physical than something mental
I almost always feel better when I am on the move than when I am sitting and thinking
I like to get out and do things more than I like to read and contemplate ideas
I seem to have more energy and a greater need for activity than most other people my age
Self-Centeredness
I try to look out for myself first, even if it means making things difficult for other people
I'm not very sympathetic to other people when they are having problems
If things I do upset people, it's their problem not mine
I will try to get the things I want even when I know it's causing problems for other people
Temper
I lose my temper pretty easily
Often, when I'm angry at people I feel more like hurting them than talking to them about why I am angry
When I'm really angry, other people better stay out of my way
When I have a serious disagreement with someone, it's usually hard for me to talk calmly about it without getting upset

While Grasmick and colleagues were quite methodical when determining the face and content validity of the items they used to measure self-control, they neglected other important measurement-related issues. For example, Grasmick and his colleagues (1993) did not give advice on which populations the instrument is appropriate (e.g., college students, juveniles, and incarcerated populations), if directions were explicitly given to respondents, and which scoring procedures should be used for scale construction.

Consequently, it is not clear whether Grasmick et al.'s self-control measure should be equally applied to different samples to discriminate between levels of self-control (or a lack thereof). Perhaps, their scale items are more suitable for low-risk samples, such as college students, rather than high-risk samples, such as serious criminal offenders. The scale items may be too easy or too agreeable for a sample of respondents who, on average, are likely to have lower self-control. This could result in the inability of Grasmick et al.'s scale to accurately measure levels of self-control in some populations.

Although Grasmick and his colleagues (1993) advise readers not to accept their work as a definitive measure of self-control, their scale remains the measuring instrument of choice among researchers attempting to quantify self-control (see Delisi et al. 2003). To support its continued use, however, there must be evidence showing that the scale is empirically reliable and valid and that it is applicable to different samples.

Reliability of Grasmick et al.'s Self-Control Scale

A handful of studies have now explicitly examined the psychometric properties of Grasmick et al.'s self-control scale (Arneklev et al. 1999; Delisi et al. 2003; Gibson et al. 2010; Grasmick et al. 1993; Longshore et al. 1996; Piquero et al. 2000; Piquero and Rosay 1998; Vazsonyi et al. 2001). Most studies employing Grasmick et al.'s scale typically estimate Cronbach's alpha as a measure of scale reliability. Assuming that the self-control construct is unidimensional, the alpha for this scale should be quite high, or at least modest, ranging from 0.7 to 0.9. Lower internal consistency scores may be a function of the scale's multidimensionality; however, this would remain an empirical question that reliability estimates alone cannot answer. Although many studies report alpha for the Grasmick et al.'s scale when testing relational propositions of self-control theory, this section specifically summarizes studies that have focused on the psychometric properties of this scale.

Using data from a simple random sample of 395 adult respondents who completed the

Oklahoma City Survey, Grasmick and his colleagues (1993) conducted the first reliability analysis of their scale. They concluded that by dropping one item (the last item under the Physical Activities component) from the scale, they could increase reliability from 0.80 to 0.81.

Two studies using the same data set emerged in 1996 and 1998, which came from a multisite evaluation of Treatment Alternatives to Street Crime (TASC) programs to identify drug-using adult and juvenile offenders in the criminal justice system to gauge their treatment needs. The sample consisted of 623 offenders. Most sample respondents had lengthy criminal histories, and the sample varied in sex, race, and age. It should be noted that the version of the scale in these studies diverges slightly from its original form in a few ways. First, Longshore et al. (1996) modified the original response scale and added an additional category to make it a five-point Likert scale: never (0), rarely (1), sometimes (2), often (3), and almost always (4). Second, item wording was changed and often reversed to detect any bias from yes-saying. Longshore et al. (1996) reported a Cronbach's alpha of 0.80 for the Grasmick et al.'s scale, whereas Piquero and Rosay (1998) reported a Cronbach's alpha of 0.71. Piquero and Rosay (1998) reported gender-specific alpha's, 0.72 for males and 0.68 for females.

Both Longshore et al. (1996) and Piquero and Rosay (1998) reported reliability estimates for each self-control dimension, which were low compared to acceptable standards. Longshore et al.'s (1996) estimates were 0.65 for Impulsivity/Self-Centeredness, 0.48 for Simple Tasks, 0.58 for Risk Seeking, 0.35 for Physical Activities, and 0.71 for Temper. Piquero and Rosay's (1998) estimates were 0.45 for Impulsivity (0.46 for males and 0.43 for females), 0.44 for Simple Tasks (0.47 for males and 0.28 for females), 0.58 for Risk Seeking (0.58 for males and 0.56 for females), 0.37 for Physical Activities (0.40 for males and 0.31 for females), 0.68 for Temper (0.71 for males and 0.59 for females), and 0.57 for Self-Centeredness (0.59 for males and 0.49 for females). The difference was that Longshore et al. (1996) reported alpha's on only five of the six components; they combined Impulsivity and Self-Centeredness items due to the results of their factor analysis that is discussed in the next section.

Delisi et al. (2003) used data collected from 208 male parolees residing in work release facilities in a midwestern state that had been previously released from prison. They reported that Cronbach's alpha for the total scale was 0.91. They also computed reliability estimates for each component showing coefficients of 0.79 for Impulsivity, 0.81 for Simple Tasks, 0.79 for Risk Seeking, 0.72 for Physical Tasks, 0.81 for Self-Centeredness, and 0.86 for Temper.

In the largest study undertaken to investigate the psychometric properties of Grasmick et al.'s scale, Vazsonyi et al. (2001) gathered data on over 8,000 adolescents from four different countries including schools in Hungary ($n = 871$), Netherlands ($n = 1{,}315$), Switzerland ($n = 4{,}018$), and the United States (2,213). While total scale reliability estimates are not reported, they do report them for self-control subscales for the total and country-specific samples. Cronbach's alpha was 0.50 for Impulsivity ranging from 0.45 to 0.62; 0.68 for Simple Tasks ranging from 0.61 to 0.73; 0.79 for Risk Seeking ranging from 0.69 to 0.84; 0.63 for Physical Activities ranging from 0.55 to 0.74; 0.60 for Self-Centeredness ranging from 0.45 to 0.68; and 0.76 for Temper ranging from 0.68 to 0.76.

Gibson and colleagues (2010) analyzed a sample of 333 college students attending a university in the southern United States. They reported alpha coefficients for the full 24-item self-control measure and each of the six components for males and females separately. They found that the 24-item self-control measure had an alpha coefficient of 0.84 for males and 0.85 for females. Their assessment of the reliability of each dimension found an alpha coefficient for Impulsivity of 0.65 and 0.69 for males and females, respectively; for Simple Tasks was 0.75 and 0.77 for males and females, respectively; Risk Taking was 0.78 and 0.75 for males and females, respectively; Physical Activities was 0.81 and 0.80 for males and females, respectively; Self-Centeredness was 0.77 and 0.65 for males and females, respectively; and for Temper the estimates were 0.79 and 0.76 for males and females, respectively.

Dimensionality of Grasmick et al.'s Scale

Grasmick et al. (1993) were the first to assess the dimensionality of their scale. First, they performed a principal components exploratory factor analysis (EFA) with one-, five-, and six-factor solutions. They could not "find strong evidence that combinations of items into subgroups produces readily interpretable multidimensionality" (Grasmick et al. 1993, p. 17). Their analysis led them to conclude that "the strongest case can be made for a one-factor unidimensional model" (Grasmick et al. 1993, p. 17). Several studies have since shown similar results using the same method across different samples (Arneklev et al. 1999; Nagin and Paternoster 1993; Piquero and Tibbetts 1996; Piquero et al. 2000; Delisi et al. 2003), concluding that all items load moderately on the first factor which is interpreted as evidence of unidimensionality. However, these exploratory analyses also provided evidence for six factors. As such, the methods used in these studies were not ideal for concluding whether Grasmick et al.'s scale is unidimensional or multidimensional.

Depending on researchers' perceptions of the original conceptualization of self-control, findings from these studies have been interpreted as having multiple factors or one factor. Furthermore, EFA, e.g., principal components analysis, reduce multiple variables (or items) without an imposed theoretical structure, and they attempt to extract the most variance possible from the initial factor. EFA leaves the task of defining the number of factors up to the factor analysis program, therefore being inadequate for construct validity purposes (DeVellis 1991).

Some criminologists have used confirmatory measurement models that are more appropriate for construct validation. Results from these models have often led to divergent conclusions compared to Grasmick et al.'s (1993) original analysis. For instance, Longshore et al. (1996) and Piquero and Rosay (1998) used the same data from a sample of drug-using offenders and found that the Grasmick et al.'s scale items fit two different models, a unidimensional solution and a multidimensional solution with slight modifications to the scale items, e.g., dropping items from the analysis.

Longshore et al. (1996) did not find initial support for a single underlying factor, and the scale did not appear to function equally well across subgroups defined by race, sex, and age. They modified the scale by dropping two items and allowing several error terms to correlate in a confirmatory measurement model, still concluding that a one-factor solution did not adequately fit the data. Next, they assessed a five-factor solution by combining two of the components, i.e., Impulsivity and Self-Centeredness. This solution also provided a poor fit to the data until they allowed four error terms to correlate and one item to load on two different factors. Their modified five-factor solution provided a better fit to the data especially for juveniles (CFI = 0.89), males (CFI = 0.92), Caucasians (CFI = 93), African-Americans (CFI = 0.92), and adults (CFI = 0.91). This solution, however, provided a poor fit for women (CFI = 0.80). Most importantly, their results questioned the unidimensionality of the scale for a criminal population.

Piquero and Rosay (1998) reanalyzed the data used by Longshore and colleagues. They argued that the scale could conform to a one-factor solution, could be equally reliable and valid across gender, and could produce a good fit to the data without allowing error terms to correlate. Their confirmatory measurement model showed that a unidimensional model fit the data for both males and females, but they did drop several items from the scale reducing it to 19 items. For example, the Physical Activities component was reduced to two items, and the Impulsivity, Simple Tasks, and Self-Centeredness components were all reduced to three items.

Although Piquero and Rosay (1998) are confident that their results garnered supported for unidimensionality, others disagree and conclude that their results are analogous to a second-order factor analysis where one overarching factor accounts for the relationships among lower-level factors (Longshore et al. 1996). This criticism is based on Piquero and Rosay's (1998) averaging of the scores within each component or dimension and their use of the final six composite scores as indicators in a one-factor measurement model. In sum, the results produced by these two studies do not provide a clear, unambiguous understanding of the internal validity of self-control. In both cases, modifications were made to the scale so that the results from the analyses could conform to either a multidimensional or unidimensional measure.

Arneklev et al. (1999) employed a second-order, confirmatory measurement model to test the dimensionality of Grasmick et al.'s scale. In doing so, they argued that a valid measure of self-control should have six distinct dimensions that load on a higher-order self-control factor. Using a random sample of adults and a convenience sample of college students, they concluded that a second-order model fits the data well. For the adult sample, the results showed that the coefficients between both the indicators and the six dimensions of self-control and the six dimensions and the self-control latent construct were sufficiently large. Although each of the six dimensions was significantly related to the second-order self-control factor, they found that Impulsivity had the highest factor loading. Additionally, the Physical Activities dimension loaded less strongly on self-control than any other dimension. Overall, Arneklev and his colleagues (1999) concluded that the second-order factor model for the adult sample provided support for Gottfredson and Hirschi's (1993) theory; the goodness of fit statistic (GFI = 0.89) had an acceptable magnitude, indicating that the proposed theoretical model fit the data well. Arneklev et al. (1999) showed similar results for their college sample. Arneklev et al. (1999) concluded that evidence of six distinct dimensions exists, but evidence also indicated that all six dimensions loaded on a higher-order construct that they called self-control.

Vazsonyi and his colleagues (2001) used both exploratory and confirmatory factor analysis in their study of Grasmick et al.'s self-control scale for adolescents across four countries. In an a priori fashion, they interpreted Gottfredson and Hirschi's (1990) conceptualization of self-control to be multidimensional, consisting of six separate dimensions. They first estimated exploratory factor analysis models for the total sample as well as for groups by sex, age, and country. Vazsonyi et al. (2001) argued that their preliminary results indicated the existence of six factors and that the scale is not unidimensional. Second, they use all 24 items to conduct a series of more rigorous confirmatory models including a one-factor and six-factor model to confirm their exploratory efforts. Using several fit statistics (e.g., CFI = 0.65, GFI = 0.82, and RMSEA = 0.09 for the total sample), they concluded that a one-factor model was not a good fit to their data. Each item, however, did show a statistically significant loading. In contrast, they showed that a six-factor solution fits the data much better (e.g., CFI = 0.91, GFI = 0.95, and RMSEA = 0.05 for the total sample), even across groups by age, sex, and country. In a final attempt to improve the six-order factor model, they allowed for two correlated error terms and dropped two items from the scale to achieve a consistent, overall, improved fit (e.g., CFI = 0.93, GFI = 0.96, and RMSEA = 0.04 for the total sample) which did not vary much across groups. Unlike others (Arneklev et al. 1999; Delisi et al. 2003; Piquero et al. 2000), Vazsonyi and his colleagues did not test a second-order factor model.

Delisi et al. (2003) tested the dimensionality of Grasmick et al.'s scale using a sample of male offenders residing in work release facilities in a midwestern state. They employed confirmatory measurement models to test one-factor, six-factor, and second-order factor models. While all loadings were statistically significant in all models, they concluded that all models fit the data poorly. These conclusions were drawn using numerous fit statistics. Most troubling for the unidimensionality hypothesis was their finding showing that the one-factor solution had the worst fit among the confirmatory factor models (GFI = 0.65, AGFI = 0.59, RMR = 0.11, and x^2/df = 4.27). From Delisi et al.'s (2003) confirmatory analyses, a model building effort was undertaken. They found that a modified six-factor model was able to fit their data well.

In sum, the evidence for the dimensionality of the most commonly used measure of self-control turns out to be inconclusive. While researchers continue to use it as if it is measuring one construct, evidence suggests that this may not be the case. This can have implications for the impact of self-control on outcomes hypothesized by Gottfredson and Hirschi. For instance, if Grasmick et al.'s self-control measure is actually multidimensional, then not treating it as such may mask the importance of each dimension's influence on criminal behavior, substance use, and other antisocial behaviors. Specifically, some dimensions may be relatively more important than others in predicting particular behavioral outcomes, or some dimensions may even interact with one another in important ways. By treating this measure as unidimensional, these possibilities will not be realized. Some criminologists have actually found that not every dimension of the scale is important in explaining criminal outcomes (Delisi et al. 2003). Others have found particular dimensions of Grasmick et al.'s scale, e.g., Impulsivity and Risk Seeking, to be more important than the overall self-control scale when predicting criminal outcomes (Longshore et al. 1996).

The Rasch Measurement Model and Self-Control

Piquero and his colleagues (2000) were the first to apply a Rasch measurement model to investigate the internal validity of Grasmick et al.'s self-control scale. The Rasch model is a confirmatory measurement model that tests for scale unidimensionality, but it diverges from traditional confirmatory measurement models discussed thus far in several important ways. First, the Rasch model produces distribution-free estimates in that the values do not depend on the distribution of the trait, i.e., self-control, across samples as do conventional exploratory and confirmatory factor models. This is important because results from Rasch models can be compared across samples when the same scale is employed, while results from factor analysis models are questionable for comparative purposes (Piquero et al. 2000; Bond and Fox 2001).

Second, a Rasch model separates person ability and item difficulty estimates and then places them both on the same logit ruler for comparative purposes. This function allows for comparisons of item difficulty in relation to people's level of ability, i.e., self-control, on the same interval-level scale. By taking into account the interaction between persons and scale items, the Rasch model overcomes the test-based approach of conventional confirmatory factor analysis. As such, the ability estimates do not depend on the difficulty of items in the scale. A Rasch model allows a researcher to detect the difficulty of endorsing items in relation to the distribution of self-control in the sample.

Third, the Rasch model is mathematically defined to assess unidimensionality. In doing so, each self-control scale item is examined to assess its fit to the model. Finally, Rasch models create interval-level measures from ordinal items, whereas factor analysis methods in several statistical software packages mistake ordinal responses for continuous responses violating statistical assumptions (see Piquero et al. 2000; Wright and Masters 1982).

Piquero et al. (2000) were interested in whether respondents used item response categories as they were supposed to. The use of response categories was orderly; those with low levels of self-control had higher probabilities of agreeing to low self-control items (selecting response categories that reflect low self-control) than those with high self-control. Second, they were interested in how well scale items fit the unidimensional Rasch model. They found that many items had poor fit to the unidimensional expectation of the model. Particularly, they found that 11 of the 24 items showed statistically significant misfit when all items were considered as a unidimensional measure. Third, Piquero et al. (2000) investigated a person/item logit ruler generated by Rasch modeling software to determine that several items were too difficult for their college sample to endorse. A logit ruler, or person/item map, allows researchers to assess the distributions of ability and item difficulty on the same metric (i.e., logit scale) to determine if items are too difficult to endorse relative to the distribution of the sample's self-control. Most of their sample had very low ability indicating high levels of self-control. The Grasmick et al.'s items did not discriminate well among a college sample with disproportionately high levels of self-control. Finally, Piquero et al. (2000) conducted a differential item function (DIF) analysis to assess item responses across high and low self-control groups. Low-self-control individuals were found in some instances to respond to items differently than those having high self-control. Particularly, the low self-control group was more (or less) willing to agree with some items than would have been expected by the Rasch model.

In a more recent study, Gibson et al. (2010) used a Rasch Model to assess how Grasmick et al.'s self-control items may perform differently for a sample of male and female college students. Gibson and colleagues' investigation found that self-control items performed differently for men and women. In fact, 33 % of the items showed differential item function. In some cases, women were less likely to agree to items compared to men even when males and females had similar levels of the trait. This means that several of the items were biased for men and women and that this could inflate or deflate aggregate self-control differences between them. When the biased items were excluded from the scale, a gender difference in aggregate self-control was still observed, but the difference was reduced.

In sum, the few studies that have used a Rasch model to investigate the internal validity of Grasmick et al.'s self-control measure have found that the items do not conform to a unidimensional trait and potential biases exist for using it to measure self-control for different groups. While this is a relatively new approach to investigating the validity of self-control measures, researchers should continue to use it in the future for several reasons. First, the differential item functioning capabilities of the Rasch model will be helpful for understanding if self-control measures can or should be applied to different groups including gender, race, community samples, adolescents, and prison samples to name only a few. Second, and from a developmental perspective, this approach will allow researchers to determine if measures of self-control such as the Grasmick et al.'s scale items will have similar or different meanings as people age. As such, this will allow a researcher to determine if true change in this construct is occurring within individuals over time or if differences observed within individuals over time are due to the items having different meanings for individuals as they age. Third, the Rasch model has the valuable property of being able to determine if self-control items are able to discriminate well between individuals with low to high levels of self-control.

Conclusions and Future Research

This entry has provided a review of key issues related to the measurement of self-control. Of these, several noteworthy themes emerged. First, much less criminological research has focused on the measurement of self-control compared to the large body of work that has investigated the influence of self-control on a variety of behavioral outcomes. This is unfortunate because the research on self-control measurement has produced little agreement among criminologists as to what measure should be used to capture this important construct.

Second, further complicating the disagreement among criminologists is the conceptual and operational definitions provided by Gottfredson and Hirschi. Although they were creative in linking elements of self-control directly to the criminal act, they leave readers questioning whether self-control should be interpreted as a unidimensional or multidimensional construct and the merits of behavioral measures. These issues have implications for how criminologists should proceed in testing the influence of self-control on behavioral outcomes; that is, should researchers examine the effect of each of self-control's dimensions on outcomes or the combined effect of self-control or both? Moreover, recent studies that attempt to expand self-control theory have used quite different and diverse measures of self-control. It is likely that some measures being used are more valid and reliable than others, but this must be acknowledged and empirically addressed before determining the true effects of self-control on behavioral outcomes or the casual underpinnings of self-control.

Third, it was noted that one of the most common measures used by criminologists to assess differences in self-control among individuals has been Grasmick et al.'s scale or a reduced version of it. The empirical studies conducted to date on the psychometric properties of this measure are mixed. Studies estimating the reliability of Grasmick et al.'s scale have employed diverse samples ranging from convicted offenders, adult community members, adolescents residing in different countries, and college students. Only one of these studies reports a Cronbach's alpha above 0.9 for the total scale (Delisi et al. 2003); however, other studies do indicate that the scale has modest to high reliability. This is necessary, but not sufficient, for demonstrating scale validity. The scale items appear to cohere more closely in some samples than others, and some studies show low reliability for subscales. In addition, Grasmick et al. (1993) explicitly stated that a factor analysis of valid and reliable indicators of self-control should produce a unidimensional measure and they found support for their hypothesis, but they used an exploratory analytic method to make such an inference. Since then, several rigorous examinations of the scale have refuted their claims. In contrast, the scale has often been shown to be multidimensional reflecting either six-factor or a second-order factor structure where dimensions load on a latent self-control factor with some dimensions loading more strongly than others. As such, more studies in the future should investigate closely how each of these dimensions differentially influence outcomes that Gottfredson and Hirschi would predict are affected by self-control.

Fourth, conflicting results have emerged as to the Grasmick et al.'s scale's dimensionality and validity across demographic groups using traditional confirmatory measurement models and the Rasch model. For example, conflicting results have been found for whether the scale is equally reliable and valid for blacks, Hispanics, whites, males, and females. Gottfredson and Hirschi (1990) do not clearly specify the factor structure that a valid measure of self-control should posses, let alone how such a structure would hold up across different races. The Rasch model holds promise for understanding if the Grasmick et al.'s scale and other measures of self-control are unbiased across different groups.

Since the 1990s, few studies have been published in criminology that primarily center on the measurement of self-control. With some exceptions, most studies that have done so focus on the dimensionality debate of Grasmick et al.'s self-control scale using a variety of samples. As such, research on the measurement of self-control is open to new ideas and can hold much promise for criminology. A set of ideas for those pursuing research on the measurement of self-control is discussed below.

First, compiling a systematic list of all self-control measures used in past criminological research would be beneficial for researchers interested in exploring self-control theory. As such, criminologists would be able to assess the positive and negative attributes of each and make decisions on which measures or measure best fits their purpose.

Second, different conceptual and operational definitions should be pursued by criminologists, especially given Gottfredson and Hirschi's disapproval of the Grasmick et al.'s scale and Hirschi's more recent re-conceptualization of the self-control concept which suggests that self-control and social control are the same (Hirschi 2004). A recent effort has been made by Marcus (2004). Opposed to the idea that six elements define the construct of self-control, Marcus (2004) argued that Gottfredson and Hirschi's (1994, p. 3) construct is simply "the tendency to avoid acts whose long-term costs exceed their monetary advantages." Marcus acknowledges that Grasmick et al.'s 24 items reflect six traits and these traits overlap with a large body of literature on the structure of personality. He argued that elements such as risk seeking and preference for easy tasks measured by this instrument reflect a motivational basis of behavioral choice and do not reflect behavioral constraint. Given this conceptual flaw, he argued that Grasmick et al.'s measure is incompatible with the main premise of self-control theory. In fact, he argued that the six elements measured by Grasmick et al.'s scale are linked to the five-factor model (FFM) of personality. So, if Grasmick et al.'s scale is a unique measure of Gottfredson and Hirschi's construct of self-control and not merely a measure that is tapping into several personality traits, then it should show divergent validity when compared to a widely used and psychometrically sound instrument of the FFM. Future research should explore this idea by empirically investigating the correlations between Grasmick et al.'s subscales and the most well-researched instrument used to measure the FFM of personality, the NEO-personality inventory.

Third, given Gottfredson and Hirschi's preference for behavioral self-control measures, an important line of future research on the measurement of self-control will be to create behavioral measures and empirically compare them to Grasmick et al.'s measure to assess divergent and convergent validity. Although such investigations have received limited empirical attention (Tittle et al. 2003), very few attempts have been made to create a behavioral measure that is consistent with Gottfredson and Hirschi's conceptual definition of self-control. Marcus (2004) has created a self-control measure that consists of 67 strictly behavioral statements that are designed to assess the frequency of prior conduct across developmental stage that have long-term negative consequences. Future research should not only investigate how Marcus's scale correlates with Grasmick et al.'s measure but should assess the predictive validity of his measure and compare it to the predictive validity of Grasmick et al.'s measure (see Ward et al. 2010).

Fourth, researchers should further explore the validity of self-control measures for different types of people, especially given the possibility that one's own self-control can affect his/her survey responses. Responses may be less valid for individuals with higher criminality and/or lower self-control (Hirschi and Gottfredson 1993; Piquero et al. 2000). With regard to the measurement of self-control, this is a topic that has received minimal empirical attention. Hirschi and Gottfredson (1993) have argued that a solution would be to collect behavioral indicators of self-control that are measured independent of respondents; for instance, having parents or teachers report on the behaviors of children and adolescents (see also Gibson et al. 2010). Acknowledging that such a solution could be a financial burden to researchers that do not have funds to collect direct observational data, an alternative to Hirschi and Gottfredson's solution would be to employ methods that would enhance the accuracy of survey responses from those having lower levels of self-control. In doing so, researchers could consider the nature of self-control and how it may guide item creation and scale formatting.

The research ideas discussed here should be seen as ways for improving self-control measures used by criminologists, but they should not be the only measurement endeavors pursued. If the concept of self-control is as important for understanding criminal and antisocial outcomes as criminologists suggest, it will be even more important to refine measures of self-control in ways that most accurately reflect the conceptual and operational definition of the construct. At the same time it is important for criminologists to move toward the creation of a psychometrically reliable and valid measure that will be used to capture differences in self-control for populations of interest to criminologists.

Measuring Crime Specializations and Concentrations

Martin A. Andresen
School of Criminology, Institute for Canadian
Urban Research Studies, Simon Fraser
University, Burnaby, Canada

Overview

Research on crime at places is a rapidly growing literature. Though Eck and Weisburd (1995) coined the term "crime at places," the starting point of this literature was Sherman et al. (1989) in a microspatial analysis of predatory crime in Minneapolis. This research area finds that calls for police service are highly concentrated in very few places: 50 % of calls for police service are generated from 5 % of street segments (or less), particularly when one considers detailed crime classifications (Sherman et al. 1989; Andresen and Malleson 2011). Moreover, research has shown that spatial crime patterns at microspatial units of analysis vary significantly across crime classifications (Andresen and Malleson 2011). Because of this consistency, Weisburd et al. (2012) put forth the Law of Crime Concentrations.

One implication from this research is that opportunity surfaces for different crimes, though they may overlap, are different – the opportunity surface for a crime is the distribution of targets across the landscape. From the theoretical perspective of environmental criminology, this statement is rather trivial: routine activity theory (Cohen and Felson 1979) posits that crime occurs when a motivated offender and suitable target converge in time in space without the presence of a guardian – this convergence occurs at a place. In the geometric theory of crime (Brantingham and Brantingham 1981), crimes occur at discrete locations (places) within the boundaries of our activity spaces. And in rational choice theory (Clarke and Cornish 1985), crimes are the result of context-specific choices that consider the immediate environment (places) within which a crime occurs. Even beyond these various theories, one only needs to consider where targets are located for different crime classifications: commercial burglary and robbery only occur in commercial districts, and residential burglary only occurs in residential districts, for example. Needless to say, whether one considers theory or the most straightforward aspects of our (built) environment, crime specializes at places.

Crime specialization is different from crime concentration. We have long known that crime concentrates in places, and those places vary by crime classification (Quetelet 1842). Specialization does not necessarily occur in the same places as concentration. Crime concentration is typically measured using crime rates (a crime count scaled by a population at risk); by the nature of this calculation, places with high crime rates (high degrees of concentration) have greater levels of crime per capita than places with low crime rates. Crime specialization, however, may occur in places with low levels of crime per capita – specialization may be defined relative to the entire study area. As such, the form of measurement necessary must consider the crime mix in some form. Location quotients provide an excellent example of this form of crime measurement.

Location Quotients: The State of the Art

The location quotient is a geographic measure of specialization. One of the benefits of the location quotient is that it only relies on data for the phenomenon in question; if a researcher is analyzing crime only, crime data are needed. This proves useful because measures of concentration (crime rates) have a number of methodological issues that emerge because they require other data (Andresen 2006). Of course, the location quotient still suffers from all the problems associated with crime reporting issues and the dark figure of crime, a concern in quantitative-based studies of crime dating back to at least the early nineteenth century (Bulwer 1836). Regardless, the location quotient is calculated as follows:

$$LQ_{in} = \frac{C_{in}/C_{tn}}{\sum_{n=1}^{N} C_{in} \Big/ \sum_{n=1}^{N} C_{tn}}, \qquad (1)$$

where C_{in} is the count of crime i in subregion n, C_{tn} is the count of all crimes in subregion n, and N is the total number of subregions. In this context, the location quotient is a ratio of the percentage of a particular type of crime in a subregion relative to the percentage of all crime in that same region. If the location quotient is equal to one, the subregion has a proportional share of a particular crime; if the location quotient is greater than one, the subregion has a disproportionately larger share of a particular crime; and if the location quotient is less than one, the subregion has a disproportionately smaller share of a particular crime. Specifically, if a subregion has a location quotient of 1.20, that subregion has 20 % more of that crime than expected given the percentage of that crime in the region as a whole – that subregion then "specializes" in that crime classification. Miller et al. (1991) provide the following classifications that are useful for interpreting the location quotient: very underrepresented areas, $0 \leq LQ \leq 0.70$; moderately underrepresented areas, $0.70 < LQ \leq 0.90$; average represented areas, $0.90 < LQ \leq 1.10$; moderately overrepresented areas, $1.10 < LQ \leq 1.30$; and very overrepresented areas, $LQ > 1.30$.

Brantingham and Brantingham (1993, 1995, 1998) introduced the location quotient into criminological research in the early 1990s, but its adoption as a standard criminological measurement has been slow. With a primary concern for violent crime, Brantingham and Brantingham (1993, 1995, 1998) use the location quotient to measure the crime mix and specialization within a municipality; they compare the location quotient results to those for crime counts and crime rates. The larger municipalities in their study, not surprisingly, had the highest counts. However, after controlling for population size, the large municipalities no longer ranked at the top of the list, but now towards the bottom of the list. Smaller hinterland municipalities topped the list when using crime rates. Yet another ranking emerged with the location quotient: some municipalities with high crime rates also have high location quotients, but there are also a number of municipalities that have low crime rates with high location quotients. Consequently, there are municipalities that have low risk of crime in general (low crime rates), but specialize in violent crimes.

Though this phenomenon of specializing in a particular crime when the risk of crime is rather low is interesting in itself (and the focus of this entry), this property may allow one to investigate a curious result that emerges when considering crime rates. In the context of illegal drugs in the United States, Rengert (1996) expects the north central region of the United States to have the greatest proportions of marijuana crimes (of all drug-related crimes) because of a lack of a coastline and its agricultural base – heroin and cocaine are expected to be greatest in coastal regions because of a greater need to transport the drugs internationally. However, Rengert (1996) finds that the spatial pattern of marijuana crimes effectively follows the same spatial pattern as heroin and cocaine when using calculations based on the crime rate: the north central region of the United States is ranked last. However, when Rengert (1996) uses the location quotient to consider crime specialization, the pattern reversed. Therefore, the other regions of the United States had greater volumes and corresponding rates of marijuana crimes than the north central region, but if one were to commit a drug crime in the north central region, it is most likely to be related to marijuana.

Curiously, aside from one study that uses the location quotient as a component in a composite index, its use in criminology is absent for 10 years. In this more recent research, McCord and Ratcliffe (2007) use the location quotient to measure crime intensity across neighborhoods and find that drug markets tend to cluster close to pawnshops, drinking establishments, and mass transit stations. Andresen (2007) performs an inferential analysis (spatial regression) using the location quotient as a dependent variable and finds that if independent variables are interpreted as attractors of a particular crime, it performs well in a predictive manner. Ratcliffe and Rengert (2008) use the location quotient to identify areas that have greater intensities of shootings, relative to the city as a whole. Andresen (2009) investigates the phenomenon of crime rates in Canadian provinces increasing as one moves east to west – crime rates in the territories are even higher than in the western provinces. Andresen (2009) uses the location quotient to show that simply because all crime rates are greatest in the west does not mean that western provinces specialize in all crimes. In fact, crime specialization is present in all provinces for at least two crime classifications in each province. This analysis vividly shows that crime concentration (crime rates) does not necessarily imply crime specialization. Most recently, Block et al. (2012) use the location quotient in the context of automotive theft in the United States. They find that states and counties that contain or are near heavily trafficked borders and ports specialize in automotive theft; Block et al. (2012) speculate that this is an indication for the presence of a "theft for export" problem in these areas. Moreover, these are not always areas that have high rates of automotive theft.

Clearly, the location quotient's popularity in spatial crime analysis has increased in recent years. However, its general lack of adoption in criminological research is somewhat surprising because it allows for the measurement of crime specialization. Regardless, there are a number of other measures of specialization that may prove to be useful to criminologists. Some of these measures are already being used within the criminological literature in other (nonspatial) contexts, whereas others are used in geography and economics that prove insightful in a criminological context. To illustrate these, calls for service data are used below to show their utility.

An Empirical Example of Measuring Specialization

In order to perform the calculations below (crime rates, location quotients, and other measures of specialization), crime data are necessary. All crime data are for 2001 in the City of Vancouver, British Columbia, Canada. The areal unit of analysis is the dissemination area (DA). These units are defined by Statistics Canada and are similar to the census block groups in the United States Census. There are 990 DAs in Vancouver in 2001. The calculations below consider both property crime and violent crime classifications: assault, burglary, robbery, sexual assault, theft, theft of vehicle, and theft from vehicle – homicide is excluded because there are so few cases, twelve homicides for the entire year. Property crime counts and percentages dominate violent crime counts and percentages, as expected; property crimes account for just over 83 % of the 60 427 incidents included in the calculations below.

All crime data used below come from the Vancouver Police Department's Calls for Service Database (VPD-CFS Database) generated by its computer-aided dispatch system. Though the VPD-CFS Database is actually a proxy for actual crime data because not all calls for service represent actual crimes, the primary advantage of the VPD-CFS Database is this raw form – these data are not dependent on a criminal charge, though few calls for service are subsequently unfounded by the VPD. The geocoding success rate for these data was 93 %; though computer algorithms for geocoding have limitations that may lead to concerns over accuracy (Ratcliffe 2001), the current success rate is well above the minimum acceptable success rate of 85 % (Ratcliffe 2004).

Mapping the Location Quotient

Though the discussion regarding the location quotient above may be instructive to show the utility of its calculation, an example using burglary highlights the distinction between concentration and specialization. The burglary rate per 1,000 households in Vancouver (2001) is shown in Fig. 1a. It should be clear to the reader that burglary has its greatest concentrations in the eastern section of the central business district, the downtown eastside, as well as in a number of other areas that correspond to commercial land use, mixed land use, and arterial roadways; burglary is also in greater concentrations within the eastern side of the city – the eastern side of Vancouver has lower income levels than the western side of Vancouver, on average.

The spatial pattern of the location quotient for burglary (Fig. 1b), however, has a very different spatial pattern. Though there are areas throughout Vancouver that exhibit specialization, by far specialization occurs within the western side of Vancouver. This region of the city contains some of the wealthiest neighborhoods of Vancouver that all have relatively low levels of concentration in burglary. If one were to analyze other crime classifications in Vancouver, the results are not as stark as with burglary, but this example shows that where crimes are concentrated are not necessarily the same places in which specialization occurs.

Alternative Measures of Specialization

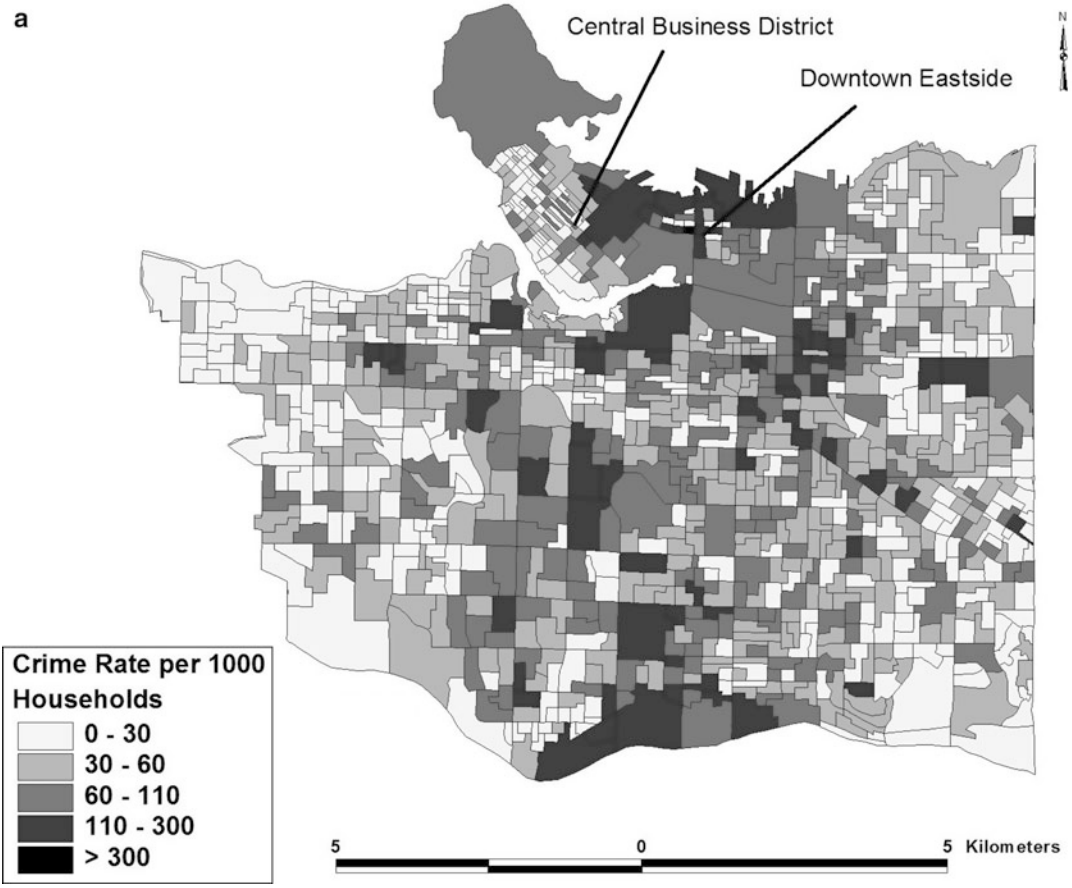
The first alternative measure considered here is a normalized version of the location quotient, normalized such that its values range from zero to unity. Though the algebra provides the same value, this normalized location quotient is based on the Balassa (1965) Index and is commonly used in the international trade literature (De Benedictis et al. 2009):

$$BI = \frac{C_{in} \Big/ \sum_{n=1}^{N} C_{in}}{C_{tn} \Big/ \sum_{n=1}^{N} C_{tn}}. \qquad (2)$$

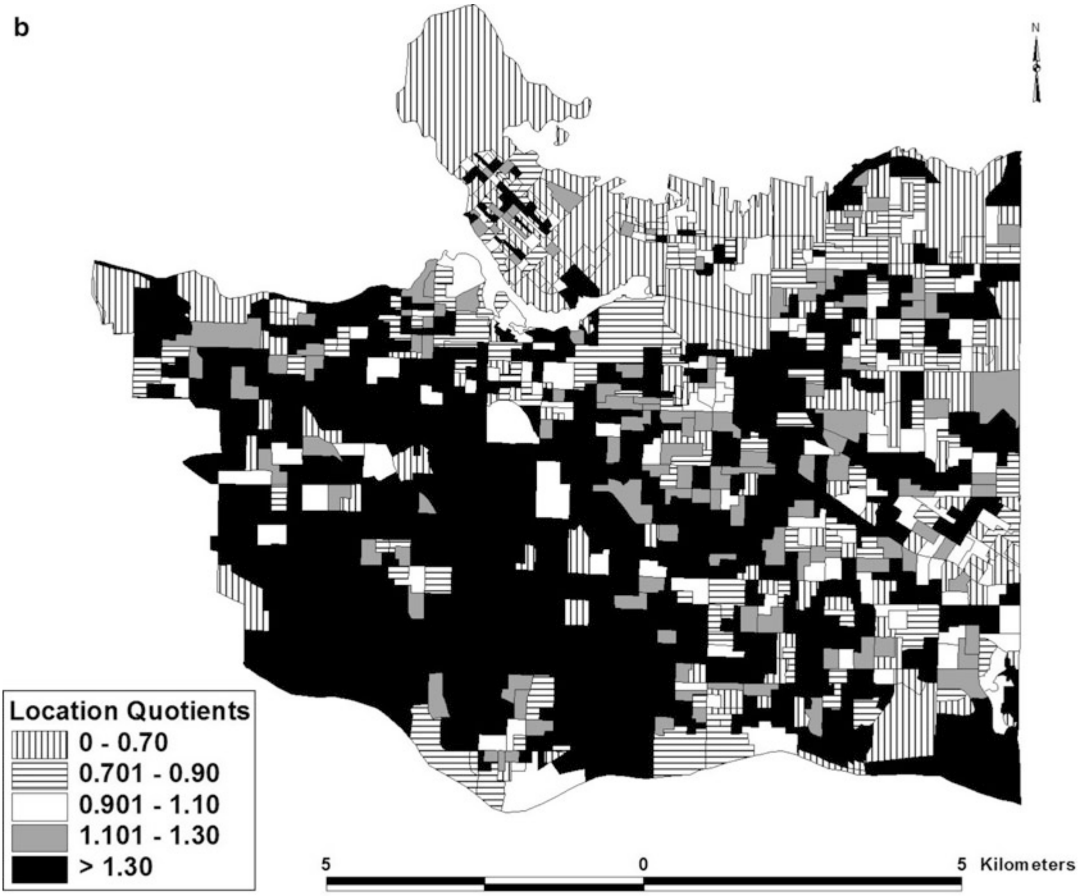
The calculation of the normalized location quotient, referred to as the relative Gini in the literature (De Benedictis et al. 2009), is calculated as follows:

$$\text{Relative Gini (RG)} = \frac{\sum_{i=1}^{N-1} (p_i - q_i)}{\sum_{i=1}^{N-1} p_i}, \qquad (3)$$

where p_i is the share of crime i within the study area as a whole (Vancouver in the current



Measuring Crime Specializations and Concentrations, Fig. 1 (continued)



Measuring Crime Specializations and Concentrations, Fig. 1 (**a**) Crime rates per 1,000 households, burglary, Vancouver 2001. (**b**) Location quotients, burglary, Vancouver 2001

context) and q_i is the share of crime i within the subregion (dissemination area in the current context). In order to perform this calculation, all q_i are ranked according to their values with the top value being excluded. All values of q_i are ranked for the purposes of identifying the top value so it can be excluded from the calculation. This is done in order for the index to have a range from zero to unity. If q_N is included and there is total specialization (that must occur in that classification, by definition), the index takes on a value of zero. Clearly this makes the index of little value if this situation is a possibility. In the case of total specialization in a subregion, $q_N = 1$ and the index value is equal to zero. As such, if the research wishes to have total specialization have a value of unity, the calculation may easily be modified to be 1 – RG.

Though the location quotient has now been normalized, this measure is not without limitations. First, the natural interpretation of the location quotient has been lost: a value of 1.20 indicates that crime i specializes in a subregion by 20 %, relative to the study area as a whole. Such statements can no longer be made. Second, the normalized location quotient is not specific to a crime classification. Rather, it is a measure of specialization, generally speaking.

Another index that uses the location quotient in its calculation is one of the many variants of the

Theil (1967) Index. The Theil Index is a measure of relative specialization:

$$T_j = \sum_{k=1}^{n} \frac{x_{jk}}{x_j} \ln\left(LQ_{jk}\right), \tag{4}$$

where x_{jk} is the count of crime k in subregion j, x_j is the count of all crime in subregion j, ln() is the natural logarithm operator, and LQ_{jk} is the location quotient for crime k in subregion j, as calculated above in Eq. 1. When $T_j = 0$ there is no specialization and T_j has an upper bound of ln(z), where z is the number of basic units (crime classifications); in the current context, the upper bound of $T_j = \ln(7) = 1.94$.

The Theil Index, though instructive, also has its limitations. As with the normalized location quotient, though the Theil Index is calculated for each subregion, it is a general measure of specialization and does not provide information regarding which type of crime classification specialization occurs in a particular subregion. Also, the Theil Index is undefined if the share of crime k in a subregion is zero because the location quotient is then zero and the natural logarithm of zero is not defined. Of course, one may use a small number in place of zero, but this is dependent on the concerns of the study. If knowing that none of a particular crime occurred in a subregion is critical information, a different measurement of specialization would be more important. This increasingly becomes a problem in the context of crime as the spatial unit of analysis becomes smaller. As shown in the crime at places literature, many places consistently have no crime (Sherman et al. 1989; Andresen and Malleson 2011).

The Diversity Index is the next specialization measure to consider here. The Diversity Index is calculated as follows:

$$DI_i = 1 - \left(\sum_{n=1}^{N} {p_n}^2\right), \tag{5}$$

where p_n is the percentage of offenses in category n and i refers to the subregions. This index has been used in the criminological literature as a measure of offender specialization (Johnson et al. 2009) – this index may only be calculated using the latter summation term, depending on whether or not the researcher wants the value of zero or unity to indicate specialization. Though criminologists often point to other criminological or sociological research as its source, this index is a variant of the Herfindahl-Hirschman Index in economics that measures industrial concentration – see Herfindahl (1950) and Hirschman (1945).

In its original formulation,

$$H = \sum_{i=1}^{N} {S_i}^2. \tag{6}$$

H ranges from $1/N$ to unity, with N being the number of firms in an industry and S_i being the market share of firm i; in the current context, the number of crime classifications is under consideration. In order to have the index range from zero to unity, the following normalized H (H*) has been proposed:

$$H^* = \frac{H - \frac{1}{n}}{1 - \frac{1}{n}}. \tag{7}$$

As with the previous two measures of specialization, the Diversity Index is a general measure of specialization and does not provide information regarding what type of crime classification specialization occurs in a particular subregion.

The following measure of specialization has not been given a name in the economics literature, so it will simply be referred to as the Specialization Index in this discussion. The Specialization Index is calculated as follows:

$$S_j = \frac{\sum_{i=1}^{n} \left|h_{ij} - h_j\right|}{2}, \tag{8}$$

where h_{ij} is the share of crime j at subregion i and h_j is the share of crime j in the study area as a whole. The Specialization Index ranges from zero to unity with unity representing total specialization. The Specialization Index does not provide information regarding which type of crime classification specialization occurs in a particular subregion.

The last measure of specialization considered here is the Entropy Index – this index has been used in the public health literature to measure mixed land use (Frank et al. 2004). The Entropy Index for area j is calculated as follows:

$$E_j = 1 - \left(\frac{-\sum_{i=1}^{n} p_i \ln p_i}{\ln n} \right), \tag{9}$$

where p_i represents the share of crime classification i and n is the total number of crime classifications. The Entropy Index ranges from zero (evenly distributed crime classifications) to unity (perfect specialization). As with all the alternative measures of specialization, the Entropy Index does not provide information regarding what type of crime classification specialization occurs in a particular subregion. Also, as with the Theil Index, the Entropy Index has difficulties dealing with zero values for p_i because ln(0) is undefined. However, in this case ln(0) may be set to zero without loss of meaningful interpretations.

There are, of course, many other measures of specialization, primarily stemming from the economics, geography, and regional sciences literatures. Though they vary in the details, they generally convey the same type of information as those shown above. The primary difference between the measures shown above and other measures of specialization found in the literature is the complexity of the calculation. However, at this stage of introducing alternative measures of specialization that may be used in the context of places, the more straightforward measures were chosen to show their utility.

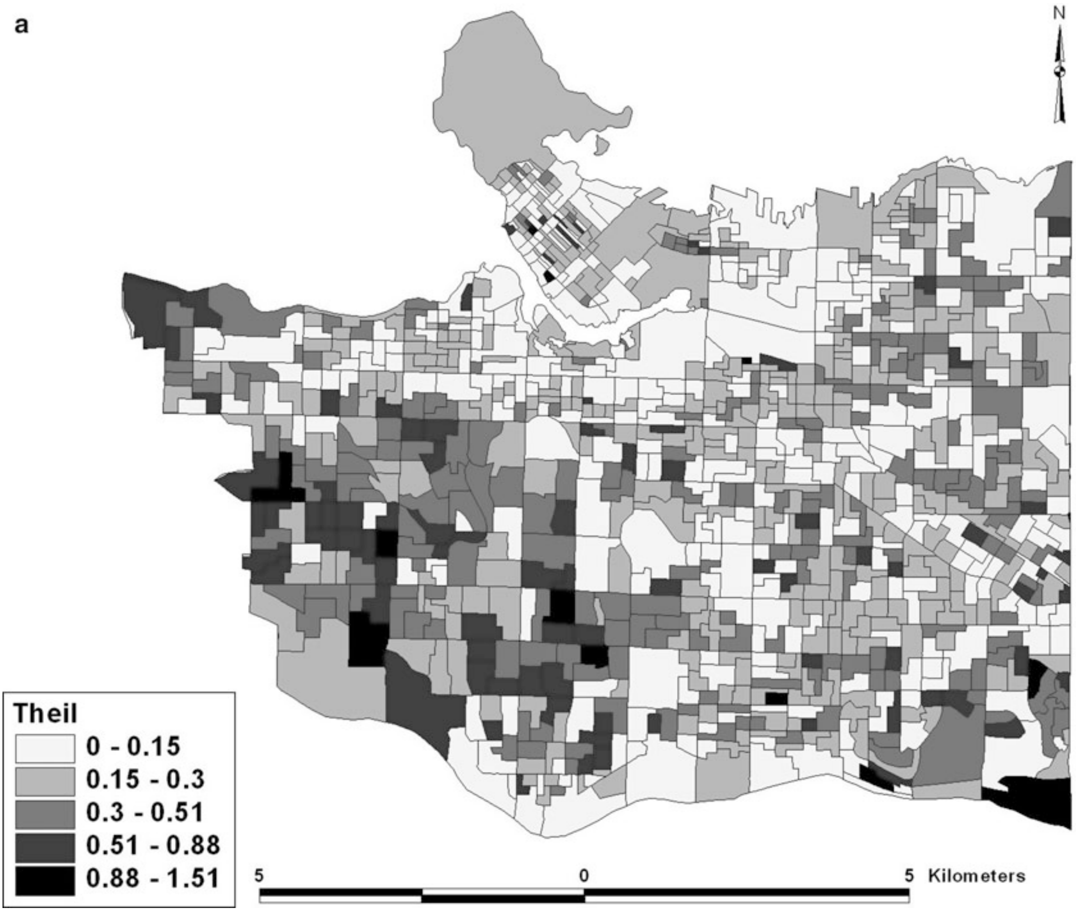
Mapping the Alternative Measures of Specialization

Before the discussion turns to the maps of the alternative measures of specialization, the similarity between the various alternative measures (and the location quotient for burglary) is of interest. The bivariate correlations (Pearson and Spearman) are shown in Table 1: Pearson correlations are shown in the upper right triangle of the table, whereas Spearman correlations are shown in the lower right triangle of the table. Though the location quotient for burglary is not highly related to the other measures of specialization (the correlations are positive and statistically significant), the alternative measures of specialization are, generally speaking, highly related with each other. Such relationships are not particularly surprising because the location quotient for burglary only considers burglary and the alternative measures of specialization are all quantifying the general nature of specialization, not being concerned with any particular crime. In fact, most of the (Pearson) correlations between the alternative measures of specialization are approximately 0.80, indicating that there is significant

Measuring Crime Specializations and Concentrations, Table 1 Specialization measures, Pearson and Spearman bivariate correlations, Vancouver, 2001

	Location quotient, burglary	Theil	Herfindahl-Hirschman	Herfindahl-Hirschman (Normalized)	Specialization	Entropy	Mean
Location quotient, burglary	1.00	0.44	0.59	0.56	0.31	0.53	0.49
Theil	0.41	1.00	0.79	0.81	0.80	0.72	0.71
Herfindahl-Hirschman	0.52	0.73	1.00	0.98	0.55	0.82	0.72
Herfindahl-Hirschman (Normalized)	0.52	0.73	1.00	1.00	0.67	0.83	0.75
Specialization	0.30	0.82	0.63	0.63	1.00	0.55	0.59
Entropy	0.50	0.70	0.94	0.94	0.57	1.00	0.73

Notes. Pearson correlations shown in upper triangle; Spearman correlations shown in lower triangle. All correlations significant at the 1 % level

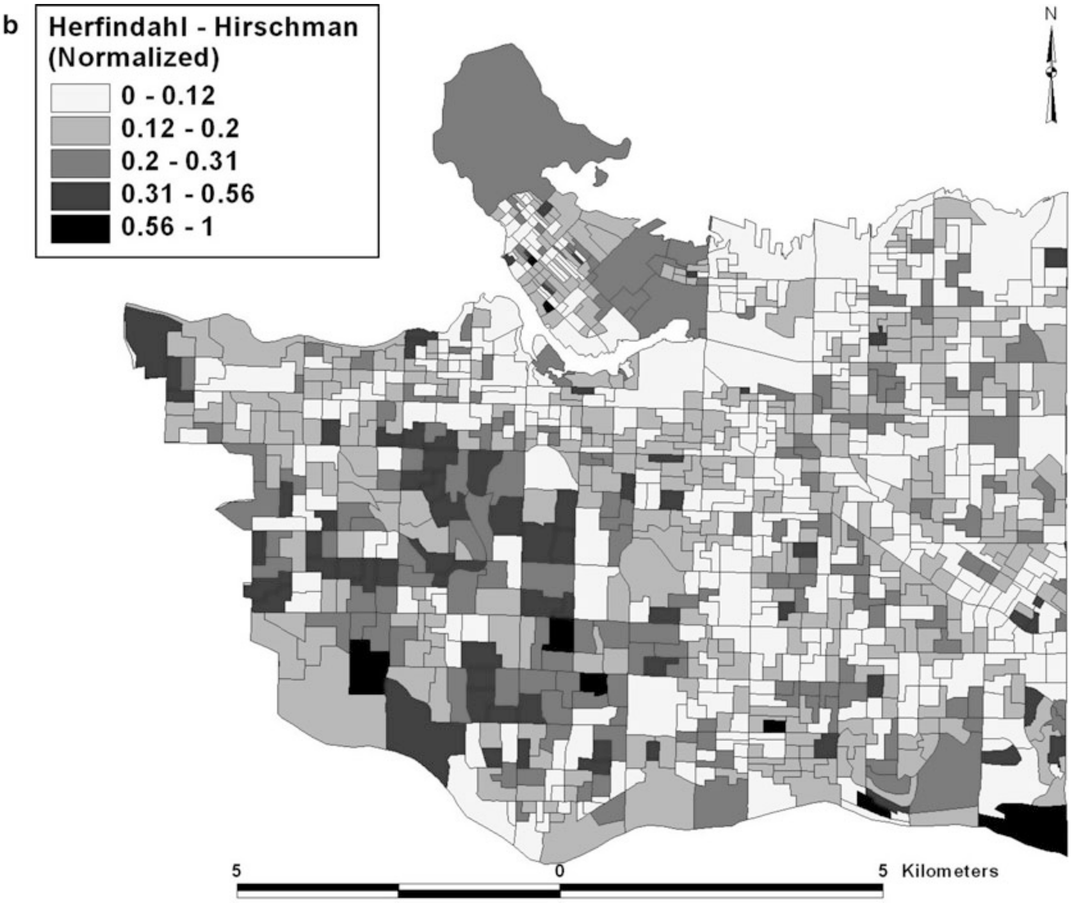


Measuring Crime Specializations and Concentrations, Fig. 2 (continued)

interchangeability among these alternative measures of specialization. The maps of these alternative measures indicate a similar conclusion.

Of all the alternative measures of specialization discussed above, only four are mapped for subsequent discussion: Theil Index (Fig. 2a), Herfindahl-Hirschman (Normalized) Index (Fig. 2b), Specialization Index (Fig. 2c), and Entropy Index (Fig. 2d) – the normalized location quotient is not mapped because the results are so similar to the location quotient shown in Fig. 1b, and the Herfindahl-Hirschman Index is not mapped because of its similarity to the Herfindahl-Hirschman (Normalized) Index. Because there are no classifications for these four alternative measures, unlike the location quotient, they are shown using natural breaks and five groups.

Immediately obvious with the Theil Index (Fig. 2a) is that the spatial pattern is similar to that of the location quotient for burglary (Fig. 1b). Though the spatial pattern is not as strong as with the location quotient, crime appears to specialize within the western side of Vancouver. This pattern is the opposite of expected when considering crime concentration because the west side of Vancouver is the wealthier section of the city – it contains some of the wealthiest neighborhoods. The DAs that have the greatest concentration is a smaller area than the similar classification for the location quotient for burglary, but is present nonetheless. The difficulty with this mapped output, as mentioned above, is that the Theil Index is a general measure of specialization and the research is forced to ask: specializes in what?

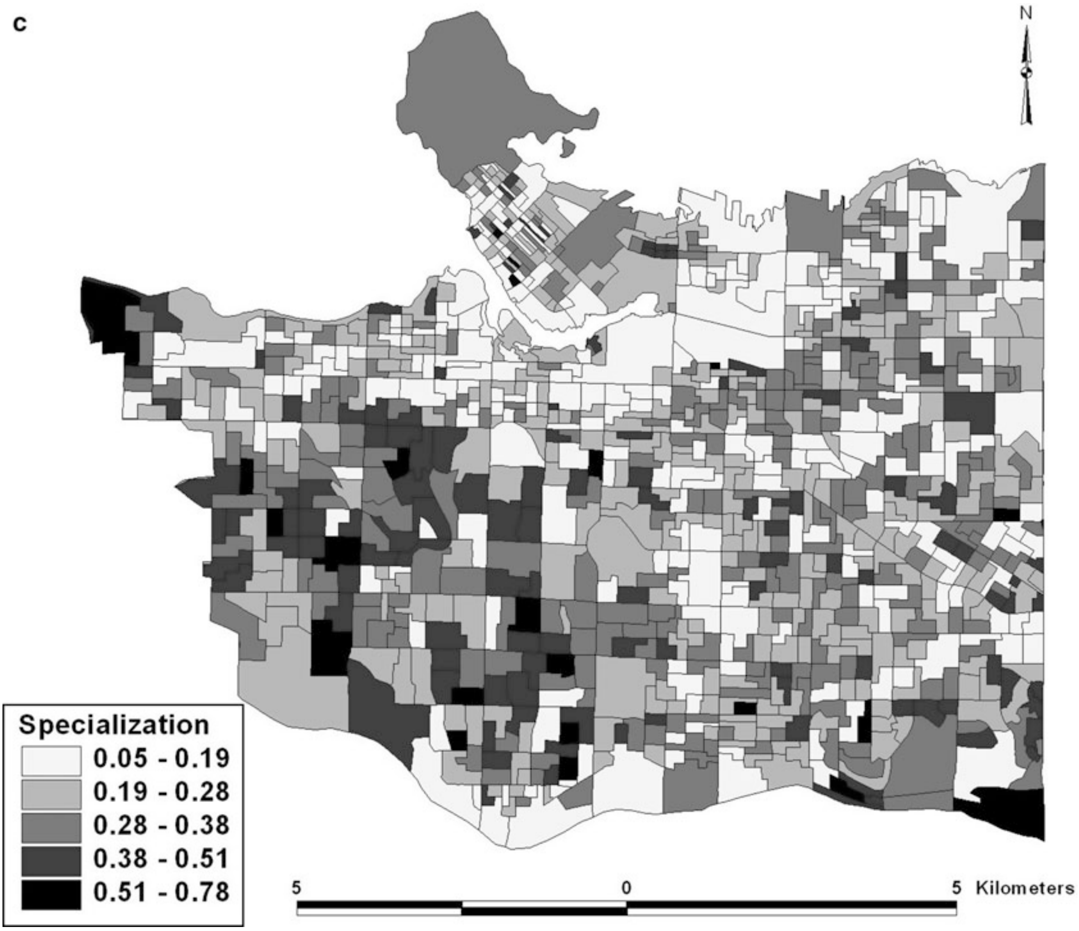


Measuring Crime Specializations and Concentrations, Fig. 2 (continued)

The Herfindahl-Hirschman (Normalized) Index (Fig. 2b) shows a similar pattern to that of the Theil Index: crime concentration in the western port of Vancouver, but not nearly as much as shown using the location quotient for burglary. Also noteworthy are the legend categories for the Herfindahl-Hirschman (Normalized) Index. Inspection of the legend and the mapped output reveals that there are not many DAs that have index values greater than 0.50. This is not problematic but shows that the Herfindahl-Hirschman (Normalized) Index is a more conservative measure of specialization than the Theil Index.

The Specialization Index (Fig. 2c) has the same general pattern as shown in Figs. 2a and 2b but is a blend of these two specialization indices: the mapped output for Specialization Index is more similar to the Theil Index, but the legend categories are more similar to the Herfindahl-Hirschman (Normalized) Index. The primary difference that emerges with the Specialization Index is that there are more DAs that exhibit specialization than in the previous two alternative measures of specialization.

Lastly, the Entropy Index (Fig. 2d) again exhibits a similar spatial pattern to the previous alternative measures of specialization. However, the number of DAs that show a high degree of specialization using the Entropy Index is rather low. Overall, and not surprising given the high magnitude correlations between the different measures of specialization (Table 1), the spatial patterns of the different alternative measures of specialization are quite similar.

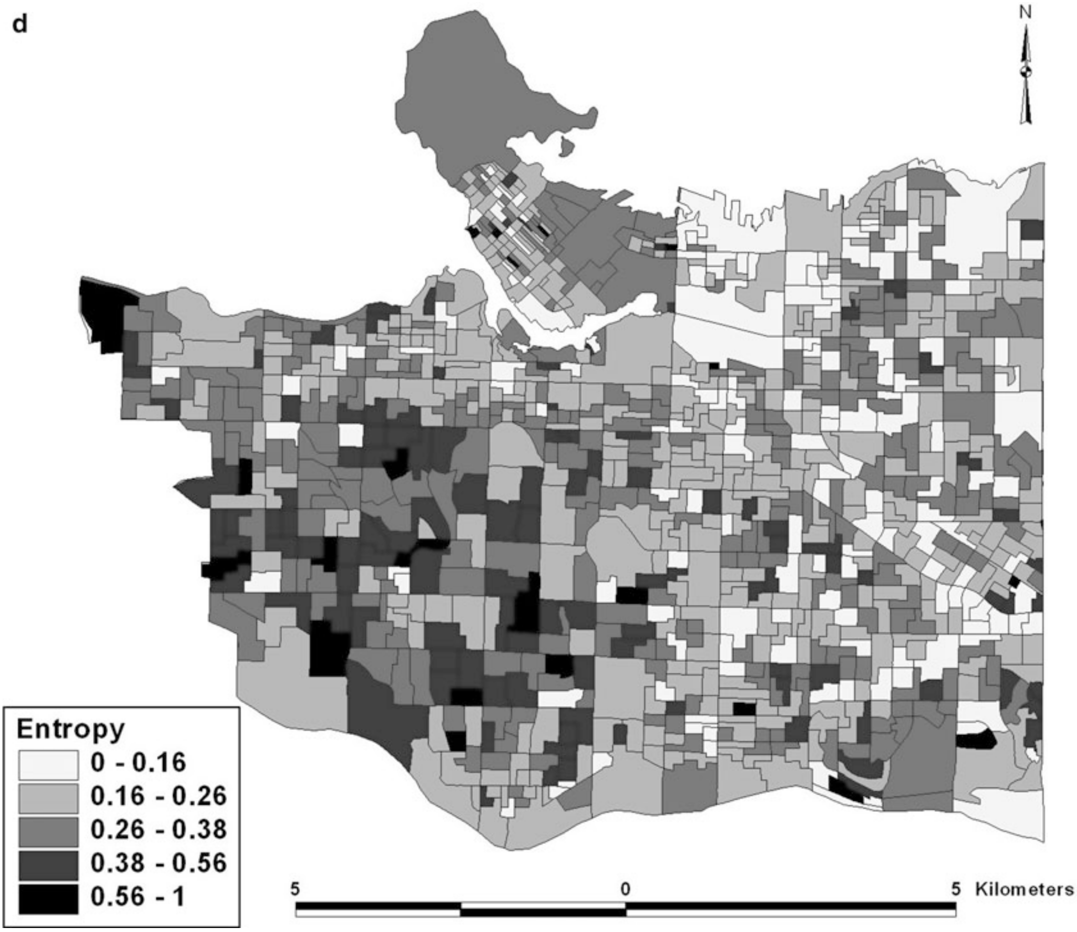


Measuring Crime Specializations and Concentrations, Fig. 2 (continued)

Future Directions for Crime Specialization

This entry has discussed the need to separately consider crime concentration and crime specialization, presented the location quotient and reviewed the criminological literature that has employed the location quotient, and presented and mapped some alternative measures of specialization. It has also opened the debate on which method might prove the most useful in measuring crime specialization. Though the different measures of specialization vary in their calculations, the output of these different measures of specialization is remarkably similar. This indicates that the choice of which measure of specialization the research decides to use has little impact on the overall spatial pattern – all of the alternative measures of specialization are general measures in that they do not show which crime classification an area is specializing in.

Because of this, unless there are very few zero values for crime in an analysis, the Theil Index and the Entropy Index are not ideal in the context of crime in smaller areal units of analysis (micro-places). This leaves the Herfindahl-Hirschman (Diversity) Index and the Specialization Index. Because of its current use in the criminological literature and its ease of calculation, the Herfindahl-Hirschman (Diversity) Index is probably the best of all the alternatives.



Measuring Crime Specializations and Concentrations, Fig. 2 (**a**) Theil Index, Vancouver 2001, (**b**) Herfindahl-Hirschman Index, Vancouver 2001, (**c**) Specialization Index, Vancouver 2001, (**d**) Entropy Index, Vancouver 2001

Again, the researcher is still left to ask: this place specializes in which crime? It is recommended that an initial measure of specialization, generally speaking, be calculated to investigate whether or not *any* specialization exists. If specialization does occur, then the time may be taken to calculate the various location quotients for each crime classification under analysis. In the case of Vancouver, only burglary specializes in the spatial patterns evident in Fig. 2a-d. As such, the alternative measures of specialization all indicate that specialization does indeed occur in Vancouver and the location quotient can then be used to identify what type of specialization is taking place. This information may then be used to identify the opportunity surface relative to each crime classification to understand the particulars of crime specialization.

With the respective opportunity surfaces identified, an obvious extension is to find what drives the specialization of different crime classifications. In other words, why is crime specialization particularly conspicuous in certain places? There are a number of data sources that may prove instructive for this endeavor. The census is an obvious data set that is available to most researchers. However, because of the time lag between census years (as long as 10 years), these data may not be the most reliable. Another data source that has proven useful in identifying crime generators and crime attractors is land use data (Kinney et al. 2008); Kinney et al. (2008) found that crime generators and crime attractors are best identified using highly specific land use classifications. It is expected to be similar for crime specialization.

Lastly, with information regarding the presence of crime specialization, the location of crime specialization, and why it is present in certain places, this may be used to inform policy decisions. Specifically, such information may be of interest to police in order to address specific crime issues. For example, the police may not only be interested in burglary in the places where it is most frequent (based on counts) but also in the places where it is the most problematic even if its incidence level is not particularly high. Similarly, this information may be of use for crime prevention initiatives, more generally, not just policing.

Overview

Successful organizations have one critical thing in common: they get the right people on the bus (Collins 2001). Selecting top quality individuals is a critical first step in creating a highly effective organization. In general, this is true but nowhere is it more the case than in a police department. Consider the fact that in almost every other type of organization, deficiencies in selection can at least be partially corrected by successfully introducing supervisors and other leaders from outside the organization. In police departments, it is rare, in fact highly unlikely, that supervisors and other leaders come from anywhere else except those who joined the force as new officers. The pool of applicants for promotions and ultimately departmental leadership is almost exclusively made up of individuals who have come up through the ranks. Ineffective selection programs and the inevitable hiring mistakes that occur even with the best selection processes result in limitations in not only current officers' performance but also in the quality of the candidate pool for promotions.

While getting the right people on the bus or in the present case, into the patrol car, is vital to organizational success, it is equally important that organizations possess well-developed performance appraisal systems to motivate and improve performance of those on the force. Such systems are essential to providing developmental feedback to officers, helping organizations increase the readiness of officers for their current assignments as well as future positions, and understanding where the department's strengths and developmental opportunities exist. Unfortunately, it is the exception rather than the rule that a department has an effective system for appraising and managing officer performance. This missed opportunity for improving the effectiveness of the department can be reversed.

The following entry addresses the role that performance appraisal research can play in the evaluation of police officer performance. First, key areas of research on performance appraisal in organizations will be summarized, pointing out traditional issues found in theory, research, and practice. Next, information is offered on those system elements that lead to effective performance appraisal programs. The process of system implementation is also presented, including preparing officers for performance evaluations, steps departments can take to create a positive environment for launching the process, and proper training of supervisors who will be the evaluators. The entry also addresses issues related to providing performance assessment feedback to officers. Highlighted also is the critical role of trust in the feedback process and the creation of an organizational climate conducive to performance feedback. Finally, the entry concludes with a discussion on the future of performance appraisal and management broadly and specifically within law enforcement organizations.

Key Research Questions in Performance Appraisal

How do we define performance? – Industrial psychologists have debated the definition of performance for decades. Austin and Villanova (1992) referred to this issue as the “criterion-problem,” suggesting that traditional measures of job performance fail to conceptualize and measure performance constructs that are complete, accurate, and multidimensional in nature. Specifically, such measures often suffer from criterion deficiency and contamination. While the former refers to aspects of the performance domain not measured by the appraisal instrument (leaving out of the evaluation critical performance factors), the latter refers to specific measurement error created by including in the assessment measures that are either not part of the job requirements or things that are out of the control of the officer being evaluated (i.e., unrelated elements that are unintentionally measured as a part of the performance domain). As such, work psychologists have underscored the importance of conducting a thorough job analysis to fully define the performance domain, develop a holistic understanding of key job-related behaviors, and thereby develop a valid appraisal system.

Before conducting a job analysis, however, it is important to have an understanding of what performance means in a given job. Campbell (1999) defined performance as “behavior or action that is relevant for the organization’s goals and that can be scaled (measured) in terms of the level of proficiency (or contribution to goals) that is represented by a particular action or set of actions.” (pp. 402–403). Motowidlo (2003) defined performance as “the total expected value to the organization of the discrete behavioral episodes that an individual carries out over a standard period of time” (p. 51). In short, performance is what employers pay employees to do (Campbell 1999). In the context of police performance, it includes departmental expectations, as well as what the public demands (viz., behaviors associated with preserving life and property).

Additionally, job performance can be described in terms of two broad arenas, task performance and contextual performance. Task performance is related to the core elements of the job while contextual performance supports the organizational, social, and psychological environment in which the task performance occurs.

For example, while task performance for police officers might include monthly documentation of traffic stops, creating accurate reports, testifying in court, and listening to citizens describing events, contextual performance includes behaviors related to boosting squad morale, providing counsel to a fellow officer, or being available for additional assignments. Both factors contribute independently to overall performance ratings.

What have we done to better understand performance assessment? – Much of the research on performance appraisal (PA) prior to 1980 was dominated by measurement issues and the search for “the right” rating format. This research focused on comparing various rating formats, including graphic ratings scales, behaviorally anchored ratings scales, traditional Likert scales, behavioral checklists, and other formats (Jacobs et al. 1980; Landy and Farr 1980). However, after thirty years of research on the topic, the field became less interested in issues of rating formats, concluding that although raters may have a preference for one format over another, differences in ratings due to format are minimal and overall inconsequential when it comes to the overall performance information provided to the individual and the organization. They did, however, note that behavioral anchors are better than simple numerical scales or ones that rely on common adjectives, and that anchoring should be based on methods that are grounded in firm psychometric theory. In fact, right now any organization, police or other, can find a variety of tools for measuring performance and can be ready to launch a program without the burden of creating a site-specific rating form. With respect to police officer performance, the reader of this entry can contact the senior author and receive a set of scales to be used for officers, supervisors, or command personnel.

Moving beyond issues of rating format, researchers began to consider the role of rater cognition in the performance appraisal process, leading to a flurry of research on the topic during the 1980s. During this time, increased attention was paid toward understanding *how* raters reach their judgments of employee performance. Such research targeted various cognitive processes of raters including observation and information acquisition, encoding and categorization, storage, retrieval, integration, and evaluation (Murphy and Cleveland 1995). Moreover, one of several themes to emerge from this literature was the effects of raters' implicit theories on ratings, including the tendency for raters to commit various rating errors including halo, leniency, and systematic distortion based on assumed rather than actual ratee behavior (Ostroff and Ilgen 1992).

The 1990s brought with it an emphasis on performance appraisal as embedded within the larger social-organizational context (Ilgen et al. 1993). Specifically, Ilgen and colleagues (1993) suggested that the appraisal process as entrenched within a rating environment or "social milieu" that raters and ratees occupy during that process. Performance appraisal became an even more complex process, given this newer social-psychological approach emphasizing a variety of contextual influences on performance ratings. Specifically, performance appraisal began to be viewed as a function of several different categories of environmental factors, including distal variables (i.e., organizational climate, culture, economic conditions, etc.), process proximal variables (rater accountability, feedback environment, etc.), structural proximal variables (appraisal goals and purpose, appraisal training, etc.) and rater and ratee behavior (i.e., rater/ratee attitudinal reactions, cognitive reactions, perceptions of justice, etc.). While cognitive research during the 1980s served to shed light on the limits of raters to make accurate ratings, the social-organizational approach expanded our view of the appraisal process by incorporating issues of rating context into the discussion.

More recent research has tended to focus on motivation and reactions to appraisal processes (Levy and Williams 2004). In terms of motivation, it appears that participation in the appraisal process is critical to motivating employees, who must perceive the appraisal system as fair and ethical. With regard to ratee reactions, research has tended to focus on system and session satisfaction on the part of the person being evaluated, perceived utility and accuracy of the performance information, and various forms of justice including procedural, distributive, and interactional, as well as due process. One important finding, in particular, by Folger, Konovasky, and Cropanzano (1992), suggests that perceptions of fairness are achieved when adequate notice, fair hearing, and judgment based on evidence are present in the appraisal system. In general, it appears that fair appraisal systems lead to a wide array of positive rater and ratee outcomes, including less emotional exhaustion, increased acceptance of feedback, more positive reactions to one's supervisor and the organization, and more satisfaction with the appraisal system and the job by the rater and ratee.

Moreover, ratees' reactions seem to be strongly tied to the opportunity to participate in the appraisal process and the amount of information provided about the process (Cawley et al. 1998). Other research suggests that aspects of the leader-member relationship may impact ratee evaluations. In particular, trust (a topic that will be returned to later), and specifically trust in one's supervisor, seems to be particularly important in predicting both incumbents' and supervisors' acceptance of their appraisal and satisfaction with the appraisal system (Hedge and Teachout, 2000). Further, the presence of a feedback culture, often enhanced by trust and strong supervisor-subordinate relationships, has been empirically related to satisfaction with feedback, motivation to use feedback, and feedback seeking (Steelman et al. 2004).

Finally, a considerable amount of work has addressed the role of rater training in the appraisal process and that work supports the importance of properly training those responsible for conducting performance evaluations. While a variety of methods are available to train raters, the general consensus is the most effective rater training is achieved using what is known as frame-of-reference ("FOR") training (Sulsky and Day 1992).

The performance appraisal literature has come a long way in the past sixty years. What began with research primarily dedicated to measurement issues and the search for the perfect rating format was followed by two shifts in the research literature, the cognitive approach of the 1980s, and the social-organizational perspective of the 1990s. This rich research history has provided us with a strong empirical framework for designing effective performance appraisal systems. Clearly, performance assessment is more than just assigning numerical values to a few categories that loosely reflect what an officer has done over the past year. Given this historical backdrop, the next section highlights system elements that lead to effective programs and evidence for performance improvement as a result of such systems.

Steps in Successfully Implementing a Performance Appraisal Programs

The Preamble: Setting the stage – Defining which competencies are required to effectively perform as a police officer is the first step in providing a framework for a useful performance appraisal and management system. However, once these competencies are in place, the question of how to best create a system that accurately measures these competencies still remains. There are a variety of aspects to consider when implementing a performance appraisal system. From training the raters to using the resulting data to make administrative decisions, there are many pieces of the performance appraisal puzzle that have to be in place in order to ensure success.

Often overlooked, some of the most important parts of the performance appraisal process take place even before the system is put in motion. For example, departments need to first ensure that officers are aware of the competencies being evaluated, how they are linked to the job, and why they are important. As referenced previously, this method of performance appraisal implementation is called "due process." Due process refers to a lifecycle approach to performance appraisal – one in which officers are informed from the start which competencies are important in defining job performance and which behaviors are viewed as effective or ineffective. This would provide officers with a clear understanding of how performance ratings will be derived.

Ensuring that officers are "on board" with the way in which performance is defined and measured, as well as the key features of the system, will result in an environment of trust in the appraisal process, as opposed to suspicion. One common finding from both research and practice is that employees do not like being evaluated. Thus, creating clear guidelines for performance from the start allows organizations to avoid the potential for surprise during the evaluation process, and enhances the overall perceptions of system fairness. Employees who perceive political motives underlying the performance appraisal process are likely to have lower job satisfaction and affective commitment, which were both found to be negatively related to job performance.

Ensuring that employees perceive the performance appraisal process as valid and worthwhile is important for maintaining a productive and satisfied workforce. Table 1 reflects a list of areas of responsibility for police officers and the basics upon which a system can be built for evaluating the performance of police officers. As can be seen, the areas of performance being rated are specific and clearly a part of a police officers' job. Specific performance assessment scales further enhance the performance evaluation process for each of the areas. Table 2 reflects a similar list that represents police supervisor/sergeant. Scales based on this type of approach are available by contacting the senior author of this entry.

In addition to presenting employees with clear and relevant criteria, it should also be made salient that it is possible for employees to voice their opinion if a part of the system appears to be unfair or unclear. The ability to participate in the appraisal process by respectfully questioning the system is also a part of due process. In line with this idea, Cawley et al. (1998) empirically demonstrated the effects of employee participation in the appraisal process. The authors found that employees had more favorable reactions to

Measuring Police Performance, Table 1 Performance evaluation dimensions for police officer

Dimension	Description
Patrol Preparation and Relief	Activities performed at the beginning and end of a shift during shift changes. This includes safeguarding and accounting for all agency property and equipment.
Patrol/Guard Duties and Responsibilities	Activities involving observing assigned area to detect unusual activities or violations of the law and preserving the safety of individuals and security of property in assigned area.
Vehicle Enforcement and Control	Activities involving the safe and legal operation of vehicles. This includes enforcing laws, handling accidents, assisting accident victims, and eliminating public safety hazards.
Responding to Crimes and/or Disturbances	Activities performed while responding to all types of offenses including crimes in progress, civil matters and domestic disputes, property crimes, serious crimes, etc. This includes the initial investigation of crimes and/or disturbances.
Apprehension and Control of Suspects, Prisoners/Inmates	Activities involving pursuit, isolation, containment, apprehension, and control of suspects or prisoners/inmates. This also includes activities performed in the process of searching to locate suspects, prisoners/inmates, or missing persons.
Search	Activities involving searches of suspects, prisoners/inmates, or crime scene/facility to locate physical evidence or contraband.
Arrest and Detention	Activities involving arrest processing procedures, transporting, detention, and lodging of prisoners/inmates or juveniles.
Evidence/Property	Activities involving the safeguarding, storing, and accounting for evidence and non-agency property.
Emergency Situations	Activities involving responding to emergency situations (e.g., natural disasters, riots, hostage situations, fires, escapes, floods/high water, etc.), maintaining order and notifying appropriate agencies to secure assistance.
Care of Victim, Prisoner/Inmate Welfare	Activities involving attending to medical and emotional needs of victims, agency personnel, other citizens, or prisoners/inmates.
Inmate Supervision	Activities involving supervising or controlling inmates during daily activities to maintain safety and security of inmates and staff. This includes communicating with inmates, overseeing the visitation of inmates and maintaining a clean and safe environment during work, meals, showers, etc.
Notifications/ Communications/ Administration	Activities involving distribution of information regarding incidents and conditions. This also includes communications with superiors, other personnel, and individuals from other agencies to coordinate activities.
Reports, Forms, and Memo Books	Activities involving the preparation of written forms, reports, photo/video records, or memo books. Forms and reports may be of a variety of types, such as: captioned (fill-in-the-blank), written narrative, or a combination of these types.
Court Activities	Activities involving providing assistance with court procedures including appearing in court and presenting testimony.
Public Interaction	Activities involving interactions with members of the public. This includes answering questions about community conditions and problems.
Agency Policies, Procedures, Rules, and Laws	Activities involving keeping current with agency policies and rules, and City, State, and Federal laws that govern the activities of officers and applying/enforcing them correctly.
Professional Development	Activities performed to improve one's skills or to improve the agency. This includes participating in specific training or education, participating in professional organizations, or conferences.

a performance appraisal system in which they could voice their opinion about the accuracy of their performance ratings and the system in general, regardless of whether or not the feedback would have an impact on organizational practice in the future. Thus, it is clear that employees are more comfortable with appraisal when they are well informed and feel that they have the opportunity to provide input about the system.

Rater Training: An Absolute Requirement – Once the performance appraisal system has been rolled out, it is important to identify those

Measuring Police Performance, Table 2 Performance evaluation dimensions for police sergeant

Supervision of Field/Case Work	
Incident Supervision	This duty involves assuming responsibility for incidents or special operations, to ensure the efficient and safe handling of the incident/operation and the preservation of life and property.
Case Management	This duty involves assuming responsibility for investigations coming under the sergeant's supervision to ensure the productive and appropriate handling of all investigative matters and to preserve the integrity of these investigations.
Personnel Management	
Personnel Assignment and Coordination	This duty involves assigning or allocating personnel so as to ensure sufficient personnel resources are available to handle workload. This area also involves planning and preparing for special circumstances such as sporting events and emergencies.
Personnel Evaluation	This duty involves observing subordinate performance to identify strengths and areas of needed improvement. It also includes conducting formal performance evaluation sessions and informal counseling sessions with subordinates to recognize performance strengths and discuss and resolve performance problems.
Policy Implementation and Enforcement	This duty involves interpreting, enforcing, and explaining the rules and regulations that govern the activities of Department personnel.
Training	This duty involves ensuring that personnel are properly trained to carry out their assigned duties. This includes planning, developing, conducting, monitoring, and evaluating formal and informal training programs. The training context can be the Academy or the field. The trainees may be Department personnel at any level, personnel from other agencies, or civilians.
Administrative Activities	
Record and Report Management	This duty involves reviewing, preparing, and/or maintaining logs, records, forms, memos, reports, and other field and administrative documents and correspondence used in the course of performing the job. This includes reviewing documents prepared by subordinate or other personnel for completeness and accuracy, reviewing and authorizing personnel requests and integrating information from multiple sources into summary documents.
Internal/External Communication and Coordination	This duty involves communicating or coordinating activities, with Department personnel and individuals from other agencies, to accomplish work objectives and discuss issues of mutual concern.
General Administration	This duty involves participating in the development, implementation, and evaluation of Division/Department programs, policies, procedures, and objectives.
Hands-on Field/Case Work	
Traffic Observation, Enforcement, and Control	This duty involves all activities conducted to ensure the safe and legal operation of vehicles on the road. This includes performing or supervising others in performing tasks such as assisting motorists, enforcing traffic laws, handling accidents, assisting accident victims, and identifying and eliminating public safety hazards.
Responding to Crimes and Disturbances	This duty involves the activities performed while responding to all types of offenses including crimes in progress, civil matters and domestic disputes, property crimes, serious crimes, etc.
Investigation	This duty involves all activities performed as part of internal or criminal investigations. This includes performing or supervising others in performing tasks such as obtaining and analyzing information, collecting physical evidence, and participating in the judicial/administrative process.
Arrest-Related Activities	This duty involves activities performed for the purpose of apprehending, restraining, arresting, transporting, and detaining suspects to be taken into custody according to the law and Department guidelines. It also includes activities performed or supervised in the process of searching vehicles, persons and/or premises for weapons, fruits of a crime, or contraband in order to effect arrest, protect self and the public, and/or to obtain evidence.

(*continued*)

Measuring Police Performance, Table 2 (continued)

Public and Community Relations	
Public and Community Relations	This duty involves activities which have an impact on the Department's image in the community by virtue of the subordinate's interactions with individual members of the public, community organizations, and the media.
Professional Development	
Professional Development	This duty involves participating in activities to keep apprised of job-related developments in laws, technology, policies, and procedures as well as to enhance job-related knowledge, skills, and abilities. This can include reading internal memos and bulletins; reading external publications; participating in training or certification drills and classes; and/or attending outside conferences, seminars, and courses.

individuals who will be responsible for providing ratings and to properly train them to use the system. As discussed previously, raters may fall prey to a variety of rating biases, such as halo (employees are either all good or all bad) or leniency (every employee is great) without proper training. Further, raters may decide to pursue personal goals when providing ratings for their officers (e.g., providing low ratings to an exemplary officer as a motivator for even better performance or providing high ratings to a poor performing officer to get them out of a particular unit and under someone else's command). There is also evidence that when raters have other goals in mind such as promoting harmony and a sense of equality across ratees, their ratings tended to be less discriminating, no longer sorting strong performers from weak ones and resulting in higher ratings in general. This provides support for the notion that when raters have a goal in mind, they can paint a picture of performance that is in alignment with that goal but not necessarily consistent with what they observe.

In the end, a system is only as good as the people who use it. It is completely possible for an organization to have a fantastic performance appraisal system in place and still achieve mediocre or even disastrous results. Thus, it is helpful to view the performance appraisal system as a vehicle – all of the parts may be in place but, without a properly trained driver and periodic servicing, the car does not function properly and thus at risk of malfunctioning. That being said, providing rater training is clearly a key component of a successful performance appraisal process.

As mentioned earlier, one type of rater training that has been touted as particularly effective in driving an accurate performance system is frame-of-reference (FOR) consisting of a variety of components which all help to make certain that raters will be able to accurately assess officers' behavior. FOR training helps in creating a unified definition of performance across raters, so that officers will receive similar ratings regardless of their rater. As such, FOR training is an extremely valuable tool for increasing the validity and predictive capabilities of performance ratings. FOR training also provides raters the opportunity to practice assessing behavior and to compare ratings with other raters to help provide a consistent and clear basis upon which raters should be formulating performance ratings. For example, raters who can effectively evaluate officers will gain additional and reinforcing insights from the training, while officers who are not accomplished performance evaluators will learn important skills and gain confidence in their ability to properly evaluate others. Systems that fail to provide rater training (i.e., FOR) will be far less effective.

Of equal concern for performance management efforts is feedback. Anxiety and lower levels of motivation in ratees often arise from misused and improperly delivered feedback. In the next section, proper feedback delivery and environment will be discussed to ensure that organizations are making the best possible use of performance information. As should be obvious, any rater training process must include information on the proper conduct of the feedback process.

Feedback in Performance Appraisal

Reference different fields of study and you will find various ways in which the term “feedback” has been conceptualized and defined. Industrial psychologists generally refer to feedback as information provided to an individual that clarifies expectations of their job and alerts them to how well their current performance meets such expectations (Ashford and Cummings 1983; Spector 2006). Although it was long assumed that employee feedback resulted in positive gains in performance, a meta-analysis by Kluger and DeNisi (1996) exposed the reality that feedback not only has the potential to produce performance gains, but also performance declines. As Taylor, Fisher, and Ilgen (1984) note, “Feedback may have no impact on the recipient at all, it may cause the individual to lash out angrily, or it may result in a response quite different from that desired by the source” (p. 82). Ilgen, Fisher and Taylor (1979) suggest that variability in response to feedback might be due to a series of psychological or cognitive processes elicited by the feedback process.

Many studies have sought to determine what characteristics of the feedback process contribute to its effectiveness or lack thereof but before considering such characteristics, it is important to understand that the effectiveness of any feedback system hinges upon recipients’ acceptance of such feedback (Ilgen et al., 1979). Ilgen and colleagues (1979) defined feedback acceptance as “the recipient’s belief that the feedback is an accurate portrayal of his or her performance” (p. 356). One way to think about this is that feedback acceptance acts as a gatekeeper or moderator between feedback delivery and effectiveness. Using self-consistency theory, Korman (1970) argued that, “individuals will be motivated to perform on a task or job in a manner which is consistent with the self-image with which they approach the task or job situation” (p. 32). Thus, one’s response to performance feedback is expected to be congruent with his or her acceptance of such feedback. As such, positive or negative feedback, which is perceived as accurate and therefore accepted by the recipient, is more likely to motivate one to respond than feedback which is perceived as inaccurate.

Given the crucial role feedback acceptance appears to play in the feedback delivery-performance relationship, what factors might predispose recipients to perceive feedback as inaccurate and unacceptable, and what can organizations do to foster acceptance? In the following sections, the effects of feedback content, specificity, frequency, delivery, and source on individuals’ willingness to accept and utilize performance feedback will be discussed. Moreover, the role of trust in the feedback process will be explored, as well as how organizations can create environments conducive to feedback.

Feedback Content – Given the sensitive and potentially anxiety-inducing nature of feedback in organizations, it is no surprise that the content of feedback may have a substantial impact on the likelihood of feedback acceptance. In general, individuals are more accepting of positive feedback, which likely stems from the motivation to preserve one’s self-esteem from the perceived failure resulting from negative feedback. Individuals are more likely to reject feedback that reflects discrepancies between one’s actual performance, relayed through feedback, and one’s perceived performance.

This does not necessarily indicate that individuals wholly reject negative feedback. It does indicate, however, that when performance discrepancies exist, individuals prefer positive feedback signs that portray them in a positive light and confirm their own self-perceptions. Moreover, it suggests that feedback providers ought to balance their negative feedback with positive feedback in order to reduce perceived performance overestimations as much as possible. By narrowing the perceived gap between one’s actual performance and perceived performance, feedback providers may be more likely to gain feedback acceptance, which in turn may lead to performance improvements on the part of feedback recipient. Additionally, Smither and Walker (2004) showed that providing a small amount of negative feedback enhances performance, but that a large amount of negative feedback impairs future performance. Atwater and Brett (2006) further suggest that feedback sessions should begin with positive feedback in order to spur feedback acceptance. Thus, feedback providers should be aware of the amount of negative feedback they provide, making sure to buffer it with positive feedback at the beginning of the feedback session and ensuring that subordinates are not overwhelmed by too much negative feedback during the process.

Other research indicates that feedback is perceived as valuable when it helps employees reduce uncertainty, provides recipients information regarding their goal progress, and indicates how one's performance is being evaluated by others. Additionally, feedback is more likely to be accepted and used when it is perceived as valid, accurate, and reliable. Thus, feedback providers should always err on the side of providing higher quality feedback during feedback sessions.

Kluger and DeNisi (1996), however, note that such feedback ought to be focused more on the performed task than the person receiving the feedback. In their influential meta-analysis, they found that feedback intervention (FI) effectiveness decreased as feedback became more directed toward the feedback recipient than the task. This is consistent with other research that supports the idea that individuals are more likely to accept feedback that compares them to a neutral standard, rather than to their peers. It is believed that such comparisons can hurt recipients' self-concept and reduce their likelihood of accepting feedback. This suggests that recipients may be less likely to accept and ultimately use feedback that they perceive as a personal attack rather than an honest assessment of performance on the task. Thus, feedback providers should be careful that their feedback is not directed toward personal characteristics or compares recipients to their peers, but rather should focus on specific performance aspects related to the task.

Feedback Specificity – To date, feedback specificity, or the level of information presented in feedback messages, has received quite a bit of attention in the performance appraisal literature. Generally speaking, it is believed that effective feedback includes specific information about behaviors that were performed incorrectly and how to correct them, rather than statements that are generalized or ambiguous. Such feedback provides a rich source of information about explicit behaviors that are appropriate or inappropriate for effective performance, thereby allowing recipients to learn from and correct their behavior. In doing so, feedback specificity is thought to decrease information-processing activities such as error diagnosis, encoding, and retrieval, which subsequently reduce the cognitive load required to make links between actions and outcomes. Moreover, specific feedback provides information on how individuals are progressing toward their goals and informs them about how their job performance is being evaluated.

In fact, empirical evidence suggests that specific, objective feedback that is consistent with actual performance leads to higher performance than less specific, more subjective feedback. Moreover, feedback interventions that are supplemented with information regarding tasks, strategies, and appropriate behaviors have been found to result in increased short-term performance during practice and training. Interestingly, Steelman and Rutkowski (2004) demonstrated that employees are motivated to use negative feedback when it is perceived to be of high quality and directed toward improving their performance than similar feedback of lower quality.

Despite such findings, overly specific narrative feedback may also introduce excessive cognitive load on recipients, hindering their understanding of the feedback. The positive impact of feedback can clearly be enhanced when the information being conveyed is easy to consume and in a form that is readily understood by the recipient. This point argues for a graphic presentation of information as perhaps a takeaway from the feedback session. It may also include the use of summary statistics that make it easy to compare current performance to expectations or even to the performance of peer groups.

In general, research has suggested that specific feedback is more effective than vague, generalized feedback. Employees must learn which specific behaviors are indicative of good and poor performance – not only so that they can correct such behaviors but also in order to protect against perceptions of arbitrariness in the feedback process.

Feedback Frequency – Feedback frequency has also been explored as a potential factor influencing feedback acceptance and perceived utility. In general, it is thought that frequently delivered feedback is more effective in promoting performance improvements than less frequent feedback. The logic that drives this conclusion is that the close temporal pairing of feedback with employee performance behavior has an overall positive effect on future performance. Frequently delivered feedback reduces the chances that interference will occur in the periods between behavior and the feedback, which have the potential to distort feedback effectiveness. This stands in stark contrast to most performance evaluation processes, which call for assessment and feedback once per year. In the course of performing any job and especially a police officer's, much can happen over that 12-month period.

In fact, research suggests that frequency of feedback is positively related to recipients' perceived accuracy and fairness of feedback. Because feedback tends to not be delivered as frequently as it should in today's organizations, recipients may view feedback as a scarce, valuable resource that decreases role ambiguity by continually informing employees about where they stand with regard to their performance levels. Thus, increasing the frequency of feedback may facilitate more positive employee reactions and outcomes during the feedback process. While once per year seems too little, other factors must be taken into consideration when deciding whether to provide more frequent feedback. For example, instituting more frequent feedback sessions may send implicit messages to employees that supervisors do not trust them as being competent and capable of carrying out their tasks without increased micro-management. In fact, it has been shown that while positive feedback provided immediately promotes a strengthening of previous behavioral responses, negative feedback is more effective after a time lag, which allows for decomposition in the strength of the previous incorrect behavioral response. As such, it stands to reason that while providing feedback on how to do a job may be perceived positively when done once or twice, such feedback may be reacted to more negatively when delivered in excess.

Supervisors should seek to provide regular feedback to employees, but they should also recognize that more is not always better. Specifically, because recipients' feedback perceptions are crucial to its acceptance, supervisors should be aware that the intent behind providing increased amounts of feedback may not be perceived accurately by recipients. What may be intended as supportive may in actuality be perceived as controlling. One simple recommendation is that supervisors find out how often their employees desire feedback and use that in conjunction with the requirements of the organization to create a dialogue about performance.

Feedback Delivery – It is also important that feedback providers take active steps to preserve and respect recipients' self-esteem by being sensitive and understanding in order to obtain feedback acceptance, rather than simply viewing their role as a provider of information. The manner in which feedback is delivered may significantly impact employees' acceptance and perceived utility of the feedback. For example, it has been found that a supportive, constructive attitude on the part of feedback providers contributes to increased recipient satisfaction, perceptions of fairness, and motivation to improve job performance. Furthermore, feedback consisting of greater interpersonal fairness has been found to be related to more favorable attributions toward the feedback provider, greater acceptance of feedback provider, and more favorable reactions to the organization. Officers can be seen as motivated to improve their job performance following negative feedback when feedback is delivered in a considerate manner and with information that helps them better understand what was done improperly as well as what might be seen as more effective.

Feedback Source – Not surprisingly, much research has also investigated whether feedback acceptance depends on who provides such feedback. This research has often investigated the feedback source's credibility, which refers to one's expertise and trustworthiness in providing feedback. Expertise on the part of the person conducting the evaluation includes knowledge of the job requirements, knowledge of actual job performance, and the ability to evaluate performance in an accurate manner, while trustworthiness represents whether or not the individual being evaluated has a belief that the feedback source can and will provide accurate performance information.

Credible feedback providers are seen as possessing expertise relative to the specific tasks being evaluated and are trusted to provide feedback that is objective and free from bias (e.g., political considerations, feedback source's mood at the time of feedback, etc.). In police settings, the former is generally the case since virtually every police officer providing evaluations came through the position they are evaluating (sergeants were police officers, lieutenants were sergeants, etc.). However, trust is a much more elusive characteristic, and one that must be developed over time between the evaluator and the officer being evaluated. This suggests that organizations should make a strong effort to ensure that feedback is delivered by highly qualified individuals with experience on the task being evaluated and professional status that is greater than the feedback recipient's. In doing so, recipients may be more likely to both accept and use feedback in order to improve their future performance.

The Role of Trust in Feedback – Further examination of the feedback process highlights the importance of recognizing that feedback does not exist within a vacuum, but rather is embedded within the larger social-organizational context or what is often referred to as the "social milieu." In fact, research suggests that context plays a potentially pivotal role in shaping aspects of the appraisal process, including feedback, and the ways in which employees react to such processes (Farr and Jacobs 2006; Murphy and Cleveland 1995). Specifically, Folger, Konovsky, and Cropanzano (1992) discussed performance appraisal as a process in which individuals at all organizational levels (including subordinates, supervisors, and upper management) have a stake, leading to potentially conflicting interests regarding the results of a given performance appraisal or feedback session. Feedback providers, in such contexts, are believed to hold power over subordinates, who inevitably make themselves vulnerable during such sessions. Therefore, in order for feedback sessions, and performance appraisal processes in general to be effective, those engaged in the process must trust in it. For feedback recipients, this means trusting their supervisors and the system used to evaluate them. For supervisors, this means having faith in the quality of their feedback and appraisal system that informs it.

An officer's trust in their sergeant influences the communication link between the two. As trust fades, information fails to make a substantive impact during communication. Thus, it stands to reason that when trust decreases so does the impact of the sergeant's feedback on officer's behavior. Providing empirical support for this idea, Herold and Greller (1977) found that supervisors who were more "psychologically close" with their subordinates had a greater impact in terms of feedback than those who were more psychologically distant. In addition, Earley (1986) found that workers' trust in the feedback source partially mediated the relationship between feedback and workers' response to and value attached to praise and criticism. Jablin (1979) provides a nice overview of the supervisor-subordinate relationship and its importance in this context.

In sum, these findings suggest that trust plays a crucial role in individuals' willingness to accept and respond to feedback. Thus, supervisors should actively try to promote trust among their subordinates by educating subordinates about the performance appraisal and feedback process, showing how the feedback process may be used to promote employee development, demonstrating consideration for employees' work and well-being, exhibiting dependability on a regular basis, and communicating a sense of honesty and forthrightness in daily activities, among other things. In doing so, it may be possible to promote a climate of trust surrounding the feedback process, which will facilitate feedback acceptance and ultimately improved job performance.

Summary of What We Know About Police Officer Performance Management

To this point, the primary focus has being on giving the reader a lot of information regarding research and practice as it pertains to performance assessment and management. Much has been done in this area and over the decades of theory building, research, and practical application, quite a bit have been learned. While the importance of being very specific about what has been done in the past is acknowledged, it is often important to step back and simply summarize what is known and what it means in terms of creating a successful performance management program. Here is the authors' perspective.

Defining Performance – Without a doubt, nothing works unless time is spent and effort is expended to accurately define the key responsibilities and expected behaviors of those who are being evaluated. Traditionally, this starts with a job analysis or a very comprehensive job description. This step helps raters and ratees when it comes to understanding performance expectations and accepting the accuracy of performance evaluations. Further, with respect to fairness and meeting potential legal challenges, a system of performance management will never be seen as reasonable unless the agency has done its homework and clearly documented what is required by the job. These descriptions should be multidimensional covering critical areas of job performance and behaviors specifying the types of actions that represent poor, average, and strong job performance.

Setting the Stage – Performance management is not just an organizational requirement. It is an organizational event. In police agencies and other organizations, the process of evaluating performance is often approached with dread. Evaluators do not enjoy conducting evaluations, those being evaluated feel like they are being unnecessarily put under the microscope, and those responsible for the process within the HR organization often feel they have to harass and cajole individuals just to do what needs to be done. It is not a happy time of the year for many members of the organization. With this backdrop, it is important that a more positive environment is created. This can be accomplished by focusing on the process and potential positive outcomes that will result from effective performance management. Creating a positive environment requires a campaign initiated by the agency and supported from the top down. Without this kind of effort, the process will wallow in apathy, and the benefits will never emerge.

Training, Training, and More Training – Organizations consistently make a faulty assumption when it comes to performance appraisal and management. They too often assume that because someone has become a supervisor, they CAN and WILL be competent in the evaluation of others. Many supervisors and command personnel are good at reviewing the work of others and may enjoy the process, but not all. The role of training evaluators on the how to's and why's of performance evaluation is critical. Even for those who are positively disposed to the activity, training helps. An essential part of any performance management system is the training of raters on all aspects of the system.

It is also critical that those being evaluated are informed regarding the process (i.e., setting the stage), which is often a neglected area. While it may be an annual agency requirement that performance reviews will occur, it is not necessarily clear to individuals being evaluated exactly how the evaluations will be conducted, what is being measured, and how the data will be used. All these topics should be explained in advance of system implementation.

Keeping Track/Monitoring the System – The most effective processes do not stop at the collection of data and the checking off of yet another organizational event required by the agency. The best systems review results, hold raters accountable for doing the evaluations in a timely fashion, analyze data for potential problems (bias, halo, and missing information as examples), and use this information to enhance the future system implementations.

Using the Data – Traditionally data from performance evaluations are used to understand individual performance, to provide feedback to the person being evaluated, and/or to trigger personnel actions such as administering rewards or reprimands. While these are clearly important uses for the data, organizations are missing opportunities unless they look across individuals to understand where the agency may have repeated performance decrements indicating needed training programs, or where the department is truly excelling and how that information can be leveraged for future motivational programs. Suffice it to say, the best performance management programs continue beyond the individual level of analysis and look at groups, departments, and agency wide data to better understand performance.

Feedback – "Don't collect information that you just put in a folder:" Over the years, quite a bit has been learned about how organizations can move from performance appraisal to using that information to drive future performance. It begins with a well-developed feedback process that brings supervisors and officers together to talk about the past and to plan for the future. Feedback does not happen automatically. Many involved in the process of delivering and receiving feedback need guidance to effectively turn observations of performance into performance improvements.

The Future of Performance Appraisal and What it Means for Police Departments

Thus far, this entry has outlined best practices for performance appraisal in organizations – from traditional issues regarding instrumentation to how to deliver performance feedback and the importance of trust between an evaluating supervisor and the officer being evaluated. However, performance appraisal methodology has never been stagnant. Changes have been seen in research emphasis and practice over the past five decades. The future will bring improvements and updates to best practice as it stands today. Although it is impossible to predict exactly what the future will hold, there are a few areas that have already begun to show promise, which may allow police departments to enhance the effectiveness of their performance assessment processes.

The first of these areas lies in the realm of online assessment. Online assessment is quick, easy, and fits in well with today's demand for technology-driven solutions. For example, E-learning has become very popular in organizational training because it is easy to use and can be completed by employees at any time. The same is true for online performance appraisal systems. Supervisors can complete surveys about officer behavior at a convenient time and in a quick, easy fashion. As the computerization of police work marches forward, more and more systems will be available for documenting and evaluating police officer performance. The use of online performance appraisal also facilitates self-evaluation and lends itself to automated comparisons between subordinate and supervisor, which can form the basis of performance discussions and goal setting. Online assessments are also extremely useful tools for organizations because they save time, energy, and allow for the automated collection and storage of performance assessment data. Making performance appraisal systems user-friendlier and more efficient is undoubtedly in the best interest of the organization. And, online appraisals certainly help to propel these goals forward.

Second, there has been a recent upswing in the use of self-assessment for performance appraisal. In this case, employees are able to provide ratings regarding their own performance. However, the literature suggests that self-appraisals are ridden with bias. For example, Atkins and Wood (2002) demonstrated that self-ratings were negatively and nonlinearly related to assessment center performance. The worst performers may report that they are doing the best as a way of overcompensating for poor performance. Atkins and Wood's (2002) findings further suggest that high performers may be hard on themselves, creating a performance profile much lower than that which exists in reality. It has also been demonstrated that self-ratings tend to be less variable than supervisor, peer, or subordinate ratings, suggesting possible halo or leniency errors (Scullen et al. 2003). Thus, while self-evaluations may provide interesting information, this information is not suggested for use in making administrative decisions. Organizations should be aware of employees' intent to distort self-ratings and should proceed with caution when determining how to make use of self-report performance data.

Finally, it is time for police organizations to move away from the perspective that they conduct appraisals because their policies and procedures manual indicates they must do so to viewing the performance appraisal system as a vehicle for enhancing communication between supervisor and subordinate, facilitating change, and setting goals for the future performance. It is tempting to consider performance appraisal in police departments a truly lost opportunity but that seems excessively negative. Rather the tone of this entry should convey the tremendous opportunity for organizational success that is embodied in well thought-out and well-executed programs in performance management and how they can truly transform a department. In this time of shrinking budgets and disappearing resources, developing and implementing a state-of-the-art performance appraisal system can be a very low cost, high impact process for any law enforcement agency. This entry, hopefully, has helped convince you and has provided you with information that can move you forward in putting a performance management program into practice in your department.

Measuring Police Unit Performance

Gary Cordner
Department of Criminal Justice, Kutztown University, Kutztown, PA, USA

Overview

Although police performance measurement has gotten increased attention in recent decades (Shane 2007; Fleming and Scott 2008; Davis 2012), it has been a longstanding concern of scholars and policy makers (Lind and Lipsky 1971; Parks 1971). The ability to measure how well the police are performing is central to notions of police effectiveness, accountability, reform, and the current emphasis on evidence-based policing. Without accurate performance measurement, aspirations toward implementation of strategic policing, scientific policing, and a new approach to police professionalism (Weisburd and Neyroud 2011; Stone and Travis 2011) are mostly rhetoric, not reality.

In the United States, where most police agencies are extremely small (one-half have ten or fewer police officers; Reaves 2011), the majority of the focus has been on the overall performance of the entire police organization, rather than on police unit performance (Langworthy 1999). Even in the United States, however, many police organizations are comprised of multiple subunits; this is the normal characteristic of police organizations in most of the rest of the world. These subunits are important to consider, because the overall performance of a medium-sized or large police agency is, at least to a degree, the sum of the performance of its parts. Top-level police executives have the challenge of measuring the performance of their organizations' subunits in order to guide resource allocation, hold lower-level managers accountable, fix problems, and coordinate interunit activity. Lower-level police managers, especially if they are responsible for specific subunits, need information about how well their own units are performing in order to carry out their responsibilities of planning, directing, and controlling in order to maximize their units' performance.

Fundamental Considerations

Conceptualizing and operationalizing "performance" is not as easy as it sounds. Commonly, a distinction is made between effort, output, and outcome. For example, the performance of a manufacturing unit within a larger company might be defined in three different ways:

1. How hard did the members of the unit work?
2. How many widgets did the unit produce?
3. How much profit was derived from the unit's performance?

Each of these measures of performance is legitimate and might be relevant. The company's top management probably wants to be assured that the members of the manufacturing unit are working hard. If not, the unit might be overstaffed and therefore costing more than necessary. Second, top management certainly wants to know the level of production (output) of the unit, particularly in the case of a manufacturing

Measuring Police Unit Performance, Table 1 Unit measures for a police district or precinct

Dimension	District/Precinct measures
Reduce crime	Reported violent crime per 100,000 population Reported property crime per 100,000 population
Hold offenders accountable	Clearance rate for crimes investigated at the district/precinct level Conviction rate for crimes investigated at the district/precinct level
Reduce fear	Personal fear of crime measured with community surveys Perceived likelihood of being a crime victim measured with community surveys
Ensure civility	Number of injury and fatal traffic crashes Perceived level of social disorder measured with community surveys
Services/ satisfaction	Public confidence in the police measured with community surveys Customer satisfaction with specific services measured with follow-up surveys
Use of force & authority	Percent of custodial arrests that involve police use of force Disproportionality index for vehicle and pedestrian stops (reflecting minority overrepresentation)
Use of financial resources	Percent of annual district/precinct budget expended Overtime expenditures per district/ precinct employee

Measuring Police Unit Performance, Table 2 Measures for a police repeat offender unit

Dimension	Repeat offender unit measures
Reduce crime	Estimated number of offenses not committed by arrested offenders (offending rate times years of incarceration)
Hold offenders accountable	Proportion of targeted offenders arrested, prosecuted, and convicted Average sentence length of targeted offenders
Use of force & authority	Percent of custodial arrests that involve police use of force Percent of cases declined for prosecution due to evidentiary concerns Percent of cases not resulting in conviction due to entrapment findings
Use of financial resources	Percent of arrests not qualifying as repeat offenders Average number of previous convictions of unit arrestees (seriousness factor) Average number of arrests per unit member Average cost per arrest, per conviction, and per crime not committed (personnel, informant payments, buy money, etc.)

unit, since that is its fundamental purpose (produce widgets). Ultimately (third), top management wants to know the unit's contribution to the company's profit. That is arguably the most important dimension of the unit's performance, since it directly coincides with the entire company's bottom line (its profit). After all, if the company is not profitable, it will go out of business, and then there will not be a manufacturing unit or any jobs for the members of the unit.

Several significant complications arise even from this simple example. With regard to effort, members of a unit might work hard, but make many mistakes. They might work hard, but be doing the wrong things. They might work hard, but not have the proper equipment needed to complete their work correctly. Also, if the unit's role is more analytical, intellectual, or creative than this manufacturing example implies, then "working hard" might not be the primary ingredient of the effort associated with good performance. Rather, wise decision making, innovative problem solving, imaginative thinking, or just "working smart" might be better ways than "working hard" of conceptualizing the effort dimension of performance as it relates to some organizational units.

With regard to output, an organizational unit might produce a satisfactory number of widgets but the quality of the widgets might not be acceptable. Similarly, the number of widgets produced might be adequate but the amount of resources consumed in producing them could be excessive – i.e., there might be wastage of raw materials,

Measuring Police Unit Performance, Table 3 Unit measures for a Police Communications Center

Dimension	Communication Center Measures
Services/ satisfaction	Caller satisfaction with services measured with follow-up surveys Percent of 911 (emergency line) calls answered within three rings Quality control assessment of call-answering performance (review of random sample of calls) Police officer satisfaction with dispatcher services measured with surveys
Use of financial resources	Calls handled per unit employee Percent of annual unit budget expended

driving up the cost of producing the widgets. As these two scenarios suggest, the output of a unit cannot be assessed in a meaningful way without incorporating some standard of quality as well as a measure of cost.

In principle, a unit's outcomes are even more important than either its effort or its output, since the outcomes are the end results of the unit's performance. This is particularly true when the outcomes are closely associated with the entire organization's "bottom line," such as its profit. Two related complications arise at this level, however. First, simply determining the end results of a unit's performance can often be difficult. A company's training unit, for example, might have as its desired end results increased employee knowledge, increased employee skills, and improved employee performance. The first two could be measured immediately after the conclusion of training programs. This would give some indication of training outcomes, but subsequent measurements would have to be made to determine whether the employees' knowledge and skills were maintained over time. It would be even more involved (and costly) to measure employee performance back on the job, in order to see whether there was any post-training improvement in actual performance. The greatest challenge would be in "proving" that the training unit's efforts either did, or did not, cause any changes in employee performance. Changes in performance could be caused by other factors – pay, supervision, new technology, etc. Or, measurement of employee performance might indicate no improvement following training – but that might be caused by workgroup pressures (e.g., output limitation norms), failure of supervisors to reinforce training, or many other factors, not necessarily some shortcoming of the training. In other words, validly determining whether a unit's efforts did or did not cause some specified end results (outcomes) sometimes requires a genuine research project, not simply collecting some information.

These challenges are multiplied when one seeks to determine the contribution of a unit's performance to the entire organization's achievement of its specified outcomes. Again, this is what matters the most, but it is difficult to determine. The manufacturing unit may have produced perfectly good widgets at a satisfactory cost, but if the marketing unit failed to market them effectively, or if the sales unit failed to sell them, or if the packaging unit failed to design and produce the right packaging for them, or if the public's taste in widgets changed, the widgets might still be in the warehouse nine months later, not contributing to the company's profit. Would it be fair then to assess the manufacturing unit's performance negatively? This scenario illustrates the fact that one unit's contribution to the overall organization's performance may be heavily dependent on the performance of other units.

A second major challenge arises when a unit's contribution to overall organizational outcomes is indirect or tangential, as in the example of the training unit. In principle, the ultimate value of the training unit is tied to its contribution to the organization's overall performance and effectiveness. If there was no connection, the training unit should not exist. However, most of what the training unit does is provide knowledge and skills to employees. Whether the employees actually use that knowledge and skill, whether they use it correctly, whether they are allowed to use it by co-workers and supervisors, whether they have the equipment they need, and many other factors are far beyond the control of the training unit. Equally important, the employees' performance might improve due to training, but the impact of this improvement on overall organizational performance may not be detectable amidst all the other dynamic conditions, both inside and outside the organization, which are constantly in flux. For organizational units, such as training, that are somewhat distant from core operating functions, assessment based on contribution to the organization's overall bottom line may be impractical or impossible.

In addition to all these complications, it should be noted that there is a tendency toward suboptimization in organizations. This refers to the tendency of organizational subunits to emphasize accomplishment of their units' objectives (outputs or outcomes) even when those conflict with overall organizational goals and effectiveness. If the manufacturing unit is judged on the number of widgets produced, it may maximize that production, regardless of whether they are selling. Or, if it is judged on the percentage of widgets produced that meet a high standard of quality, it may slow production in order to take more time in making each widget, regardless of whether the sales unit then loses customers because the rate of delivery is too slow. This happens, of course, in part because members of a unit come to identify with it, often more closely than they identify with the entire organization. Also, if a unit is judged on a specific criterion of effort, output, or outcome, its members and its manager will often focus their entire energy on meeting that criterion, to the exclusion of other criteria that may be important, and without regard to how it may affect other units or the organization as a whole. This is a reflection of the common refrain, "what get's measured gets done." Sometimes, what does not get measured, does not get done.

Measuring Police Performance

All of the general considerations noted above apply to police organizations. Unit performance is sometimes measured based on effort, such as vehicles stopped, miles driven, average response time to reported incidents, properties checked, number of vehicle crashes reconstructed, and number of K-9 unit responses. It is particularly common to measure police unit performance in terms of outputs – number of reports taken, quantity of drugs seized, number of citations issued, number of arrests, proportion of cases cleared, etc. It is substantially less common to assess police organizational units based on outcomes. This is not surprising since the same is generally true regarding overall police organizational performance – police agencies have traditionally resisted being held accountable for the level of crime in their jurisdiction, and few if any other outcome measures were even considered. Until fairly recently, overall police organizational performance has generally been measured using response time, arrests, citations, and case clearances – measures that mainly address effort and outputs, not outcomes.

A few key characteristics of the police mission make performance measurement particularly complex. One is that a police organization's "bottom line" is multidimensional. In the simple example given above, the widget company's bottom line was *uni*dimensional – profit. The company could easily and accurately tell how well it was doing, and, within the constraints discussed above, determine how well or poorly the manufacturing unit was contributing to the bottom line. Compare that to a police department that has a hypothetical three-part bottom line: reduce crime, maintain order, and protect constitutional rights. Right away, it is more difficult for the police department to know how well it is doing, because it must monitor three separate indicators, each of which may be quite hard to measure. In addition, working toward accomplishing any one of the three criteria may lead to some neglect of the others, since time and resources are always limited. Moreover, pushing hard on one may actually conflict with accomplishment of another. What is created is a tricky balancing act built on a foundation of uncertainty, since data on each of these conditions are liable to be incomplete at best.

Another important factor is that "how the police behave" (process) is of equal importance to "what the police accomplish" (outcome).

For the most part, this is not true of the fictional widget company and its manufacturing unit. The company CEO could say to the head of the manufacturing unit, "I want you to produce 1,000 widgets a day and I do not care how you do it." Certainly, there would be cost considerations, but the method by which the unit produced the widgets could be left entirely to the discretion of the manufacturing unit head. The same cannot be said in police organizations (Sunshine and Tyler 2003; Cordner 1978). A police chief might say to a police tactical unit commander, "I want you to reduce crime by 10 %," but the unspoken remainder of the message would be that it would have to be done within the budget, within the law, without interfering with the accomplishment of other important outcomes, and without upsetting the community. And it would have to look good in the next day's newspaper (or that night's blogs). The point is not simply that police organizations operate under constraints, but also that police organizations are judged as much on how they behave (their actions, efforts, and outputs) as they are on outcomes (what they accomplish). To put it another way, even though, in principle, we should want to assess organizations (and their units) as much as possible in relation to outcomes, in the case of police organizations (and their units), there are valid reasons to measure what they do in addition to what they accomplish.

Because of the nature of the police mission, it may also be important to measure performance outcomes that are not immediately obvious. To give an exaggerated example, a desired outcome might be reduction of traffic accidents and fatalities. A police organization might achieve this outcome by reducing all speed limits to 5 miles per hour and writing citations to every driver who went any faster. Merely on the basis of the specified outcome, it would seem that the organization's performance could be judged exemplary. However, there would probably be other outcomes of this brand of police performance, including greatly inhibited traffic flow, commercial trucking losses, irate drivers, and reduced police performance in relation to other outcomes, since officers would be totally consumed with traffic enforcement. The point is that measurement of police performance may sometimes need to take account of the side effects, negative effects, and unintended consequences of performance. Otherwise, false conclusions might be drawn about the effectiveness of the performance.

A useful framework for police performance measurement that incorporates a multidimensional bottom line and that also includes process and outcome dimensions was developed by Moore and Braga (2003). The framework identifies seven categories of performance that can be used to assess a police organization's overall effectiveness, as noted below. A nice feature is that the seven categories also cover some of the most likely side effects and unintended consequences of police activity, such as abuse of authority, decreased legitimacy in the eyes of the public, and excessive cost. The first four categories reflect mainly outcomes, the fifth combines outcome and output, and the last two refer to processes. These same categories can be used in assessing the performance of individual police units, particularly to determine whether they contribute to overall organizational effectiveness, recognizing that all seven dimensions may not be directly applicable to every separate unit within the organization.

- Reduce crime and victimization
- Call offenders to account
- Reduce fear and enhance personal security
- Ensure civility in public spaces (ordered liberty)
- Quality services/customer satisfaction
- Use force and authority fairly, efficiently, and effectively
- Use financial resources fairly, efficiently, and effectively

Police Unit Performance

Based on the preceding discussions, it makes the most sense to measure police unit performance in two ways: (1) measures of effort, output, and outcome directly tied to the unit's specific responsibilities, and (2) measures of the unit's performance in relation to the seven performance categories noted just above. The first set of measures is likely to be the most specific and tangible, while the second set is ultimately the most important. In other words, the number of citations issued might be a clear indication of how hard the traffic unit is (or is not) working, but what ultimately matters the most is the number of traffic crashes and fatalities (as long as the means of reducing crashes is not too draconian, as per the earlier example), an element of “ensure civility in public spaces.”

Measurement of police performance in three different types of police units is discussed below: a police district or precinct, a specialized operational unit, and a support unit. These three types of units represent the vast majority of units likely to be found in police organizations.

Police District or Precinct

Large police organizations are usually divided into districts or precincts, which are geographically based units responsible for providing a variety of police services. Districts or precincts almost always provide patrol services – preventive patrol, response to calls, community policing, and problem solving. Whether they are also responsible for other operational functions such as investigations and traffic enforcement varies. Some police organizations decentralize one or more specialized functions to the district/precinct level, while others centralize everything other than patrol at the headquarters level.

Compared to other police units, the responsibilities of a district or precinct are broad, and therefore, a variety of measures are likely to be needed to measure performance. In fact, all seven of Moore and Braga’s dimensions of police performance might be applicable. In order to assess the performance of a police district/precinct, a top police executive might want data for the following measures:

A positive feature of using this measurement approach is that it employs a breadth of measures to match the breadth of functions performed by the district/precinct unit. Also, the measures are mainly associated with outcomes, which arguably is both preferable and reasonable when focusing on a core operational unit – the district/precinct has the opportunity to reduce crime, solve crimes, make the public feel safer, and so forth, in contrast to support units that can only hope to accomplish these kinds of outcomes indirectly. Of course, the two specific measures listed for each performance dimension can certainly be debated and better measures might be identified.

One disadvantage of this measurement scheme is complexity. Fourteen measures are quite a few, and it could be argued that the tendency would be to divide the district/precinct’s attention across too many indicators, resulting in scattered rather than focused performance. This is similar to the observation that too many objectives are almost worse than none. In response, though, it must be argued that multiple indicators are necessary when functions are so broad. It then becomes the manager’s responsibility to set priorities and identify areas of performance in need of greater emphasis, based on the performance data.

This multi-measure approach contrasts sharply with Compstat, which has become the most popular method for measuring the performance of police districts/precincts, and for using performance measurement to hold commanders accountable (Henry 2002). Compstat systems typically rely on just one measure, reported crime, perhaps supplemented with information about arrests and crimes solved. Pressure is put on district/precinct commanders to reduce reported crime and to show arrests in response to any crime increases that occur. While this system has the virtue of focusing everyone’s attention on the one measure that probably does deserve the highest priority, it typically fails miserably in taking into account the full range of the police mission in a geographic area, and thus, its one measure grossly misrepresents the full performance picture. Also, the extreme emphasis on one measure creates temptations on the part of unit managers to manipulate the data in order to look better on that measure (Eterno and Silverman 2012).

Another feature of the seven-dimension, fourteen-measure framework presented above is that it does not incorporate much information on effort or outputs. It does not measure miles driven, number of arrests, or response time (or at least it does not present them as measures of unit performance). A three-part explanation can be offered. First, these measures of effort and output may simply not matter in and of themselves, but only in relation to the accomplishment of larger outcomes. A police chief probably does not care whether the public in a district is reassured by the sight of many police cars driving about, or by the sight of police officers walking about, or by the sight of police officers in the mall when they go shopping, or by their knowledge that their local officers are systematically working to solve neighborhood problems – the police chief only wants to know the degree to which the district's public is reassured.

Second, by not emphasizing some of the most traditional measures of effort and output, the framework avoids sending a mixed message about whether it is necessary to perform those kinds of activities at some specified level, in order to avoid getting in trouble. The intention is to encourage the district/precinct unit and its commanders to emphasize the achievement of important outcomes, and to give them reasonable flexibility in determining how best to do it. The measures do not discourage the use of motorized patrol, quick response, or making arrests; they just do not send a message to the district/precinct that some level of those activities is required. It will inevitably be recognized by district/precinct commanders that some level of motorized patrol is probably necessary for public reassurance, that slow response to emergencies will result in low customer satisfaction, and that too few arrests might allow crime and disorder to increase. Thus, including these kinds of measures in a district/precinct performance measurement framework is probably not necessary – they will happen regardless.

Third, the truth is that someone, somewhere in the police organization will be measuring miles driven, response times, and arrests anyway. If customer satisfaction in a district/precinct declines, the unit commander as well as his or her bosses at headquarters will want to know why, and response time data may (or may not) provide some of the explanation. Lots of effort and output data are routinely generated and stored within police organizations, and can be used to diagnose and analyze unit-level performance-related problems. The framework above simply suggests avoiding most of those types of measures for the ongoing review of unit performance, especially core operational units, such as a district or precinct, whose performance is directly tied to the accomplishment of most of the overall organization's primary missions.

Repeat Offender Unit

One type of specialized police operational unit is a repeat offender unit (Martin and Sherman 1986; Abrahamse et al. 1991). Typically, this type of unit targets repeat offenders, also called prolific offenders. The underlying rationale is that some offenders commit a disproportionate number of offenses. The earlier in such offenders' careers that police can identify, arrest, and successfully prosecute them, the quicker they come under correctional supervision (including incarceration), and therefore the fewer offenses they will be able to commit. Similarly, if offenders are released from jail or prison and resume a prolific career, the sooner police rearrest them, the fewer offenses they will be able to commit.

Police repeat offender units usually target robbers, burglars, and thieves, as these are high-volume crimes, although other types of offenders may also be targeted, and it is not uncommon for targeted offenders to commit a variety of types of crimes, to be drug offenders as well, and/or to be gang members. It is not unusual for such a unit to conduct surveillance on a suspected active robber and catch him in the act of a theft or drug purchase. Methods for targeting often include plainclothes operations, surveillance, sting operations, and the use of informants.

One other method used by repeat offender units is to conduct enhanced investigations following the arrest of offenders who qualify under "three strikes" laws as career criminals or prolific offenders (criteria vary from jurisdiction to jurisdiction), whether these offenders are arrested by the unit or by other officers in the police department. These enhanced investigations are intended to build stronger cases on the instant offense, as well as assemble the necessary documentation to prove to the court that the individual meets the eligibility criteria for an additional sentence under the three strikes law.

As described, the responsibilities of a repeat offender unit are fairly narrow, but they are directly tied to some of the overall police organization's important dimensions of performance. A framework like the following one might provide a well-rounded picture of the unit's performance.

This suggested framework includes ten measures, nine of which are within three of the seven dimensions of police performance. It does not seem reasonable to utilize measures related to reducing fear, ensuring civility, and satisfying the public when assessing the performance of a repeat offender unit, simply because the unit's functions are not tied closely enough to these outcomes. It *is* anticipated that the unit's activities might contribute to crime reduction, but care needs to be taken since such a unit is usually comprised of just a few officers/detectives – expecting the impact of their work to be detectable on the overall crime rate in the jurisdiction is somewhat unrealistic. The suggested measure focuses on the crimes not committed by the offenders who are arrested by the unit. Of course, the measure is nothing more than an estimate. But if a robber who has been committing ten robberies a year is incarcerated for 3 years, it is not too unreasonable to give the unit credit for preventing thirty robberies from occurring.

The other nine measures try to get to the heart of the repeat offender function. Reflecting the basic issues of productivity and effectiveness, they focus on whether the unit is successful in arresting, prosecuting, and convicting the repeat offenders that are targeted. Recognizing one important negative consequence of this type of strategy, they focus on whether the unit is able to operate within the law. Similarly, they focus on whether the unit is able to maintain its focus on repeat offenders, rather than broadening its criteria and making arrests of less significant offenders – experience has shown that this kind of "mission creep" often occurs, especially if the unit feels pressure to produce larger quantities of arrests in order to justify its existence. Lastly, the measures incorporate some cost criteria. These are particularly important because, again, experience has shown that repeat offender units tend to be costly on a per-arrest basis, because their tactics are personnel-intensive. However, on a per-conviction basis, or in relation to the seriousness of the offenders who are arrested, the cost of the unit's performance may be rated more favorably.

A question might be raised as to why arrests figure so prominently in the repeat offender unit's measures, when they were not suggested among the district/precinct measures. The response would be that the repeat offender unit's narrower function is directly focused on identifying and apprehending particular offenders, whereas the district/precinct's function is much broader – so much so that the number of arrests made by the district's or precinct's officers might or might not contribute positively to the achievement of its desired outcomes.

Communications Center

One type of support unit within a police organization is the communications center. This unit normally answers telephone calls to the police agency from the public, including emergency calls, and also uses the police radio system to dispatch police officers to incidents and to respond to inquiries from police officers in the field. The communications center may also be the hub for inquiries to databases on wanted persons, vehicle registrations, driver licenses, and so forth, although in many police agencies today, officers can initiate these kinds of inquiries themselves via hand-held computers or computers in their patrol cars, without requiring any assistance from dispatchers.

A police communications center does interact directly with the public, mainly via the telephone, but otherwise its performance is entirely in support of other units of the organization. Because the communication center's performance is only indirectly tied to the accomplishment of a majority of the overall organization's desired outcomes, it is not reasonable to use most of those seven categories when measuring the performance of the unit. A framework like the following, emphasizing two of the seven categories, might provide an adequate indication of the unit's performance.

This framework includes six measures, four associated with providing quality services that satisfy customers, and two related to efficient use of resources. The main emphasis is on measuring the quality of services provided to the communications center's primary clientele – members of the public who call to request assistance or seek information, and police officers who interact with dispatchers over the police radio system. The quality control assessment mentioned in the measures reflects a common practice in the communications field. Telephone conversations are routinely recorded, and a sample is later reviewed, either by supervisors or quality assurance specialists, using a standard rubric.

Comparisons, Benchmarks, and Standards

This entry has focused mainly on measuring police unit performance, but a brief discussion of analysis and interpretation of the measures is in order. A few of the measures identified above are meaningful on their face, such as the percent of the unit budget expended, which is expected to be 100 % or less. If it exceeds 100 %, the unit manager would likely be required to explain why the budget was exceeded. Any subsequent action would probably depend on the explanation.

Most of the measures of police unit performance become meaningful through comparison. As an example, 75 % of the recipients of police service in a police district/precinct might report that they were satisfied with the services they received, or 75 % might report that the officer treated them with respect (the specific survey items used to measure customer satisfaction are likely to vary from one organization to another). The question then arises, is 75 % a good score? Does it indicate that police performance in the district/precinct is excellent, satisfactory, or in need of improvement? Without any additional context, we would likely conclude that performance is fairly good, but not fantastic. But interpretation could become much more meaningful by making two types of comparisons: (1) comparison to all the other districts/precincts in the same police organization, and (2) comparison to previous reporting periods (years, in most cases). Such comparisons would reveal whether the public's satisfaction with police services received in the district/precinct is higher, about the same, or lower than in other districts, and also whether it is improving, staying the same, or declining over time. These kinds of simple comparisons typically add a great deal of meaning to most of the unit performance measures described above.

A third type of comparison is external. Comparing performance in one police department to others is usually done at the organizational level, such as comparing crime rates and clearance rates. Particularly when scores on performance measures are published, they can serve as benchmarks to which a police organization can easily compare itself. This becomes somewhat more challenging at the police unit level, in part because such data are rarely published, and in part because similarly named units in two different police departments may not actually perform the same duties or have comparable resources devoted to the functions. Nevertheless, a police communications center, for example, could identify other police agencies that also measure the proportion of incoming emergency calls answered within three rings, or even participate in a consortium of agencies that agree to collect data on the same unit performance measures. Establishing a system that enables such external comparisons of performance would be very valuable for the police communications center manager, allowing she or he to gauge much more accurately how well the unit is performing, and which aspects of performance might be most in need of improvement. Naturally, this kind of performance information would also be extremely useful for higher-level executives who, otherwise, would have a difficult time determining whether their department's communications center is performing as well as it should.

An additional form of comparison is sometimes available when recognized standards of performance have been established. Within a police organization, for example, a standard of three minutes or less might be established for average response time to high-priority calls. This might be an organization-wide standard monitored monthly or annually, but it could also be applied to districts/precincts. When a performance measure includes such a standard, a message is sent to unit managers that they should allocate their resources and direct their personnel in such a way that the standard is met. If a unit does not meet such a standard, its manager knows that a convincing explanation will be expected, and in fact, the manager should be able to point to efforts made to meet the standard, and should have notified his or her superiors in advance that the unit was at risk of not meeting the standard.

External standards of police performance are potentially the most powerful, but they are rarely available. A standard-setting body does exist, the Commission on Accreditation for Law Enforcement Agencies (CALEA). However, the commission's standards primarily address administrative processes rather than true performance standards. For example, a CALEA standard requires periodic audits and inventories of evidence and property under the control of the police agency. The standard has some specific requirements, such as a minimum of an annual audit and a required audit whenever a new person is assigned to the position of property custodian. But the standard does not specify that the audit must be able to account for 100 %, or 99 %, or 95 % of the evidence and property that is supposed to be in storage. Similarly, a standard specifies that "if the agency participates in a tactical team, the agency requires that all personnel assigned to the team engage in training and readiness exercises." CALEA standards do not specify how much training, though, nor do they set any kind of standard for the tactical team's actual performance.

Despite the general lack of external performance standards for police units, it is practical and feasible for a police organization to establish a robust system for measuring the performance of its subunits, as described in this entry. Certainly there are challenges to both measurement and interpretation, but establishment of such a system is essential for effective police administration, accountability, reform, and ultimately, for the delivery of quality services and adequate protection to the public.

Measuring Wrongful Convictions

Marvin Zalman
Department of Criminal Justice, Wayne State University, Detroit, MI, USA

Overview

Measuring wrongful convictions includes counting exonerations, estimating the incidence of wrongful convictions, and measuring the correlates of wrongful convictions in known exoneration cases. Measuring wrongful convictions is an important task because it can be used to evaluate the inaccuracy and unfairness of the criminal justice system.

A wrongful conviction is a conviction that is factually inaccurate, that is, the wrong person was convicted or a person was convicted for a crime that did not occur. An actual innocence exoneration is an official act that erases the legal status of guilt based on a judgment of factual innocence.

Wrongful convictions are inherently difficult to establish because they are "invisible" when they occur, the process of reconstructing equivocal evidence that led to a conviction in the first place is difficult, and prosecutors and courts are resistant to opening old convictions.

Lists of exonerations are not kept by government agencies but by private organizations like the Innocence Project and the National Registry of Exonerations.

Quantitative studies of wrongful death penalty convictions estimate that about three in 100 defendants sentenced to die are factually innocent. Qualitative estimates of wrongful convictions among all felonies, based on descriptions of the quality of criminal justice and other factors, plausibly conclude that at least 1 % of all felony convictions are factually inaccurate.

Studies of exoneration cases show that such factors as eyewitness misidentification, police tunnel vision, false confessions, informants' deception, erroneous forensic evidence, and misconduct and incompetence by prosecutors and defense attorneys occur in wrongful conviction cases in significant quantities.

Introduction

This entry discusses the measurement of wrongful convictions occurring in the United States. Two types of measurement are discussed: (1) the number and rates of factually wrongful convictions and (2) measures of the factors (correlates) discovered in such cases. Measuring the number of wrongful convictions is divided into counting wrongful convictions and estimating their rates.

Inaccurate convictions are indicative of an improperly functioning criminal justice system. Convicting factually innocent people means that the process is not effective or efficient.

More important, convicting the innocent is an injustice that every legal system wishes to avoid. Knowing something about such cases, including their overall numbers and correlates, is necessary to decide whether the problem requires a policy response and, if so, how to respond.

It should be noted that "false acquittals," when juries acquit defendants who in fact committed criminal acts with the requisite criminal intent, are also injustices. As both kinds of errors of justice may stem from operational flaws and informational deficiencies in the criminal justice process, research on measuring and correcting wrongful convictions should help reduce wrongful acquittals. Although a large number of factually guilty people are never convicted of crimes, such "errors of impunity" mostly result from crimes never being discovered or reported in the first place and other deficiencies of police agencies (Forst 2004). Such injustice is not usually related to the kinds of justice system processing errors that lead to wrongful convictions or acquittals.

The terms prevalence and incidence, used in medicine and epidemiology, which are sometimes confused, have been used to describe rates of wrongful convictions. Prevalence is an epidemiological measure of the existence of a disease or condition in a population and is calculated by dividing the number of persons with a disease or condition at a particular time by the number of individuals examined. Incidence measures the rate of occurrence of new cases and is calculated as the number of new cases of a disease or condition in a specified time period (usually a year) divided by the size of the population under consideration who are initially disease free. Both measures can be expressed as rates (Crichton 2000). It makes some sense to measure the prevalence of wrongfully convicted *prisoners*, but the more useful measure of wrongful conviction rates for the purpose of assessing the criminal justice process is the incidence that occurs in a year.

Defining and Measuring Wrongful Convictions

To measure a social category, it must be defined. Wrongful conviction can mean different things. A conviction can be wrong and reversed on appeal because it was obtained on the basis of a serious violation of the defendant's procedural or constitutional rights. Such a conviction is wrongful in the procedural or legal sense. A conviction can also be wrong because a jury was mistaken about a defendant's culpability, as, for example, regarding a self-defense claim. In this entry, a wrongful conviction means actual or factual innocence. This occurs when a crime was committed and the person convicted had nothing to do with it (i.e., the "wrong person" scenario, where a jury erroneously discounted an alibi), or no crime was committed, but a court imputed criminal liability (Risinger 2007). The latter situation has occurred in cases involving fire-related deaths and the deaths of infants, where guilt was wrongfully based, respectively, on erroneous technical or medical evidence about arson or shaken baby syndrome. The term false conviction is a synonym for convictions that are wrongful in the factual sense. Scholars agree that false convictions should be included in measurements of factual innocence. There is some uncertainty about whether cases that are wrongful in the culpability sense should be included in the measurement of wrongful convictions.

A measurable entity "must be identifiable by some means and identified by us. And we must know something about its properties and behavior, so that we can relate these to our measures of it" (Gorard 2010:390). This insight raises the question of what exactly is meant by a "conviction," as a wrongful conviction presupposes a conviction. A conviction is an official decision that is formally entered in the record of a politically legitimate entity following a process of investigation, prosecution, and adjudication. The process leading to a conviction involves many actors and subprocesses and can be brief and routinized or very complex.

A conviction, therefore, is a socially constructed artifact. As a result, a wrongful conviction simply does not "exist" but is itself a socially constructed artifact that comes at the end of a process of deconstructing a prior conviction. The process of deconstruction can be done by a private entity (e.g., journalist, legal scholar, social scientist, or research group), resulting in an unofficial judgment of a false conviction. The process can also be accomplished by an official body, resulting in an official exoneration. Understanding the process by which a conviction (and therefore a wrongful conviction) is produced allows researchers to not only count them but also to measure the factors present that may logically have led to the erroneous verdict.

The definition of a false conviction raises several difficulties. The inherent limitations of proof in the absence of incontrovertible evidence have led to the standard of conviction "beyond a reasonable doubt." This means that a conviction might be false and that, concomitantly, an acquittal might also be false. Lingering uncertainty about the relationship between legal and factual guilt or innocence provides an initial basis for exploring whether some convictions are false, especially when non-DNA exonerations are compared to DNA exonerations. To avoid this difficulty, some enumerations of wrongful convictions or exonerations either apply or claim to apply "objective" standards. However, in some cases (e.g., an acquittal in a retrial of a case after a successful appeal), the "objective" *legal* acquittal can raise the same lingering uncertainty as an initial acquittal regarding factual innocence. This suggests that some level of judgment about case facts (similar to the *judgment* leading to a conviction, but not similar to the *process* of jury deliberation) is necessary to generate a conclusion that a conviction was false and that the exoneree is factually innocent.

Another issue is that some person or institution must define whether a conviction was wrongful. The standard applied by the particular writer or research group, or by a governmental body, must be examined to determine how it defines a wrongful conviction; the goals and organizational imperatives of the decision-making person or body should also be considered. This will be considered below in the section on "Counting Wrongful Convictions."

A clear distinction must be drawn between exonerations and wrongful convictions. In common usage, the terms are sometimes employed interchangeably. An exoneration is an official act by a judge or governmental officer that erases the legal status of guilt previously imposed on a person. Researchers listed four kinds of exonerations: pardons issued by governors or other executive officers based on evidence of innocence; cases dismissed by courts after new evidence of innocence, like DNA, is presented; acquittals in retrials, but only if the basis is evidence that the defendant had no role in the crime; and a few cases where states posthumously acknowledged the innocence of defendants who had died in prison (Gross et al. 2005). This definition of exonerations includes both objective and subjective or judgmental elements. Exonerations may also be issued by official bodies with jurisdiction to determine the amounts of compensation for wrongful convictions or to declare a status of innocence (discussed below).

Official exonerations are a subset of a larger number of cases identified as wrongful convictions by authors, research scholars, and private organizations, often as a result of exhaustive research. Unless an official body declares that a conviction was wrongful, and as a matter of law erases the conviction, the wrongful conviction cannot properly or legally be called an exoneration. This is so even if the judgment that a false conviction occurred is based on ample and powerful supporting evidence. Indeed, prosecutors in some cases in which a prisoner won an appeal and is facing retrial will offer to dismiss the case if the prisoner, facing the risk of reconviction, pleads guilty to a lesser crime and is released for time served. This allows prosecutors to claim that the prisoner was actually guilty in the face of contrary evidence, thereby saving face and avoiding a lawsuit against police and prosecutors. Such action depresses and distorts the number of justifiable exonerations.

A more controversial point, addressed in the section on "Estimating Wrongful Convictions," is that known exonerations and wrongful convictions are a minor subset of all wrongful convictions. This is plausible, considering that social measurements, including the United States census and official crime data, tend to undercount the phenomenon being measured (Loftin and McDowall 2010).

The Inherent Difficulty of Measuring Wrongful Conviction

Whether data about wrongful convictions are collected by researchers or potentially by government agencies, the task is inherently difficult. In most jurisdictions, there is no routine legal mechanism to review prior convictions for the possibility that they were factually erroneous, although this is beginning to change (discussed below). Moreover, a wrongful conviction is invisible when it occurs. Miscarriages of justice are typically uncovered years after they occur and only after arduous investigations on behalf of prisoners by friends and relatives or by innocence projects. They are often discovered by chance, as when a forensic analyst happens to save biological evidence samples (when to do so is not standard procedure), which later provide exonerating DNA profiles. As a result, although lists of wrongful convictions have been collected by several organizations, it is not possible to relate them to the context of similar cases that occurred at the same time. This makes it close to impossible to directly measure the incidence of wrongful convictions (Gross and O'Brien 2008).

Another difficulty in establishing that a conviction was false is that many cases have equivocal evidence, and determining whether the conviction was accurate in the first place requires an element of judgment. As a result, convictions that are deemed false by many will be disputed by others. Additionally, the limited resources of innocence projects and their high standards in accepting cases, other attendant costs of seeking exonerations, and the general reluctance or opposition of government agencies to open closed cases inevitably mean that many wrongful convictions will never be uncovered.

Innocence scholars and critics generally agree that it is impossible to precisely measure the incidence of false convictions (Schehr 2005). This understanding has led some to opine that the number of such miscarriages of justice is minuscule (Marquis 2006; Hoffman 2007). No writer now suggests that wrongful convictions never occur, acknowledging at least the accuracy of the Innocence Project's list of DNA exonerations (Innocence Project n.d.). Analysts who closely study wrongful convictions, however, assert with confidence that the small number of known DNA and non-DNA exonerations are indicative of much larger numbers of false convictions (Gross et al. 2005; Garrett 2011).

Government Institutions That Establish Actual Innocence

The traditional methods of establishing official exonerations – pardon, judicial dismissal, and acquittal after a reversal – are ambiguous. These methods may exonerate former and current prisoners for legal or humanitarian reasons, rather than on account of factual innocence. Even if raw counts of such decisions were kept, the records that underlie the decisions would have to be inspected to determine if the ground was actual innocence. In addition to these modalities, courts and agencies given the authority to grant state compensation for wrongful convictions have the potential to keep and publish records of false convictions. The federal government has had a compensation law since 1938, and awards are made by the United States Court of Federal Claims. In recent years, the number of states that authorize compensation for wrongful conviction has grown to twenty-seven (Norris 2011).

Nevertheless, some recent compensation statutes set very high standards of proof and include numerous disqualifications that may deny compensation and, by implication, a finding of innocence to claimants with justifiable wrongful conviction cases (Norris 2011). For example, James Richardson had been exonerated by Florida for murder in 1989 in a special proceeding in which Janet Reno, later Attorney General of the United States, was appointed a special prosecutor. She moved to dismiss his prosecution on a nolle prosse in a memorandum which concluded that he was "probably wrongfully accused." When Florida enacted the Victims of Wrongful Incarceration Compensation Act in 2009, Richardson petitioned for compensation, but was denied because the nolle prosse did not establish by clear and convincing evidence that he was actually innocent. The anomalous situation of one state institution exonerating a person and another institution of the same state not exonerating the person for the same crime can play havoc with clarity in determining the existence of exonerations and wrongful convictions (Zalman 2012).

Several states have, by statute, authorized courts or other agents to declare convicted persons actually innocent. In 2001, Virginia authorized its Supreme Court to issue writs of actual innocence based on biological evidence and in 2004 authorized the issuance of such writs on the basis of nonbiological evidence. North Carolina established an Innocence Inquiry Commission in 2006 to investigate petitions by prisoners and where it finds sufficient evidence of actual innocence to refer such cases to a superior court for a three-judge trial to determine actual innocence. In 2008, Illinois authorized circuit courts to issue certificates of innocence to petitioners who can prove their innocence on a preponderance of the evidence. In that year, Utah also established a procedure allowing district courts to find a person factually innocent. Several states, including Illinois and Texas, now have provisions for governors or pardon boards to issue pardons based on innocence.

Courts typically do not keep accessible records that are useful to the public or the research community, and records of findings of actual innocence will be no different. Innocence issues, however, are now visible to such organizations as the National Registry of Exonerations (n.d.) and Justice Denied (n.d.), making it more likely that exonerations announced under new state compensation laws and declaration-of-innocence procedures by court and pardon boards will be tracked and listed.

Counting Wrongful Convictions

No government agency or court maintains an accessible list of exonerations, although several have the authority to issue exonerations. Most information on wrongful convictions, including counts, has been produced by journalists, writers, researchers, and organizations.

Big Picture Books. Beginning with Borchard's 1932 book, *Convicting the Innocent*, a number of "big picture books" (Leo 2005) detailed cases of exonerations, describing the factors that appeared to be sources of the miscarriages of justice. Borchard listed 65 cases, most of which had occurred within a decade or two of the book's publication. Although he was a law professor, Borchard wrote a journalistic book designed to arouse popular concern. His goal was to firmly establish that wrongful convictions can and do occur. He used the book to successfully lobby for the passage of a federal compensation law for exonerees. His list of 65 exonerations (most were American, a few were English) was the first such compilation. The number grew as other similar books have been published since the 1950s (Frank and Frank 1957; Yant 1991). In addition, scores of books, typically written for a popular audience, have been written about single wrongful conviction cases. They provide a wealth of detailed information about wrongful convictions but typically do not relate the information to a growing body of wrongful conviction scholarship (Leo 2005).

Scheck et al. (2000), a popular and influential book describing DNA exonerations obtained by the Innocence Project in the 1990s, focused on factors related to wrongful convictions. An appendix provides data on 74 false convictions, including jurisdiction, twelve causal factors, length of maximum sentence, time served before exoneration, the number of mistaken witnesses per case, and the race of the crime victims and the exonerated defendants.

Scholarly Lists and Evaluations. Rattner (1988) analyzed 205 "old and new legal cases" of wrongful conviction occurring in the United States after 1900 "derived from books, documents, and newspaper clippings." Most of the cases had been previously described in big picture books, supplemented with more recent news reports. Most resulted in legal exonerations (three were paroled, and data was missing for 15). In 40.5 % of the cases, the real culprit was apprehended. The violent crimes of murder, robbery, and rape accounted for 87 % of the convictions. Rattner described the distribution of sentences (45.8 % of the known sentences were death or life in prison) and the types of error associated with the wrongful convictions (52 % of the cases with known or listed errors included eyewitness identification error).

Gross (1987) assembled 136 cases of misidentification that led to criminal prosecution in the twentieth century. The cases were divided between those occurring before and after the Supreme Court's lineup decision (U.S. v. Wade 1967). The pre-Wade cases were accounts of convictions derived from the big picture books, while the post-Wade cases were derived from news accounts. Thirty-nine cases, mostly from the post-Wade set, did not result in convictions. Gross used the cases to describe the processes of misidentification and exoneration and to describe historical trends in case processing.

Bedau and Radelet (1987) enumerated 350 capital or potentially capital murder or rape convictions imposed in the twentieth century believed to have been factually erroneous. The list was based on evaluations of the case facts in which the scholars exercised their judgment to conclude that either no crime occurred or the defendant was legally and physically uninvolved in the crime. The article listed the jurisdiction, date, crime of conviction and type of sentence, the primary evidence for the judgment that the conviction was false, and the factors associated with the erroneous convictions.

Gross et al. (2005) scoured many sources to identify 340 official exonerations occurring in the DNA era – for the years 1989–2003. More than half, 57.6 %, were non-DNA exonerations. The vast majority were convicted by trial rather than by plea, and all but 14 cases were convictions for murder or rape. The authors suggested that the fortuitous nature of exoneration must have excluded many robbery cases based on faulty eyewitness identification. They excluded two and possibly three "mass exoneration" cases in which corrupt police planted evidence on innocent people, followed, after discovery, by the exoneration of masses of such people. They also excluded from the exoneration count pending cases, pleas of guilty or no contest where evidence of innocence was strong, inexplicable failures to exonerate people who were patently innocent, and people falsely convicted in the child care sex abuse and satanic ritual cases that swept through America in the 1980s and 1990s.

Organizational Lists. The Death Penalty Information Center (n.d.) (DPIC) maintains an on-line list of exonerated death row inmates since the reinstatement of capital punishment in 1976. The number was 142 as of March 2013. The list includes name, state of conviction, race, year convicted and exonerated, number of years served, the reason for exoneration, and whether it was a DNA exoneration. The DPIC applies an objective standard of legal innocence, which means that a few of the exonerees may have been factually guilty, although wrongful conviction scholarship has established the actual innocence of many.

The Innocence Project (n.d.), affiliated with the Benjamin Cardozo Law School of Yeshiva University, is a self-described "national litigation and public policy organization dedicated to exonerating wrongfully convicted individuals through DNA testing and reforming the criminal justice system to prevent future injustice." It lists the number of DNA exonerations that have been obtained in the United States since 1989 on its website home page. As of March 2013, the number stood at 303. An accessible list includes each exoneree, the state and years of conviction and release, and a link to a page of more detailed information, including whether the real perpetrator was found, contributing causes, and whether compensation was awarded. This list is frequently cited and is so prominent that some conflate the number of DNA exonerations with the total number of exonerations. This may result from the fact that until recently there has been no other prominent and easily referenced source of total exonerations. Furthermore, DNA exonerations are viewed as virtually incontrovertible, while non-DNA exonerations can be subject to some levels of doubt.

The National Registry of Exonerations (n.d.) (NRE), launched in the spring of 2012, is a joint product of the University of Michigan Law School and the Center on Wrongful Convictions (CWC) at the Bluhm Legal Clinic of Northwestern University School of Law. Its exoneration list, numbering more than 1,060 in early 2013, was drawn from raw lists kept by CWC, the data collected by Gross et al. (2005), the Innocence Project (n.d.), and other sources. It relies on the methodology pioneered by Gross et al. (2005). Each case is reviewed by staff to meet the criteria for exonerations based on actual innocence. For each exoneree, data include county and state of conviction; federal jurisdictions; most serious crime; additional conviction; year of crime; conviction and exoneration; exoneree's sentence, race, sex, and age at conviction; whether DNA exoneration or not; and contributing factors: mistaken eyewitness identification, false confession, perjury or false accusation, false or misleading forensic evidence, official misconduct, and inadequate legal defense. Clicking on the exoneree's name displays a few pages listing relevant data items and providing a narrative account of the case. Some narratives are by named authors.

Forejustice.org (n.d.) maintains a searchable database of the wrongly convicted that as of early 2012 included 3,310 exonerated people from 98 countries. The list can be searched by last name of the party or by location. Searching by location allows a search by American state and federal cases. Each name links to a page that lists years imprisoned, the charge, sentence, year convicted and cleared, location of trial, result, and case summary. Each page provides such sources of information as news articles and legal cases with citations and/or links and books. The listed cases are legal exonerations that include miscarriages of justice that cannot always be classified as cases of factual innocence. Forejustice.org is closely related to Justice Denied (n.d.), a volunteer group that publishes *Justice Denied* magazine in paper and on-line, which "publicizes cases of wrongful conviction, and exposes how and why they occur."

These lists provide a wealth of raw information about miscarriages of justice. The Innocence Project list is widely cited because it provides a "gold standard" of DNA cases that establish wrongful convictions with little doubt of error. The DPIC list focuses exclusively on death sentence exonerations and is often consulted given the prominence of the death penalty issue. The NRE has the potential of becoming the authoritative source for known DNA and non-DNA exonerations in the United States. The Justice Denied list is accessible and useful for gaining a quick overview of the scope of the numbers of wrongful convictions in the United States and other countries. None of the on-line lists are in formats that allow for quantitative analysis by researchers, although they are useful starting points for scholars wishing to explore the cases more systematically.

Estimating Wrongful Convictions

The fortuitous nature of obtaining exonerations means that counting and cataloging them can never amount to a "census" of all exoneration, let alone of all wrongful convictions that occur in a year. As a result, the incidence of wrongful convictions can only be estimated. In the alternative to estimating, many writers simply assume that the number of wrongful convictions is large enough to constitute a policy issue. Two kinds of estimates have been generated: precise quantitative estimates and qualitative estimates.

Precise Estimates. Poveda (2001) estimated a wrongful conviction rate of 1.4 % for released New York inmates convicted of murder based on (1) an official 1989 New York state study establishing that 21.2 % of inmates committed for murder were granted new trials, (2) the fact that 21.2 % of murder inmates whose cases were discharged by new trials in 1995 were discharged for substantial error, and (3) the assumption that these discharges, constituting 1.4 % of all murder commitments to New York prisons in 1992, were actually innocent.

Risinger (2007) established a wrongful conviction rate for rape-murder death sentences based on eleven DNA exonerations for rape-murder convictions occurring between 1982 and 1989. The numerator was set at 10.5 to produce a conservative estimate. The denominator of 319 was determined by finding (and listing) those individuals sentenced to death for rape-murders in the same time frame when the exonerees were convicted, discounted by the rate of similar cases where no usable DNA was available. This resulted in a wrongful conviction rate of 3.3 % (or 2 % before discounting the denominator for cases in the same period for which no usable DNA was available). Risinger also speculated that in some rape-murder cases the facts of guilt were so clear that DNA testing was not requested, which would further deflate the denominator of rape-murder death sentences consistent with the 11 (or 10½) exonerees, possibly yielding a maximum exoneration rate for this crime of 5 %. Risinger asserted the highly plausible conjecture that rates of wrongful convictions are unevenly distributed.

Gross and O'Brien (2008) examined 2,394 death sentences pronounced in US courts from 1973 to 1984. By 2004, the process of identifying exonerations for these cases had run their course. Fifty-four had been exonerated – a rate of 2.3 %. They then calculated the exoneration rate as of 2004 for those sentenced to death through 1989, again finding a rate of 2.3 % (86/3792). They then assessed the relation between capital exoneration and wrongful conviction rates among those sentences to death. Some capital defendants who were innocent may not have been exonerated because they did not participate in the arduous exoneration process or because they were executed, died from other causes, or had their sentences commuted to life terms (which reduces the pressure on innocence projects or others to seek their exoneration). It is possible that some among the exonerated participated in the murders for which they were convicted. Nevertheless, Gross and O'Brien estimate that the probability of innocence is very high for capital exonerees and the number of misclassifications low enough for the capital exoneration figure (2.3 %) to stand as a proxy for false death sentences of the actually innocent.

Roman et al. (2012) examined an unbiased cohort of 634 Virginia post-conviction sexual assault and/or homicide cases with DNA evidence resulting in 715 convictions, dating from 1973 to 1987. In 5.3 % of the cases, the offender was eliminated as a source of DNA, and the DNA exclusion was accompanied with probative evidence that appeared to support exoneration. In another 2.5 % of the cases, the offender was eliminated as a source of DNA, but the exclusion was not accompanied with probative exoneration evidence. This is the strongest empirical evidence to date that establishes the existence of a substantial proportion of wrongful convictions in a sample of *general* cases, rather than in group of cases that were targeted because they appeared to be miscarriages of justice.

General Estimates. Death sentence data tracked by the government and private groups are unusual in providing precise numbers of capital sentences, exonerations, and other case disposition information. This allows precise estimates of exonerations and wrongful convictions for this tiny fraction of the approximately one million felony convictions handed down by courts annually. The lack of precise or easily accessible data from court records makes it impossible to estimate wrongful felony conviction levels in the way that has been accomplished with capital sentences. In the absence of any general estimate, many wrongful conviction writings, especially by legal scholars, simply assume that the number is sufficiently large to constitute a problem needing to be addressed.

Huff et al. (1986) surveyed the opinions of state attorneys general and Ohio justice officials and defense lawyers about the annual incidence of wrongful conviction. Their estimates in the mid-1980s ranged from never (5.6 % of respondents) to less than 1 % (71.8 %), to 1–5 % (20.3 %), and to 6–10 % (2.3 %). The authors suggested that if an overall estimate of 0.5 % was accurate, it would mean more than 5,000 wrongful convictions occur each year. Observers have noted that these estimates are essentially guesses. Huff et al., however, did not assert that these estimates are a precise measure of wrongful convictions, but rather that the broader sampling of expert opinion provided some boundaries for the authors' *own* estimate of wrongful conviction incidence.

Ramsey and Frank (2007) updated and replicated Huff et al. (1986) with a sample of Ohio justice officials and defense lawyers reporting their beliefs about the frequency of wrongful convictions. Their modal response, taken as a whole, was that such error occurred in less than 0.5 % of cases in their own jurisdiction and in 1–3 % of cases in the United States. Defense attorneys reported higher estimates and police and prosecutors lower estimates, with the estimates of judges lying between. Zalman et al. (2008) replicated Ramsey and Frank's study and reported very similar opinions for Michigan officials. Neither survey claimed that officials' estimates were precise measures of wrongful convictions. Zalman et al. (2011) conducted a general residents' survey in Michigan at the time of their survey of experts and found that among the general population in 2005, the modal category of believed wrongful conviction incidence was 4–5 % and that 61 % of respondents believed that wrongful convictions occurred in between 4 % and 10 % of all felony convictions.

Zalman (2012) provided his own qualitative estimate of wrongful convictions for all felony convictions generally in the United States at a *minimum* of 0.5–1 %. The qualitative estimate was based primarily on a review of descriptive literature showing widespread defects in the quality of criminal case processing throughout the United States, supplemented by information provided by the precise death penalty wrongful conviction estimates (about 3 %), the validity of qualitative estimation techniques, and the approximations of officials, which are lower than estimates provided by residents in a statewide opinion survey (Zalman et al. 2011). Zalman (2012) concluded that a lower estimate than 0.5 % was highly implausible and that a higher general wrongful conviction rate of 2–3 % was possible, but less plausible than the lower rate. A 1 % wrongful conviction incidence rate would mean that about 10,000 wrongful convictions occur each year in the United States and that about 4,000 of those cases would result in prison sentences.

Estimates of the incidence of wrongful conviction have been contested by critical scholars and criminal justice system personnel who argue that in the absence of firm quantitative data, it can be assumed that decisions made by criminal justice system actors are virtually flawless. Controversy about wrongful conviction rates is not unique to criminal justice. As soon as a social problem becomes a political issue, legislators begin asking for numbers. It then becomes important to distinguish between scientific numbers and political numbers (Jencks 1994). Scholars who study child sexual abuse, for instance, report that there are probably more incentives to hide facts than to reveal them (Tucker and Cheit 2010). Some critical scholars and officials may compare qualitative wrongful conviction estimates to the seeming precision of crime statistics, without being aware of the many difficulties that accompany the development and interpretation of official crime data (Loftin and McDowall 2010). The nature of wrongful convictions and the inherent difficulty of finding them, however, make any attempt to generate a precise quantitative national estimate impossible.

Measuring the Correlates of Wrongful Convictions

What is known about wrongful convictions is derived from the cases that were discovered by various authors, researchers, and organizations, which then analyzed and catalogued them. Virtually every author or organization identified in the section on "Counting Wrongful Convictions," and many others, has described the factors associated with false convictions and typically has tallied the frequency with which the correlates of wrongful conviction have occurred.

It is as or more important to measure the correlates of false convictions by deconstructing the original conviction than simply to tally up a case and place it on a wrongful conviction or exoneration list. Examining the facts of a case to determine whether it led to the conviction of an innocent person proceeds simultaneously with determining what factors – errors in an investigation, prosecution, or adjudication – might have been responsible for the miscarriage of justice. Most wrongful conviction studies focus on these correlates. The most prominent sources of wrongful conviction, according to many sources, include eyewitness misidentification combined with suggestive lineup procedures, police tunnel vision that leads investigators to overlook exculpatory evidence, false confessions, reliance on informants and other witnesses who lie, erroneous forensic evidence (as a result of substandard laboratories, use of highly unreliable techniques or judgment errors, and deliberate falsehoods by forensic examiners), prosecutorial error and misconduct (especially the failure to divulge exculpatory evidence to the defense), ineffective assistance of defendant counsel, and such trial errors as misleading forensic science testimony and erroneous or biased judicial evidentiary rulings.

Although the correlates are often called *causes* of wrongful convictions, they cannot be deemed causal factors in a scientific sense (Gould and Leo 2010). Many errors such as misidentifications or false confessions occur in cases that do not result in convictions (Gross 1987; Drizin and Leo 2004). A handful of studies have compared samples of wrongful convictions to other convictions and have found some of the usual factors to be statistically associated with wrongful convictions but not others (Harmon 2001; Harmon and Lofquist 2005; Garrett 2008; Gross and O'Brien 2008). Because of the difficulty of matching wrongful conviction cases, which are discovered episodically and often by chance, with a cohort of similar, purportedly accurate convictions, this kind of research is arduous. Nevertheless, such measurements of wrongful convictions are research paths that ought to be pursued by criminologists (Leo 2005).

Another serious limit of false conviction-correlate accounts is that they overgeneralize their findings. For example, many writings claim that eyewitness identification error is the most common wrongful conviction correlated factor. The factors that are discerned in false conviction cases are dependent on the fortuitous discovery of exonerations and wrongful convictions and their unsystematic inclusion in a database. Studies identifying the frequency of correlates should be limited to the particular source of cases and not be extended to wrongful convictions generally. This is recognized by researchers who are aware of the unusual circumstances by which particular groups of cases come into being. Both Garrett (2011), analyzing the first 250 DNA exonerations listed by the Innocence Project, and Gross et al. (2005), analyzing 340 exonerations they discovered, have noted that the cases were an extremely unrepresentative sample of convictions. Almost all resulted from jury trials, whereas more than 95 % of convictions are obtained by guilty pleas. Their samples were almost entirely murder and rape cases, which constitute less than 1 % of all convictions. Thus, Garrett (2011) reports that flawed eyewitness evidence is found in 88 % of his sample, while the 2005 sample of Gross et al. reports such error in 50 % the murder cases and 88 % of the rape cases. Gross (2011) compared the correlates of his expanded exoneration list to the smaller percentage of murder and rape cases found in Gross et al. (2005) or Garrett (2011) and indicated that the proportionate list of correlates has changed. Covey (2011) studied the correlates in two sets of "mass exoneration cases" (which were acknowledged by Gross et al. (2005) and Gross (2011) but were not included in those exoneration lists). Covey discovered that the correlates of error in the wrongful conviction cases among the mass exonerations, virtually all of which were drug or gun possession convictions, were perjury and false confessions, with misidentification playing no role in those wrongful convictions.

Conclusion

The measurement of wrongful convictions is a question asked by all who study the subject (Gross 2008). Providing an answer to a general "how many" question is not easy. The inherent difficulties in discovering wrongful convictions, and governmental resistance and/or inability to identify and list them, hobble a more complete understanding. Nevertheless, precise estimates of wrongful death sentences, combined with a sound overview of the problems within the criminal justice process, lead to a conclusion that the numbers are more than minuscule.

Studies of individual wrongful convictions and lists of miscarriages of justice provide a wealth of information about how they occur, how they are discovered and exonerated, and what factors are correlated with them. A large number of studies by psychologists, legal scholars, and forensic experts are exploring ways to correct criminal justice processing errors, whether or not they directly cause wrongful convictions. Viewing the correlates of wrongful convictions as likely sources of these miscarriages of justice, however, is a sound conjecture. Criminologists can contribute to this research by applying the tools of social science to advance the study of the correlates and causes of wrongful convictions and the relationships among correlates and to more systematically study wrongful convictions in order to clarify our understanding of why errors of justice occur and how to correct them.

Overview

Mental health disorders are overrepresented within United States prison systems. Available national statistics show that nearly one quarter of state prisoners had received a clinical diagnosis or treatment within a 12-month period; when prisoners with symptoms of a mental disorder were also included, 56 % of state prisoners were defined as having a mental health problem (James and Glaze 2006 4). This alarming overrepresentation has been linked to the deinstitutionalization of mental care facilities and the lack of creation of outpatient services to fill the void created by their dismantling. Some of these mentally ill individuals that have fallen through the cracks of the health-care system have instead been swept up by the criminal justice system, in many cases for offenses related to the lack of treatment for their mental illness. Once they become a part of the criminal justice system, these mentally ill individuals often receive inadequate care for their mental illness and begin a cycle of reoffending and institutionalization in which their mental health needs are never appropriately addressed. James and Glaze found that almost one in four of state prisoners or jail inmates who had a mental health problem had been incarcerated three or more times (compared to one-fifth of those without, *Id.* at 1). Their analysis of national data also documents more homelessness, substance abuse, and prior traumatic abuse for mentally ill inmates compared to other offenders, as well as less utilization of treatment for these populations within the criminal justice system. Criminal justice agencies from police to corrections are increasingly concerned about the costs associated with using the justice system as the treatment facility of last resort, a function it is rarely equipped to adequately perform.

Mental health courts (MHCs) fall under the auspice of problem-solving courts as they seek not only to reduce the number of mentally ill persons cycling through the criminal justice system but also to improve the lives of their clients by helping them cope and better manage their mental illnesses. MHCs attempt to do this by restructuring the courtroom into a cooperative work group, where defense lawyers, prosecutors, probation officers, and mental health case workers work together providing monitoring, treatment, and linkage to external mental health facilities for the court's clients. During these proceedings the judge abandons his/her traditional role as a neutral arbitrator and interpreter of the law and becomes a risk manager who relies on the expertise of the courtroom staff but has the final decision about the potential risk the court's clients pose to themselves and the public, as well as implementing treatment plans designed specifically for each client and monitoring clients (Talesh 2007).

The Nature of Mental Health Courts

While there are many ways to address the insufficient approach to mentally ill offenders, one of the most notable and popular approaches is through the adaptation of problem-solving courts, best known through the longest-running variation, the drug court. Problem-solving courts use the concept of therapeutic jurisprudence. According to Berman and Feinblatt (2001) problem-solving courts share five elements: (1) They seek tangible outcomes for victims, offenders, and society such as reduced time in hospitalization for mental illness, (2) they seek to restructure how the government responds to social problems such as drug addictions and mental illness, (3) the use of judicial authority to change behavior of litigants and solve problems, (4) the collaboration between the courts and social services, and (5) nontraditional roles for judges, attorneys, and prosecutors.

Nationally, mental health courts are one of the fastest-growing types of problem-solving courts. Examples such as the Nathaniel Project in New York and the Behavioral Health Court in San Francisco are models for innovations across the country. The first MHCs were developed in the 1990s in the United States and Canada out of grassroots movements combined with government interest in diversion (Scheider et al. 2007, 34). The growth in the United States is partially due to the availability of seed money from the federal government, including a mental health court grant program established by the America's Law Enforcement and Mental Health Project Act of 2000 (Scheider et al. 2007, 167). However, matching funds are often required and the federal start-up funds are short term, so jurisdictions must be committed to providing internal funding. The spread of MHCs is also assisted through the information sharing made possible by organizations like the Criminal Justice/Mental Health Consensus Project, coordinated by the Council of State Governments Justice Center, which releases reports and maintains a database of best practices and model programs (http://consensusproject.org/, accessed 4/12/13). The well-established Center for Court Innovation, a public/private partnership between the New York State Unified Court System and the Fund for the City of New York, includes a focus on mental illness and also provides research, expert assistance, and demonstration projects such as the Brooklyn Mental Health Court (http://www.courtinnovation.org/, accessed 5/19/12).

The Process

Although MHCs fall under the rubric of problem-solving courts, their rapid proliferation, the multiple forms they assume, and the way they operate make defining what exactly a MHC is and how it operates problematic. For example, Griffin et al. (2002) describe how MHCs use at least three different methods of disposition of criminal charges to get their clients to adhere to their treatment regime. While people may enter a MHC at different stages of the justice process (at arrest in a true diversion program or after conviction or sentencing), referral is typically initiated by the public defender's office, a judge, or a probation officer. Most programs restrict participation based on an offender's criminal record, current offense, and mental health diagnosis. Eligibility is often determined by the prosecutors, and then selection is finalized by the mental health court team itself. Although the selection and admission details vary depending on the stage and level of the criminal justice process at which the court functions (e.g., misdemeanor diversion vs. felony violation of probation), generally, if an offender with mental illness agrees to participate, he or she is read a mental health court explanation that explains the trade-offs that must be accepted in order to participate in court, including the right to contest the charges if the MHC is a pretrial diversion. Often, the judge estimates a time frame for program enrollment and provides a sense of the graduated sanctions that may be employed. Common conditions include regular contact with a probation officer, regular therapy or counseling sessions, drug and alcohol treatment, and abstinence from criminal behavior. Time frames range from a few months to a few years.

While the client is in the mental health court program, they attend regular status hearings. Before each status hearing there is a pre-court meeting of the MHC team members: the judge, the prosecutor and defense attorney, the probation officers, the treatment staff, and some support personnel. At these pre-court meetings the team members review each client's behavior, discuss the client's situation, and give recommendations to the judge regarding the disposition of each client. The clients are not present at these pre-court meetings.

The in-court status hearings resemble traditional court proceedings in some ways; they take place in a courtroom open to the public, with the judge, the prosecuting attorney, and the defense in their traditional places within the courtroom. One of the team members typically gives an account of a client's progress since the previous status hearing, the individual and the judge talk briefly, and the judge rewards, sanctions, and advises the client accordingly. The performative nature of these sessions is even more striking than in traditional court proceedings; for example, the judge often gets his/her script from the other team members prior to court ("What should I say to Ms. Smith?"), and the order of client appearances may be calculated to send a message to other participants. For example, graduations may be conducted first, to dramatize what the other participants are working towards.

Though the exact definition of what a mental health court is and how it operates is elusive, Steadman et al. (2001) put forth four basic criteria which MHCs follow: (1) All persons with mental illness identified for referral to community-based services on initial booking are handled on a single court docket, (2) a courtroom team's approach is used to arrive at recommended treatment and supervision plans with a person specifically designated as a "boundary spanner" to ensure actual linkage, (3) assurance of existing appropriate treatment slots is necessary before the judge rules, and (4) appropriate monitoring occurs under the court aegis with possible criminal sanctions for noncompliance, such as reinstituting continued charges or sentences. Redlich et al. (2005) describe a second generation of MHCs which are more likely to accept felony cases, use jail as a sanction, and offer different forms of court supervision. In 2006, Redlich et al.

conducted a comprehensive survey of all the existing MHCs, and their results supported Redlich et al. (2005) in concluding that MHCs are continuing to evolve, as well as describing additional characteristics that are common to MHCs. In a 2009 review of the literature and based upon a consultation with leading researchers and practitioners, Almquist and Dodd also found that MHCs increasingly include violent offenders and recognize the co-occurring substance abuse needs that accompany the serious mental illnesses of their clients (2009).

Empirical Results

Increasing Treatment

While the earliest work on MHCs was descriptive in nature, studies of the effectiveness of MHCs have recently begun to emerge. These studies have generally relied on outcome comparisons between a certain MHC and a similarly situated court that handles the same type of offenders but that does not follow a MHC model. The results indicate that MHCs produce favorable outcomes in both providing their clients with increased mental health care and services, as well as reducing recidivism.

Boothroyd et al. (2003), in their evaluation of the Broward misdemeanor MHC, found that the use of behavioral health services by MHC participants increased from 36 % to 53 % after enrollment, and clients were 50 % more likely to continue receiving treatment after their court appearance than defendants in the comparison group. They also found that the amount of behavior health services that MHC participants received increased by 61.6 %, while the amount of behavior health services received by those in the comparison court decreased by 18.3 %. Trupin and Richards (2003), in their evaluation of two Seattle MHCs, found that those who opted into the MHC received more treatment and access to mental health care than mentally ill offenders that opted not to participate in the MHC. Using a 12-month pre-post comparison design, Herinckx et al. (2005) found that offenders who participated in the Clark County misdemeanor MHC in Washington "received more hours of case and medication management and more days of outpatient service after enrollment" in the 12 months after enrollment as compared to the 12 months before enrollment into the program, as well as spending less time in inpatient treatment facilities (855). Keator et al. (2013) also found that participants in MHCs accessed community treatment more frequently and at a quicker pace following discharge than those who did not participate in a MHC. The preceding studies indicate that MHCs have increased the amount of treatment their clients receive, which is an important step in breaking the cycle of continually re-incarcerating mentally ill offenders. Not only do MHC participants seek out community treatment at a greater rate than those who do not participate in a MHC, but participants have greater perceptions of procedural justice than those who do not participate in a MHC (Canada and Watson 2013).

Reducing Recidivism

A recent meta-analysis performed by Sarteschi et al. (2011), which quantitatively examines a large number of MHC studies to determine a pattern of significant results, found two distinct patterns: (1) that MHCs are consistently found to reduce recidivism among participants and (2) that the majority of participants in MHCs in the United States are white males in their mid-30s. The idea that MHCs reduce recidivism for participants is important because it is one of the main goals of a MHC; this illustrates the potential success of MHCs for the misdemeanor offenders who are chosen to participate. A multisite study conducted by Steadman et al. which compared 407 MHC participants with 600 matched offenders who had no contact with MHC, similarly found that in the 18 months following entry into mental health court, the MHC group had a lower rearrest rate, fewer post-18-month arrests, and fewer post-18-month incarceration days than the comparison group (Steadman et al. 2010).

Sarteschi et al. (2011) also indicate that MHCs appear to reduce recidivism among participants. MHCs are moderately effective in curtailing subsequent criminal activity, and as expected, the reduction in recidivism is most pronounced for individuals who participate and complete the guidelines outlined by the MHC. Examining the results of the meta-analysis, it appears that the reason for the reduction in recidivism for participants who complete a MHC has to do with their GAF (Global Assessment of Functioning) scores. The successful completion of a MHC has been found to increase participants' GAF. The GAF test measures how well an individual deals with problems they encounter in their daily lives. The higher the GAF score, which ranges from 0 to 100, the lesser extent to which mental illness symptoms are present in the individual. These increased GAF scores indicate that individuals who complete a MHC are able to function to a greater degree in their daily lives and are less likely to be bothered by an unexpected problem. This could lead to a reduction in psychiatric emergency room visits for successful MHC participants, thus reducing individual and state costs, a finding supported by the meta-analysis performed by Sarteschi et al. (2011).

Specific case studies can allow for a more in-depth analysis of how MHCs can reduce recidivism. McNiel and Binder compared 170 participants in the San Francisco Behavioral Health Court to 8,067 other adults with mental disorders who were booked into an urban county jail after arrest during the same interval (2007, 1396). Based on an intent-to-treat sample (i.e., all of those who enrolled in MHC regardless of completion), both the participants and the graduates were less likely to have any new charges than the comparison groups. After 18 months, only 34 % of MHC graduates had received any new charges, compared to 56 % of the treatment comparison (*Id.*). Most strikingly, the MHC graduates evidence half the rate of violent charges when compared to the other group (just 6 % of MHC graduates were charged with violent offenses during the follow-up, compared to 13 % of the others) (*Id.*).

Examining the 12 months after enrollment in a MHC, crime rates for individuals with a severe and persistent mental illness who completed the program were four times less than individuals who did not complete a MHC program (Herinckx et al. 2005). When examining just those participants who completed the program, after 1 year approximately 55 % had no arrests and probation violations were reduced by approximately 60 % (Herinckx et al. 2005). Overall, successful completion of a MHC reduced the likelihood of rearrest by approximately 3.7 times compared to participants who do not successfully complete a MHC program (Herinckx et al. 2005). MHCs also reduced the likelihood of new charges for violent crimes, and when new charges did occur, participants in MHCs had a greater period of time between charges than those who do not participate (Herinckx et al. 2005). The examination of violence and MHCs also indicates the reduction in new charges is maintained once the MHC graduate is no longer under court supervision. In general, studies indicate that MHCs reduce recidivism for individuals who successfully complete the court-mandated guidelines by showing the participant how to deal with problems that can arise in their daily lives, which reduces psychiatric emergency room visits and costs for both the individual and the state. However, it should be noted that the reduction in recidivism might only be a result of structured follow-ups with the MHC. According to Burns et al. (2013), once the structured period of follow-up with the MHC concludes, participants may see recidivism more in-line with the average of those who did not participate in a MHC. Their conclusions are based on a MHC in northern Georgia and a comparison of completers and non-completers 2 years after involvement in the MHC. While Burns, Hiday, and Ray's results may not be representative to all MHCs, they are worth mentioning as an issue facing graduates of MHCs.

An additional cautionary note is needed here: the empirical support for mental health courts is promising, but it suffers from selection biases. No large random assignment study has been performed to date (but see Cosden et al. 2003). As McNiel and Binder explain in their study, "Although propensity weighting helps control for nonrandom assignment, it can only adjust for observed covariates, and it may not have adequately adjusted for unobserved variables that may have influenced selection into mental health court (e.g., as participants who entered mental health court voluntarily agreed to have their cases handled in mental health court rather than traditional court, it is possible that they differed in unobserved variables such as treatment motivation) (2007, 1402)." Thus, whether MHCs are helping the offenders who would likely have performed better without this intervention remains unknown.

Key Issues and Controversies

As discussed in the previous section, MHCs appear to be successful based on the empirical analyses completed to date, including the ability to successfully link participants with mental health services, reduce recidivism, reduce costs, and aid the decriminalization of individuals with less severe mental illnesses. However, this does not mean there are no controversies surrounding MHCs. Critics contend that they are coercive, ineffective when the proper mental health services are not provided, and that selection bias is present along gender and racial lines. This section discusses some of these controversies more closely.

MHCs as Reactive

The first major controversy surrounding MHCs is that they are reactive and fail to address the larger systemic and structural factors that account for the overrepresentation of the mentally ill in the criminal justice system (Leon 2007). Individuals with a mental illness who participate in these programs only receive treatment after they commit a criminal offense. While the specialty courts provide a link to treatment for those who need it, scholars echoing this criticism feel that mental health services need to be more adequately available for all individuals who need them. Instead of waiting for an individual to commit a criminal offense, mental health services must be more fully funded by all levels of government and available to individuals with mental illnesses who are untreated or undertreated. A more proactive response could include advertisement to inform individuals about available services, along with outreach to the community. Allocating resources for preventative care instead of providing a reactive "drop in the bucket" will entail providing services to all relevant persons within a community, instead of only those committing criminal acts. This would reduce any privileging of one group over another.

MHCs as Coercive

Another major criticism of MHCs is the troubling concern that individuals may not have a full understanding of the potential consequences when they choose to participate. While Canada's approach demonstrates an insistence on reminding participants that they can withdraw at any stage, this is not typically the case in courts within the United States. Many of the studies find that although participants agree to participate, many claim they were not told that the program is voluntary (Sarteschi et al. 2011). Participants may not be told that the increased supervision they will undergo through the specialized program by its nature extends the opportunity for their failures to be detected and penalized. Another important concern to come out of this line of research is that many of the participants in MHCs do not understand facts about court procedures (Sarteschi et al. 2011). This is troubling because of the legal requirements of MHCs. Participants who are involved in the programs usually must plead guilty to their charge (Sarteschi et al. 2011). Once the participant successfully completes the program, their record may be expunged and the guilty plea should be erased. However, that does not always happen. Once the individual pleads guilty, a criminal record is established. If the individual does not complete the program, the criminal record stays with them and can subsequently haunt them. When an individual successfully completes the program, the charges and plea should be automatically expunged or dismissed and the criminal record should also disappear. Unfortunately, studies have found that this is not always the case. For whatever reason, some successful graduates of MHCs continue to have a criminal record even though the charge should have been expunged or dismissed.

Selection Bias

The meta-analysis performed by Sarteschi et al. (2011) indicated that the majority of participants in MHCs are white males in their 30s, even though African Americans, especially young African American males, are disproportionately represented in the criminal justice system. This indicates selection bias in MHCs, another major criticism of the specialty courts. This is not uncommon for jail diversion programs in general, as a disproportionate number of individuals being placed into jail diversion programs are older white females. Not only are there racial differences in admittance into MHCs, but there are also gender differences. While the majority of participants in MHCs are white males, females, especially white females with a severe mental illness, are more likely to be diverted into a MHC than men. This is even true when controlling for type of charge, crime, and race.

Furthermore, the other major finding of the Sarteschi et al. meta-analysis is troubling: the majority of participants in MHCs in the United States are white males in their mid-30s. Considering that a disproportionate number of African Americans are involved in the criminal justice system and that mental illness is found in a similar proportion of blacks and whites, the number of blacks and whites participating in MHCs should be almost equal. Having a majority of white males as MHC participants could indicate selection bias by the courts.

Critics of the selection criteria of MHCs argue that it is hard to examine whether a selection bias exists because there is often great leeway in selecting participants for the specialty court. Instead, it is up to the MHC to decide when someone fits the criteria to participate in the program; this comes up, for example, when deciding whether the details of past offenses count as "violent." This allows for the MHC to choose participants that they think most likely to succeed and ignore a possibly more deserving individual who they think will not succeed: "cherry-picking." A selection bias could indicate that MHCs are ignoring a certain population who needs treatment but might be seen as too difficult to treat. These views about who will be successful could ultimately lead to skewed research findings indicating MHC efficacy when they have not been tested across the eligible population.

Future Directions

Given the institutional support for mental health courts, as well as the promising data regarding their efficacy, their continuation and expansion seem likely. Researchers, practitioners, and advocates must remain attuned, however, to concerns about coercion and biases in the selection and treatment of participants, as well as to the broader efforts needed to prevent contact with the criminal justice system through comprehensive mental health care for all.

Overview

Offenders with serious mental illness (schizophrenia, bipolar, major depression) are overrepresented in criminal justice settings. Most offenders – both with and without mental illness – are not incarcerated but instead are supervised in the community on probation and parole. Offenders with serious mental illness are more likely to fail on community supervision than their relatively healthy counterparts. With a focus on community supervision in North America, this entry distills research on (1) explanations for why offenders with mental illness are at increased risk for supervision failure and (2) promising- and evidence-based practices for reducing this risk.

Statement of the Problem

Overrepresentation of Offenders with Mental Illness

Of the 7.2 million people under correctional supervision (Bureau of Justice Statistics 2011), nearly one-sixth have a serious mental illness (SMI; Fazel and Danesh 2002). Disorders that fall under this classification include schizophrenia (i.e., symptoms such as delusions and hallucinations, disorganized thought processes, and even catatonia), bipolar disorder (i.e., fluctuations in mood and activity levels that range from severely depressive to manic), and major depressive disorder (i.e., intense feelings of sadness and anhedonia). All three disorders can severely affect daily functioning. The current rates of SMI in correctional populations are approximately three times higher for men and twice as high for women than that found in the general population (see Teplin 1990; Kessler et al. 2006).

Community Supervision Failure

The majority (~70 %) of offenders both with and without SMI are supervised in the community on probation or parole (Bureau of Justice Statistics 2011). While on community supervision, offenders with SMI are at greater risk of failure (i.e., breach supervision and return to custody in jail or prison) than offenders without SMI. Based on a cohort of 45,000 California State parolees (20 % of whom were pre-identified as having a mental illness), Eno Louden and Skeem (2011) found that those with mental disorder were more than three times more likely to have parole revoked (i.e., terminated) than those without mental disorder. Moreover, those with acute (i.e., severe, sudden increase/onset of symptoms) mental illness had even higher rates of return to custody than parolees with more stable (i.e., ongoing, managed symptoms) mental illness. Similarly, in an unpublished dissertation that compared 115 probationers with SMI to 518 randomly selected non-disordered probationers, Dauphinot (1996) found that probationers with SMI were more likely to be arrested (54 %) and revoked (37 %) than those without SMI (30 %, 24 %, respectively) over a 3-year follow-up.

Technical violations appear to be an especially problematic concern for offenders with SMI. Relative to non-disordered offenders, offenders with SMI have disproportionately high rates of technical violations and are more likely to fail community supervision failure as a result of a technical violation. This finding has been demonstrated in a small sample of Canadian federal offenders (37 SMI vs. 37 non-disordered; Porporino and Motiuk 1995) and parolees in New York (147 SMI vs. 400 non-disordered; Feder 1991) and California (Eno Louden and Skeem 2011). All three studies indicate significant proportional differences between offenders with SMI and non-disordered offenders in their failure due to technical offenses. One study, in particular, showed that the relative risk of supervision failure due to technical violations (vs. person, property, drug, and minor offenses) is almost twice as great for offenders with SMI (52.9 %) than non-disordered (29.7 %) offenders (Eno Louden and Skeem 2011).

The Link Between Mental Illness and Recidivism

Several explanations for community supervision failure among offenders with SMI have been proposed. Skeem and colleagues (2006, 2011) provide a framework for understanding three important paths to failure for offenders with SMI. The first two paths, direct and indirect proximal effects, keep the role of mental illness central to the equation (see Skeem and Eno Louden 2006). The third path by which offenders with SMI can fail community supervision de-emphasizes mental illness as a proximal or immediate cause of supervision failure. Instead, this path views mental illness as a distal factor that is related to – or mediated by – other, stronger predictors of supervision failure (see Skeem et al. 2011). Although these pathways can overlap, evidence for each of these three routes is distilled separately below.

The Proximal Direct Route

The direct route between mental illness and community supervision failure suggests that symptoms of mental illness lead directly to criminal behavior. For example, someone may experience hallucinations in the form of voices compelling them to engage in an illegal act (e.g., theft). In this particular case, the criminal act is directly attributable to the experience of psychotic symptoms.

Although lay people may endorse beliefs that support a link between mental illness and crime or violence, the empirical evidence suggests such beliefs may be unfounded. In fact, among offender samples, mental illness is either unrelated or negatively correlated with future criminal behavior. In a meta-analysis conducted by Bonta et al. (1998), p. 35 predictors of general recidivism and 27 predictors of violent recidivism were examined across 64 unique samples. A clinical domain, comprised of clinical variables such as psychosis, treatment history, mood disorder, and current mental disorder, showed significant negative effects for both general ($r = -.02$) and violent recidivism ($r = -.03$; for a recent update, see Quinsey et al. 2006).

Even though mental illness does not predict recidivism for the majority of offenders with SMI, the symptoms of mental illness may directly lead to criminal behavior for a small proportion of offenders. In one study, 113 individuals with mental illness in a jail diversion program were interviewed about the cause of their index offense. Three independent raters used a 100-point scale (definitely not [0] to definitely [100]) with 5 point increments to rate the likelihood that the offense was attributable to either "the specific influence of concurrent delusions or hallucinations on the criminal offense identified in the police arrest report" or "any other symptom-based influence, such as confusion, depression, thought disorder, or irritability" (Junginger et al. 2006, p. 880). Results indicated that the index offense for only about 8 % of the sample was attributable to the symptoms of mental illness.

In a similar study, Peterson et al. (2010) matched 111 parolees with SMI to 109 parolees without SMI and examined their pattern of offending using official parole records. Parolees were classified into one of five groups based on their offense patterns by four independent raters: (1) psychotic (violent offenses driven by delusions or hallucinations), (2) disadvantaged (survival crimes such as shoplifting), (3) reactive (crimes driven by hostility or impulsivity), (4) instrumental (goal-driven crimes that involve manipulation or deceit), or (5) gang or drug related. Here, the offense pattern was attributable to psychosis in only 5 % of the parolees with SMI. Although replication is needed, the two studies taken together emphasize the importance of the link between mental illness and crime for a small proportion of offenders – less than 10 %. Meanwhile, the relationship between mental illness and crime for the majority of offenders with SMI may be better understood through other avenues, which are reviewed next.

The Proximal Indirect Route

This second avenue by which offenders with SMI can fail community supervision also emphasizes a proximal link between psychiatric symptoms and failure, but this route is indirect. In this path, offenders with SMI are believed to fail supervision not because their psychiatric symptoms lead to criminal behavior but because these symptoms lead to another outcome such as declined functioning or substance use. This third variable then leads to the termination of supervision.

For instance, it could be that the symptoms of mental illness prevent offenders on community supervision from doing what is required of them. If a supervisee is severely depressed and physically unable to get out of bed to attend probation or parole appointments, he could incur a technical violation or even be revoked for noncompliance. Alternatively, supervision can be revoked due to the inability to stay clean and sober – a standard condition of community supervision. Indeed, having SMI raises the likelihood of a co-occurring substance disorder; almost 75 % of offenders with SMI also have a substance use problem (James and Glaze 2006; Abram and Teplin 1991). In both scenarios, mental illness leads to the failure of meeting conditions of community supervision, which can then lead to revocation.

The Third Variable Route

The final pathway of the mental illness-recidivism link suggests that a third variable – not mental illness – is actually responsible for community supervision failure. In this route, something that is separate from – but related to – mental illness can explain supervision failure. The mental health status of the individual remains important, but it is viewed as a distal variable that exposes offenders to more proximal factors that contribute to supervision failure.

The research examining this "third variable" route has identified two very distinct but important factors that contribute to the community supervision failure of offenders with SMI. The first factor, the role of supervision practices among probation and parole officers, demonstrates a truly spurious relationship of the mental illness-recidivism link. The research on this topic suggests the manner in which an officer supervises an offender can directly affect the offender's criminal justice outcomes. This process can occur with offenders with and without SMI, but there are some concerns that officers' stigmatizing attitudes about mental illness can influence officers' supervision style with this population in particular. The second factor, an offender's criminogenic risk, demonstrates a mediated relationship between mental illness and recidivism. Here, mental illness exposes individuals to risk factors that strongly relate to criminal behavior (e.g., poverty, antisocial associates).

Supervising Officer Effects. Officer orientation (i.e., guiding viewpoint) toward rehabilitation versus public safety can influence offenders' outcomes, whether they have mental illness or not. In a seminal ethnographic study of 7,000 probationers and parolees and their supervising officers, Klockars (1972) found that officer supervision orientation characterized by extreme emphasis on law enforcement/control or social casework/rehabilitation, as opposed to a blend of these approaches, can negatively affect supervisees' outcomes. Decades later, Paparozzi and Gendreau (2005) provided further evidence to support this theory when they examined similar supervision styles (punishment, social casework, and balanced) in a matched sample comparing 142 parolees on intensive supervision to 142 offenders on standard parole. Offenders who had "balanced" officers were least likely to be revoked for any offense or due to a new conviction than offenders who had punishment-oriented or strictly social casework-oriented officers.

Results from these studies of general offenders likely also apply to offenders with SMI, and recent evidence indicates that officers may be particularly likely to adopt these supervision strategies with offenders with SMI. Doing so can adversely affect their outcomes. In other words, officers may be inclined to supervise offenders with SMI in ways that increase their likelihood of returning to custody.

In an experimental study, Eno Louden and Skeem (2013) presented 234 probation officers with a vignette portraying a probationer with mental disorder, substance abuse, both, or neither. Officers were asked to provide risk assessment ratings for the probationers then predict how they would supervise that probationer if he were placed on their caseload. Officers judged probationers with mental disorder, particularly schizophrenia, as being at high risk for both new offense and violence, compared to probationers with no disorder or only substance abuse. Specifically, officers estimated that a probationer with schizophrenia had a 68.6 % chance of committing a new offense and a 55.2 % chance of committing violence while on probation, compared to 49.3 % and 39.0 %, respectively, for a probationer with no mental disorder. Further, they also sought to monitor these probationers closely via frequent meetings – wanting to meet with a probationer with schizophrenia an average of 6.1 times per month compared to 3.3 times per month for a probationer with no disorder (Eno Louden and Skeem 2013). Other research has shown that closer supervision can increase detection of noncompliance, particularly for technical violations (Petersilia and Turner 1993; Paparozzi and Gendreau 2005). Although much work remains to be done on why officers may hold certain beliefs about the risk of offenders with mental illness and the reasons for supervising them more closely, the strong influence officers have on supervisees' outcomes is apparent.

Shared Criminogenic Risk. In addition to officer effects, another "third variable" that has a strong influence on community supervision failure of offenders with SMI is criminogenic risk (e.g., risk factors related to criminal behavior). As established through several comprehensive meta-analytic studies, the strongest risk factors for criminal behavior – dubbed the "central eight" – are history of antisocial behavior; antisocial personality pattern; antisocial cognition; antisocial associates; family and marital instability; deficits in school or work aptitude, productivity, or motivation; lack of pro-social leisure and recreational pursuits; and substance use (see Andrews et al. 2004, 2006; Andrews and Dowden 2006). Research suggests that the criminogenic risk factors most strongly related to recidivism in non-disordered offenders also predict recidivism for offenders with SMI (Bonta et al. 1998).

In fact, mental illness may disproportionately expose offenders with SMI to specific criminogenic risk factors such as poverty and antisocial associates that lead to community supervision failure. Several studies have indicated that not only do offenders with and without SMI share the same risk factors for recidivism but also that those with SMI actually are higher on many general criminogenic risk factors. In one study of 627 offenders with and without mental health problems (defined as the presence of depression, psychosis, prior suicide threats or attempts, and other emotional distress), Girard and Wormith (2004) found higher risk/needs scores for offenders with mental illness than those without mental illness on an Ontario version of the Level of Service Inventory, a variation of the popular, well-validated risk assessment. Moreover, the relationship between offenders' specific risk/needs profile and general recidivism was stronger for those with mental health problems than those without them. In another study, Skeem et al. (2008) examined 112 parolees with SMI and 109 parolees without SMI and found those with SMI had higher general (total scores) and specific risk/needs profiles on the Level of Service/Case Management Inventory (LS/CMI; Andrews et al. 2004) than non-disordered parolees.

Routes of Supervision Failure: A Summary

In summary, the relationship between mental illness and community supervision failure for offenders with SMI is complex. There are various routes by which offenders with SMI fail community supervision. For a small proportion of offenders with SMI, community supervision failure is directly attributable to the symptoms of mental illness. However, the symptoms of mental illness can also influence a trajectory of noncompliant behavior that leads to technical violations, an especially problematic concern for this group. For the majority of offenders with SMI, however, supervision failure is likely attributable to criminogenic risk factors that are shared with non-disordered offenders. Finally, and perhaps to a lesser extent, the specific supervision styles and strategies employed by community corrections officers can also play an important role in community supervision failure. Equipped with an understanding of how offenders with SMI can fail community supervision, this entry now turns to an overview of the current approaches used to supervise offenders with SMI in the community, highlights their evidence base, and discusses the strengths and weaknesses of the current policy model in light of this empirical evidence.

Strategies for Supervising Offenders with SMI in the Community: Specialty Mental Health Caseloads

Perhaps the most common current approach employed in the community supervision of offenders with SMI is specialty mental health caseloads. The last decade has seen increasing implementation of specialty mental health caseloads to manage offenders with SMI on community supervision. In 2002, the Council of State Governments recommended the implementation of specialty caseloads in response to the problem of supervision failure for this population and the growing concerns about the consequences of offenders with SMI becoming more deeply entrenched in the criminal justice system. At the time of this recommendation, there was unfortunately no data to support the effectiveness of implementing this type of caseload, nor did the recommendation include directives for establishing specialty caseloads. Since that time, Skeem et al. (2006) conducted a national survey of specialty mental health probation. This study provided some basic insight into what these caseloads look like in practice.

Although there is heterogeneity in how specialty mental health caseloads are implemented across jurisdictions, they do share five distinct features: (1) reduced caseload sizes, relative to non-specialty caseloads, (2) caseloads comprised solely of offenders with SMI, (3) officer interest or training in mental health, (4) coordination of internal (i.e., probation) and external (i.e., treatment) resources, and (5) emphasis on problem-solving over sanctioning (Skeem et al. 2006). Additionally, specialty mental health community supervision places a very strong emphasis on mental health treatment (psychiatric medications and therapy). In doing so, as argued elsewhere (see Skeem et al. 2011), these programs make an implicit assumption that symptom reduction can lead to improved criminal justice outcomes.

Perhaps the most rigorous examination of specialty probation performed to date is that recently completed by Skeem and colleagues. In this study, 183 offenders with SMI on specialty mental health probation were matched to 176 probationers with SMI on traditional probation on the following criteria: age, gender, race, time on probation, and index offense. Probationers and their supervising probation officers were followed over the course of 1 year. During this time, probationers completed three semi-structured interviews – one approximately 2 months after beginning probation and again 6 and 12 months later. Officers completed questionnaires on the same schedule. Participants' official criminal justice outcomes (FBI arrests rap sheets and violation and termination reports filed with the court) were collected 2 years post baseline.

Two important preliminary findings have emerged from this study. First, what officers do in specialty supervision differs from what they do in traditional supervision. Specifically, specialty probation officers used more problem-solving strategies than threats and sanctions, had better skills in navigating and working with outside social service agencies (i.e., "boundary spanning"), and established better relationships with their supervisees than officers in traditional probation supervision (Manchak et al. 2007). Additionally, offenders with SMI on specialty probation received more evidence-based integrated dual diagnosis treatment (i.e., treatment that targets mental health and substance use symptoms simultaneously) than those on traditional probation (Manchak et al. 2010). Second, specialty probation reduced recidivism but not for reasons that were expected. Effectiveness of specialty probation was not mediated by probationers' symptom reduction but by high-quality officer-probationer relationships characterized by firmness, caring, and trust (Skeem et al. 2010). These findings would suggest that the implicit model guiding practices like specialty supervision may be flawed; effective officer practices – not treatment – appear to be essential for affecting outcomes for offenders with SMI.

Moving Research into Practice: Prescribing Evidence-Based Practices

Practice

The available research on specialty caseloads underscores the importance of what is already being emphasized in correctional intervention with general offenders: "Core Correctional Practices" (CCP). First discussed by Andrews and Kiessling (1980), these practices place strong emphasis on *how* correctional interventions are implemented. Appropriate use of authority, modeling, behavioral reinforcement, and problem-solving are viewed as essential CCPs. Additionally, CCPs entail linking offenders to needed community resources and services. Perhaps most important, however, is the establishment of strong relationships between supervisees and probation and parole officers; these relationships are most effective when they are characterized by warmth, flexibility, empathy, openness, mutual respect, and liking and use "directive, solution-focused, structured, non-blaming, or contingency-based communication" (Dowden and Andrews 2004, p. 208). A meta-analysis of 273 effect sizes shows that the relationship component correlates strongly with average effect sizes in recidivism reduction ($r = .25$), and the additional CCP components enumerated above can increase this correlation ($r = .41–.47$; Dowden and Andrews 2004).

Other work that has come to dominate the landscape of general correctional intervention, and which is slowly beginning to take hold in policy recommendations with offenders with SMI (see Prins & Draper, 2009), is the application of the principles of effective intervention: risk, need, and responsivity (RNR). These principles suggest that (1) intensity of supervision should be matched to the offender's individual level of risk (risk principle), (2) supervision should focus on the primary criminogenic risk factors known to relate to recidivism (need principle), and (3) the manner in which supervision is delivered should be consistent with the offender's learning style and abilities (responsivity principle). Like CCP, adherence to the RNR model can substantially reduce recidivism risk among general offenders. One meta-analysis, for example, found an average reduction of 20–38 % (depending on how many principles were applied) among high-risk offenders (Andrews and Dowden 2006). Additionally, the more time officers spend discussing criminogenic needs in supervision, the greater the reduction in recidivism (Bonta et al. 2008).

Although little is known about how well officers use RNR practices when supervising offenders with SMI, there is some evidence that suggests they may intuitively apply these principles without being specifically trained to do so. In an investigation of a specialty mental health probation agency, Eno Louden et al. (2012) examined audiotaped meetings between 83 probation officer-probationer pairs and coded them for adherence to these principles. Although the most common topic discussed in these meetings was issues related to probationers' general mental health, officers also discussed probationers' criminogenic needs. One-third of meetings (33.7 %) included discussion of criminogenic needs that are most predictive of recidivism (antisocial attitudes, antisocial personality, criminogenic peers), and three-quarters of these meetings (75.9 %) also included discussion of criminogenic needs moderately predictive of recidivism (financial problems, employment, family problems, and substance abuse). Thus, supervision practices in specialty mental health caseloads may already adhere in some respects to important components of RNR.

Implementation

Even though officers may unintentionally employ the evidence-based practices of RNR and interact with supervisees in ways consistent with core correctional practices, greater recidivism reduction for offenders with SMI is more likely achieved through officer training and effective implementation practices. There are several important steps that must be taken to do so effectively. First, researchers must be able to communicate their findings to practitioners in a manner that is not only accessible but also conveys the value of adopting new evidence-based practices. Directors and frontline staff must recognize the short- and long-term benefits of these practices and be committed to ensuring their implementation. Second, agencies need to be provided with guidance in the application of these practices. Without proper training, certain evidence-based practices may be misinterpreted or misapplied, therefore undermining their intended goal of recidivism reduction. Finally, safeguards must be in place to ensure the sustainability of the evidence-based practices. For example, procedures should be in place for training new hires and maintaining quality control in the long term.

Several scholars in the USA and Canada are already making strides in bridging this research-practice gap. Researchers at George Mason University and the University of Cincinnati have been actively involved in training correctional officers in the application and use of RNR and CCP using innovative implementation strategies and rigorous training protocols. Agencies such as Policy Research Associates and the National GAINS Center have also made significant contributions to both research and practice by disseminating their findings on correctional programs for offenders with SMI, in particular. Such programs are essential in translating the research evidence into real-world practice in an accurate, ethical, and efficient manner.

Policy

The research supporting the various routes to supervision failure among offenders with SMI has informed the current policy model recommended by the Council of State Governments for managing this population on probation or parole. This model provides a classification system for offenders with SMI where offenders are classified and managed based on their individual level of criminogenic risk, issues with substance abuse/dependence, and the severity of the individual mental health symptoms and functioning (D'Amora et al. 2012). In accordance with the risk principle, the model recommends that services in each domain be contingent upon severity of problems. For example, high criminogenic risk is matched by more intensive supervision that adheres to the RNR principles. Severe substance problems are met with intensive substance abuse treatment and, if coupled with mental illness, integrated dual diagnosis treatment. Finally, for those with severe mental health symptoms and poor psychosocial functioning, more intensive psychiatric treatment is proscribed. For offenders who are "high" in mental health, substance use, and criminogenic risk, integration of intensive services and supervision is recommended.

Extensive evidence now indicates that there is little utility in emphasizing the role of mental illness in recidivism, except for a small minority of offenders with SMI. As policy and practice shifts away from mental illness as the master status around which correctional interventions and programming are designed, future research should seek to identify new approaches to reducing recidivism for offenders with SMI. Even more, efforts should be made to identify the mechanisms by which (i.e., mediators) and the conditions under which (moderators) current evidence-based practices operate. Doing so can maximize recidivism reduction for this population. Current and forthcoming research examining the effectiveness of practices like specialty caseloads and RNR will continue to help refine the policy model guiding interventions and improve outcomes for offenders with SMI.

Methodological Issues in Evaluating Police Performance

Cody W. Telep
School of Criminology and Criminal Justice,
Arizona State University, Phoenix, AZ, USA

Overview

Measuring and evaluating police performance is not easy. Both technical issues, such as designing the best measures, and normative concerns, such as deciding what tasks the police should be performing, are important to consider (Moore and Braga 2004). The focus here is on methodological issues, not normative ones, but one cannot assess the methodological quality of police performance measures without some consideration of what "good" performance entails.

Police performance traditionally has been evaluated with data on crime-related outcomes (e.g., calls for service, incidents, and arrests). "Measurement of the police's impact on crime has long been the *sine qua non* of those endeavors that might be loosely dubbed 'police performance measurement'" (Wycoff and Manning 1983: 15). This does not mean that crime measures are the only relevant performance measures, but crime is logically one important indicator of police performance. The focus below is on the flaws of using aggregate crime data to assess departments and the prospects for using crime data from evaluations as one means to assess performance.

Measures of arrests, clearance rates, and response time are all crime-related outcomes, but they shift the focus to the activities the police are engaged in. None of these measures, however, gives a true representation of how the police are spending their time. Better data on actual activities and resource allocation are needed. Advances in technology offer possibilities for improving departmental knowledge of officer activities, and methods such as systematic social observation (Mastrofski et al. 2010) allow for a rigorous assessment of policing activities.

One component missing from traditional measures is an assessment of citizen views of the police. This seems particularly important in efforts to evaluate the dual police goals of fairness and effectiveness noted by the National Research Council (2004). What can the police do to assess the fairness of their actions? Interviews and surveys of citizens offer police important feedback, although these methods are not without flaws. Police cannot truly evaluate their performance without understanding the demands and viewpoints of their "customers," the citizenry at large, and particularly the citizens they have contact with.

Multicomponent measurement systems help generate as valid a picture of police performance as possible. Quantifying success remains a challenge however, and so proxy measures are often used. Such measures are necessary but problematic (Swindell and Kelly 2000). Measuring police outputs may not necessarily provide reliable data on outcomes. These proxy measures that police can use for assessing performance are discussed below. Methodological issues in using official data on crime are addressed first, followed by issues in understanding what the police are spending their time on, and then a discussion of measuring citizen perceptions. Finally, concluding remarks on the prospects for evaluating police performance are included.

Official Data on Crime

If measures of crime are one piece of the puzzle to evaluating police performance, how can official crime data best be used? One major concern in most current assessments of police performance is the focus on citywide crime data and trends. In some ways, this focus makes sense, because such data are easily available. Over 18,000 police agencies provide data to the Federal Bureau of Investigation (FBI), which then presents annual crime totals by agency for the Uniform Crime Report (UCR).

The problems with the UCR are numerous (see Mosher et al. 2002), but a few important points are worth reviewing. First, the UCR only covers crimes reported to the police, and for crimes other than homicide, a large portion of crime goes unreported. Second, the FBI has specified definitions for each offense type that do not necessarily match up with each jurisdiction's statutory definitions. As an example, the 2010 Annual Report of the Washington, DC Metropolitan Police Department (MPD) presents FBI versus DC Code definitions for a number of offenses to demonstrate that UCR data and DC data do not always match. Such differences are not always minor. The MPD reported 3,538 aggravated assaults to the FBI in 2010, but using the DC code definition for the close to equivalent offense of assault with a deadly weapon, the city had 2,615 offenses. Third, even when focusing on just the most serious Part I crimes, jurisdiction-wide crime rates are dominated by the least serious of these crimes, larceny thefts. These issues are raised here to emphasize the difficulties of using UCR data to assess performance. If police performance measurement is inherently difficult, starting with a flawed data source makes things even more challenging.

While the FBI strongly discourages using the data from the UCR for ranking cities, this does not prevent annual rankings of the "most dangerous" and "safest" cities from being published by media outlets. As the FBI warns on its website, these rankings do not consider the many variables that affect crime in particular jurisdictions and thus can be misleading and incomplete. Ranking cities based on UCR data is like running a regression model on the correlates of crime and only including a single predictor variable. There is far too much variance unexplained in an approach that looks exclusively at crime at the jurisdiction level and ignores other jurisdiction-level characteristics.

Despite the warning from the FBI, agencies are interested in knowing how they compare to their peers. Evaluating performance is difficult without benchmarks, and so comparisons to "similar" departments would ideally be an important part of judging how typical the results in one agency are. Colleges and universities keep a close eye on rankings from *US News and World Report*, and many evaluate their performance in relation to peer institutions. Should police departments be expected to do the same? Not everyone believes ranking cities is inherently problematic. Sage Publications publishes an annual book ranking cities by crime rate. The latest version is *Crime City Rankings 2011–2012: Crime in Metropolitan America*. The International City/County Management Association (ICMA) provides performance measures across 18 areas including policing for over 200 cities through their Center for Performance Management. Cities report information to ICMA, which then compiles a variety of crime and service-related measures for agencies. The organization actively encourages comparisons between peer organizations. What ICMA offers to cities that the FBI does not is an extensive effort to ensure collected data are valid. While the issues in comparing across jurisdictions still exist, one improvement here is the review of the data by an outside organization. Similar arguments have been made by Sherman (1998), who points to the benefits of police agencies using auditors just like private companies to ensure that crime data are reported validly. Alpert and Moore (1993: 122) also argue that "existing measures could be improved to live up to the challenge of professionalism. This would include audited clearance and arrest rates."

In contrast, in the United Kingdom the government is explicitly involved in assessing and ranking police forces. The UK is not entirely comparable to the USA because statutes and crime definitions are consistent across the UK, and the government has national oversight of the police. Still, the work of Her Majesty's Inspectorate of Constabulary is far more comprehensive than anything in the USA at the local or national level. The public has access to comparable data for each of the 43 forces on crime, quality of service, and expenditures. Importantly, the data are checked for quality, and each agency has been assigned peer agencies, which are as similar as possible in population and demographics.

While comparing agencies is one challenge, the major issue with the use of crime data to assess performance is with the unit of analysis. As the unit increases in geographic size and scope, it becomes increasingly difficult to estimate to what extent police practices contribute to changes in observed crime. Linking police performance to crime at the jurisdiction level is most difficult of all. In recent years, scholars have increasingly recognized that the police can have some beneficial impact on crime (see National Research Council [NRC] 2004). This is a change from conventional wisdom even as recently as the early 1990s. Still, even the strongest advocates for the police role in reducing crime do not believe that police have complete control over crime rates. A multitude of factors combine to influence crime, and disentangling how each component influences crime is an impossible task. That is what makes evaluating police performance at the city level so challenging. There is no validated way of estimating how much the police contributed to the crime rate in a city for a particular year versus all the other factors that influence crime.

Such efforts to link police performance to crime rates are not hopeless, however. Importantly, when the scope of the geographic analysis is narrowed, it becomes possible to link police activities to crime declines, and this becomes especially true when smaller geographic units are used in concert with rigorous research designs to test the impact of particular police practices. In many ways, this makes more sense than a citywide assessment. While police are responsible for crime across the entire city, in reality their resources tend to be concentrated in a small number of places, and it is in those places where one would expect police performance to make the most difference.

This point is made by Bayley (1996: 49), who argues that police efforts to prevent crime should be evaluated only when they are targeted on specific sorts of crime in specific locations, “To demonstrate their effectiveness, the police have to target their shots.” Similarly, Wycoff and Manning (1983) note that efforts to improve the measurement of police performance should focus on either improving the methodology of measurement or better conceptualizing what is to be measured. Aggregate official crime data should not be used in comparative studies, because the data across cities are not comparable. They point to a model of evaluating performance that relies on rigorous evaluation and close attention to differences across cities: “The most reliable analyses will be experimental studies conducted on a site-by-site basis...The next most reliable method will be longitudinal studies, again done site-by-site, with particular attention to contextual and organizational factors” (Wycoff and Manning 1983: 19).

Wilson (1993) also argues persuasively about this point, recognizing that a problem in police performance measurement is that there are no adequate performance measures, because it is impossible to precisely estimate what portion of any measure of public safety in a city is attributable to police actions. If the police are unable to adequately assess their performance with citywide crime rates, they often turn to proxy measures, such as response time or clearance rates, which have their own flaws, and are not necessarily related to the crime rate. Focusing attention on specific police actions in specific geographic areas is Wilson’s (1993) solution. He suggests the usefulness of police targeting particular problem neighborhoods (however, the agency defines neighborhood) and then using “microlevel” measures (e.g., changes in calls for service in that neighborhood) to assess the effectiveness of police efforts to address neighborhood problems. As Wilson (1993: 162) argues, “These micro-measures are likely to be among the few valid measures of police performance. They may well lead to conclusions quite at variance with city-wide, aggregate data.”

Randomized experiments are particularly useful in combination with these micro-measures because such designs are assumed to have the highest internal validity and allow for the strongest causal statements about the effects of interventions (see Cook and Campbell 1979). This is the case because subjects are randomized into treatment and control conditions, and thus, their inclusion in one group or another is simply determined by chance. If an agency uses a randomized design to assess an intervention in a specified geographic area, then a crime decline observed in this area (when comparing the treatment area to a randomly allocated control site) can reasonably be attributed to the efforts of police. Randomized experiments of geographic police interventions offer the opportunity for police to persuasively and validly evaluate how their performance influences crime and disorder. Randomized experiments do not solve the problems with official data and the UCR, such as the vast underreporting of most crimes, but experiments offer a way to more rigorously assess how police performance affects crime.

Hot spots policing is a particularly good example of a policing intervention that takes place in a small unit of geography and which has been rigorously evaluated with a series of randomized trials (NRC 2004). A large body of research suggests that police can have a significant beneficial impact on crime and disorder when they narrow their focus to microgeographic units with high rates of crime (see Weisburd and Eck 2004). Importantly, work examining hot spots of crime in Seattle also suggests that citywide crime trends tend to mask the trends at particular street blocks in the city (Weisburd et al. 2012). While Seattle enjoyed a citywide crime decline in the 1990s, this decline was isolated to a small percentage of blocks, while the vast majority of blocks showed little change and some even showed substantial crime increases. This reinforces the problem of using citywide crime data to assess police performance.

Compstat provides another good example of how crime data can be used as a means of evaluating police performance. Compstat forces police commanders to focus in on crime problems occurring in short-time periods and assess how police actions can address these problems quickly and efficiently. Compstat was an effective approach for evaluating and altering performance in the New York Police Department. Moore and Braga (2003: 446) note that in Compstat, “the measures are simple, objective, reliably measured, and continuous so that changes in performance can be observed over time within an operational unit, and across units that are roughly similar.” While Compstat does not make use of randomized experiments in its assessment of performance, it does make important strides in generating measures that are consistently measured over time, allowing for comparisons within and across units and making it possible to more closely link police actions in a specified time period to changes in crime.

What Are the Police Spending Their Time on?

The police rely heavily on crime measures to assess their performance, but these are not the only measures traditionally used. Police also are interested in understanding what officers are doing with their time, and hence, they often track measures of police activity such as response time to 911 calls, arrests made (and citations written), and clearance rates. These measures, however, provide only limited data on what officers are doing with their time, and, if crime control remains a primary measure of police performance, research suggests that rapid response and general increases in arrests are not effective ways to address crime (see Weisburd and Eck 2004). Additionally, these measures give insufficient attention to police resource allocation. Systematic social observation research (see below) suggests that only a very small portion of officer time is spent arresting offenders and a fairly small proportion of time is spent responding to calls for service. Departments are not adequately measuring performance by focusing on these two measures alone.

Clearance rates can also be a problematic measure. The FBI reporting rules allow for situations in which data are presented in a way that is technically correct but misleading. For example, the MPD widely touted a 94 % homicide clearance rate in 2011. One would likely assume that DC police made an arrest in 94 % of 2011 murder cases. The FBI, however, counts homicide closures that occurred in any year in the current year's clearance rate. DC homicide detectives closed 62 of the 108 homicides in 2011 and also closed about 40 homicides that occurred in earlier years. While the 94 % homicide clearance rate is accurate under FBI reporting rules, it would seem to make more sense to report on the percentage of homicide cases closed within 12 months, rather than report a percentage that is not entirely related to current year data. Additionally, while clearance rates have been on the decline in recent decades, the factors associated with these declines may be outside police control. Ousey and Lee (2010) find that changes in police personnel and workload are not associated with changes in the clearance rate, but that changes in immigration can decrease clearance rates. Like crime rates, certain factors that police have no control over may contribute to decreased clearance rates.

Number of arrests and police response time are both measures, to some extent, of police productivity. These measures, however, give police little information about what officers are spending their time on day to day. How are departmental resources being used, and is resource allocation effective and efficient? These are also important questions for police and present challenges for measurement. Unlike profits in the private sector, there is no single bottom line in policing, and so assessing whether resources are being properly used is not easy.

Ostrom (1983) makes this clear in her discussion of equity in the delivery of police services. What should be the standard for equity and how should this standard be measured? Should services be distributed based on taxes paid, or based on need, or to all citizens equally, or to ensure that all citizens get equal results? These are normative questions, but the effort to assess equity presents a host of methodological problems. The service that police are providing is ambiguous, making it difficult to measure whether service is being distributed equitably. Expenditure data can be used for assessing level of service, although budgeted resources do not necessarily correspond to services delivered to particular communities. Ostrom (1983) points to four flawed ways researchers typically assess equity in policing. Data on the distribution of police across jurisdictions typically shows that higher crime areas receive more police (i.e., the needier areas get more), but this says little about what police are actually doing in these areas. As Ostrom (1983: 110) notes, "The difference between an occupying army and a service-oriented police force cannot be determined solely by examining personnel allocation." Similarly, response time data and crime data do not provide much information on the actual delivery of police services in these areas. A final less commonly used method is citizen surveys to assess fear of crime, which are potentially useful, but survey data do not necessarily provide insights into why citizens feel the way they do (see below).

A recent study in Dallas (Weisburd et al. 2013) was the first randomized experiment to make use of data from automatic vehicle locators (AVL). AVL technology tracks the exact location of a patrol car repeatedly. This has obvious benefits for officer safety in terms of monitoring patrol cars, but it also has benefits for assessing where officers are going during their shift. In hot spots policing studies, saturation patrol is often an important component of the intervention, and so AVL technology could allow the department to assess how often officers are visiting hot spots and whether treatment is being delivered as intended. While police unions are reluctant to allow departments to closely monitor AVL data, there is potential here to better identify officers' spatial location during their shift.

To fully evaluate performance, police agencies must know not only where officers are but what they are doing. While agencies have increasingly moved towards a greater embrace of problem solving and working with the community, there is little or no official departmental data on whether officers are actually engaging with the community or using proactive problem solving (Alpert and Moore 1993). One option is to better survey officers about their activities while on duty. Most police agencies currently keep track of how long officers spend on particular calls for service, but have much less data on what officers are doing in their uncommitted time. Dadds and Scheide (2000) discuss the use of activity measurement in Australia as a way to better monitor what officers are doing in the field and how these activities may be linked to desired outcomes. Officers spend 1 or 2 weeks annually filling out a survey on specifically how they are spending their time on each shift. This method relies on the veracity of officer responses, and it can be difficult to place officer activities into specific categories. Still, the survey provides an opportunity to estimate how officers' time is divided between traffic services, community police services, crime management, emergency response management and coordination, and criminal justice support.

Similarly, Mastrofski (1983) calls for greater police attention to noncrime services provided to citizens. While incident reports and arrests are well recorded, police devote a substantial portion of their time to providing information or assistance, dealing with nuisances, or breaking up disputes, and unless a report is written, none of this noncrime service is well recorded. Providing officers with a set of response activity codes that could be used to report what actions were taken in a particular citizen encounter would be useful and would provide more data on how police were allocating their noncrime services.

Mastrofski (1996) provides five different methods for evaluating what officers are doing in interactions with citizens. The first, as described above, is officer self-reports of behavior. While inexpensive, this method suffers from potential problems in reporting validity. The reports of citizen who have interactions with the police are another possibility and are discussed more below. A third possibility is using evaluations by other human service professionals who regularly interact with the police. While such evaluations would be less subjective than self-report data, such professionals would not be present during a large proportion of citizen interactions. The last two methods offer the most objective means of evaluating police performance: the use of indirect third-party observation (e.g., video recording) and the use of direct third-party observation. Direct third-party observation is discussed below as a means for systematic social observation. The use of police video recordings has been fairly uncommon to date, although as more departments record police-citizen interactions increases and as technology improves, this would seem to be a promising and inexpensive route for future research on police performance.

Systematic social observation (SSO) offers an even better way to assess what activities officers are engaged in and provides a more objective measure of police-citizen interactions. SSO makes use of protocols in field observations of the police to ensure that data collection is standardized within and across observers. As Mastrofski et al. (2010: 243–244) note, "it offers enhanced prospects of validity, and in many situations it provides for increased confidence in reliability, because of the researcher's direct access to the phenomenon of interest and greater control and transparency of data encoding. Further, it affords greater precision in capturing details of the phenomenon and its context." SSO is not without potential threats to validity. A primary one is the possibility of observer error in recalling events. While multiple observers of the same scene would be ideal to avoid this, it becomes difficult both in terms of cost and logistics to use more than one observer per officer. Another concern is reactivity effects. Are officers responding differently when observers are watching their actions? Research on this topic is limited, but in a long-term project where officers are being observed repeatedly, it seems less likely that reactivity would be a major problem. Systematic social observation has been an important component of a small but growing number of research studies on police behavior. Famega et al. (2005) used systematic social observation in Baltimore to assess both how officer time was allocated and the reason for officer actions over the course of 163 shifts. Their finding that 75 % of officer time is unassigned suggests that simply examining calls for service data is insufficient for understanding what officers are doing during their shifts.

An important question with data on police activities and interactions with citizens is how these data can be used to evaluate police performance. Even with the problems with crime data, it seems clear what the desired outcome is – overall crime reduction. When evaluating what officers are spending their time on and how they interact with citizens, the outcomes become fuzzier. In terms of what officers spend their time on, if the goal is to relate these activities to crime control effectiveness, then it is easier to assess whether or not officers are performing in ways that are evidence based. But what about evaluating how an officer handles a particular domestic violence call, or how officers carry out a traffic stop? One part of evaluating performance here would be assessing levels of citizen satisfaction and beliefs about the fairness of the interaction, an issue discussed in the next section.

But police, like other professionals, do not want their performance assessment based only on the views of outsiders. Mastrofski (1996) suggests that police master craftsman, as chosen by surveys of fellow officers, could work to develop performance criteria for difficult or common police problems. Then, observed officer actions could be compared to these criteria. The development of such criteria would not be easy and would take much deliberation among highly regarded officers, but could be quite useful for helping to evaluate what good performance should look like. Recent research by Mastrofski et al. (2011) suggests both that officers can identify master craftsman (i.e., officers whose performance and opinion they respect) and that officers can be interviewed about evaluating police performance in particular situations. While officer views are not always consistent on what constitutes good performance, this is a promising area for future research on how police can use observational data to evaluate police performance based on agreed-upon departmental standards.

Measuring Citizen Perceptions

While innovations such as community policing have stressed the need for police to partner and work closely with community members to effectively address crime and fear of crime, the police have not been quick to add measures that will help gauge the community's view of the department (Alpert and Moore 1993; Moore et al. 2002). As Mastrofski (1996: 210) notes in arguing for more attention to be placed on police-citizen encounters, "Crime rates, fear levels and citizen satisfaction – though keenly felt at the personal level – are hard to observe directly. . .It is not at all clear that the public holds the police accountable for the crime rate, but they do hold them accountable for their actions." This makes assessing how citizens view officer actions an important aspect of evaluating police performance. While departments have traditionally collected data on citizen complaints, such data are not sufficient for evaluating performance (Moore et al. 2002). While complaint data are an important way for departments to learn about and remedy improper police behavior, complaint data do not give a full picture of police-citizen encounters, and importantly for efforts to evaluate "good" performance, complaints provide no data on positive police-citizen interactions.

Data on citizen perceptions can be gathered in multiple ways. Some police departments, regularly survey 911 callers in satisfaction surveys. A number of researchers have used telephone surveys to gather information on recent citizen encounters with the police and how citizens viewed such encounters, or on citizens' perceptions of their neighborhood and/or recent victimization experiences (see Skogan 1999). Rosenbuam et al. (2008) were successful in assessing citizen views of the police through an Internet survey in Chicago. In addition to large-scale surveys, qualitative interviews can also be an important way to gather detailed information on police-citizen encounters.

Brown and Benedict (2002) point to some methodological issues that can arise in research on citizen perceptions of the police. Broad-based citizen surveys may not capture a sufficient number of witnesses, victims, and suspects and thus may oversample individuals who have not had direct contact with the police. Even when researchers have access to lists of individuals who have had recent police contact, it is not always easy to track these people down and to acquire their consent to participate in research. Such individuals, particularly suspects, are often skeptical of any research related to the police and are reluctant to believe that confidentiality measures are in place. Victims or witnesses may not feel comfortable discussing a sensitive matter, particularly for violent crimes. It may be especially difficult to survey young minority males, a group of particular interest in assessing police performance, because of their typically high levels of contact with the police and low levels of perceived police legitimacy. Wolfer and Baker (2000) suggest the additional problem of "halo effects" in survey research, especially in small and rural agencies. Citizens in these areas may rate the police as satisfactory based on personal relationships and not on actual good performance. In their study of problem-oriented policing, citizens tended to rate the police highly in areas where other objective measures suggested the police were not doing a particularly good job.

Brown and Benedict (2002: 562) also stress the benefits of efforts to "develop objective, independent measures of police activity to better determine the impact of officers' behaviors on attitudes towards the police." Efforts to combine SSO and citizen perception data could be particularly beneficial here. While this raises concerns about citizen privacy, an ideal research design would be to use SSO data to objectively assess police-citizen encounters and then conduct follow-up interviews with these citizens to better understand their views of the encounter and the police. Such a design would help better link citizen attitudes and officer performance.

While large-scale survey research has the benefit of generating larger sample sizes, Shilston (2008) stresses the importance of using qualitative data to assess police performance. General satisfaction surveys will likely be unable to provide detailed depictions of citizen views of and attitudes towards the police. Such surveys can be useful as a quantitative summary of perceptions, but they fail to provide insight into the individual experiences of those who interacted with the police. Interviewing those who had direct contact with the police is a better method for gaining in-depth information on citizen perceptions.

Fielding and Innes (2006: 135) also call for a more qualitative approach to assess public perceptions of the police and argue that "A better approach than using randomly selected respondents to measure change may be to employ judgements made by key informants: individuals who have detailed knowledge of communal life in a locale and are in a position to provide a meaningful assessment of how policing there has improved or worsened." This purposive sampling technique may provide a richer data source for police. They also point to the benefits of qualitative assessments of the narratives from complaint data to get a more descriptive view of negative police-citizen encounters. This could provide greater insight for police departments than a simple count of the number of complaints.

Conclusions: What Should Police and Researchers Be Measuring?

In efforts to evaluate police performance, it is important for police and researchers to use multiple methods of data collection to create a fuller portrait of police performance. Cordner (1996: 200) sums this up well by noting "The bottom line is that policing must be judged by *bottom lines*." Police should continue to collect data on the traditional measures above, but should be cognizant of the problems with these measures. They should also expand the list of measures to include variables that reflect the importance of police activities and interactions with citizens and the views of citizens, particularly in terms of the fairness of police actions. For example, official data on drug calls for service and drug arrests are problematic, because they do not always match up with drug market boundaries. Official data should be supplemented with resident surveys to assess the severity and visibility of problems, as well as data sources from other agencies, such as the location of 911 calls for drug overdoses. Just as multiple data sources are a better way to identify drug markets, they would also be important to assess whether police are having an impact on drug markets. Arrest patterns reflect more about police enforcement priorities than whether police reduced harm from particular drug markets. But the triangulation of official data, health data, and resident data could help indicate whether police actions were having impacts on citizen safety and well-being. Skogan (1999) also points to the benefits of triangulation in his review of methodological challenges in using both survey and official crime data. When victimization data, official crime data, and citizen perception data are all pointing in the same direction, then evaluating police performance can be done with greater confidence.

Moore et al. (2002) provides a series of goals for police and measures that would be useful to include in what he describes as a "model annual report." These include not only traditional measures, in efforts to reduce criminal victimization and call offenders to account, but also measures explicitly focused on the views of citizens in efforts to reduce fear of crime and satisfy customer demands and achieve legitimacy with those policed. Such efforts to view citizens as the customers of police fit in well with the private sector notion of total quality management (TQM). Hoover (1996) describes how TQM focuses on a number of aspects relevant for evaluating police performance, including using routine and constant measurement to enhance performance, focusing on the concerns of customers, and being explicitly concerned with counting and quantifying interactions with customers and the outcomes of these interactions. Management strategies from the private sector do not transfer perfectly to policing. "Good" policing has no clear definition, and so success is not as easy as raising profits. Hoover (1996: 19) points out that "Not all qualitative elements of police work can be quantified. There are too many exigencies, contingencies and intangibles." Nonetheless, efforts to better measure various aspects of police performance are worthwhile and important to more fully evaluating police fairness and effectiveness.

One final issue is whether police performance measurement should be focused on outputs or outcomes. Stephens (1996: 121) points to the need to supplement standard measurements of police performance with measures of outcomes and notes, "The issue of measuring effectiveness is not entirely one of discarding the old and replacing it with new measures. It is one of putting the traditional measures in perspective (using them when appropriate) and placing greater emphasis on outcomes than process or 'proxy measures.'" While it seems reasonable to focus on the outcomes of policing, Moore et al. (2002) argues that while outcomes are often seen as more important, one cannot ignore the outputs (and inputs) of policing. Outcome measures can be challenging to collect, and in policing, the concern is not just about outcomes but also how police are doing their job. While reducing crime and disorder is a desired outcome that should be assessed as well as possible, it is equally important that the police are being fair in their use of force, their allocation of resources, and their interactions with citizens.

Starbuck (2004: 337) summarizes the problems and prospects of evaluating performance in any agency: "Performance measures are everywhere, but they are filled with errors, and these errors are likely to cause faulty inferences. We should distrust performance measures, but we cannot ignore them because they are powerful motivators that can produce dramatic improvements in human and organizational performance." While evaluating police performance entails a number of methodological challenges, measuring performance is an important way to both bring about desired changes in police organizations (e.g., Compstat) and assess whether police performance fits in with notions of what "good" policing should entail.

Microsimulation Models of the Criminal Justice System

Anna Stewart
School of Criminology and Criminal Justice,
Griffith University, Brisbane, Australia

Overview

This entry provides an introduction to the use of microsimulation models for informing decision making by criminal justice system professionals. Microsimulation models are placed within a framework for understanding computer simulation models. A brief history of the use of simulation models and microsimulation models in the criminal justice system is provided. The processes involved in the development of the Queensland Juvenile Justice Simulation model are described to illustrate the steps required to develop, validate, and use a microsimulation model. Finally, some of the challenges and advantages to using microsimulation models in the criminal justice system are explored.

Overview of Social Science Microsimulation Modelling

Within the social sciences three broad approaches to computer simulation models have been identified: macrosimulation approach, microsimulation approach, and agent-based modelling approach (Macy and Willer 2002). The development of macrosimulation models (also known as system dynamics models, world models, stock and flow models, dynamic systems simulation modelling) coincided with the first use of computers in university research in the 1960s. These models have their roots in systems of difference and differential equations and are used for understanding the dynamic nature of complex nonlinear systems. The second modelling approach, microsimulation (also known as discrete event simulation modelling), simulates a “macro” system by modelling and simulating the actions and interactions of the systems “micro” units (usually individuals) (Spielauer 2011). The results of the effect of system changes on each unit can then be analyzed at the microlevel or aggregated up to show the overall “macro” effect of change. This type of modelling has its roots in economics, engineering, and operations research. The final approach to simulation modelling, agent-based modelling, was developed during the 1980s coinciding with the advent of the personal computer (Macy and Willer 2002). This type of modelling has its roots in artificial intelligence and computer science. Unlike macro- and microsimulation the focus of agent-based modelling is on theoretical development and explanation rather than applied research (Gilbert and Troitzsch 2005).

Social science microsimulation enables the experimentation with a virtual society of thousands of individuals created by a computer. These models can either be static (examine the short-term effect of a policy change) or dynamic (follow individuals over the life course). In static models time has no effect on the individuals modelled. However, dynamic simulation models explicitly include time. For dynamic microsimulation models characteristics associated with the individual units change in response to accumulated experience or the passage of time.

Consequently these models enable us to simulate future conditions and project the outcomes of a proposed policy or operational change. By understanding the likely consequences of a proposed change, it is possible to evaluate if the policy change would be beneficial, contributing to the process of policy analysis and implementation. Dynamic microsimulation models allow virtual individuals to be followed over their entire life course adding a whole new dimension to policy analysis.

There are two steps to social science simulation: first, building the computer model and the second is to "play" or "experiment" with the model. To build a microsimulation model, detailed data are required on the individuals in the system. Individuals are then modelled with a number of key attributes (e.g., sex, age, race) and a number of transition probabilities that reflect changes over time. Once the models are built, they are run (multiple times) to establish a baseline scenario. These baseline scenarios reflect expectations of how current conditions will impact future populations, assuming the policies and the system remain constant and the only changes are the underlying demographics.

Simulation scenarios ask the "what if" questions. They are like mini experiments that identify the downstream impact on the system of a proposed change if everything else was held constant. Of course, systems are extremely dynamic and models do not and cannot predict the future. Rather, models provide predictions on the basis of past trends and take into account what is known about a particular system. As such, policy simulation modelling provides decision makers with additional information that would assist them in making rational decisions on the optimal use of scarce resources and improve the accountability of the criminal justice system.

Microsimulation provides a tool for examining the impact of the behavior of individuals on the whole system. The social science literature is rich with statistical micro data. However, most research stops after the estimation of individual processes. As Spielauer (2011) stated, "With a microsimulation model, we go one step further: microsimulation adds synthesis to analysis" (p. 11). Spielauer (2011) identifies three circumstances under which microsimulation is the appropriate simulation approach, when population heterogeneity is important, when behaviors are complex at the macro level but better understood at the microlevel, and when individual histories matter. These circumstances make microsimulation modelling an appropriate modelling technique for policy analysis in the criminal justice system.

History of Simulation Modelling of the Criminal Justice System

Microsimulation is widely used in the social sciences for policy analysis. Policy-orientated microsimulation modelling is commonly used in areas such as pensions, tax policy, income and poverty issues, and health policy. Within the criminal justice system microsimulation is not currently widely used; however, this modelling approach was quite prominent in the criminal justice system in the late 1960s (Auerhahn 2008a).

The pioneer of criminal justice system simulation modelling is Alfred Blumstein. Over 40 years ago, he, in his role as Director of President Johnson's Commission on Law Enforcement and Administration of Justice, introduced techniques from operations research, quantitative modelling, and system perspective and planning to criminal justice (Blumstein 2007). This work formed the basis for the development of the seminal computer-based criminal justice simulation model – the Justice System Interactive Model (JUSSIM) (Belkin et al. 1972). JUSSIM made it possible for the first time to examine how actions in one part of the criminal justice system affected other parts of the system pioneering the use of policy analysis tools in the formulation of criminal justice policy (Nagin 2012). This model represented the criminal justice system as a sequence of stages, starting with crime, leading to arrest and leading through the stages of the criminal justice system, ending with parole and release from parole. A major limitation of the model was the inability to incorporate feedback (recidivism) into the model. This limitation was addressed in the second version of the model JUSSIM2 (Belkin et al. 1973). This model and its variants are still in use in the USA.

Following on from this work simulation models were developed in the UK (Morgan 1985a, b) and in Australia (Crettenden et al. 1983). These early representations of the operation of the criminal justice system did so in great detail allowing for a greater range of policy simulations to be conducted. However, this increase in detail resulted in a more complex model with more assumptions included and more parameters to be estimated. This made these models difficult, time consuming, and expensive to update and maintain, and mostly these models have disappeared (see review Stewart et al. 2004).

One of the most significant findings of the early work on understanding and modelling the criminal justice system was that people in the criminal justice system are likely to end up back in the criminal justice system – the problem of recidivism. This initiated a productive line of research by Blumstein and colleagues examining the criminal careers of offenders. Criminal careers are the characterization of longitudinal patterns of offending and the distribution of these over population subgroups (Blumstein 2002). This research is still very active today (Piquero et al. 2003), and the findings have considerable policy implications for the control of crime including prevention, career modification (deterrence), and incapacitation. Furthermore, this work is the forerunner to developmental and life-course criminology (Farrington 2003), currently the most influential theoretical paradigm in criminology (Cullen 2011).

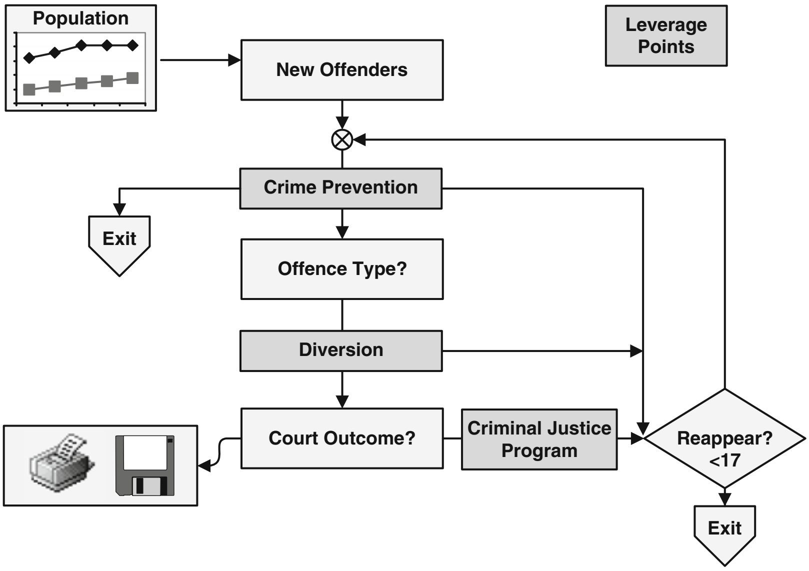
In recent years there has been a resurgence in criminal justice simulation models for policy analysis. Much of this work is carried out in house and is not published in the academic literature. Examples of work that has been published included Zarkin and colleagues (Zarkin et al. 2005, 2012) who utilized microsimulation to demonstrate the lifetime costs and benefits to society of improving prison-based post release substance abuse programs. Auerhahn (2002, 2007, 2008b) used system dynamic modelling to examine sentencing reforms, the increase of the length of stay, and the impact of aging prison populations on future prison populations. The New South Wales Bureau of Crime Statistics built a stock and flow model of the criminal justice system (Clark and Lind 2003; Lind et al. 2001) and used this model to simulate flows through the New South Wales criminal justice system.

The construction and use of the Queensland Juvenile Justice System Model is described in the next section. This description will provide the reader with a brief introduction to steps involved in building a model. There is very little publicly available documentation on the building of criminal justice microsimulation models. Following this description two published examples of the use of this model for policy analyses are briefly described. The difficulties in maintaining and using the model will then be briefly outlined.

Queensland Juvenile Justice System Model

An example of a criminal justice system microsimulation model is the Queensland Juvenile Justice System (QJJSM). The development of this model is fully explained in a technical report (Stewart et al. 2004). This model was developed in collaboration with the Office of Economic and Statistical Research, Queensland Treasury, to provide a tool for policy makers and legislators to estimate the *relative* impact of potential changes to the system in the medium term. The model was designed to assess "what if" questions, with the underlying assumption that, apart from the system change being modelled, the only changes to the youth justice system relate to demographic changes. Therefore, the focus of the model was on a comparison over time between the baseline situation (i.e., the current system) and the proposed change to the system.

This model is a parsimonious model that simulates the initiation of new offenders, the commission of specific offences, the decision of the youth court, and reoffending behavior (Fig. 1). The model is a microsimulation model, that is,



Microsimulation Models of the Criminal Justice System, Fig. 1 Diagrammatic description of the Queensland Juvenile Justice Simulation Model including leverage points

individual offenders are simulated. This allows for the examination of both the way individuals move though the system and the number of young people at various points in the system (e.g., detention). The outputs of this model are individual-based data that can be summarized and analyzed using standard statistical techniques to examine and explore the medium-term impacts of the intervention programs on the number of young people flowing through the system.

There are a number of leverage points included in the model. These leverage points represent components of the youth justice model where the implementation of a program, policy, or legislative change may result in the reduction of offending. These leverage points were designed to allow the user to add crime prevention, diversion, and post-court intervention programs to the base system. This enabled the comparison of the impact of these interventions with the baseline system.

Keeping the model simple resulted in three benefits. First, the model captured the critical components of both the system (court outcomes and supervision) and individual offender behavior (initiation, desistance, and reoffending) required. Second, the model's simple structure made easy to explain to policy makers thereby avoiding alienating the model's user base through over complexity. Third, the structure of the final schema ensued that the data required to parameterize the mode were readily available in the administrative datasets maintained by Queensland government.

The model was developed in the proprietary microsimulation package Extend. The logic for choosing a proprietary package and this particular package is provided in the technical report (Stewart et al. 2004). Prior to building the model, the administrative data collected by Queensland government to manage the operation of the youth justice system were statistically examined to develop offending rates, offence probabilities, sentencing models, and models of reoffending and desistence. Separate analyses were conducted for each stage of the system and included a series of logistic regressions for the court decisions and survival analyses for reoffending. The details of these analyses are presented in Stewart et al. (2004).

In the model new offenders enter the system from the general population. Based on the analyses of the administrative data, these offenders are probabilistically assigned demographic characteristics (age, sex, Indigenous status, and geographic region). The offence types and court outcomes were reduced to categories that meaningfully reflected statistical differences in behavior and outcomes among the demographic groups. Eight offence types were modelled. These included offences against the person, break enter and burglary, theft and related offences, drug offences, traffic offences, public order offences, property damage, and other offences. Analyses indicated that gender and Indigenous status determined the offending profiles for young offenders and there was no evidence of offence specialization. That is, regardless of the number of previous offences, the probability of a particular offences category remains constant. Consequently, the model assigns probability parameter to each demographic group, corresponding to the offending profiles identified in the data.

To determine the court outcomes (divert from formal order, non-supervised order, community supervised order, detention order suspended (immediate release order), and detention order served), a series of logistic regressions were performed to examine a range of predictive variables (number of prior appearances, Indigenous status, gender, offence type, previous detention, number of previous detention orders, number of offences finalized at appearance, total number of prior finalized offences). These analyses indicated that two variables accounted for the majority of the variation in sentencing (offence type and the number of prior finalized appearances). Probability tables based on these two variables (and gender, due to the simplicity of including it and its significance in some, but not all, of the logistic models) were created and used in the model to assign court outcomes to offenders.

The final, and arguably the most critical parameter, to be modelled was the reappearance of offenders. Young offenders re-appeared in the model if they reoffended before they turned 17 years. The analyses revealed that 65 % of court appearances were by young offender reappearing in the system. Consequently, the reappearance parameters were critical to ensure the model replicated the system. The number of times an individual reappears in the model also determines the number of prior appearances assigned to that individual. This variable was identified as critical in predicting sentencing outcomes. Survival analyses indicated that there were significant differences in the time to reappear between the four demographic groups (gender by Indigenous status). These differences were apparent in the time from first to second appearance, second to third appearance, and third to fourth appearance. After the fourth appearance the survival curves for the four groups were converging (and the numbers in each group were small). Two population Weibull distributions (with a desistance term) were fitted to the 16 categories (gender, indigenous status, and appearance number (1,2,3,4+)) to provide reappearance parameters for the model.

The model was validated by comparing the simulation results for court outcomes for the financial year 2002/2003 with the actual court outcomes for that year. These results were aggregated by court outcome and Indigenous status of the young offender. Only the detention outcomes for both Indigenous and non-Indigenous offenders fell outside the 95 % upper and lower bounds of the simulated values. The simulation model underestimated the number of young people sentenced to detention orders. These numbers are small, show high variability, and therefore are difficult to estimate. Consequently, these underestimations do not invalidate the model. However, the detention numbers produced by the model need to be treated with caution.

Policy Analysis Using the QJJSM

The primary purpose of the QJJSM is the analysis of proposed changes to policy in the youth justice system. The model cannot predict exactly what is going to happen in the future, as there are too many influential factors that cannot be modelled accurately. Instead, the model provides a baseline set of data assuming the currently system behavior will remain stable over the time period modelled, with only the underlying demographics changing (Baseline Scenario). These demographics are obtained from the projected population estimates, which indicate differential population growth between Indigenous and non-Indigenous young people. This baseline model provides a set of standard output that can be used for comparison with the proposed system changes (Policy Scenario).

Once the baseline results have been recorded, the user can include one or more prospective programs at the leverage points. The model is then rerun with the proposed programs included and the relative reduction in the flow of young people through the youth justice system can be examined. Due to the nature of microsimulation models, the resulting data are individual based and consequently can be analyzed using conventional statistical techniques to examine the impact of the proposed intervention both on the system (e.g., the reduction in court appearances or detention orders) or individuals (e.g., the reduction in Indigenous offenders). Furthermore, the model allows some simple cost analysis by incorporating the costs associated with court appearances, supervision of community-based orders, and detention.

Two examples of policy analysis using the Queensland Juvenile Justice Simulation Model have been published (Livingston et al. 2006; Stewart et al. 2008). Each of these will be briefly described.

Modelling an Early Intervention Program

Livingston et al. (2006) presented the results of the introduction of a family-based counselling program aimed at 5- to 10-year-olds. This simulated program targets young people who have yet to come into contact with the youth justice system. The results of Farrington's (1994) meta-analysis were used to provide estimates of the efficacy to parameterize this scenario. This meta-analysis indicated that such programs demonstrate a 12 % reduction in the initiation of offending by young people. Consequently, the model assumed that this program will prevent 12 % of generated new offenders from commencing a criminal career. Furthermore this simulated program was geographically targeted into areas with high populations of young Indigenous Australians.

The results of simulation indicated that immediately after introduction the program there was little impact of the program on the number of young people initiating offending. This was primarily due to the young age of the program participants. However, after a period of 10 years (the life of the simulation), the simulation estimated a reduction of 6.5 % in the number of court appearances by Indigenous young people and a reduction of 1.7 % in court appearances by non-Indigenous young people. This example highlights the benefits resulting from programs that target preadolescents can take a number of years to realise but over the longer term such programs can have a substantial impact on the number of young people appearing in the youth justice system.

Modelling a Youth Justice Conferencing Program

In Australia the use of restorative justice conferencing for youth offenders to divert young people from formal processing in the court has been introduced in all state jurisdictions. The QJJSM model was used to examine the impact of the introduction of youth justice conferencing in Queensland on the overrepresentation of Indigenous young people in the youth justice system (Stewart et al. 2008). Wider utilization of youth justice conferencing was proposed as a key strategy for reducing the high levels of overrepresentation of Indigenous Australians in the criminal justice system. Young offenders who have pleaded guilty are referred to a youth justice conference by police as a diversion from court or by the courts either in lieu of sentencing or prior to sentencing. Limited research has examined the impact of youth justice conferencing on reappearance in the criminal justice system. Work conducted in New South Wales (Luke and Lind 2002) compared the rate of rearrest for young offenders whose matter was finalized in the youth court with those who attended a conference. They estimated the rate of rearrest for conferences was 15–20 % lower than that for offenders who attended the youth court. This figure was used in the model as a measure of the efficacy of youth justice conferencing.

In 2003 when this simulation was carried out, a pilot of youth justice conference had been completed and the program was about to be rolled out across Queensland. In the policy scenario youth justice conference was equally available to all young people in Queensland regardless of gender or Indigenous status. This scenario was consistent with legislation and anticipated practices. The results of this simulation indicated the introduction of youth justice conferencing had an immediate effect of the number of finalized court appearances for both Indigenous and non-Indigenous young people. By 2011, there was a drop of 12.5 % in court appearances; non-Indigenous young people had a 13.7 % drop and Indigenous had a 10.5 % drop. However, these results need to be interpreted cautiously as over half the estimated reduction results from diversion for the court system, not a reduction in offending. The differential impact of youth justice conferencing is a result of the different offending profiles of Indigenous and non-Indigenous young people. Indigenous young people are younger at their first appearance, offend more frequently, and are less likely to commit property offences that their non-Indigenous counterparts (Stewart et al. 2004). Consequently a diversion program available principally for first time offenders and property offenders will have a greater impact on the number of court appearances and offending behavior of non-Indigenous young people.

The results of this simulation indicate that youth justice conferencing is unlikely to contribute to a reduction in the overrepresentation of Indigenous young people in the criminal justice system. In fact it has the potential to increase the disparity in the ratio of Indigenous to non-Indigenous offenders. These results contribute to the increasing debate about the need to focus outside the criminal justice system to reduce the rates of offending in Indigenous communities. Rather than focusing on criminal justice interventions (such as youth justice conferencing), more progress might be made if the focus was shifted to the underlying causes of aboriginal crime (e.g., substance abuse, family violence, poor school performance, and unemployment).

Current Status of the QJJSM

Unfortunately, the QJJSM has followed the footsteps of many previous models and is no longer functioning. Not only are microsimulation models extremely resource intensive to build; they also require ongoing resources to maintain and operate them. This model needed to be re-parameterized annually with new data to ensure that the model reflected current practices in the system. The model also needed to be updated to reflect changes occurring within the system such as new legislation and new sentencing options. Additionally, computer technology and microsimulation software is constantly changing and this model needed to be updated to take advantage of these new developments. Finally, it was difficult to convince criminal justice policy analysts about the value of simulation modelling. Within Queensland Treasury the model had “champions” who assisted with the initially building of the model. However, across the criminal justice system, policy analysts struggled to understand how they could use the model. The developers identified and tested the different policy scenarios. However, the ultimate aim was to have these policy scenarios generated from within government. Despite best efforts to educate the policy analysts, this did not happen. Consequently government did not continue to resource this model. However, the work in building the QJJSM has resulted in two important outcomes.

First, to build the model it was necessary to gain access to and develop a good understanding of the administrative data held by the various agencies of the Queensland criminal justice system. A critical parameter in building the model was the reappearance of young people in the criminal justice system. To analyze reappearance a longitudinal database was built by linking together administrative data for individuals born in 1983 or 1984, who offended and had contact with the youth justice system (police cautioning and youth court appearances). This work is ongoing and administrative data for these birth cohorts was last linked in 2011 when the individuals were 25/26 years old. The current longitudinal database (1983/84 Queensland Longitudinal Database) includes administrative data on contacts with the child protection system, the youth justice system, the adult court system and administrative data concerning their contacts with the mental health system are currently being negotiated. These data provide the basis of a productive ongoing research program examining the life course of offending, transition and turning points, cost of offending, evaluation of interventions, and geographic distribution of chronic and serious young offenders.

The second major benefit of the modelling program has been the development of strong relationships with influential public servants across the various agencies of the criminal justice system. These relationships have facilitated the research policy nexus, enabling researchers to influence the development of policies and legislation within the Queensland criminal justice system.

The Future of Microsimulation Modelling of the Criminal Justice System

In a special issue of *Social Science Computer Review*, Spielauer (2011) presented a very optimistic future for microsimulation modelling in the social sciences:

> Microsimulation is an approach whose time has come. More than half a century after the introduction of microsimulation into the social sciences, the main obstacles to this approach have almost disappeared. Computer power has increased exponentially, the collection individual data has become routine, social scientists are trained in micro data analysis and longitudinal research and the research itself has moved from a macro to a micro approach and is on the way toward a multilevel integration. The life course perspective has become a dominant paradigm and many of the pressing problems we faces are of a nature which makes dynamic microsimulation the most suitable study approach. (p. 10)

Despite this optimistic approach and the acceptance of policy-orientated microsimulation modelling in areas such as pensions, tax policy, income and poverty issues, and health policy, microsimulation modelling is still rare in the criminal justice system (Anderson and Hicks 2011). As Blumstein (2002) concluded, *Management of the agencies of the criminal justice system is still far from the model of efficiency one might like, and is still slowly moving into the information technology era* (Blumstein 2002, p. 22).

There are two key obstacles to simulation modelling practices becoming an inherent part of criminal justice planning, program, and policy development: the lack of skills among criminal justice policy makers and the politicized nature of the criminal justice system. The first obstacle to the use of simulation models is that criminal justice policy makers and practitioners do not understand simulation technology. These professionals struggle with assumptions required to build a model of a highly complex system, do not understand the various sources of data and analyses required to parameterize the model, and do not have the skills to develop and quantify policy scenarios. These professionals consider simulation models to be hard-to-operate-and-understand black boxes (Spielauer 2011). The traditional training of the criminal justice policy analyst and professional decision makers provides little or no exposure to simulation modelling. While graduates from criminal justice programs need not have the expertise to develop the models, they should be taught to appreciate the benefits of modelling and to incorporate the outputs of models into their professional practice. Without such training it is difficult for these professionals to develop a professional culture conducive to the use of models and simulations in criminal justice decision making. Without an understanding of the benefits of modelling, it is difficult for governments to justify the financial investments necessary to build, maintain, and operate the models.

The second obstacle to simulation modelling becoming normative practice in the criminal justice system is the highly politicized nature of the system. Arguably, crime and justice issues are the most politicized of public agendas. In recent years, with an increasing public concern about crime and crime rates, we have seen increasingly unsophisticated responses by our politicians to the management and prevention of offending. In these circumstances it is very difficult for researchers to encourage the use of "evidence-based" policy development let alone the use of simulation models. Furthermore, the reactive nature of current policy responses result in fluctuations within the criminal justice system that are extremely difficult to model. Auerhahn (2008a) argues that given the politicized nature of criminal justice policy, simulation modelling enables the consideration of more “radical” policy ideas at very little political or operational cost. Unfortunately, there is limited evidence that these policy ideas are implemented into actual practice in the criminal justice system.

Despite these challenges to the use of microsimulation modelling, three ways in which simulation modelling has the potential to aid decision making within the Australian criminal justice system have been identified. First, and perhaps most importantly, modelling has the potential to lead to a more informed debate about the allocation of scarce public resources. The Australian criminal justice system cost over $13 billion in the 2010–2011 financial year. These costs are increasing dramatically. However, crime victimization data indicates only slight increases in actual crime. In essence, the additional costs to the system can be largely attributed to changes in policing practices, public policy, and legislation, which are often the result of politically driven decisions in response to public concern about crime. This is reflected in criminal justice policies summed up in political catch phrases such as “get tough on crime,” “three strikes and you are in,” “zero-tolerance policing,” and “truth in sentencing” which have resulted in increases in police numbers, prison beds, and more punitive legislation. Indeed, as a result of such policies, the male incarceration rate in Australia has grown from 281 per 100,000 in 2002 to 324 in 2011. However, little attention has been paid to both the initial and cumulative costs of adopting such policies and services over a period of time (Austin et al. 1992).

A second way that policy simulation modelling may aid decision making is that such models can provide information that could assist decisions aimed at providing a more just and equitable criminal justice system. As demonstrated by the use of the QJJSM, microsimulation modelling enables an examination of the differential impact of indigenous status, gender, and geographic locality on young people entering and reappearing in the youth justice system. Currently, Indigenous young people are grossly overrepresented across Australian criminal justice systems. The modelling process facilitates the identification of points in the system where Indigenous young people (and other population groups) are differentially treated. Consequently, the use of modelling has the potential to lead to a more effective, accountable, and equitable criminal justice system.

A third benefit of policy simulation modelling is that it may provide information to decision makers crucial for the effective short-term and long-term planning of the system and the implementation of a whole-of-government approach to criminal justice in Queensland. There is an increasing recognition of the need for a more coordinated criminal justice system. Each section of the criminal justice system has its own policies, data collection strategies, and legislation. However, the complex interdependent nature of the criminal justice system means that any change in one section of the system could have substantial flow on effects to other parts of the system. Statistical models are required in order to determine the consequences of changes in policy and legislation not only for the host agency but also for other agencies in the criminal justice system.

The criminal justice system has much to gain from the use of dynamic microsimulation models. The process of modelling requires a sophisticated understanding and analysis of both the system and the data in the system. The modellers are required to understand what data are collected, why they are collected, what the limitations of these data are, and what gaps there are in the data collection. Simulation modelling transforms these data, which are routinely collected at great expense by the criminal justice agencies, into sophisticated decision support systems. This information has the potential to facilitate policy analysis, planning, and decision making leading to a more equitable and just criminal justice system.

Minorities Within the Police Workforce

Simon Holdaway
School of Law, Centre for Criminological
Research, The University of Sheffield,
Sheffield, UK

Overview

It is important for police forces to serve all communities. Questions about the just use of police powers have fostered criminological research, not least in relation to their racially discriminatory use. Notions like racial profiling, for example, have signalled police unfairness and injustice. It has become clear that some communities are policed in ways that are unfair and unjust. Research, however, has also turned attention to justice and fairness within police forces. Questions about black and other minority ethnic officers' experiences of racial prejudice and discrimination as an aspect of relationships with colleagues; of whether and, if so, why women are underrepresented in the police ranks; about unequal promotion opportunities for majority and minority ethnic and other minority officers within the workforce; and many other related questions have been explored by social scientists.

Social inequalities within the police workforce might follow those found in wider society, but there might also be a distinct experience of prejudice and discrimination among minority ethnic and women officers. Gay officers' experiences might be different from those of other minorities. Race and gender are not fixed characteristics of individuals: they are social constructs and, if policies to alleviate discrimination and prejudice from within police forces are to be developed, it is necessary to understand how they are articulated and sustained.

Introduction

Many societies retain deeply embedded laws, policies, customs, norms, and related ideas that sustain social inequalities. Equality between men and women, between the members of majority and minority ethnic groups, between people of different sexual orientations, and between able bodied people and those with physical disabilities has therefore become a major theme of politics, law and policy across the world. Societies are at different points of development when their attempts to reform and create a more equal society are evaluated. Although often faltering, major reforms of law and policy, as well as many other aspects of social change, have nevertheless contributed to attempts to form societies within which social inequalities diminish and, ideally, become wholly insignificant. Indeed, reforms to create social equality have stimulated phenomena like the civil rights movement in the USA and womens' movements that reach across continents. What has come to be called "identity politics," where participants engage in debates and action about inequalities on the basis of one criterion, their personal identification as a woman, black, or gay, for example, is recognized as a keynote of contemporary politics (Phillips 2007; Young 1990).

Police forces are not immune from these wider social trends. Discriminatory policing of ethnic minorities has become a subject of significance in many societies and of criminological research (Lamberth 2003). The failure of police officers adequately to protect women who are victims of domestic violence has gained public and criminological attention (Council of Europe 2002). A glance at programs for all the major criminology conferences will reveal sessions on ethnicity and gender as standard subjects, and scholarly societies like the American Society of Criminology have established women's and Afro-American sections. Criminology has not been immune from identity politics.

When a person is recruited into a constabulary, they join an institution that predates their membership. This means that police recruits are socialized into a structure of existing relationships and ideas, some of which relate to minorities and, therefore, to prejudice and discrimination. Individuals respond to these relationships and ideas in different ways but always with reference to what have become dominant, powerful, taken-for-granted ideas, and relationships that officers accept as commonsense (Holdaway 1983). In this sense, the police is an institution with a structure that frames individual officers' ideas and actions, including ideas about and actions related to women officers and ethnic minority officers that include views about their appropriate career paths, the ways in which they understand policing, their place within a wider social hierarchy of equality and status, and many other subjects. These ideas and related actions, appropriately called aspects of the police occupational culture, can be prejudicial and discriminatory to minorities serving in the police workforce. Criminological research has therefore to some extent focussed upon the police workforce and the experiences of women, ethnic minorities, and gay officers within it.

Two aspects of prejudice and discrimination within the police workforce are of particular importance. The first is the mediation and expression of wider social inequalities that lead to prejudice and/or discrimination within constabularies. Police officers, police policies, and related actions are not immune from widely held assumptions about women, for example. There is a strong view, for instance, that policing is a man's job; that masculinity, so called, is essential to an officer's fulfilment of his duties (Brown 2007).

The second point is that, during the last two decades, an increasing number of applicants for recruitment to the police have been women, members of ethnic minorities, and gay people. They are more than familiar with being categorized by others in prejudicial and discriminatory ways. Despite expectations to the contrary conveyed in recruitment literature and policy statements, the experience of being a member of a constabulary becomes different for women officers and for those from majority and minority ethnic groups. Indeed, the experience can lead to a view that prejudice and discrimination pervade police culture (Holdaway 1991).

This is not to suggest that all police officers are individuals who are racists, women haters, or homophobic. Neither is it to suggest that all officers from minorities perceive and respond to prejudice and discrimination in the same way. Police officers are not clones. Rather, the research described and analyzed in this entry charts contours of relationships, beliefs, ideas, and related actions that form a framework for police employment and, therefore, the experience of officers from minority groups in the workforce. Particular importance is given to the occupational culture of the police, which is precisely the context within which categorizations and understandings of group membership vie with and yield to each other. Categorizations, remember, are external to and therefore imposed upon women, ethnic minorities, and gay people. Ascriptions of group membership, however, are subjective responses to categorizations that may lead to particular actions. The institution of the police and its occupational culture are not set in stone. Rather, they should be conceptualized as processes of interaction between categorizations and understandings of group membership (Brubaker et al. 2004).

Police forces are obviously not the only work institutions that exhibit prejudice and discrimination within employment. They are however particularly important because they are a central state institution, policing on behalf of the whole population. Inequalities within police forces that demonstrate a failure to address prejudice and discrimination portray a central institution of the state with a workforce that is not representative of the general population and one that perpetuates rather than ameliorates prejudicial and discriminatory experiences of policing for minorities. This is why the experiences of minorities within the police workforce are important and have captured the attention of criminologists.

Researching Minorities Within Police Forces

Questions about whether or not a police workforce is representative of the population it serves are usually researched by statistical comparison of the percentages of a particular minority within the general population and their number within the police workforce. Controls for the age profile of the minority population ensure that only people within the recruitment age range, requisite educational qualifications, and other variables are included in the analysis. The research task here, however, is rather uncomplicated.

Other studies, mostly about women officers, have used questionnaires to ask a sample about aspects of their work. They have then often compared findings with a sample of male officers asked the same questions. Subjects of relevance, for example, have been the balance between police work and family commitments, attitudes towards police work and particular aspects of it, and relationships with male officers (Brown and Savage 1992).

“Race” and “gender,” however, are not facts that can be measured straightforwardly. Their meanings differ across societies, within different contexts and they change. The category “Asian police officer,” for example, means a person from the Indian subcontinent in England, but in the USA a person with origins in Japan, China, Indonesia, or other close geographical areas. As far as membership of an ethnic group is concerned, some British Asian police officers regard themselves as “black” and some do not. Some Asian officers prefer to signify their ethnicity by identifying with their affiliation to Islam – they are Muslim police officers – others do not and call themselves “Asian” or “black.” Similarly, characteristics attributed to women officers by male officers have been found to be highly partial: their natural ability to deal with children, for example.

The main point here is that “race,” “ethnicity,” and “gender” are social constructs. We attribute particular meanings to them within particular contexts, often assuming they are shared generally and constitute commonsense. From this perspective, interesting research questions arise about the meanings attributed to women and to ethnic minority officers. Analysis of the interaction between categorizations and ascriptions of ethnicity and of gender within the particular context of the police workforce reveals social processes through which race, ethnicity, and gender are constructed, sustained, and, maybe, changed (Holdaway 1997a). The systematic analysis of qualitative data from interviews with minority and majority ethnic and with women police officers, of policy documents, and employment law informs research of this type.

Although gender and ethnicity are distinct subjects for research, they are combined in this entry. The aim is to make clear a theoretical perspective based on the view that they are both social constructions, understood through an analysis of similar social processes that constitute and sustain them within constabularies.

Beginnings: The Power of Ideas About Subordination

The general recruitment of women into the police is a relatively recent phenomenon, realized within a historical legacy of resistance to the idea that policing can be an occupation for females (Brown 2000; Heidensohn 1992). Comparing the history of women police officers in many European societies, Jennifer Brown and her colleagues concluded that, "The idea of women officers appears to have been met with both incredulity and hostility wherever the suggestions were first made" (Brown et al. 1999).

Initial advances in the recruitment of women are due more to pressures from circumstances external to constabularies than the fostering of the idea within the police or by governments that, indeed, policing is as much a job for women as for men. In England, for example, women could only fill the void left by the diminution of men available for recruitment following national conscription in 1914 (Brown et al. 1999). Expediency rather than views about equality was in the ascendancy. Elsewhere and to some extent in England, the advancement of women into constabularies developed by a perceived need for the policing of moral concerns suited to women's attentions. Bathers who lacked adequate clothing, the spread of venereal disease in postwar Cologne, the care of lost and wayward children, fears about the sexual promiscuity of women at a time when men were at war, and a need to police prostitution formed in different societies a rationale for the recruitment of women into forces (Brown et al. 1999). The suitability of women to care for children, to prescribe and police women's morals, and, by default, not to engage in the round of routine policing that includes arresting criminals, investigating crime, and patrolling the streets sustained ideas about women's roles.

The origins of these ideas lay beyond constabularies. Given expression within the particular context of policing, however, characterizations of women as "naturally" morally sensitive, as the carers of children, in summary, as different and supporters of rather than independent from or equal to male officers were sustained. Women recruited into this context and who did not wholly share these and related dominant ideas had to develop strategies and tactics to accommodate their own understandings and related styles of policing.

A historical context of subordination to white, often colonial, or immigrant ruling minorities is a key point for understanding the early recruitment of ethnic minorities into the police. The legacy of slavery, itself a policing system, forms the background and to some extent continuing context of the position of Afro-American officers in the USA (Dulaney 1996). In Africa and in India, colonial rule framed recruitment from indigenous populations. When first recruited into constabularies, indigenous Africans and Indians entered the rank and file. Colonial rule established a continuing, natural "officer class" for what were usually white immigrants into Africa, India, and the USA. Whereas a notion of "femininity" framed women officers, different, lasting ideas about the innate intellectual and moral inferiority of indigenous people structured commonsense views about the recruitment of ethnic minorities into the police.

Following the abolition of slavery and the movement of Afro-American, former slaves from southern to northern states, the policing of exclusive, black areas of cities had to be considered (Dulaney 1996). In most northern cities, black officers were recruited to police black communities. They were prohibited from arresting white suspects and not promoted above the rank of sergeant. In many places black officers were not allowed to wear uniforms similar to those worn by white officers. Slavery ended but confining the work of black officers in terms of what was suited to the innate characteristics of "blacks" perpetuated what would eventually be regarded by Afro-American officers as systemic racism.

Understanding Origins and the Perpetuation of Structures and Ideas

The history of ethnic and gender relations within particular societies is of importance when the contemporary situation of police recruitment is analyzed. The point is not that slavery and colonial rule remain, perhaps in a covert form. It is not that the notion of women as traditionally feminine wholly perpetuates police recruitment. Ideas and hierarchical relationships that flowed from them have nevertheless been influential and resistant to change. They have formed a structure, sometimes tightly woven, sometimes much less so, with a legacy that for many years and now places constraints on women and ethnic minority officers. Highly partial categorizations related to the long-standing subordination of ethnic minorities and of women officers remain and to some extent have become taken for granted as "commonsense."

Women and ethnic minority officers work within this structure of constraint, but their experiences of policing have not been determined wholly by it. Police officers, as said earlier, are not clones (Holdaway 1997b). Some will have accepted and maybe taken for granted constraints of gender or ethnicity. Others, experiencing the symptoms of gender and racialized inequalities within policing, have responded in ways that challenge apparent commonsense. Human beings are creative and in the next section constraints that have led to distinct responses to reform are discussed.

The Beginnings of Change

Social change is complex and many different circumstances should be taken into account when understanding why the recruitment of women and of ethnic minorities into the police are subjects of public debate and policy. Although every society exhibits unique points, key features that research needs to consider apply to all of them.

The first point is that basic changes in the governance of a significant group previously denied police employment, sometimes realized through political settlement, sometimes through protest and violent conflict, provide opportunities for women and minorities to enter new sectors of the labor market. The abolition of slavery in the USA created opportunities for recruitment to the police; the end of colonial rule in parts of Africa and in India opened up similar prospects. In England, although not central to police recruitment, a women's political protest movement, the suffragettes, lobbied successfully for the extension of the political franchise to women, acting as an agent of general change to ideas about suitable employment for women (Brown et al. 1999).

No matter how dramatic events that create change might be, the past nevertheless continues to constrain the present. It was some time before black officers patrolled white areas of the USA (Dulaney 1996). A key influence was the entry of Afro-Americans into city politics and the lobbying for the election of black mayors, who then appointed black police officer, including some chiefs. The civil rights movement would eventually pave the way for greater change. Similarly, it was many years before women officers in England undertook routine rather than specialist duties. In India, the caste system prohibited members of particular social groups from police employment. Apart from this constraint, after the end of colonial rule, it was some time before indigenous Indians could hold police rank. The same situation applies to the context of independence in many African societies.

Legal change, which can follow wider political changes of the type described, has also been very important for minorities' and women's recruitment to the police (Jones 1986; Heidensohn 1992). In the USA, the introduction of positive discrimination laws and related quotas for ethnic minority officers allowed the mounting of important legal challenges in cities like New York, where a deficit of Afro-American officers was apparent (Leinen 1984). With limited success, federal law in Ontario, Canada, has required constabularies to justify why they have not realized targets for the recruitment of women and for ethnic minorities (Todd and Todd 1992). In England, the Equality Act, 2010, is the latest legislation that builds on the Sex Discrimination Act 1975 and the Race Relations Act, 1976. Public bodies now have a statutory duty to demonstrate that their policies do not discriminate against legally defined minorities within their workforce.

Once equalities legislation has been passed, chief officers can introduce policies based on positive or affirmative action and, sometimes, positive discrimination (Edwards 1987). They can and in many countries have been required to publish equalities policy statements. Combined with legislation, these policies have a number of important functions. Law and policy publicly states actions to which a police force should aspire and against which they are monitored. They make clear what should be occurring in police forces and therefore offer a tangible reference point for redress when minorities within the police workforce are underrepresented or are the subjects of prejudice and/or discrimination. They therefore offer a protection, providing a measure of confidence among potential recruits and serving officers.

Cases brought by officers who allege discrimination in employment indicate a further function of equalities legislation, which is to create cases that become public landmarks for minorities in police forces (Leinen 1984). Such cases symbolize police forces' and chief officers' lack of commitment to legislation and that chief officers can be brought to account. Reporting of cases raises the public profile of inequality within the police; litigants are named and precedents are set.

Legislation also plays a part in placing a subject like equal opportunities in the police on the wider public policy agenda, which leads to further action within and out with constabularies. Governments begin routinely to collect statistics about the number of people from different groups – ethnic minorities and women, for example – entering police employment. In many cases the under-recruitment from these groups is revealed and further questions are asked about why this is so. Regulatory bodies concerned with monitoring and in some instances the prosecution of police forces (among other public bodies) become the justification for these organizations' existence. Regulatory bodies rarely work to abolish themselves.

These conditions relevant to the beginnings of change also have a wider relevance than, for example, individual acts of legislation being passed, discrete cases being brought, and unconnected policies being developed and regulated. They do not constitute a necessary, fixed point of development but are important features of a social process leading to changing the position of women and ethnic minorities within constabularies. The personal experience of, for example, a woman who is hesitant about police recruitment or of a black British person concerned about the possible experience of police employment is not viewed as events in the lives of untypical people. They are recognized as a part of a shared experience within an identified institution and therefore amenable to public comment. As the sociologist C. Wright Mills put it, "personal issues" become "public problems" (Mills 1959). Once realized, the status of a public issue changes. It begins to be secured as a recognized subject of public debate and confirms a reality of police employment for women and for ethnic minorities. Its dismissal as a personal grudge of a few individuals or a partial concern of minorities is challenged strongly.

Experience After Joining

Most research about women police officers has been concerned with documenting dimensions of prejudice and discrimination. One of the much cited, early studies is Susan Martin's participant observer research with Washington's police.

She summarized women officers' experiences in the following way:

> (Women) are excluded from the information exchange network and informal social life... Police women's behaviour is circumscribed by the stereotypical roles in which they are cast... which reminds women that as females they are sex objects, vulnerable to harassment yet held responsible for the outcomes of the interaction. (Martin 1980)

Attempts to integrate women into the police workforce have been challenged by what some have called a "cult of masculinity" articulated through the occupational culture (Heidensohn 2005). Among others, beliefs about the need for physical strength, bravado, and reliability to support colleagues in trouble have framed women officers' experiences of police work. Jokes and stories about women officers have sustained these views. Women have been excluded from socializing and working with male colleagues. Before considering them as colleagues who can be trusted, male officers have wanted to determine where their loyalties lie. Reviewing research studies undertaken in a good number of societies, Jennifer Brown found policemen exhibit hostile attitudes about women as patrol partners in the USA, Sweden, England, Scotland, Northern Ireland, and India (Brown 1997).

A number of important consequences have arisen from these circumstances. One is that women have not been promoted in adequate numbers to the supervisory ranks (Silvestri 2003). The other is that women officers are underrepresented in some specialist areas of policing traditionally regarded as most suitable for men. Brown found this in firearms squads in English constabularies (Brown and Sargent 1994). Westmarland found during her study of a provincial force that women were working disproportionately in specialisms related to child victims (Heidensohn 2005). More recent work has found that women working in the London Metropolitan Police child abuse units have been afforded a low status (Heidensohn 2005, p. 569).

Ethnic minority officers have a similar experience of discrimination and prejudice. Studies conducted in England and Wales documented the widespread use of racist language by white officers, racist jokes and stories, exclusion from socializing with white colleagues, and a diminished status within the workforce (Holdaway and Barron 1997). Research in American police forces has documented similar findings (Bolton and Feagin 2004).

The occupational culture has been analyzed to understand more precisely how race and ethnicity are articulated through it. A routine and necessary use of typifications which lend themselves to stereotypes of race (and gender), the demands of perceived teamwork as fundamental to policing, and the telling of stories and jokes that can articulate race prejudice sustaining discrimination have been found to be important (Holdaway 1997a). Officers' racialized identities were dominated by their ethnic majority colleagues' categorization of them as "black" rather than of police officers who happen to be black. White officers place the racialized identity of colleagues in the ascendancy.

Further dimensions of discrimination have been charted, identifying a lack of promotion prospects, premature resignation from constabularies, and unwillingness by senior officers to understand the context within which their minority ethnic officers work (Holdaway and Barron 1997).

Responses

One of the most interesting changes in policing has been the response of ethnic minority and of women officers to experiences of prejudice and discrimination. Ethnic minority and women police associations have worked within a context of legal change, where sex and race discrimination laws have become prominent and public expectations about the composition and management of the police workforce have been supportive.

Police forces are hierarchical organizations. Policy is developed by senior officers, with more junior ranks expected to implement it. An important feature of change in the position of ethnic minority and women officers, however, has been the reversal of this policy process (Holdaway 2009). Women and ethnic minority officers have formed police associations with memberships based solely on gender or ethnic identification.

The associations have in many respects become social movements within police forces. Forms of identity politics have entered debates and action to change police policy. Virtually all of the 43 constabularies in England and Wales have a Black Police Association and representative membership of the British Association of Police Women. American police forces have hundreds and probably thousands of similar associations. Discrimination and prejudice is challenged by all of these associations, as it is by larger groupings, the National Black Police Association and the European Network of Women Police, for example.

Criminologists can continue to describe and to some extent analyze the outcomes of associations' actions. The experience of officers can be documented. Previous studies can be repeated to assess the extent and character of change. This type of work will provide interesting information but not address important theoretical and related, empirical questions about the ways in which "race" and "gender" are constructed and sustained within the police.

It was argued in an early part of this entry that race and gender are social constructions. From this theoretical perspective it becomes possible to research changing meanings of such phenomena and, therefore, the ways in which race and gender are articulated within police forces, processes that lead to the changes, specific contexts within which prejudice and discrimination are experienced, and to compare and contrast what might be similar processes that marginalize minorities within the police workforce.

Race and gender are now matters for police policy. That has not always been the case. Race prejudice and discrimination were once phenomena of relevance to individuals who sometimes sought legal remedies – individual cases – to deal with the difficulties faced. The same could be said of gender and the situation of women officers. Once defined as phenomena to be addressed by policy, the meaning and status of race and of gender change. They are phenomena representing a collective experience requiring the attention of senior officers. What was an individual experience of a black officer or a women officer is now an organizational problem. In England what was once defined as race prejudice and/or discrimination and sometimes as "equal opportunities" became "institutional racism," called "systemic racism" in North America and Canada. The history of women's and ethnic minority police associations can be understood as aspects of a process within which race and gender are refined as they are related to a distinct, shared experience of police employment (Holdaway and O'Neil 2006). Differences between male and female officers and between black and white officers are emphasized within this process and presented as the widely shared experience of police employment. The notions of women officers and of black officers, for example, are accepted as representing particular experiences of police employment related to distinct realms of policy. While apparently secure, such experiences require the continuing vigilance of women's and black police associations. Their work sustains particular constructions of the relevance of gender, race, and ethnicity to police work and its management by senior officers.

One feature of the development of black police associations in the USA and in the UK has been an awareness of a distinct experience of police employment among minority ethnic officers who, despite having a dark skin color, do not identify as "black." These officers cannot unite with black officers, who define the experience of race prejudice and discrimination as common to all colleagues from minority ethnic groups (Holdaway and O'Neill 2004). The consequence of this situation has been the development of many police associations representing different ethnic groups – Asian, Greek, Italian, and Turkish police associations, for example. Other associations have been formed by the criteria of religious affiliation and in the UK, for example, there are Muslim, Jewish, Hindu, and Sikh police associations. The difference between these associations and those for black colleagues is a focus upon culture rather than race. Their claim is that unless particular cultural practices are recognized by a police force, they experience discrimination and prejudice. Halal food, access to prayer rooms in police stations, and freedom from work on the Sabbath have become subjects of policy.

Each ethnic group of officers, with its distinct culture, has been recognized, leading to conflicting understandings of minorities within the police workforce. Black officers argue that there is one experience of race discrimination, irrespective of membership of an ethnic minority group. To argue otherwise is to cause division, to weaken the claims of those who experience discrimination, and to privilege partial, cultural interests above those shared by all ethnic groups. Multicultural policies recognize differences between many groups; race policies address a fundamental, shared reality of discrimination.

Police forces throughout the world have responded to the claims of women officers and, though to a lesser extent, minority ethnic officers. Work is not yet finished, but policies to address many of the problems encountered by the members of these groups have been developed. Despite this situation, research in the UK suggests that while overt prejudice and discrimination has all but disappeared, their covert forms frame the reality of police employment. When asked for examples of covert discrimination and/or prejudice, as part of a study of black police associations, black officers presented examples that relied on their ability as a black person to know the motive lying behind a white person's action. They could sense it in a way a white person could not identify prejudice or discrimination (Holdaway and O'Neill 2005). It would be interesting to research women police experiences to understand whether they identify with similar forms of prejudice or discrimination.

The difficulty with these explanations of covert racism, as it is called, is that they rest on an assumption that black police officers are *essentially* different from white officers. They have a privileged access to the motives of white officers because, and only because, they are black. Their claim is an essential one, which is in conflict with ideas about race equality because claims to race equality are dependent on the assumption that all human beings are essentially the same. Black officers who define covert racism in these terms are thus arguing that they are the same as the ethnic majority but also essentially different.

An implicit argument here is that future research about minorities in the police workforce is that both similarities and differences between women and minority ethnic officers characterize experiences of discrimination and prejudice. Research has so far focussed upon differences between majority and minority groups in the police, which are important and the continuing subject of policy. Comparative research within and between police forces could however analyze in greater detail whether or not similar processes and forms of prejudice and discrimination lead to what are defined as essentially different experiences. We know, for example, that racist and sexist jokes, that exclusion from informal networks, and that stereotyping are processes that marginalize officers from both groups. Closer attention to this matter could clarify the essential and phenomenal forms of marginalization and exclusion within police forces and, maybe, in other work organizations.

Mitigation and Aggravation at Sentencing

Julian V. Roberts
Faculty of Law, Centre for Criminology,
University of Oxford, Oxford, UK

Overview

The determination of factors which aggravate or mitigate punishment is an under-researched yet vital subject in the field of sentencing. Sentencing factors affect the severity of sentences imposed. Indeed, the determination of sentence may be regarded as a judicial weighing of all relevant mitigating and aggravating circumstances. The important word here is "relevant." Before a court takes a particular factor – X – into account, it needs to be satisfied that this factor is relevant to the sentencing decision. Factors unrelated to sentencing – such as the offender's income, gender, race/ethnicity, or social class – should be ignored. As will be seen, some sentencing guidelines explicitly direct courts to ignore irrelevant factors such as race and employment status.

After some introductory comments this chapter notes the sources of guidance for sentencers with respect to mitigation and aggravation. This is followed by a discussion of the problems associated with this guidance. At present, guidance regarding sentencing factors tends to be modest: guideline schemes around the world generally adopt a relaxed approach to the use of sentencing factors. Even in the US-based systems where some factors are excluded from consideration, guidance regarding the application of other factors is quite limited. This state of affairs may reflect the view that consideration of mitigation and aggravation is more properly left to the exercise of judicial discretion, with only minimal direction from the legislature, the guidelines authority, or the appellate courts (for further discussion on aggravation and mitigation, see Walker 1999; Ashworth 2010; Roberts 2011b).

Establishing the Relevance of Factors

How do we establish that a factor is relevant? One definition is that a factor is relevant if it relates to the objectives of sentencing. For example, an offender's expressed intention to take a drug treatment program is relevant to the sentencing purpose of rehabilitation. Accordingly, a court may reasonably take this fact into account and mitigate the sentence imposed, because the offender is taking steps towards rehabilitation. Now consider an aggravating factor such as hate motivation. Imagine that an offender is convicted of racially abusing his victim prior to and during an assault. This factor makes the crime more serious: the victim's social identify and social group have been threatened. Since one of the purposes of sentencing is to impose a sentence which reflects the harm caused, the offender can legitimately be punished more severely; hate motivation is therefore a relevant aggravating circumstance.

In most jurisdictions, the objectives of sentencing are enshrined in statute. For example, the Criminal Justice Act 2003 identifies the sentencing purposes in England and Wales, while Section 718 of the *Criminal Code* of Canada lists the sentencing objectives for courts in that country. Across the USA, guidelines manuals such as those in Minnesota or at the federal level provide this information for courts. Consulting these purposes will provide courts with insight into the relevance of any particular factor at sentencing. Since most countries pursue multiple sentencing objectives, including deterrence, rehabilitation, incapacitation, and retribution, the list of potential mitigating and aggravating factors is vast, hence the need for guidance from either the legislature, courts, or a sentencing council or commission.

Factors Unrelated to Sentencing Purposes

Finally, there are some factors considered by courts – usually mitigating in nature – which are clearly unrelated to any specific sentencing purpose but which are nevertheless recognized as legitimately affecting sentencing. The best known of these is probably the guilty plea discount. Pleading guilty does not make the crime less serious or reduce the offender's level of culpability for the offence. Nor can it be said that giving reduced sentences to offenders who plead guilty is relevant to deterrence. If anything, significant reductions in severity for offenders who plead guilty may undermine the deterrent power of sentencing: offenders may be encouraged to offend – or at least not deterred from offending – by knowing that they can get a lighter sentence by pleading guilty.

Yet almost all countries offer offenders who plead guilty a significantly discounted sentence. Why? It is done in the broader interests of justice. When an offender pleads guilty, the state saves the cost of a trial, and victims and witnesses are saved the trouble of testifying. So in order to promote more efficient administration of justice and to spare victims and witnesses, we offer an incentive to offenders in the form of a reduced sentence. The same argument is used to justify sentence reductions in cases where the offender provides assistance to the state in prosecuting other offenders. These two factors – a guilty plea and providing assistance to the state – are unrelated to crime seriousness or offender culpability but are nevertheless taken into account to promote broader goals of the criminal justice system.

The concept of crime seriousness is primordial across most jurisdictions, whether common or civil law. Gravity is a function of harm and culpability. Crimes cannot be precisely calibrated by legislatures – although gross differentiations can be made and are reflected in the relative severity of statutory maximum penalties. Accordingly, courts must weigh a wide range of offence – and offender-related factors in order to determine the seriousness of the offence and hence the severity of the sentence. Some factors enhance sentence by increasing or lowering the seriousness of the crime; others influence sentence by enhancing or diminishing the culpability of the offender. Mitigating and aggravating factors are often taken for granted by members of the public – we all have intuitions about whether factor X should result in a more lenient or a harsher sentence. But many problematic circumstances exist. Factors may be considered relevant by some, irrelevant by others.

Consider intoxication, a circumstance explored by Padfield (2011). Should the fact that the offender was drunk at the time of the offence mitigate the sentence on the grounds that the offence was uncharacteristic ("I have never seen him act like that – it must have been the booze")? On this line of reasoning, intoxication sustains a more general claim that the offence was "out of character." People who normally lead law-abiding lifestyles sometimes commit criminal acts under the disinhibiting effect of alcohol. But are they reasonably adjudged less blameworthy as a result? There is a strong counterargument in cases in which the offender has a history of heavy drinking: he or she may be seen as being more culpable for failing to exercise some restraint regarding a known problem. Might intoxication actually aggravate the sentence – as in the case of an offender who drinks heavily knowing that this often results in criminal assaults in pubs? As with a number of other factors then, intoxication may aggravate or mitigate, depending upon the particular circumstances of the offender. Intuition, in short, is often a poor guide to principled sentencing.

Conceptual Frameworks

Despite the importance of sentencing factors, as Ashworth notes, the concepts of aggravation and mitigation have attracted little close examination or theoretical discussion (2010, see also Walker 1999; Roberts 2011b). Categorical breakdowns of sentencing factors exist but surely more than this is needed. More recently, Jacobson and Hough propose a categorical framework for factors relating to personal mitigation (Jacobson and Hough 2007a; Roberts and Hough 2011). They propose classifying factors into categories relating to the crime, the offender's response to the offence and prosecution, and the offender's past (including previous convictions) and future. Classifying factors is one way of bringing some order to the vast array of factors potentially relevant to the determination of sentence. As will be seen, there is considerable variation across the common law world with respect to the degree and nature of guidance regarding sentencing factors.

Sources of Guidance: Legislature and Appellate Courts

The Legislature: Statutory Sentencing Factors

Legislatures affect sentencing factors through codification. Almost all common law jurisdictions have placed certain mitigating and aggravating factors on a statutory footing – albeit with some exceptions: in Tasmania, for example, the sentencing legislation does not identify any factors. According to some statutes judges are directed to consider these statutory factors when determining the seriousness of the offence. For example, Sects. 2 and 3 of Chap. 29 of the

Swedish Criminal Code 1988 specify factors that enhance or diminish the penal value of the crime. In addition, Sect. 5 of the chapter specifies eight additional mitigating circumstances that a court shall consider "to a reasonable extent." These include factors such as whether the punishment would have a disproportionate effect on the offender due to advanced age or ill health. Finland adopts the same approach.

The number of codified factors is generally small: in Finland a sentencing statute specifies only five factors which should increase the severity of the punishment, while the Canadian *Criminal Code* specifies only a handful of aggravating factors and no mitigating factors. This reflects a trend found elsewhere, including England and Wales, to provide more guidance with respect to aggravation than mitigation. The explanation for this asymmetry is unclear; it may reflect a view that aggravating factors are relatively straightforward and consistent in application. This means that the legislature can specify a factor as being relevant, confident in the knowledge that this factor is easily and consistently applied by courts. For example, if one agrees that hate motivation is an aggravator, it surely operates across all offences and offenders. There may be less consensus about the relevance and weight of different mitigators, in which case it is hard to be more prescriptive.

In England and Wales, only a few sentencing factors have been placed on a statutory footing. The *Criminal Justice Act 2003* provides no indication regarding the relative weight of these factors, their potential to affect the decision of whether a term of custody is imposed, or whether they are more important than other sentencing factors emerging from the case law. The statute thus provides only limited guidance to sentencers regarding the sources of aggravation and mitigation. This reflects the existence of the sentencing guidelines issued by the Sentencing Council and which are designed to supplement and interpret the statutory framework. Other jurisdictions provide more comprehensive lists of statutory factors. Thus, the Crimes (Sentencing Procedure) Act 1999 in New South Wales identifies 21 aggravating and 16 mitigating factors. Section 9 of the *Sentencing Act 2002* in New Zealand notes ten aggravating, seven mitigating, and one statutorily excluded sentencing factor (see Young and King 2011).

Guidance from the Appeal Courts

Until the advent of sentencing councils and commissions to disseminate guidelines, the appellate courts have been the traditional source of guidance at sentencing. An evaluation of the adequacy of appellate guidance regarding mitigating and aggravating circumstances is beyond the scope of this chapter. However, numerous academic commentators and commissions have identified the limitations on appellate guidance in general and the area of mitigation and aggravation in particular. Most sentence appeals address a specific point of law or provide a test for whether the sentence imposed was manifestly unfit. Guideline judgments in which the court sets out the mitigating and aggravating factors relevant to the offence are rare.

Sentencing Guidelines and Mitigating/Aggravating Factors

United States

Under most American sentencing guideline schemes, the role of mitigating and aggravating factors is generally to justify the imposition of a sentence that is outside the range prescribed by the guidelines or to move the case from the normal range up to an aggravated or down to a mitigated range. In the landmark decision in *United States vs. Booker*, the US Supreme Court held that the federal sentencing guidelines are merely advisory rather than bindingly presumptive in nature. The mitigating circumstances therefore may be reasonably described as mitigating factors rather than "departures" in the stricter sense of the pre-*Booker* era (see also discussion in Berry 2011).

The Utah guidelines manual notes that "There are occasionally circumstances that compel deviation from the guidelines" (Utah Sentencing Commission 2007, p. 12). Directions are provided to courts with respect to the consideration of the sources of mitigation and aggravation. A non-exhaustive list of factors is provided, and courts are directed that in considering all aggravating and mitigating factors in a particular case, the number of each should not merely be added up or otherwise mechanically applied in the balancing process. Rather, the totality of the mitigating factors should be compared against the totality of the aggravating factors. The sentencing guidelines in North Carolina provide sentencers with three sentence ranges: presumptive, aggravated, and mitigated (see Lubitz 1996; North Carolina Sentencing and Policy Advisory Commission 2007).

England and Wales

Sentencing guidelines exist for most common offences and are issued by the Sentencing Council for England and Wales or its predecessor, the Sentencing Guidelines Council (see discussion in Ashworth 2010). Rather than forming part of a grid encompassing all offences, the English guidelines are offence specific. They provide sentence ranges for categories of seriousness – most offences are divided into three levels. Each definitive guideline also contains a list of relevant mitigating and aggravating factors of particular relevance to the specific offence which is the subject of the guideline. For example, for the crime of domestic burglary, committing the offence at night, when a child is present in the residence, and creating damage to property are all cited in the guideline as aggravating factors (Sentencing Council 2011). In addition, there is a guideline for the determination of offence seriousness which is applicable to all offences (Sentencing Guidelines Council 2004).

In its definitive guideline regarding the determination of offence seriousness, the Council provides two lists containing 31 aggravating factors that arise from a higher level of culpability or a greater degree of harm (or sometimes both conditions). These are described as being the most important aggravating circumstances with application across many offence categories. The lists are non-exhaustive and provide no hierarchy of importance. The lists include both statutory and non-statutory factors but make no commentary on the relative importance of the two. They are then followed by four factors that indicate when an offender's culpability is unusually low or that the harm is less than usually serious. There is an imbalance in the lists therefore: 31 factors are identified that enhance sentence severity, while only four factors are noted which may reduce the level of culpability or harm (Sentencing Guidelines Council 2004).

Guilty Plea Discount

With respect to one important sentencing factor – a guilty plea – the Sentencing Guidelines Council (now the Sentencing Council) has provided clear and detailed advice. The Council's definitive guideline makes it clear that the reduction for a guilty plea "derives from the need for the effective administration of justice and not as an aspect of mitigation" (Sentencing Guidelines Council 2007, p. 4). Nevertheless, in other jurisdictions a guilty plea is interpreted as a mitigating factor and so the issue is worth comment in the present context. The definitive English guideline published in July 2007 specifies the range of the reduction in sentence as well as the circumstances that justify different levels of reduction (Sentencing Guidelines 2007). This level of guidance reflects the importance of this factor in terms of sentencing and the administration of justice (see earlier discussion). With respect to other aggravating and mitigating factors, however, guidance is less comprehensive or precise. In all the guideline schemes, a number of elements are missing or require greater elucidation.

General Issues Arising from Mitigating and Aggravating Factors

Rationale for Mitigating or Aggravating Sentence

It would be useful for a guidelines authority to articulate the *rationale* for considering specific mitigating and aggravating factors. This is not simply an academic exercise; awareness of the rationale for mitigation will focus sentencers' attention on the question of relevance. The English Sentencing Guidelines Council's

Seriousness guideline provides only a limited rationale for the invocation of any specific factor. Sentencing factors are particularly relevant when they indicate a higher or lower level of culpability or harm. Some sentencing factors however are unrelated to these concepts and are applied because they are relevant to the statutory objectives of sentencing identified in s.142 of the *Criminal Justice Act 2003*. Sentencers should be encouraged to use this section to guide their application of the factors. When contemplating a potential mitigating or aggravating circumstance, it is important to consider whether it is relevant to one of the sentencing objectives or principles.

Some factors may be relevant independent of any link to the statutory objectives, but in general, the coherence of the sentencing process is impaired if many factors unrelated to the sentencing purposes are taken into account. A clear statement of the rationale for any specific factor would also help members of the community and crime victims to understand why the factor was taken into account at sentencing. A good example of an ambiguous or controversial factor is positive actions by the offender which speak to his or her good character but which are unrelated to the offence.

Criminal History

Perhaps the most important sentencing factor operates in mitigation and aggravation, potentially increasing the severity of sentence in some cases and reducing it in others. Generally speaking, the absence of any prior convictions is a powerful mitigating factor: the offender claims a "first offender" sentencing discount. The argument is advanced that the offence was out of character since he has never been convicted before. Moreover, first offenders receive a discount because the state recognizes human frailty – everyone can fall into crime at some point; this is known as the "lapse" theory (see von Hirsch 2010). First offenders are also less likely to re-offend (compared to repeat offenders), and so the absence of prior convictions justifies more lenient treatment under a rehabilitation or deterrent sentencing rationale.

On the other hand, as the offender re-offends, accumulating more convictions and becomes a repeat offender, sentences generally get harsher. The presence of prior convictions is in fact the most important aggravating factor under the US guideline schemes. Some US systems (including the federal guidelines) use a two-dimensional grid where one dimension or axis is crime seriousness, while the second is criminal history.

Several justifications exist for imposing harsher sentences on repeat offenders. First, they may be regarded as more blameworthy for having committed a crime after repeatedly being sentenced for other offences (Roberts 2008). Second, repeat offenders are in general more likely to re-offend and therefore should receive harsher sentences according to a deterrent or incapacitation perspective. It is important that guideline schemes articulate the justification for the use of prior convictions and also the weight that previous convictions should carry at sentencing. Otherwise, courts will apply their own criteria in considering this common factor. The US guidelines provide this direction, but no other jurisdictions have followed this example.

Worthy Conduct Unrelated to the Offence of Conviction

A recurrent mitigating circumstance in many jurisdictions arises when prior to or after conviction the offender has performed some commendable action for the community. This is sometimes recognized in sentencing law. For example, s.6 of the Sentencing Act 1991 in the Australian state of Victoria states that "any significant contributions made to the community by the offender" is a relevant factor to be considered at sentencing. The classic case involves the offender who shows some act of exceptional bravery shortly before or after conviction. It is unclear why this kind of action should justify leniency, yet sentencers sometimes mitigate the sentence on this basis. Indeed, there is a strong intuitive appeal to a policy of mitigating sentences for offenders who have a history of very creditable social behavior.

Most jurisdictions permit courts to recognize a mitigating factor that is unrelated to the principal theoretical orientation of sentencing. The Wisconsin Sentencing Commission provides a list of "additional factors" that do not relate to the primary sentencing rationale. The list includes items as diverse as the contents of the victim impact statement and whether the offender suffered public humiliation or loss of employment as a result of having been convicted (Wisconsin Sentencing 2007, p. 8). However, these factors should not carry the same weight as more fundamental sentencing factors – those relating to crime seriousness or culpability. Guidance would be particularly useful with respect to the weight that should be attached to collateral consequences of the offence. Here, too, distinctions will need to be made between consequences that the offender should have foreseen – such as loss of driving privileges and subsequent employment for taxi drivers – and other, exceptional and unusual consequences such as the death of a relative or friend as a result of a fatal accident arising from a driving offence. It is surely more reasonable to consider the latter than the former as justifying a mitigated punishment.

Power of Sentencing Factors to Influence Sentence

Guidance is seldom provided with respect to the power or influence of a specific sentencing factor. For example, how much should a sentence be reduced to reflect the fact that the offender is remorseful and has apologized to the victim? How much harsher should a sentence be because the offender spent some considerable time planning the crime? One explanation for this absence of guidance is that it is hard to specify in advance; the importance of premeditation or remorse will depend on the individual circumstances of the case appearing for sentencing. In some cases remorse may be much more important than others – and it is therefore impossible to specify this in advance. Legislatures for this reason leave courts free to make the decision as to how much weight should be ascribed to particular factors.

Some guidance may be useful regarding the relative weight to be assigned different aggravating and mitigating factors – they are clearly not all equally important. The circumstances identified by the English Council in its Seriousness guideline represent a wide range, some important, others less so. For example, by virtue of its statutory foundation and the number of cases to which it is relevant, the existence of previous related convictions should carry far more weight than factors such as "causing gratuitous damage to property over and above what is needed to carry out the offence." Sentencers should be provided with some sense of the relative power of these factors to influence the quantum of punishment. This is not to say that precise weights should be assigned to factors, rather that if a factor is particularly important, sentencers should be aware of this fact – otherwise they are free to develop their own hierarchies of impact.

This level of guidance is provided in some guideline schemes. For example, in Sweden the existence of mitigating factors permits the court to impose a sentence below the statutory minimum sentence. Allowing a factor this much influence is controversial, but at least sentencers are given an indication of the extent to which a mitigating factor may reduce the custodial term. In a similar fashion the sentencing statute in the state of Alaska identifies two gradations of mitigation. If the presumptive term is 4 years or less, mitigating factors may reduce the sentence by up to this amount. If the presumptive term is longer than 4 years, mitigating factors may reduce the sentence by up to 50 %. Placing limits on the impact of sentencing factors provides sentencers with an idea of the extent to which these factors can affect the sentence. Moreover, it would surely be useful to indicate to courts whether sentencing factors taken together, or on an individual basis, can make the difference between custody and a community sentence. Some guidance should be provided with regard to the factors which have the potential to move the offender above or below the custodial threshold.

Categorizing Sentencing Factors

The sentencing factors provided by statutes or guideline schemes include a mixture of different factors, some relating to the offender, some to the offence. A more coherent approach would involve providing categories of factors. This approach has been recommended in a report by the Australian Law Reform Commission (ALRC 2006). The ALRC proposed grouping sentencing factors into eight categories with the intention of setting them out "in a logical and clear manner, such as within groups that share a common theme" (p. 168). If sentencers worked through each category systematically, this might result in a more thorough and consistent review of the circumstances of each case.

Excluding Factors and Controversial or Asymmetrical Factors

The English Sentencing Guidelines do not specify factors that should *not* be considered in mitigation or aggravation. It would be both unrealistic and undesirable to construct a sentencing guideline which would specify all potential mitigating and aggravating circumstances. However, greater consistency of application would be promoted by identifying problematic factors that should not mitigate or aggravate or by specifying the way that factors should be considered. Most sentencing guideline systems identify a number of factors that should be excluded from consideration. For example, the detailed series of proposals made by the Australian Law Reform Commission includes a number of grounds which should not aggravate sentence.

Similarly, many US guidelines identify specific grounds which should not be considered by a sentencing court. For example, in Minnesota, the guidelines exclude a number of factors including race. Establishing a list of proscribed as well as permitted factors also compels the guidelines authority to confront the underlying principles and consequences of different mitigating factors. Consider the offender's employment status or employment history. This circumstance is often cited by sentencers as justifying the imposition of a mitigated sentence, in order to preserve the offender's source of income or possibly to prevent the infliction of collateral harm upon his or her dependants. Research has repeatedly demonstrated that employment status is a significant predictor of whether a custodial sentence is imposed (e.g., Moxon 1988). However, the application of this factor obviously disadvantages unemployed defendants or offenders with poor employment histories. Visible or immigrant minority offenders may be particularly affected, which is why a number of commentators have advocated the prohibition of this factor and why some sentencing guidelines (such as those in Minnesota) explicitly exclude it.

Personal Mitigation

Finally, sentencing guidelines around the world say little about "personal mitigation" – factors relating to the offender rather than the offence and which typically serve to mitigate punishment. In his sentencing text Thomas argued that allowance for mitigation should not be considered to be an entitlement of the offender (1979, see p. 174). Times may have changed since he expressed this opinion. Today, personal mitigation is generally accepted as a fundamental element of the sentencing process – as noted by Lovegrove (2010). A distinction has sometimes been made between personal mitigation and mitigating factors relating to offence seriousness – to which an offender is entitled. The distinction is spurious and invites disparity of application. If a particular factor reduces crime seriousness or the offender's level of culpability – whether as a result of personal factors or not – the sentence should be mitigated accordingly.

The English Council's Seriousness guideline notes only the statutory provision in the Criminal Justice Act 2003 which authorizes courts to take account of any matters that "in the opinion of the court, are relevant in mitigation of sentence" and then states that courts should "consider any offender mitigation. The issue of remorse should be taken into account at this point along with other mitigating features such as admissions to the police in interview" (Sentencing Guidelines Council 2004). The Magistrates' Court Sentencing Guidelines simply direct magistrates to consider "offender mitigation" and offer three or four examples.

Personal mitigation surely requires more attention from scholars. Research conducted in 1980 found that personal mitigating factors appeared more than any other category in speeches for mitigation (Shapland 1981). More recent research with sentencers in England and Wales has demonstrated that personal mitigation still plays the largest part in tipping the balance away from the imposition of a term of custody (see Hough et al. 2003, at p. 37). The most recent English study found that in approximately one-third of the cases observed, judicial recognition of personal mitigation changed what would have been a custodial sentence to a community-based sanction (Jacobson and Hough 2007; Roberts and Hough 2011). This research study also revealed that many different personal mitigating factors were taken into account by sentencers and that while agreement was expressed with respect to some factors, participants disagreed on many others. As the authors note, the Council needs to provide better guidance in this area, beginning with the principles on which personal mitigation is based.

Role of Public Opinion

Ideally, mitigating and aggravating factors should be recognized by the community as being relevant to sentencing. If courts take a factor into account deemed irrelevant by the community, confidence in sentencing will decline. There is a considerable literature on public attitudes to mitigating and aggravating factors. This research reveals that the public recognize a wide range of factors as being relevant to sentencing (e.g., Lovegrove 2010; Roberts and Hough 2011). In this sense they are like judges, who, as noted, take a wide range of factors into account at sentencing. On the other hand, there are some factors where the community and courts diverge. In practice, the absence of prior convictions is an important mitigating factor; first offenders usually receive a significantly reduced sentence compared to repeat offenders convicted of the same offence. The public, however, are less enthusiastic about offering this discount to first offenders, particularly for more serious crimes.

In order to promote a greater degree of "fit" between courts and communities regarding sentencing factors, guidelines authorities often undertake research into public attitudes to mitigation and aggravation, to see which factors attract greatest support (e.g., Roberts et al. 2008, 2009). The findings from this research then help guidelines authorities shape the mitigating and aggravating factors found in the guidelines (Roberts and Hough 2011). Of course there are limits to this kind of exercise; an offender should not receive a harsher or more lenient sentence just because his case contains a factor the public perceive to be relevant to sentencing; there must be some legal relevance to the factor.

Conclusion

The number of potentially relevant mitigating and aggravating factors is, as noted, huge. For this reason, it is important to establish which are relevant and to provide courts with some guidance regarding the application of sentencing factors. Over a generation ago, scholars called for more judicial guidance regarding the criteria for mitigation and aggravation. Thus, Ashworth lamented the absence of "any thorough consideration of the claims of the various personal factors" and argued that "this is a sphere in which discretion has led largely to anarchy" (1987, pp. 30–31). So long as it does not unduly impair a court's ability to impose an appropriate disposition, any attempt to structure judicial discretion is welcome. Courts around the world would benefit from more detailed and structured guidance regarding the use of mitigating and aggravating factors at sentencing. The search for relevant sentencing factors should not involve a fishing expedition but rather an inquiry into principled adjustments to the sentence.

Modus Operandi of Sex Offenders

Eric Beauregard
School of Criminology, Simon Fraser University,
Burnaby, BC, Canada

Overview

Traditionally, the research on sex offenders has focused on the etiology of these crimes in order to inform treatment modalities as well as risk prediction practices. Needless to say that the classification of the individuals committing sexual crimes has attracted a lot of attention, first from clinicians and then from academics. The first typologies have mainly focused on the offender and his characteristics. But subsequent typologies have started to take into account the specific characteristics of the offense as well. These behavioral features were easier to observe, thus facilitating the classification of offenders based on these features. However, when one carefully examines the behavior of sex offenders, several problems emerge with the existing typologies. To begin with, typologies of the offending process focus on the aggressor, ignoring the entire criminal event – that is, the offender, the victim, and the context (Meier et al. 2001). Second, these typologies presuppose that the offending process, more specifically the modus operandi, does not fluctuate with the given sexual aggressor; they assume, that is, that such offenders always act in the same way, "specializing" in a single type of victim and remaining insensitive to situational factors and opportunities. Finally, these typologies were unable to account for the situational factors, the majority of them suggesting that individual characteristics (e.g., personality, sexual preferences, thoughts) are the principal factors influencing the offending process. In order to understand the modus operandi used by the offender – that is, the pattern of actions and behaviors prior to, during, and following the illicit act in order to perpetrate the offense successfully (Sutherland 1947) – and the different resulting outcomes at the crime scene, a different approach is needed.

From the Offender to the Criminal Event

In criminology, two complementary theoretical approaches are useful to examine and understand the modus operandi of sex offenders. The criminal event perspective (CEP) (Sacco and Kennedy 2002) is the term that has been used to describe a technique of organizing ideas and data (Meier et al. 2001). CEP is not itself a theory of criminality or criminal behavior but rather a tool that can be used to design explanatory models of crime that account for the importance of interactions (Anderson and Meier 2004). Thus, in order to understand the process and structure of crime, it is crucial to identify and understand the social context in which offenders live and interact with victims (Anderson and Meier 2004). According to Sacco and Kennedy (2002), the behavior of any one participant (offender and victim) in the criminal event intersects with and influences the behavior of other participants, shaping the course of the event and determining the stages through which it progresses and the extent to which it will be judged a serious one. CEP, then, can be used as an exploratory tool which organizes information about multiple elements of a criminal case or criminal event and which ultimately could lead to inductive theory building. Criminal events are different from criminal acts (Sacco and Kennedy 2002). Acts are instances of behavior, while events involve the context of the behavior. The major advantage of CEP is that it conforms to the way the world works; like all forms of social events, criminal events have a beginning and an end and occur over time in a sequential fashion (Sacco and Kennedy 2002).

Similarly, according to the *social interactionist* perspective, in the course of any personal crime, the behavior of one actor is shaped by the behavior of the other (Goffman 1967). Within the context of a sexual crime, this could mean that the victim's behavior depends – in whole or in part – on the offender's level of violence and coercion. Similarly, the offender may change his modus operandi depending upon the victim's perceived willingness or resistance. Luckenbill (1977) applied this concept of a social interaction between victims and perpetrators of homicide, referring to this exchange as a "collective transaction." Essentially, Luckenbill suggests that each participant develops a role within the criminal interchange; this role is shaped by the other actor and ultimately plays its own part in the resulting fatality. Similarly, Block (1981) examines the effect of the interaction between victim and offender on the outcome of violent crimes. However, rather than viewing the event as a "working agreement" between victim and offender, Block (1981) simply states the importance of the victim's role and actions on those of the offender. What takes place within the confines of the microenvironment surrounding the crime is most often a result of the actions of the victim and how those actions intersect with the strategies and modus operandi of the offender. Tedeschi and Felson (1994) further developed these ideas through their decision-making theory of coercive action, wherein harmdoing is goal-oriented behavior arising from social interactionist processes. The essence of goal-oriented behavior assumes a certain level of rationality within the decisions made during the course of a coercive encounter. Borrowing from the rational choice perspective (Cornish et al. 1986), choices regarding one's actions are made based on the perceived value of rewards (positive outcomes), the perceived value of costs (negative outcomes), and the estimated probabilities or likelihoods of the positive and negative outcomes achieving fruition. Self-preservation is intrinsic to human nature, and thus, all behavioral choices are made based on what is perceived as the best possible option in a particular scenario that is most likely to yield valued rewards.

Modus Operandi and Rational Choice

In line with the previous theoretical perspectives described above, the *modus operandi* (MO) is conceived as a dynamic process which needs to be adapted to situational circumstances (Cornish 1993). In criminology, the rational choice perspective is a theoretical framework specifically designed to address offender decision-making in the course of a specific crime (Cornish et al. 1986). The rational choice perspective assumes that criminals offend because crime provides the most effective means of achieving desired benefits (e.g., sexual gratification). As a corollary, the choice of methods for carrying out these crimes is best regarded as instrumental behaviors to achieve these goals. Offenders decide whether or not to commit a crime by weighing the effort, rewards, and costs involved in alternative courses of action. The making of decisions and choices, however rudimentary this process might sometimes be, exhibits a measure of rationality, albeit constrained by limits of time, ability, and the availability of relevant information (Johnson and Payne 1986). In fact, an offender's cost-benefit analysis may not take into account every possibility, both because such an analysis is time-consuming and because the relevant information is only partially available to him. In addition, an offender's cognitive deficits may restrict his information-processing concerning the crime (e.g., an offender intoxicated prior to the crime). Consequently, offenders usually rely on heuristics partially based on the success and failure of previous criminal activities, including previously used detection-avoidance strategies which did not lead to apprehension. The course of action selected by an offender is usually the first minimally satisfactory one identified, rather than the optimal one (Tversky and Kahneman 1981).

In departure from previous studies which classified sex offenders' behaviors into typologies, recent studies on the modus operandi of sex offenders have shown the complexity of the criminal event – more so when the context, the victim, and the dynamic aspects of the crimes are taken into account. Some recent studies have examined different outcomes related to sex offenders' modus operandi using different approaches.

Offenders' Reaction to Victim Resistance

The most influential action a victim can take within the criminal event is one of resistance. Varying levels and types of resistance can have a range of effects on the offender's modus operandi, especially with respect to how violent and coercive the offender becomes. Interactions between victim and offender become exceptionally important within this particular context, as the resistance itself is a reaction to the modus operandi of the offender. In fact, the resistance level employed by the victim has been found to closely match the offender's strategy to commit the assault (Ullman 2007). Thus, if an offender attempts to verbally coerce or threaten his victim, the victim will likely utilize screaming and pleading in an attempt to stop the sexual assault. However, if the offender physically attacks the victim, the victim is more likely to use a similar level of physical forcefulness to avoid the assault.

Victim resistance has been examined in its effects on two outcomes: victim injury and/or sexual assault completion. Although these are pertinent factors to investigate, two recent studies have shifted the focus from these more terminal outcomes to the more direct relationship between the victim's resistance and the offender's immediate reaction to that resistance. There could very well be a multitude of factors that come into play between when the victim resists and her later injuries (e.g., victim frailty) or whether the crime results in its completion (e.g., interference or not of a bystander). However, the dependent variable used for these two studies questions the *offender* (rather than the victim) as to his *direct response* to that resistance.

In the first study, Balemba et al. (2012) found that specific variables and interactions among variables increase the risk of sexual assault victims experiencing a violent reaction to their resistance. Overall, the most influential situational factor is the strategy used by the offender to commit the crime. If the offender uses a violent persuasive strategy, the most likely scenario is one of violence; even after interaction with other variables, violence remains the consistently predicted offender response. This relationship is logical, since it is reasonable to suppose that an offender who begins his crime in a violent manner is more likely to react violently to resistance from his victim. However, it is also plausible that situational factors influence violence and increase the offender's anger or modulate other factors that increase aggression. Tark and Kleck (2004) have found that when victims who resisted were hurt, it was almost always injury that came first, suggesting that the offender had decided to use violence before any interaction with the victim.

Moreover, the results found the type of victim resistance to be significant and to interact with offender strategy. The importance of this variable, and specifically its interaction with offender strategy, is consistent with previous findings indicating that resistance strategies of the victim tend to match offender strategies (Ullman 2007). Essentially, if the offender begins the assault using physical aggression, the victim is more likely to react with physical resistance. Finally, it was found that use of a weapon by the offender would lead to a violent reaction (Balemba et al. 2012).

The second study used a similar approach but this time distinguished the offender's reaction to victim resistance between adult and child victims. In this study, Balemba and Beauregard (2012) concluded that characteristics of the victim – often beyond their control – may increase their likelihood of victimization, the type of offender they will attract, and the amount of violence that may occur during the assault itself. Additionally, the victim's actions during the commission of the crime affect the offender's modus operandi, just as the offender's actions will affect the victim's (see for instance Block 1981). Thus, substantial differences in situational factors and interactions were found when comparing offenses against adult victims to those against child victims. In general, the findings show that adult victims are more likely to encounter violence from the offender than child victims, as has been previously shown in the literature (e.g., Scott and Beaman 2004; Weaver et al. 2004). Moreover, the findings suggest a different offense planning and stratagem, dependent upon the type of victim. In essence, it appears that when an offender chooses a child victim, there is a higher degree of preparation that occurs before the crime takes place. In contrast, an offense against an adult victim appears to be somewhat more impulsive and a reaction to the situation.

These results suggest that, with an adult victim, an offender is more likely to resort to violence according to the resistance level of the victim. This is a very important finding, especially because previous studies have found the resistance of the victim to have no effect on the physical forcefulness of the offender (Ullman 2007). However, previous studies have consistently suffered from an inability to distinguish a temporal sequence in the event. If, for example, the offender begins with a violent offense strategy and the victim reacts physically, this is a much different scenario than if an offender reacts violently to a victim's physical resistance. Such a distinction has been made in these studies, as the dependent variable was specifically designed to represent, as the name states, the offender's reaction to victim resistance.

There appears to be a completely different social environment surrounding a sexual assault of a child. According to the findings, such assaults seem to be premeditated to a greater degree in an attempt to circumvent the use of expressive violence to complete the assault. Offenders against children are prepared, with regard to the surrounding setup and physical environment, and are aware of the amount of force they are likely and willing to use prior to the commencement of the assault (thus, the importance of the strategy to commit the crime). These interpretations are congruent with findings showing that planning is an important step, either implicitly or explicitly, in the offense process of child molesters (Ward et al. 1995). This planning often involves an assessment of victim vulnerability and chance of apprehension (Leclerc and Tremblay 2007). Furthermore, the notion of offenders "grooming" children as a way of normalizing or legitimizing sexual contact also corroborates the assertion that the element of premeditation is an important factor within the offending strategy of sexual abusers of children.

The social interactionist perspective emphasizes the true importance of behaviors of the various players within a coercive interchange (Luckenbill 1977; Tedeschi and Felson 1994). As evidenced by the findings within the two studies previously discussed, offender modus operandi has the potential to drastically alter victim behavior, especially the level of victim resistance. However, the current analyses have shown the reverse to be true as well: victim behavior also considerably affects offender modus operandi. Behavior appears to be cyclical in the sense that actors continually affect one another: offender assaultive behavior leads to victim resistance, which, depending upon the presence or degree of certain factors, may then lead to offender coercion in response to that resistance.

Victim's Death

Sometimes during the interaction between the offender and the victim in a sexual assault event, the victim does not survive. Research has shown that the likelihood of a sexual assault becoming a homicide differs mainly based on victim characteristics and circumstantial factors. For instance, Felson and Messner (1996) found that the likelihood of the victim suffering serious injury or death was higher when sexual offenders used a weapon. Mieczkowski and Beauregard (2010) identified particular combinations of characteristics differentially associated with sexual assaults that end in the homicide of the victim. Using the method of conjunctive analysis (Miethe et al. 2008), they highlight those attributes in the victim, the situation, and the modus operandi which are associated with a lethal outcome. In brief, what was found in this analysis is that the most telling domain for a lethal outcome is contained within the modus operandi. For instance, the most lethal combination is when the offender uses a weapon and spends more than 30 min with the victim but does not commit intrusive sexual acts on the victim nor force the victim to commit sexual acts on him (ratio approaching 25 to 1). However, the weakest differentiation is seen in the *situational characteristics*. The domain of *victim characteristics* occupies an intermediate level. It has a relatively high number of combinations – five – which attain a ratio value greater than 1. Of these five combinations, the most lethal attains a value of 4.53, which is characterized by a victim aged under 14, stranger to the offender, and not from a criminogenic environment. These findings, although still preliminary, demonstrate the importance of looking at combination of factors instead of individual factors and the "practical" usefulness of the CEP.

Sex Offenders' Criminal Mobility and Choices of Crime Location

A different outcome which can be influenced by the modus operandi of sex offenders is the geography of the crime. More specifically, recent studies have looked at sex offenders' criminal mobility as well as the choice of crime location for these same offenders. Beyond the basic measure of the journey to crime, some authors have attempted to further our understanding of the criminal mobility of sex offenders by examining two types of factors influencing their journey to crime: the offender and the modus operandi. Here we are particularly interested in the latter factor, the modus operandi. Lebeau (1987) focused on how the journey to rape varies as a function of the offender's approach method. Results revealed that offenders traveled the shortest mean distance to assault their victims when they illegally entered the victim's residence. In a different study, Canter and Gregory (1994) found that rapists who offend during the weekend travel farther than those who commit rape during a weekday and that rapists who attack outdoors traveled approximately 2.7 times farther to offend as those who raped indoors (e.g., in a house). Davies and Dale (1995) suggested also that rapists who target victims from a particular area (e.g., prostitutes from a red-light district), who commit sophisticated property offenses during a sexual assault, who spend large amounts of time roaming and using public transportation, and who are familiar with numerous neighborhoods (previous habitation, locations of significant people, current or past workplace locations) travel longer distances to commit their crimes. This was echoed by Warren et al. (1998) who found similar results in relation to the sophistication of the crime. Their results showed that rapists who used forced entry and who burglarized the victim during the assault tended to travel farther. Although interesting, it appears that all the studies have taken for granted that journey to crime was the only and probably the most adequate measure of criminal mobility. Whether or not this is true, none of these studies have questioned the use of the journey to crime to measure their criminal mobility.

In order to go beyond the journey-to-crime measure, criminal mobility has been conceptualized as the use of multiple locations for the purpose of repetitive sexual contact with the same victim. In their study, Leclerc et al. (2010) set out to examine whether offending differences existed between perpetrators who used multiple locations for sexual contact and those who used a single location for the entire crime-commission process. Overall, the results demonstrate that mobile offenders are more likely to isolate their victims, use violence, involve the victim in several sexual episodes, abuse the victim for over a 1-year period, and make the victim participate and perform sexual behaviors on them during sexual episodes. The authors concluded that by examining mobility of pedophiles from a location angle rather than measures of distance and direction provides a different perspective on the crime-commission process of these offenders (Leclerc et al. 2010).

Following Leclerc et al. (2010) study, Beauregard and Busina (2012) used a similar approach with serial sex offenders. They proposed that criminal mobility can be defined as the number of changes of location during the criminal event. As discussed previously, rape events present different stages – that is, encounter, attack, crime, and victim release – that may be associated with different locations. Although some sex offenders decide to commit all their action at the same location (i.e., stable offender with zero change of location), other mobile offenders may change location up to three times during the same event. As criminal mobility can be interpreted as a purposive action necessary to successfully commit a crime, the aim of their study was to predict the criminal mobility patterns exhibited in serial rape events from situational and modus operandi characteristics. The situational characteristics of the rape events and the modus operandi used in serial sex crimes might explain why some offenders need to be mobile and change location during the criminal event while others do not. Using negative binomial regression, the authors found that events which involve child or adolescent victims, committed during daytime, when the offender did not use pornography prior to crime, and where victim resistance is observed should display more criminal mobility. Moreover, when the victim is selected, the victim is alone when approached by the offender, and the crime is characterized by sexual penetration and a lack of premeditation is exhibiting more criminal mobility. These results point toward the fact that criminal mobility is a goal-oriented action taken by serial sex offenders in order to complete successfully their crime and to avoid detection and apprehension (Beauregard and Busina 2012).

As mentioned previously, much research in the field of spatial decision-making has concentrated on distance to crime, but less focus has been on those factors that affect the types of environmental locations where crimes are likely to take place. As rapes are complex crimes largely influenced by contextual factors, environmental variables, and offender decision-making (Beauregard et al. 2010), it is necessary to examine these factors when determining offenders' choice of crime site locations. The study by Hewitt, Beauregard, and Davies (Hewitt et al. 2012) analyzes temporal factors, offender hunting behavior, and modus operandi strategies in a sample of 361 sexual crimes committed by 72 serial rapists, to determine their utility in predicting the type of location where victim encounter and release sites are likely to be, as these two sites are the most likely to be known by the police during the investigation (Rossmo 2000). Findings showed that temporal factors, hunting behavior, and modus operandi variables are all important to the victim encounter and release sites, but the significance of these factors varies depending on whether or not the location is in a residential land-use area, private site, inside location, and familiar to the offender. For instance, the study shows that in terms of offender modus operandi strategies, victims are more likely to be encountered in residential land-use areas, private sites, and inside locations when the crime is structurally premeditated. These findings suggest that offenders purposefully hunt for victims in these locations because they know that they will find victims who satisfy their criteria. As noted in the *home-intrusion rape track* proposed by Beauregard and colleagues (2007), offenders following this script enter a private, inside location that is unfamiliar to them (e.g., the victim's residence). Thus, crimes taking place in private or inside locations require more premeditation on the offenders' behalf as they are entering a space that is removed from the public domain. Because the offender does not belong in these locations, it requires more effort and planning on his part to enter these spaces unlawfully and be able to successfully commit the crime in areas where he is considered to be an outsider. Moreover, offenders who structurally premeditate their crimes tend to release their victims in an inside location. As rapists who premeditate their crimes are more common than those who do not (Rossmo 2000), many offenders select their victims by window peeping or following women on their way home, which suggests some degree of planning on behalf of the perpetrator. As such, the victim attack, crime, and release locations tend to be at the victim's residence, which in many cases is classified as an inside location. In addition, victims of sexual assault where the rapist uses a vehicle to commit the crime are less likely to be released in a private site or inside location than those victims where the offender does not use a vehicle. As Beauregard and Leclerc (2007) note, sex offenders do not usually use vehicles throughout the commission of their crimes for several reasons, including lack of a driver's license or car, or the rape takes place in an inside location, thereby not necessitating the use of a vehicle. However, in crimes where rapists do utilize a vehicle, they may do so because it helps them to search for victims and provides them with a private site to rape the victim and/or a means to move the victim from one location to another (e.g., moving her from the rape site to the release site; Beauregard and Leclerc 2007). By using a vehicle as the rape site and/or to move the victim from one geographic location to another, the rapist may release the victim in a variety of land-use or public spaces.

These studies illustrate not only the complex dynamics of sexual assault events but also how the modus operandi strategies used by the offenders may impact the different geographical outcome of the crime, that is, the decision to move during the event or the decision as to where to encounter and release the victim.

Forensic Awareness

One of the stages of the criminal event which has been understudied is the aftermath – that is, what are the actions and behaviors of the offenders after committing the crime. One of these modus operandi strategies which is of great interest for the criminal investigation is the use of particular precautions by sex offenders in order to avoid getting caught. When committing their crimes, offenders take actions that inherently have the potential to leave evidence at the crime scene (e.g., breaking and entering into a residence may leave fingerprints, ejaculating during a rape may leave DNA). Despite all these potential opportunities, unavailability of many forms of forensic evidence has been observed at crime scenes. In fact, research has shown that physical evidence is being collected in less than 10 % of cases investigated by the police (Horvath and Meesig 1996). Although little empirical evidence has been found for the "*CSI* effect" – by which juries supposedly will no longer convict without forensic evidence (Podlas 2006) – some authors have contended that perhaps a more serious aspect of the availability of all these TV shows is the knowledge gained by potential criminals (Durnal 2010). For example, it has been noted that offenders are increasingly wearing gloves to avoid leaving fingerprints, using tape to seal envelops to avoid leaving DNA, and even using bleach (which destroys DNA) to clean up blood (Stevens 2008).

Some offenders will adapt their modus operandi or take precautions before, during, or post crime commission to decrease their risk of apprehension. Arguably, this adaptation of crime strategy may be deemed an indication of evolving criminal sophistication on the part of the offender. Offenders who adapt their modus operandi to thwart police investigative efforts may be said to be exhibiting investigative awareness (i.e., a knowledge or understanding of police investigative practice). A related concept coined in criminological research as "forensic awareness" (Davies 1992) refers to an offender's knowledge or understanding of the importance of forensic evidence (e.g., DNA, fingerprints, dental impressions) to police investigation.

There is a dearth of research on the extent of forensic awareness among offenders and the impact that this awareness has on the crime process and investigation. A small number of studies, specific to sexual crime, have addressed the issue of forensic awareness and provide some insight on how certain offender behaviors may be indicative of forensic and/or investigative awareness. Davies and Dale (1995) studied stranger rapists and suggested that traveling longer distances to commit an offense may be indicative of forensic awareness. Beauregard and Field (2008) identify a precaution (i.e., moving a victim's body post murder) that may be undertaken to delay apprehension but may also be considered an indicator of both investigative and forensic awareness. Moving the body complicates the investigation by decontextualizing the crime, potentially decreasing the likelihood that the victim will be found or, if found, identified. This action may also indicate forensic awareness as the offender is removing a significant source of forensic evidence from the scene of the homicide. In their examination of 222 stranger sexual assaults, Beauregard and Bouchard (2010) found that certain modus operandi strategies (i.e., nonrandom selection of a victim, selecting a victim who is alone, and hunting for a victim in certain locations, such as a prostitution stroll), arguably indicators of investigative awareness, were related to forensic awareness, which was evident at the crime scene. Furthermore, offenders who break and enter the homes of their victim and exhibit certain sexual behaviors (i.e., penetrate the victim and ejaculate) are more likely to exhibit forensic awareness. A negative relationship was found between forensic awareness and the use of drugs and/or alcohol prior to commission of the offense (Beauregard and Bouchard 2010).

Conclusion

Although typologies based on offenders' behavior have been useful to classify offenders for the purpose of suggesting treatment modalities and assessing the risk, recent studies on the modus operandi of these sex offenders have shown the complex dynamics in the criminal event. The findings reveal that the modus operandi decided by an offender may change during the criminal event, depending on the context, more specifically on the victim's behavior. But in order to uncover these complex dynamics, it is important to look at the modus operandi of sex offenders through a criminal event perspective, where the offender, the victim, and the context of the crime are taken into account. Such an approach requires not only a theoretical shift in the study of sex offenders' modus operandi but also a shift in the analytical methods used. Methods which can take into account the multiple interactions between the variables under study (e.g., conjunctive analysis, regression tree) should be prioritized over classification methods (e.g., cluster analysis). These new approaches help to gain a better understanding of the sex offender's decision-making during the criminal event as well as better predict different outcomes within the criminal event. The modus operandi is a purposive set of actions taken by an offender which will inevitably lead to an outcome (e.g., death of the victim of not). But to understand why certain offenders are associated to one outcome in particular, it is important to be able to look at the dynamics involved during the criminal event and examine which factors can influence the offender's modus operandi.

Moffitt's Developmental Taxonomy of Antisocial Behavior

Alex R. Piquero[1] and Terrie E. Moffitt[2]
[1]Department of Criminology, The University of Texas at Dallas, Richardson, TX, USA
[2]Departments of Psychology and Neuroscience, Psychiatry, and Behavioral Sciences, Institute for Genome Sciences and Policy, Duke University, Durham, NC, USA

Overview

This entry provides an overview of Moffitt's developmental taxonomy, highlights key findings from subsequent research, identifies critical challenges to the taxonomy, and outlines several important directions for future research. The entry concludes by noting that some of the taxonomy's key hypotheses have been supported by empirical research, while other findings have presented challenges to the taxonomy.

Introduction

The age/crime relationship is one of the brute facts of criminology, which any theory of crime must be able to explain. The curve evidences a slow rise during early adolescence, peaks in mid to late adolescence, and then decreases rapidly in early adulthood. The fact of the curve is unassailable; however, what is especially contentious is the reason(s) underlying this consistently documented correlate of crime. One theory in particular, Terrie Moffitt's (1993) developmental taxonomy, seeks to develop a better understanding of the age/crime relationship by focusing on the mixture of two distinct groups of offenders, whose offender styles combine to represent the overall aggregate relationship – yet with unique age/crime curves. This entry provides a background description of Moffitt's theory, provides a very broad review of key findings, identifies controversies that exist with respect to the theory and empirical research, highlights open questions, and provides an overall conclusion.

Background Description

In her original statement of the developmental taxonomy, Moffitt suggested that the age/crime relationship could be summarized by the existence of two distinct types of offenders, each of whom evince unique age/crime patterns and who offend for distinct reasons. The first group, adolescence-limited (AL), is comprised by a large segment of the offending population who constrict their antisocial behavior to the adolescent time period. For ALs, delinquency is a function of two features of adolescence: the "maturity gap" and the peer social context. The maturity gap recognizes that adolescents biologically resemble adults but are not socially or legally recognized as adults and are consequently denied most adult privileges and responsibilities. Young people's recognition of this mismatch between their social maturity and their biological maturity leads to a feeling of strain that is also characteristic of their similarly situated peers. Because peers are an exceedingly influential socializing agent during adolescence, and because all ALs are negotiating the adolescent period and experiencing the same sets of strain, they encounter potential role models in other older-aged peers who have alleviated their sense of strain by becoming involved in delinquent activities that bring them forbidden adult pleasures. Life-course-persistent age peers, as will be seen below, also constitute delinquent role models. Thus, ALs engage in delinquent activities that resemble adult status such as smoking, drinking, sexual activity, and theft (so as to obtain economic resources and goods) in order to alleviate their strain and acquire a sense of being recognized and treated like adults. As they exit out of adolescence and enter emerging and early adulthood, and because they are now legally permitted all of the things they once coveted, most but not all AL offenders cease their antisocial behavior. It is expected that most ALs will successfully transition into adult roles and responsibilities and leave their antisocial ways behind. However, a subset of ALs may encounter snares as a result of their antisocial behavior, such as drug addiction, school dropout, or a criminal record, that may entrap them in a delinquent lifestyle and delay desistance.

Unlike their AL counterparts, LCP offenders comprise a very small group of individuals (<10 % of males), who exhibit antisocial tendencies and behaviors very early in the life course (i.e., early childhood). The antisocial repertoire of LCPs is of a varied nature, chronic, persistent, and serious and spans distinct phases of the life course (childhood – adolescence – adulthood) and continues largely unabated via different manifestations and across various life domains well into adulthood. Unlike the more social origins of antisocial behavior among ALs, LCP-style antisocial behavior originates from compromised neuropsychological development that is exacerbated by disadvantaged familial and economic environments. Specifically, LCPs tend to be born with neurodevelopmental problems of weak cognitive abilities and low self-control that exert negative effects on their immediate caretakers. If caretakers are unskilled at parenting, these early deficiencies are not addressed nor corrected. As a result, LCPs become involved from early life in a series of antisocial behaviors that eventually produce negative outcomes in virtually all aspects of their lives, including failures in education, interpersonal relationships, and employment. Thus, their antisocial behavior gradually becomes part of their overall personality. This developmental process of cumulative continuity results in adverse reactions by prosocial agents and produces barriers to, or knives off, conventional opportunities for success. The neglected injurious childhoods, poor neurocognitive abilities, and resultant antisocial lifestyles of LCPs limit their prospects for change.

Although Moffitt's taxonomy focused on two distinct groups of offenders, it also describes a third group of young people who stand in stark contrast to the more normative, adaptational ALs: a group of teens who abstain from delinquency. Moffitt views these "abstainers" as somewhat extraordinary because they eschew delinquency during a period of the life course when delinquency is the norm. Abstainers are viewed as encountering barriers that preclude their foray into delinquency, either through structural barriers that prevent them from learning about delinquency, no maturity gap because of early access to adult roles, or personal characteristics unappealing to other teens that cause them to be excluded from teen social group activities.

Any serious contender for a theory of delinquency is obliged to address two of the most salient facts about delinquency: sex variation and ethnic-minority variation. The original statement of Moffitt's taxonomy asserted that the theory describes the behavior of females as well as it describes the behavior of males. Thus, it is important to discuss Moffitt's (1994, pp. 39–40) specific expectations of the role of gender in the taxonomy:

> The crime rate for females is lower than for males. In this developmental taxonomy, much of the gender difference in crime is attributed to sex differences in the risk factors for life-course persistent antisocial behavior. Little girls are less likely than little boys to encounter all of the putative initial links in the causal chain for life-course persistent antisocial development. Research has shown that girls have lower rates than boys of symptoms of nervous system dysfunction, difficult temperament, late verbal and motor milestones, hyperactivity, learning disabilities, reading failure, and childhood conduct problems... Most girls lack the personal diathesis elements of the evocative, reactive, and proactive person/environment interactions that initiate and maintain life-course persistent antisocial behavior.
>
> Adolescence-limited delinquency, on the other hand, is open to girls as well as to boys. According to the theory advanced here, girls, like boys, should begin delinquency soon after puberty, to the extent that they (1) have access to antisocial models, and (2) perceive the consequences of delinquency as reinforcing... However, exclusion from gender-segregated male antisocial groups may cut off opportunities for girls to learn delinquent behaviors... Girls are physically more vulnerable than boys to risk of personal victimization (e.g., pregnancy or injury from dating violence) if they affiliate with life-course persistent antisocial males. Thus, lack of access to antisocial models and perceptions of serious personal risk may dampen the vigor of girls' delinquent involvement somewhat. Nonetheless, girls should engage in adolescence-limited delinquency in significant numbers....

The original theory thus proposed that (a) fewer females than males would become delinquent (and conduct disordered) overall and that (b) within delinquents the percentage who are LCP would be larger among males than females. Following from this, (c) the majority of delinquent females will be of the AL type, and further, (d) their delinquency will have the same causes as AL males' delinquency (Moffitt 2006).

Moffitt's (1994, p. 39) taxonomic writings also anticipated that the taxonomy would apply to socially disadvantaged ethnic-minority populations as well as to whites:

"In the United States, the crime rate for black Americans is higher than the crime rate for whites. The race difference may be accounted for by a relatively higher prevalence of both life-course persistent and adolescence-limited subtypes among contemporary African-Americans. Life-course persistent antisocials might be anticipated at elevated rates among black Americans because the putative root causes of this type are elevated by institutionalized prejudice and by poverty. Among poor black families, prenatal care is less available, infant nutrition is poorer, and the incidence of exposure to toxic and infectious agents is greater, placing infants at risk for the nervous system problems that research has shown to interfere with prosocial child development. To the extent that family bonds have been loosened and poor black parents are under stress,. . .and to the extent that poor black children attend disadvantaged schools. . ., for poor black children the snowball of cumulative continuity may begin rolling earlier, and it may roll faster downhill. In addition, adolescence-limited crime is probably elevated among black youths as compared to white youths in contemporary America. If racially-segregated communities provide greater exposure to life-course- persistent role models, then circumstances are ripe for black teens with no prior behavior problems to mimic delinquent ways in a search for status and respect. Moreover, black young people spend more years in the maturity gap, on average, than whites because ascendancy to valued adult roles and privileges comes later, if at all. Legitimate desirable jobs are closed to many young black men; they do not often shift from having "little to lose" to having a "stake in conformity" overnight by leaving schooling and entering a good job. Indeed, the biological maturity gap is perhaps best seen as an instigator of adolescent-onset delinquency for black youths, with an economic maturity gap maintaining offending into adulthood."

Thus, the taxonomy expected that both LCP and AL processes should work the same way within African-American and white American groups, but any excess of offending among poor African-American youth could be attributed to an excess of the risk factors for both delinquent subtypes (Moffitt 2006).

The original theoretical taxonomy asserted that two main trajectories of offenders (LCP and AL) account for much of the age/crime relationship and thus warrant the lion's share of attention by theory and research. As a result of subsequent empirical studies, a small but additional group of offenders have been identified that does not fit either of the other two offender groups. First identified in trajectory analyses of a British cohort (Nagin et al. 1995), this third group of offenders has been labeled "low-level chronics" because they have been found to offend persistently but at a low rate from childhood to adolescence or from adolescence to adulthood.

State of the Art

There has been a very active set of studies seeking to explore various aspects of Moffitt's developmental taxonomy and the results from this research have been effectively summarized in several publications (see Moffitt 2006; Piquero and Moffitt 2005). Here, a very brief overview of the findings regarding key hypotheses from the taxonomy is presented.

Since the publication of the taxonomy in 1993, it can be stated with a good degree of certainty that the hypothesized LCP antisocial individual exists, at least during the first three decades of life. Near universal agreement about this group has emerged from all studies that have applied trajectory-detection analyses to a representative cohort sample having longitudinal repeated measures of antisocial behavior (Piquero 2008). In fact, it remains the case that no research that has looked for a persistent antisocial group has failed to find it. A number of other postulates from the taxonomy have received empirical support, ranging from robust to modest, but overall they appear to be supported and are listed here.

First, there is good evidence that LCP antisocial behavior emerges from early neurodevelopmental and family-adversity risk factors, but AL delinquency does not. Second, many studies show genetic etiological processes contribute more to LCP than AL antisocial development. Third, longitudinal follow-ups reveal that childhood-limited aggressive children, if followed to adulthood, become low-level chronic criminal offenders with personality disorders. Fourth, there is some evidence that abstainers from delinquency are rare individuals, who become unpopular with teen peers. Fifth, LCP and AL delinquents have been shown to develop different personality structures by adulthood. Sixth, LCP development is differentially associated with serious offending and violence in adulthood in all studies. Seventh, epidemiological studies confirm that LCP antisocial development is almost exclusively male, whereas most female antisocial behavior is of the AL type.

Some findings have received beginning support, but more research is needed. For example, AL antisocial behavior is influenced by the maturity gap between childhood and adulthood and by social mimicry of antisocial role models. Also, childhood-onset antisocial behavior persists at least into middle adulthood, whereas adolescent-onset antisocial behavior desists in young adulthood. Recent studies report that LCP antisocial individuals are at high risk in midlife for poor physical health, cardiovascular disease, and early disease morbidity and mortality (see Odgers et al. 2007; Piquero et al. 2010, 2011).

Some predictions from the taxonomy have received only minimal empirical attention. For example, according to the theory, AL offenders must rely on peer support for crime, but LCP offenders should be willing to offend alone (although in adolescence they serve as magnets for less expert offenders). Additionally, "snares" (such as a criminal record, incarceration, addiction, or truncated education without credentials) should explain variation in the age at desistence from crime during the adult age period, particularly among AL offenders. Lastly, the two groups should react differently to turning point opportunities: ALs should get good partners and jobs that help them to desist from crime, whereas LCPs should selectively get undesirable partners and jobs and in turn expand their repertoire into domestic abuse and workplace crime. These predictions need testing.

Possible Controversies in the Literature

As is true of many theories of antisocial behavior, results from empirical research provide some challenges and controversies for the original statement of the theory. Here, the single most important challenge to the taxonomy is highlighted. Two life-course criminology theorists and researchers, Robert Sampson and John Laub, have called into the question not only whether there are indeed LCP and AL offenders and whether such groups could be prospectively identified in childhood, but also whether the two groups follow their hypothesized crime trajectories.

Sampson and Laub (2003) conducted a follow-up study of a sample of 500 adolescent male inmates from the 1940s, covering the period from age 7 years to the end of each offender's life up to age 70 years. Sampson and Laub reported two findings from their analysis that challenged the taxonomy. First, they found that almost all of the men desisted from criminal offending sooner or later, and second, they found heterogeneity in adulthood crime career patterns within the sample of adolescent inmates, and they found that this heterogeneity was not explained by measures of childhood risk.

Moffitt (2006) has observed that Sampson and Laub's findings are potentially premature and perhaps overstated for several reasons. First, virtually all of the men in the sample might have been regarded as candidates for the LCP subtype (i.e., they had been incarcerated as young adolescents as inmates in reform schools; they had backgrounds of marked family adversity, social disadvantage, and childhood antisocial conduct, low IQ, and an early first arrest). Second, Moffitt argued that Sampson and Laub misrepresented the taxonomy's prediction because they set up a "straw" prediction to test, i.e., that LCP offenders would continue committing crimes at the same high rate from adolescence through old age, and to their deaths. Moffitt's taxonomy had not implied this expectation, largely because of the well-known population-wide process of aging out of crime in midlife. The taxonomy claims that LCP-type delinquents would continue offending well beyond the age when most young men in their cohort would ordinarily have stopped offending and ought to retain detectable features of an antisocial personality into late life (such as lying, irresponsibility, or callous attitudes), but perhaps not criminal offending itself.

With respect to Sampson and Laub's second finding of heterogeneity in adulthood crime career patterns, this again is viewed by Moffitt as a "straw man." The alternative would be that males who spent their youth and early adulthood on the LCP pathway can show no variation in subsequent offending during midlife and aging, over a span of many years. Such uniformity is implausible, and no such prediction was made in the taxonomy. As Sampson and Laub argue, child and family characteristics were unable to distinguish between the different offender trajectories they identified. But Moffitt contends that this failure of discrimination is not unexpected in the sample they studied, because the childhood backgrounds of the males were almost uniformly high risk. At the same time, this particular result suggests that to the extent that different crime careers emerge during midlife within a group of LCP men, concurrent life experiences must account for the divergence. This would constitute an interesting extension to the taxonomy: heterogeneity within LCPs in the ways they age out of crime. In any case, the main point Sampson and Laub made was that it is a risky business to predict that a child is doomed to a life of crime, and thus early identification advocates may have gone too far. Moffitt's work provides consensus on this important point about potential misuse of the taxonomy.

Open Questions

Although there has been extensive research into Moffitt's taxonomy, open questions remain. Here, a few of these questions that are important for subsequent inquiry are provided.

First, there have been few empirical investigations regarding the extent to which the taxonomy explains the association of key demographics of crime, namely, that of race and gender. Although Moffitt anticipated that the theory would explain the antisocial behavior of males and females as well as whites and socially disadvantaged nonwhites (especially African-Americans), the lack of data and requisite measures of key predictors has prohibited extensive analyses on these associations.

Second, while Moffitt clearly advanced some sort of neurocognitive deficit among LCP offenders, she also noted the relevance of a sociobiological disjuncture to predict patterns of offending among AL offenders: the maturity gap. Thus, the role of biology and genetics, especially in concert with social environments, is an important aspect of Moffitt's taxonomy. Yet, due to data constraints, there has been little investigation of the taxonomy's implications about joint effects of biological and social factors and the extent to which such factors help explain variation across offenders and in offending.

Third, there has been virtually no research exploring the decision-making process across the two offender types. How do LCPs weigh the risks and rewards of offending at the point of decision-making? Do AL offenders consider the costs more than their LCP counterparts? Do AL offenders alter their decision-making criteria as they enter adulthood? Different personality styles and different cognitive abilities characterize the two groups, which imply that they should differ on their typical decision-making strategies too. Integration of research from deterrence/rational choice would provide a good extension of Moffitt's theory to consider situational factors.

Conclusions

Moffitt's developmental taxonomy was originally advanced as a framework to help explain and understand the age/crime relationship. Since its publication in 1993, it has generated much interest and research. Some findings have been consistent with some of the key, original hypotheses, some findings have pointed to important revisions needed to improve the fit between the taxonomy and empirical reality, and some findings have brought critical challenges to various aspects of the taxonomy. All three kinds of findings are important as the empirical knowledge base accumulates with respect to the taxonomy and its predictions. Continued research – especially with respect to some of the understudied and unresolved questions – will permit a more concrete statement about how well the taxonomy explains criminology's most basic facts.

Monetary Strain and Individual Offending

Stephen W. Baron
Department of Sociology, Queen's University, Kingston, ON, Canada

Overview

Monetary strain theories, including anomie and general strain perspectives, outline that individuals who are unable to reach monetary goals utilizing legal channels, or who are experiencing negative economic circumstances, will be more likely to engage in a range of illegal activities. The probability of an illegal response is strengthened when individuals perceive their opportunities to achieve the monetary goal to be blocked, attribute the cause of their failure to external sources, and feel deprived relative to the others with whom they compare themselves. The failure to reach the monetary goal, or the negative economic experience, in these situations leads to frustration, dissatisfaction, and anger. These negative emotions supply the incentive for individuals to utilize numerous illegal avenues that focus on financial gain to facilitate the realization of monetary goals or address negative economic circumstances. Individuals experiencing monetary strain may also strike out at others in response to their feelings of failure and frustration or they may use drugs and alcohol in an attempt cope with the negative emotions generated by the strain. Illegal reactions in response to monetary strain are also more likely when individuals associate with peers who also experience monetary strain and utilize deviant means to cope with the strain. Further, individuals who have adopted values that support the use of illegal means to cope with strain and who lack conventional social support and social control are more likely to respond to monetary strain with crime. Monetary strain is also more likely to lead to crime when individuals lack self-efficacy and self-esteem, view the rewards of crime as greater than the potential costs of punishment, and have developed personality traits that leave them more likely to react to strain with negative emotionality and low constraint.

Fundamentals

The link between monetary strain and individual offending has a long tradition in criminology. Beginning with the work of Merton (1968) through to more recent arguments (see Agnew 2006; Baumer 2007), scholars have attempted to theoretically and empirically show that the failure to reach monetary goals, or the experience of adverse economic circumstances, can lead individuals to engage in crime to address these failures, improve their circumstances, and reduce the frustration that these experiences create. Scholars have provided a complex and nuanced map of the way that monetary strain is linked to individual offending and have presented a range of "research puzzles" that researchers have tackled to lend evidence to support our understanding of the causal process.

Scholars working within the strain perspective of criminology argue that everyone within North American society, regardless of class position, is encouraged and expected to strive to become monetarily successful. The goal of monetary success is emphasized and promoted in the media, family, and education system, making it difficult to avoid its influence. The result of this process is that a "substantial" or "significant" portion of individuals across all social classes adopt strong aspirations for financial success (Merton 1968). When an individual places a great deal of importance on the goal of financial success and prioritizes it over other goals, the failure to reach financial objectives creates dissatisfaction. When individuals experience monetary dissatisfaction, they begin to consider utilizing alternative means to satisfy their monetary goals including illegal means.

Beyond the failure to reach the goal of monetary success, negative economic circumstances including poverty, unemployment, and homelessness can also create monetary strain. These types of negative economic situations are viewed as undesirable in the broader society and for the individual immersed in these circumstances, the experience can be extremely negative. These types of situations serve to threaten an individual's goals and identity and influence their ability to carry out activities and satisfy basic needs. The adverse economic experience in the context of cultural failure creates an additional possible starting point for utilizing crime to cope with financial difficulties. Important here is not only that these are objectively negative financial circumstances, but also that an individual subjectively perceives them to be negative and is dissatisfied with these conditions. If an individual does not interpret their economic circumstances to be negative, then strain will not emerge despite the adverse economic circumstances being experienced.

While the cultural emphasis on monetary success is advanced for all in the population, large portions of the populace are inhibited from achieving financial success due to barriers in legitimate channels. Monetary goals are more likely to lead to crime when individuals experience hurdles to the achievement of their financial goals. The major channel emphasized to achieve financial success by strain theorists is the acquisition of education and the subsequent securing of high quality employment. These avenues, however, are more available to some individuals than others. These channels can be undermined by prior familial and community socialization that fail to promote qualities that facilitate educational and employment success, including the development of work ethics, deferred gratification, self-discipline, and thorough planning skills. Certain familial and community situations may also be unable or neglect to provide the knowledge, connections, and social and financial support necessary to facilitate an individual's success at school and in the job market. Finally, individuals from certain social and economic backgrounds may experience discrimination in educational and economic institutions that restrict their ability to reach their financial goals. Beyond inhibiting educational success and the reaching of financial goals, community and family dynamics can lead directly to negative economic outcomes including unemployment, poverty, and homelessness that are not only experienced as strain but can also serve as barriers in and of themselves to monetary goal achievement (Hagan and McCarthy 1997). Individuals with strong monetary goals are more likely to respond with crime when they encounter obstructions that undermine their ability to reach their goals through legal avenues. Further, those experiencing adverse economic circumstances are also more likely to engage in crime when they experience blockages to legal methods for improving financial circumstances.

The emergence of monetary strain does not take place in social isolation. Beyond the failure to achieve financial goals, monetary dissatisfaction, or the experience of negative economic circumstances, the development of monetary strain is also influenced by an individual's perceptions of the efforts, financial achievements, and life situations of other people. Scholars argue that individuals will be more likely to experience monetary strain when they conclude that they are financially worse off than the people with whom they compare themselves (see Agnew et al. 1996; Burton and Cullen 1992; Passas 1997). This negative evaluation of one's financial situation or goal achievement in comparison to others is referred to as relative deprivation. What is important here is the reference group that the individual adopts to make this comparison of achievements or life situations. Monetary strain is less likely to occur when reference groups selected share efforts and achievements similar to the individual's own efforts and achievements. The choice to adopt a reference group with achievements much greater when compared to the individual will lead to greater feelings of monetary strain. The selection of a reference group can be influenced by one's peer group who can guide one's choice to appropriate comparisons. Further, in some societies, there is a significant weight placed on individuals to choose nonmembership reference groups. For example, the egalitarian ideology of North America and the "American Dream," often lead an individual to evaluate themselves with reference to those higher in the stratification system (see Passas 1997). While this allows for individuals at all economic levels of achievement, except those at the very top, to experience relative deprivation, it is those lower in the stratification system that are at greater risk of feeling relatively deprived. This is because the selection of possible reference groups for those lower in the stratification system is broader and more likely to differ economically (see Passas 1997). It may also be that relative deprivation has a greater impact on the behavior of those in lower socioeconomic situations since the "subjective experienced gravity of these discrepancies" will be greater (Passas 1997, p. 65). The negative evaluation of one's financial situation in comparison to others generates feelings of resentment and hostility. Perceptions of relative deprivation, therefore, can lead directly to crime. It is argued, however, that it is those with strong monetary goals, or who are experiencing negative economic situations, that are more likely to engage in crime when they perceive themselves to be relatively deprived.

Monetary strain is also more likely to emerge and lead to crime when individuals place the blame for their failure on sources outside of themselves (Cloward and Ohlin 1960; Hoffman and Ireland 1995). Individuals who externalize blame and attribute their failure to the labor market, education system, economy, or governmental activities are more likely to become alienated and withdraw their support for the legitimacy of conventional social norms. In contrast, individuals who make internal attributions and internalize blame for their economic failure or circumstances are likely to continue to support conventional avenues for goal achievement and refrain from illegal activities. Further, the impact of these external attributions is greater when individuals believe that the causes of their goal failure or adverse economic circumstances are controllable, intended, or preventable by others. In addition, perceptions that the external causes of one's failure and financial difficulties are unlikely to change in the future can exacerbate the role that external attributions play in increasing the risk that monetary strain will lead to crime (Baron and Hartnagel 1997). Like the selection of reference groups, the directions and content of attributions can be influenced by one's peer group. Situations where blame is placed externally, perceived as intentionally caused or controllable and unlikely to change, generate feelings of injustice and perceptions of unfairness that facilitate the potential link between monetary strain and crime. Those who fail to reach their monetary goals and are monetarily dissatisfied, and/or who are experiencing adverse economic circumstances, are more likely to engage in crime when they make external attributions for these situations.

The experience of failing to reach monetary goals, monetary dissatisfaction, and adverse economic circumstances, along with blocked opportunities, relative deprivation, and external attributions for failure, generate a negative emotional reaction. Possible reactions can include depression, frustration, and anger. Anger, in particular, is a key factor that intervenes between negative economic circumstances, monetary goal failure, and crime. Anger promotes feelings of power and stimulates desires for revenge, retaliation, and the righting of perceived unfairness and injustices which can lead to criminal reactions (Agnew 2006). How angry one becomes in response to monetary strain may be influenced by people's beliefs about the level and degree of emotional reaction appropriate for these types of negative experiences. Once again, one's peer group may also influence interpretations of monetary strain and the type and level of emotional response that evolves.

Recent theoretical work also outlines that the chronic failure to reach monetary goals and long-term experiences with negative economic circumstances can leave an individual at risk to develop trait anger, a personality characteristic where one is persistently angry (Agnew 2006). In these situations, individuals will often be in a state of angry arousal leaving them vulnerable to become easily angered when faced with additional negative economic experiences and outcomes. Those who respond to negative economic experiences and outcomes with anger are more likely to use criminal means to reach their goals, reduce their negative economic circumstances, and cope with the negative affect. This may involve active means, such as violence, vandalism, and offenses involving instrumental gain, or through more passive means, such as illegal substance use, to soothe the negative emotions.

There are a number of other factors that can strengthen the link between monetary strain and crime. First, all strain theorists outline that monetary strain is more likely to generate a criminal response when the commitment to, and belief in, institutional norms is weak. The failure to reach monetary goals, the negative economic circumstances, the monetary dissatisfaction, and the perceived injustice generated by relative deprivation and external attributions can lead individuals to "withdraw legitimacy from conventional social norms" (Cloward and Ohlin 1960; Hoffman and Ireland 1995). It may also be the case that individuals from certain backgrounds may never acquire strong conventional values that emphasize the use of legal avenues for reaching monetary goals (Merton 1968). When commitment to the conventional norms is weak, or destroyed, individuals may create, embrace, and implement illegal methods to achieve success and overcome negative economic situations. Further, they will be more likely to retaliate against perceived sources of their monetary strain, or to act on, or cope with, the negative emotions generated by monetary strain more easily than if they felt these criminal actions were morally wrong. The weakening of conventional beliefs allows for the development and adoption of nonconventional beliefs that promote various forms of law breaking as a method to cope with monetary strain. Therefore, deviant values increase the likelihood that negative economic situations and monetary dissatisfaction will lead to crime. Further, monetary goals themselves will be more likely to lead to crime in the presence of deviant values, particularly, when legitimate opportunities are blocked, people are economically dissatisfied, and there is peer approval (Baumer 2007).

Strain theorists emphasize that criminal peers can have a strong influence on whether individuals experiencing monetary strain turn to crime. Individuals who fail to reach their monetary goals, who experience negative financial situations, and who are monetarily dissatisfied often seek or develop collective solutions with other people who are also experiencing monetary strain. These similarly situated peers can work together in attempts to overcome financial frustrations and negative economic circumstances. Peers can provide strained individuals with encouragement, support, and rewards for engaging in crime to deal with monetary strain. If peers are utilizing criminal means to cope with monetary strain, they may educate the individual in this avenue as a means to deal with strain and provide training, opportunities, and assistance to successfully engage in these behaviors. Criminal peers can assist in creating an alternative value system and may further break down allegiance to conventional norms and promote beliefs that encourage breaking the law increasing the potential causal link between monetary strain and crime. Alternatively, they may fill the gap left by the breakdown of conventional norms caused by strain providing a value system that favors illegal means to cope with strain. Peer groups can also affect perceptions of what is considered to be monetary strain, influence causal attributions of monetary strain, impact the choice of reference groups when making assessments of relative deprivation, and provide parameters for the appropriate emotional reaction to negative economic outcomes and goal failure (Cloward and Ohlin 1960; Hoffman and Ireland 1995).

Strain theorists also suggest that an individual's personal resources can influence reactions to monetary strain (Agnew 2006). Levels of self-esteem will influence an individual's sensitivity to monetary strain and sway the ability to engage in legal coping strategies in response to strain. High self-esteem will buffer an individual from monetary strain, leaving the person less likely to utilize criminal coping strategies. Those with low self-esteem who are overwhelmed by monetary strain will be less able or likely to adopt conventional coping strategies. Self-efficacy will also influence an individual's sensitivity and reaction to monetary strain. Individuals high in self-efficacy will be more likely to feel that they can cope with their monetary strain in a legal manner, leaving them less likely to utilize criminal coping. Lacking a sense that they can deal with monetary strain in a legal manner effectively will lead those low in self-efficacy to utilize criminal means.

Strain theorists also recognize that levels of social control can influence whether monetary strain leads to crime. Individuals who have few emotional attachments to conventional others and who have a low commitment to conventional institutions are more likely to respond to monetary strain with crime. People in these circumstances have little to risk or damage in terms of relationships, opportunities, and reputations if caught engaging in crime. In contrast, bonds with conventional others, a continued commitment to conventional activities, and a belief in the conventional value system may buffer the effect of monetary strain since the person risks damaging relationships, opportunities, and reputations by engaging in crime. Further, those with high social control have greater opportunities to learn skills and access resources to cope with monetary strain in a legal manner. Many negative economic situations, however, including unemployment and homelessness are associated with low social control. These negative economic circumstances often destroy or even evolve out of low social control. These conditions are often related to reduced emotional attachments to conventional others, a decrease in investments in conventional institutions, including employment, and a distancing of values supportive of conventional behavior (Agnew 2006; Baron 2008).

Related to this is the degree of social support that an individual has at their disposal to cope with monetary strain in a legal manner (Agnew 2006; Cullen and Wright 1997). Social support refers to the transfer of resources. Social support can come in two broad forms. First, it can be instrumental. This includes material or financial assistance, networks for positive advancement in conventional society, or the provision of information, guidance, and advice. Alternatively, social support can be expressive. This includes one person offering another understanding, allowing the display and sharing of emotions, as well as providing avenues that enable the expression of dignity, self-worth, and positive regard. When individuals experience monetary strain, those with social support can draw on this multifaceted resource to mitigate the potentially criminogenic impact associated with strain. The availability of supportive relations guards individuals against the impact of monetary strain by providing legitimate coping skills that inhibit the development of negative emotions and prevents the withdrawal of support for, and commitment to, conventional institutions and values. Social support can also reduce opportunities for crime by providing alternative settings and isolating at-risk individuals from criminally supportive peers. This is important because criminal social support from strained peers can lead to increased rather than decreased criminal reactions to strain. Therefore, the link between monetary strain and crime will be greater for those who lack conventional instrumental and expressive social support (Cullen and Wright 1997).

Individuals who exhibit personality traits such as negative emotionality and low constraint are also expected to be more likely to react to their monetary strain with crime (Agnew 2006). Individuals with negative emotionality and low constraint are easily upset and angered, tend to be impulsive risk-takers, and lack empathy for other people. These characteristics are likely to increase the relationship between monetary strain and crime because individuals with low constraint and negative emotionality are more likely to be sensitive to their goal failure and adverse economic situations, interpret these situations as strain, and view these situations as unjust. Individuals with these characteristics care little about the reactions of others and give little thought to the consequences of their actions, leaving them more likely to adopt criminal coping strategies. Further, individuals with these traits tend to have an aggressive interaction style and proneness for risk that increase the likelihood of an illegal reaction to monetary strain (Agnew 2006).

Finally, the perceived likelihood of formal punishment for crime also influences whether an individual will choose to cope with their monetary strain using criminal means. Criminal coping is much more likely when individuals experiencing monetary strain find themselves in situations where the costs of engaging in crime are low and the benefits are high. Thus, those who fail to reach their monetary goals or who are unemployed, homeless, or living in poverty will view criminal behavior as an attractive alternative when they believe that the odds of apprehension and punishment are minimal and the material, social, and emotional rewards great (Agnew 2006). The conditioning impact of potential punishment may be even more important when the strong monetary goals or negative economic circumstances are accompanied by minimal moral reservations against crime (Baumer 2007).

State of the Art

There have been a number of recent research projects that examine the complex relationship between monetary strain and crime. This recent research has tended to show support for the argument that monetary strain can lead to criminal behavior. Some of this work shows support for the basic relationships between monetary strain and crime, as outlined by the theorists. For example, research shows that those who express monetary dissatisfaction are more likely to engage in property offending, violent offenses, drug distribution, and drug use (Agnew et al. 1996; Baron 2004, 2006, 2008). There is also evidence that economic problems (Agnew et al. 2008) and adverse economic circumstances like homelessness and unemployment can lead to a range of offenses (Baron 2004; Hagan and McCarthy 1997). Work also tends to show that relative deprivation is linked to property and violent offending (Baron 2004, 2006, 2008; Burton and Dunaway 1994).

While encouraging, the more complex arguments outlined by theorists stress the need to examine combinations of factors that link monetary strain to crime. The cursory work conducted so far has provided initial support for a number of the components of the multifaceted reasoning contained in these claims. Turning first to monetary goals, evidence suggests that such goals are not in and of themselves criminogenic. Instead monetary goals are more likely to lead to property and violent offending when individuals do not *expect* to reach those goals (Baron 2006). Further, monetary goals also appear more likely to lead to crime for people with lower levels of monetary satisfaction, and lesser occupational and educational achievement (Cernkovich et al. 2000) or if they are experiencing adverse economic circumstances (Baron 2006). Thus, it is in situations where reaching monetary goals are not viewed as attainable, are difficult to reach because of economic position, or are not satisfactorily attained, that individuals with strong monetary goals are more likely to engage in crime.

At an even more complex level, some work has revealed that the availability of legitimate opportunities reduces the criminogenic impact of monetary goals, even in the presence of reduced support for conventional values. Similarly, being economically satisfied reduces the criminogenic relationship between monetary goals and instrumental crime even when one is supportive of crime as a method to reach these goals. Alternatively, holding values that support the use of illegal means to reach monetary goals when an individual places strong importance on those goals is extremely criminogenic, particularly when opportunities to reach the goals through legitimate means are blocked or one is monetarily dissatisfied (Baron 2011).

Research has also shown that monetary dissatisfaction is more likely to lead to crime when accompanied by negative economic circumstances, including homelessness and unemployment (Baron 2006). Further, scholarship reveals that the criminogenic effect of relative deprivation is greater when accompanied by negative economic circumstances like homelessness. This suggests that while negative interpretations of economic situations can lead to crime, the likelihood of these negative interpretations leading to illegal behavior is stronger when individuals are also experiencing adverse economic situations. The research also shows that although adverse economic circumstances, like unemployment and homelessness, can lead directly to crime, they are more likely to result in offending when individuals experiencing these conditions associate with deviant peers and hold values that support breaking the law. Similarly, negative interpretations of adverse economic circumstances, like monetary dissatisfaction and relative deprivation, are more likely to lead to various forms of crime when individuals have adopted values that favor law breaking and also associate with peers who break the law. Therefore, the criminogenic effect of negative economic circumstances and negative interpretations of these circumstances is influenced by the types of people one associates with (specifically, people who support using illegal means to attain monetary goals), as well as the types of values one adopts (that is, where there is a withdrawal of support for the legitimacy of conventional routes to success) (Agnew et al. 1996; Baron 2004, 2006; Baron and Hartnagel 2002).

It has also been uncovered that negative economic situations like unemployment are more likely to lead to crime when people make external attributions for their circumstances (Baron and Hartnagel 1997). In addition, when negative economic outcomes are viewed as unfair, they are more likely to lead to offending behavior when people place blame externally (Baron and Hartnagel 2002). Further, negative interpretations of economic circumstances, like monetary dissatisfaction, are also more likely to lead to crime when one attributes blame to external sources (Baron 2008). Thus, adverse economic situations and negative interpretations of economic circumstances are more likely to lead to a criminal response when blame for the negative circumstance is placed on outside sources like industry, government, and the economy.

Research has also provided support for the argument that monetary strain leads to the development of negative emotions. For example, research shows that negative interpretations of economic circumstances, like relative deprivation and monetary dissatisfaction, lead to the development of anger over economic circumstances (Baron 2004, 2008). Work has also provided insights to suggest that negative economic circumstances are more likely to lead to anger when individuals attribute the cause of their situation to external sources (Baron 2008). Further, peer influence, together with external attributions for the cause of negative economic circumstances, also contributes to the development of anger over economic circumstances (Baron 2008). Finally, there is support for the argument that the angry emotions that develop out of negative economic circumstances are predictive of some forms of criminal offending, including violence and drug dealing (Baron 2008).

In sum, recent work has provided a great deal of initial support for various aspects of the argument that monetary strain leads to individual offending. This research, however, also clearly demonstrates that this linkage is anything but straightforward and that evidence is still required to test some of the proposed linkages outlined by theoretical scholars.

Possible Controversies in the Literature

Despite what has been called a common sense explanation to crime, the link between monetary strain and individual offending has been attacked because of the perceived lack of empirical support for the perspective. Early work examining the perspective tended to offer minimal or marginal support for the approach (see Burton and Cullen 1992). Many prominent scholars went so far as to declare that searches for links between monetary strain and crime should be abandoned. However, as can be seen from the summary of recent work reviewed, there appears to be a significant connection between monetary strain and crime. The controversy appears to be a product of researchers oversimplifying and frequently misinterpreting the way monetary strain is linked to crime (see Agnew and Passas 1997). For example, empirical tests have often reduced the monetary strain/crime explanation to the simple assertion that when individuals are unable to gain monetary success through legal channels, or experience negative economic circumstances, they will engage in crime. Further, these tests have often ignored theoretical developments that expand the explanation of the role monetary strain plays in the generation of individual offending (Agnew 2006; Agnew et al. 1996; Baumer 2007; Cullen and Wright 1997; Hoffman and Ireland 1995; Passas 1997). The result is that much of the research does not do justice to the complex process outlined by theorists. The failure to take into account reference groups, attributions, perceptions of monetary dissatisfaction, negative emotions, deviant peers, deviant values, social support, social control, deterrence, and personality characteristics, such as self-esteem, self-efficacy, and negative emotionality/low constraint, has been a serious oversight. The tendency to ignore the way that these factors condition the development and impact of monetary strain means that many of the hypothesized linkages have never actually been explored. As can be seen, preliminary explorations into these more complex relationships have provided evidence that monetary strain leads to crime. Through the efforts of a number of scholars, the argument linking monetary strain to individual offending has survived (see Agnew and Passas 1997).

In addition to the poor theoretical application, much of the past empirical research examining the monetary strain/crime link has been beset by methodological issues. First, the operationalization of strain has proved problematic. For a considerable period of time, researchers relied on a financial strain measure focusing on the disjunction between educational/occupational aspirations and educational/occupational expectations. Criticism has emerged outlining that this type of operationalization is dubious since it does not tap into the notion of the importance of monetary goals so core to the explanation, nor does it capture the sense of dissatisfaction associated with the failure to reach those goals or the subjective unhappiness with one's monetary situation (Agnew et al. 1996; Baron 2006).

While advances have been made regarding this issue, there remains some debate regarding how to actually conceptualize and measure monetary strain (Agnew 2006; Agnew et al. 1996; Baumer 2007; Burton and Cullen 1992; Passas 1997). Although there is some agreement among researchers about the core concepts that need to be taken into account when exploring the theory, the way that researchers have chosen to interpret where in the causal process these factors should be placed and how they might possibly come together has led to an array of causal model types to be tested. These alternative interpretations will certainly provide research puzzles for future researchers to resolve. Over time researchers will hopefully clarify the causal linkage between monetary strain and crime.

A third issue that has plagued the research has been the tendency for scholars to utilize school populations to explore if monetary strain is linked to very minor forms of crime (Baron 2006; Burton and Cullen 1992). This trend has led observers to suggest that the monetary strain/crime research has been misdirected. Critics argue that the monetary strain/offending link should be strongest among those not in school, for whom money is of a greater concern, and among the urban poor who experience larger barriers to achieving their goals. Further, the explanation, they argue, is designed to explain more serious forms of offending. Again recent work tends to support the approach advocated by critics, thereby rescuing monetary strain from being discarded as a potential cause of individual offending.

Open Questions

It is becoming clear that the link between monetary strain and individual offending is quite complex. Researchers continue to debate the precise manner in which monetary strain is linked to crime, regularly providing alternative interpretations, extensions, and operationalizations. This process has resulted in a myriad of ways to both conceptualize and measure monetary strain. As the overview to the current state of affairs illustrates these extensions, alternative readings and methodological advances have all provided valuable insights into the manner in which monetary strain can be linked to crime. Yet, these extensions also create further questions that will need to be resolved. For example, more work is required outlining the precise direct and indirect paths by which various forms of monetary strain can lead to crime. Here, for instance, the role of emotions has been overlooked in most research exploring monetary strain. While there is some supportive research, more work will need to be carried out to determine how anger emerges from the array of variables that can be characterized as strain, and whether anger mediates their impact on crime, or whether their role is direct. Also, to date, there has been little research exploring the conditioning roles of social support, social control, deterrence, and personality characteristics such as self-esteem, self-efficacy, and negative emotionality/low constraint and certainly, more work on reference groups, attributions, perceptions of monetary dissatisfaction, deviant peers, and deviant values is required.

Another issue is that the array of factors that can moderate the effect of monetary strain on crime is quite extensive, leading to debates over how these factors should be combined and which ones are the most important both in terms of creating anger and increasing the likelihood of offending directly. Related to this is the fact that it is still unclear how many of the factors should or need to be combined to provide an accurate understanding of the link between monetary strain and crime. Work has begun exploring how combinations of two factors, for example, monetary goals and low expectations, work together to create crime. However, recent theoretical reinterpretations stress the need to examine how a larger number of factors, for example, three factors, work together to increase offending likelihood (Baumer 2007). The potential combinations between theoretically central variables provide a number of avenues for exploration and suggest that the link between monetary strain and crime may be more complex and nuanced than what has been discovered so far.

There is also still some uncertainty over the application of the perspective to various populations. For example, while there is a theoretically strong argument linking monetary strain and crime for disadvantaged racial and ethnic groups, little work has explored this possibility and the minimal empirical work is not supportive to date (see Cernkovich et al. 2000). Further, the role that gender plays in the criminogenic process of monetary strain has been relatively underexplored (Baron 2007). This is important since perceptions of monetary strain may vary across gender, emotional reactions might be different, and criminal responses might be dissimilar depending on gender (Agnew 2006). Sparse work suggests that perceptions of monetary strain and emotional reactions to monetary strain may not vary across gender. The way males and females react to negative economic circumstances, and interpretations of those circumstances with crime, however, may be more gender specific and differ depending on deviant peers, deviant values, and attributions (Baron 2007). It is also the case that while the monetary strain explanation is certainly pertinent to understanding the crimes of economically marginal populations, it can also be applied to understanding crime in other socioeconomic locations. Again, there is sparse work that suggests that the ideas here can be utilized to explain white-collar offending as well as street-oriented offenses (see Passas 1997).

There is also some disagreement about the link between strain and different types of offenses. Classic scholars, for example, suggest that goal failure leads to giving up monetary goals which in turn leads to using illegal substances. In contrast, contemporary work focuses on how having strong monetary goals can lead to substance use under the more complex process outlined. These seemingly contradictory arguments need to be further explored. It may be that the types of emotions that can be generated by strain, for example, depression, need to be examined, and linked to specific offenses. Further, internal attributions, or self-blame, that lead to more passive deviant responses to monetary strain may be a fruitful avenue to explore. It is clear that research examining a diverse range of populations and offenses, attempting to apply a more complex model using appropriate operationalizations, is certainly needed to provide broader support and explanatory refinement to the way monetary strain leads to crime.

Conclusions

In sum, monetary strain emerges when an individual is unable to reach monetary goals, experiences negative economic circumstances, or is dissatisfied with their monetary situation. This experience is exacerbated by blocked opportunities, feelings of relative deprivation, and external attributions of blame. This strain creates a negative emotional reaction that motivates individuals to engage in crime to cope with the monetary strain. The likelihood that monetary strain will lead to crime is increased when the individual experiencing the strain has few moral reservations about using illegal means, associates with criminal peers, has low social control and little conventional social support, has lowered personal coping resources like self-esteem and self-efficacy, exhibits negative emotionality/low constraint, and views the chances of legal apprehension and punishment to be minimal. The instrumental illegal actions taken can be seen as an attempt to satisfy monetary goals and overcome negative economic circumstances, while violence and substance use can be viewed as efforts to reduce the negative emotional affect created by monetary strain. Recent empirical work has provided early support for this explanation of crime. Yet, much work is still to be done to explore the full complexity of the theory and its application to an array of populations to explain a range of offending behaviors. These research challenges encourage current and future scholars to make strides to more precisely understand the important link between monetary strain and individual offending.

Overview

Laundering money entails disguising the illicit origins of proceeds of financial manipulation, drug trade, fraud, corrupt enrichment, or other crimes, bringing back money into the financial circuit of the legal economy. Some underlying misbehavior, the so-called predicate offense generates illicit gains which are to be turned legal. Hiding or disguising the source of these proceeds will not amount to money laundering *unless* they were obtained from a criminal activity (Busuioc 2007).

Predicate offenses for laundering can be "hard" crime involving drugs or violence, but may also be white collar crimes, such as illicit real estate dealings, fraud and embezzlement, and finally tax fraud and tax evasion. Laundering the resulting (typically large amounts of) money can be achieved through fake invoicing for exports and imports or unusually priced real estate transactions. Disguising is further attempted through pumping money around foreign banks (typically in tax haven countries), through gambling or buying expensive consumer goods which can be moved around without effective controls (e.g., diamonds, highly priced art, or yachts). Each of these innovative ways of spending money (which can be recovered in legal markets) may require a different set of expertise of the investigation agencies: It might be the criminal police, customs, or forensic auditing firms. In many cases, only a combination of these might be able to trace these complex crimes.

With the growth of financial markets and instruments, money-laundering constructions have become ever more sophisticated. Swaps and other derivatives can be involved; multiple housing transactions and complicated insurance instruments can blur the origins of the illegal proceeds. Take, for example, a real estate agent collecting say 10 million dollars from a tax evader in cash money for selling a business complex. The listed price of the object is 5 million dollars; the true price is 15 million dollars. The real estate agent takes the cash money to his or her bank and transfers this money to his abroad company X, who in turn gives a fake loan of 10 million dollars to a company Y. Company Y pays back the fake loan to company X. The real estate agent now has an official receipt of income of his company X of 10 million dollars. Tax evading now results in an object bought worth 15 million dollars of which only 5 million in official money has been paid, the rest with laundered money. When the object is sold again, there are official sales receipts for 15 million dollars. Finally, the tax evader has a non-traceable supposedly legal revenue of 10 million dollars which can be spent on investments in business, hotels, or for luxury consumption of cars, jewelry, and real estate.

Money laundering, however, owes its name to a much simpler technique dating back to Chicago gangster Al Capone. He used the cash-intense business of launderettes to hide his illegal alcohol proceeds in times of prohibition in the 1930s. Slipping money from alcohol proceeds into the cash register of his launderettes, he pretended this was turnover of the regular business. By 2009, money laundering is estimated to amount between 1.5 and 3 trillion US dollars that circulate across the globe as illegal money transfers (see Walker 1995; Unger 2007; Walker and Unger 2009; Review of Law and Economics 2009). With the exception of the group around Truman and Reuter (2004) who think that the estimates of laundering are exaggerated, money laundering is considered a huge global phenomenon.

Laundering transfers can take place using the banking sector. They can use transfers by regular invoice or payment including new electronic methods like digital cash, e-gold, or prepaid phone cards (see http://www.fatf-gafi.org). Pressure from national regulators has led to the introduction of more electronic control systems. Financial institutions set barriers for the transfer of larger amounts (such as 10,000 dollars in cash or unusual transfer) which are to be checked for their source or purpose. Gambling casinos are obliged to control the identity of customers who invest unusual amounts of cash. Internet gambling, however, can easily avoid national borders and controls.

Such controls are devised to detect the predicate crime. The United States has developed a list of more than 130 predicate offenses suspect for money laundering. More predicate offenses were added into the money laundering definition over the years. Upon political requests, also terrorist financing and lately tax evasion have been included (see: FATF 2010). As a consequence, the amount of laundering has increased by definition.

Setting Money Laundering on the International Agenda

Money laundering is a relatively young topic and only recently an issue on the international agenda (see Unger 2007 for a survey of the money-laundering literature). Sure, already in ancient Chinese trade, there were other forms of hiding proceeds from authorities and there were punishments for dealing in stolen goods (“fencing”). However, money laundering in its current meaning dates back to the 1980s when it was first criminalized in the United States.

Fighting drug dealing has for a long time been of central concern in combating money laundering. After several decennia of the unsuccessful US “War on Drugs,” the Clinton Administration chose a hard crime fighting approach: If drug dealers and other criminals could not got caught directly, at least they should be discouraged by not being able to reap the monetary benefits of their dealings (see Unger 2011). Thus, in 1986 (Title 18, US Code Sec. 1956), money laundering got punished in the USA with up to 20 years in prison and $500,000 in fines. Further legal arrangements permitted seizing, freezing, and confiscation of assets by the authorities.

Since money laundering is a global crime without borders, the USA made large efforts to convince the international community of the importance of the topic. On a global level, anti-money-laundering policy started in the late 1980s with the UN Convention on Drug and Narcotics of 1988. In 1989, the Financial Action Task Force (FATF), an intergovernmental body to combat money laundering, was established by the G-7 countries. Since then the global movement against money laundering steadily gained support. Today, the FATF comprises of 34 member jurisdictions and two regional organizations, representing most major financial centers in all parts of the globe. The combat accelerated after the terrorist attacks of 9/11, when getting hold of terrorists by combating the financing of terrorism became part of anti-money-laundering policy.

However, one principal objection to FATF's work is its nondemocratic character. Groups of experts are nominated by their governments; they are not accountable to any parliament, and nobody can dismiss them. In such an "expertocracy," some countries send delegates to FATF meetings who may not be fully aware which enormous consequences these meetings can have on their national legal system and institutional setting.

Hindrances for Compliance: Victimless Crime and Unproven Effects

Money laundering itself does not seem to have direct victims. No individual suffers from the Colombian drug mafia sending 10 billion dollars from one country to another; on the contrary, many might rightfully profit from the resulting business. There are no victims who would complain, no liability claims that would be raised, and no tort law that could be applied. Legal literature therefore debates whether crime without victims should be punished at all and whether punishment is a deterrent. Would society be damaged by this maleficent behavior and fall into decadence (Mill, Chapter 1, p. 21)? The damage incurs on the level of the common goods of society. "*Public order crime*" would be the preferred term in place of "victimless" crime.

The harm of money laundering is indirect. Unger (2007) lists 25 negative and positive effects that money laundering can have. It can deter honest business activities: If criminals invest their money in particular sectors like the transport industry, restaurants, housing, it can lead to changes in relative prices, savings, output, employment, and growth or it can affect the liquidity, reputation, integrity, and stability of the financial sector. The public sector can suffer from unpaid taxes and criminals might buy up public enterprises during privatization efforts. There are also social and political effects, such as increased corruption and bribery. Criminals might undermine political institutions: As laundering needs facilitators, professionals such as lawyers, notaries, real estate agents, and accountants can become contaminated. None of these effects, however, can be observed directly which renders it difficult to prove. Reaching compliance for anti-money-laundering policy needs the backing of civil society.

Development of International Anti-laundering (AML) Standards That Need Compliance

For larger amounts which are dealt within international finance, the FATF sets international standards, which, in order to comply to, member countries have to arrange for enforcement and execution. Lawyers in ministries, policemen, public prosecutors, and judges may be involved in antiterrorism and money-laundering combat. Special organizations, called Financial Intelligence Units (FIU), have to be established in each country. Countries have to introduce plans to implement ongoing customer due diligence (CDD), identify nondomestic politically exposed persons (PEPs), and ascertain identification of beneficial ownership of offshore accounts. Banks, real estate agents, notaries public, traders in large values are obliged to screen their clients and to identify persons, activities, or transactions suspicious of money laundering or terrorism financing among their clients. The FIU collects their suspicious transaction reports. Supervisory authorities are involved to control the compliance of banks and other sectors with the anti-money-laundering regime (AML). Some countries, such as the USA, have high sanctions for not reporting, with fines as great as $250,000 or 5-year imprisonment (IRS 2011).

However, there has also been criticism of too harsh penalties. Takats (see Masciandaro et al 2007) warned stricter sanctioning might lead to a "crying wolf problem," referring to the boy who always cried wolf but once the wolf really came nobody paid attention. The private sector might, from fear of being punished, drown the FIU by reporting all sorts of transactions as suspicious without indicating what might a predicate offense.

Multiple Actors Involved in Money Laundering

The money-laundering process may be divided into three phases. In the placement phase, the criminal, after he has committed the predicate crime, such as selling drugs, committing fraud, working illegally, or producing fake brand products, wants to get rid of the criminal cash. He or she tries to hand the proceeds of crime over to a person from the "upper world." This can be putting it into the cash register of a launderette as Al Capone did and bringing it to the bank as legal proceeds from washing people's laundry, bringing illegal cash to a bank employee who accepts a suitcase of cash money, to a company who issues fake invoices, or to a transport entrepreneur who transports cash as a courier to another country where it is placed at a bank. Other actors involved in this first phase may be bank employees, business owners, or employees from the transport sector, the restaurant business, etc. After, the second phase called "layering" starts, which tries to make it difficult to detect the illicit proceeds. Transfers may be wired; offshore banks may be involved; fake shell companies may pump the money around the globe. Here the international financial sector would be involved. In the last phase, the integration phase, the money is parked in either financial investment and business. Actors involved may be real estate investors or notaries who are involved in buying and selling houses and accountants in companies, tax advisors, etc. Smaller amounts which could possibly be carried in cash might be laundered by luxury consumption or gambling. Actors involved might be dealers in diamonds or cars, custom officials, etc.

All private sector actors listed, such as bank employees, accountants, tax advisors, dealers, notaries, and lawyers, can get consciously or unconsciously involved in money-laundering transactions. Complicity is an offense wherever laundering is prosecuted. It is the task of all professional services involved to stay alert to money-laundering transactions and to report suspicious transactions to public authorities. Their commitment can be either voluntary, as to help fighting crime, but increasingly statutes try to enforce it by reporting duties and threat of punishment.

Compliance of a Great Variety of Actors

Combating money laundering is as strong as its weakest link in the chain. Coordination and compliance of many policy actors is crucial. Diverse actors for whom the policy is not necessarily given priority or not even in their own interest must be brought into one line. Unlike food or tobacco regulation, combating money laundering does not have a private sector lobby. It is governments and with them the media engaging in a fight against laundering. Not *all* governments are however as active in engaging in the combat. For some countries, it can be beneficial to attract criminal money. Unger and Rawlings (2008) speak of the "Seychelles effect," referring to the island state which in the 1990s deliberately advertised that if investors invested more than ten million dollars, they would not check where the money came from. As they are hardly confronted with the underlying crime, offshore islands and small countries may see the incentive of attracting criminal money. Large countries on the other hand often attract a bigger volume of laundering due to their financial centers and expertise (see Gnutzmann, McCarthy and Unger 2009).

By membership of the FATF or belonging to a FATF-Regional Style Body, states are obliged to implement international standards of anti-money-laundering policy, even though there are divergent national interests – some are tax havens and profit, others suffer from the experience of crime. Lack of a common interest among countries and the divergence of who bears the costs and who the benefits of the combat against money laundering makes it difficult to effectively implement anti-money-laundering policy. Seeing the variety of actors, different ways of circumvention and peculiar forms of compliance can be expected.

Public Actors Involved in Combating Anti-money-laundering

Governments must implement the international standards of FATF into national law. For some countries, this can pose a legal problem. Export-intensive countries such as Austria, Germany, and the Nordic countries feared double punishment for laundering money as well as the underlying crime and therefore originally excluded self-laundering from the money-laundering definition. In the FATF Third Mutual Evaluations of Austria and Germany, authorities explained that the predicate crime includes the concurring act, the laundering, and that the sanction set for the predicate crime is deemed to cover the entire unlawfulness of the criminal's act (FATF 2010). Most of these countries had to revise their money-laundering definition due to pressure of the FATF. In strongly legalistic countries, this change in the principles of law might lead to resistance when practicing the law, so that law in the books and law in practice diverge. Compliance would here be only in the books but not in practice.

Combating money laundering goes from designing the national anti-money-laundering law(s) to the establishment of an FIU. It can be located at the Ministry of Finance as financial intelligence unit, at the Ministry of Justice, the police, or at the Central Bank. It receives reports of suspicious transactions from the private actors, especially from banks and the financial sector, and has to screen these reports. A finance person may concentrate on different reports than a police officer used to hunting drug dealers. The FIU located in the Ministry of Finance might be more inclined to identify tax fraud, while the police might be more after corruption and drug cases. Thus, data access and the interpretation of data vary widely among the different FIUs.

The further chain of judicial procedures can be frustrating if police investigations are judged to deliver insufficient proof. Reports found sufficient by the investigators are sent to the office of public prosecutors who may decide whether to indict and proceed with an accusation or to drop the case, either because of lack proof or because of lack of legal relevance. In principle, the prosecution has to prove suspects guilty, but in some countries, the judge may allow for reversal of the burden of proof about where a big amount of money (relative to the suspect's means) came from.

An effective indictment presupposes all public actors, the legislative, the executive, and the judiciary are willing and able to recognize anti-money-laundering policy as an important goal to pursue and that they are willing and able to cooperate. They should have a similar understanding of the goals of anti-money-laundering policy and how it can be practiced in each country. Compliance policy will be counteracted from within, when public actors are themselves involved in money laundering: such as may be the case when government officials or customs and police officers are part of the laundering gang.

Reporting and Supervision

Anti-money-laundering policy requires penal codes which clearly define offenses and punishment as well as an active enforcement administration. If private actors (such as banks) are obliged to report suspicious transactions to the FIU, noncompliance may risk high fines (as in the USA) or even a jail sentence (as in Luxembourg).

Reporting obligations bring into life reporting systems. Banks and financial institutions may have to establish a software system to recognize suspicious transactions including compliance officers who can be held responsible. They have to check on lists of internationally blacklisted persons and companies, to fill in forms and forward them to the FIU, sometimes for privacy reasons handing them over personally. In short, the reporting system is costly and cumbersome for the private sector. As the private sector has no particular interest in fighting money laundering (there is no private sector lobbying for this policy issue) and in so far as compliance poses extra costs, it might be difficult to be reached.

Supervision of reporting entities is important. Many supervisory authorities are engaged in supervising reporting. In many countries, the Banking Supervision Authority also supervises anti-money-laundering matters. But do they find money laundering as important as, for example, the Financial Intelligence Unit might find it? Lawyers are usually supervised by their Bar Association which might put more emphasis on legal privilege and privacy of customer relations. In some countries, the FIU itself supervises. It remains doubtful whether the FIU knows enough about diverse sectors in order to supervise banks, financial service sectors, accountants, car dealers, and diamond dealers. Countries differ with respect to the competent actor for supervision. Some agencies might be centrally organized, others at a state or provincial level.

Hindrances to Compliance

Anti-money-laundering policy is mainly a public sector concern; hence, the private sector needs to be persuaded to collaborate. This means both good relations between the public and private sector as well as strict laws, punishment, and supervision should be in place. However, some countries benefit from the underlying crime while others bear the costs it. Disinterested countries may need to risk international sanctions or receive side payments in order to combat money laundering. As long as some countries hunt drug dealers but stick to bank secrecy while others fight tax evaders, compliance lacks a common policy goal to which one should comply.

Private actors have different priorities and often a double relationship: A launderer is also a client of banks and lawyers. Reporting a client with a close relationship to a bank (particularly when cash business is involved) means losing money, while not reporting may entail reputation damage to the bank. Similarly, there is the legal privilege of lawyers and notaries, which guarantees privacy of the lawyer-client relationship. Reporting a client therefore becomes a delicate balance between reporting duty and right of legal privilege, which might be very difficult to supervise and actors involved are definitely not interested in cooperation.

Seeing the many reasons why the private sector might not comply with anti-money-laundering policy, and seeing the many ways in which anti-money-laundering policy might be circumvented, the FATF has opted for blacklisting as a drastic step of enforcement.

Blacklisting Countries for Noncompliance

Many institutions, among them all central banks of the OECD countries (18 members) as well as the European Union, are maintaining white lists of countries: countries which are cleared for controlling their banks and financial institutions as well as multinational corporations for money-laundering transfers. Transfers from countries which are cleared may be accepted on the basis of simplified identification research of their financial institutions.

Similar lists, only with a reversed definition as *black lists* of countries with insufficient controls, are issued by the FATF (23 members). It has issued forty anti-money-laundering recommendations for controlling the financial sector and nine recommendations for combating terrorist financing. Countries face regular mutual evaluations and in case of noncompliance with the recommendations, they can get blacklisted as noncooperative countries (Unger and Ferwerda 2009). This can be economically very harmful, since countries risk that no American bank will do business with them. It is doubtful, however, whether blackmailing dogs really want to bite. In a first evaluation of the International Monetary Fund (IMF) in 1999 when a definition of financial havens was used, 69 noncooperative countries were listed, among them 19 European countries such as the financial centers of the UK, the Netherlands, Switzerland, and Luxembourg. This cross-border transfer of capital leads to extraction of capital in countries where the crime is committed and leads to an inflow of capital in countries where the integration phase takes place. The IMF (with 188 members including developed as well as developing countries) stopped their rankings because they felt that they could not take into account both ends of the chain. Consequently, they criticize the FATF (with 18 predominantly richer members) which simply checks the financial control infrastructure by intergovernmental assessments (Table 1).

Money Laundering, Table 1 Blacklists for noncooperative countries and territories

Blacklist	Number of countries worldwide	IMF: financial havens FATF: anti-money laundering and countering the financing of terrorism
IMF list 1999	**69**	**Nineteen** European countries: Austria, Hungary, Ireland, Luxemburg, Netherlands, Russia, Switzerland, Ukraine, UK, Liechtenstein, Luxembourg, and 8 smaller European jurisdictions
FATF 2000	**15 high risk**	**Two** European countries: Liechtenstein, Russia
FATF 2001	**19 high risk**	**Three** European countries: Hungary, Russia, and Ukraine
FATF 2002	**10 high risk**	**One** European country : Russia
FATF 2005	**3 high risk**	**no** European country
		Only Nigeria, Myanmar, and Nauru left on the list
FATF 2012	**2 high risk**	**no** European country
		Iran, North Korea

IMF, FATF: only high risks
In addition to the high-risk label, the FATF since 2011 indicates a gray list of deficiencies every year. In 2012, it included 15 countries: Cuba, Bolivia, Ethiopia, Ghana, Indonesia, Kenya, Myanmar, Nigeria, Pakistan, São Tomé and Príncipe, Sri Lanka, Syria, Tanzania, Thailand, and Turkey

And indeed, on the FATF list of noncooperative countries, none of the financial centers are listed. The first official FATF rating in 2000 lists 23 countries, later blacklists included only 15 noncooperative countries of which two were European: Liechtenstein and Russia. Eventually the list got shorter and shorter. In 2006, Myanmar was the only noncooperative country left, and was finally also removed from the list in October 2006. The regular mutual evaluations of the FATF look for "risks of anti-money laundering and countering the financing of terrorism." As soon as the Financial Control Agency cooperates (such as the financial center countries), the country does not appear on the blacklists.

The FATF blacklist was heavily criticized for its lack of transparency and legitimacy, as it did not rate all countries and was biased against small countries (Unger and Ferwerda 2009). Since 2011, there is a new "gray list" which distinguishes in four categories in how far they are fulfilling the FATF recommendations (either fully, making efforts in the right direction or not having made any effort for change). Countries make great efforts to be removed from this list, but this might show only "shallow compliance" in the books instead of effective action. They might strategically produce statistics to satisfy the FATF (such as by just reclassifying cases or counting a case with several transactions by each transaction separately).

Monitoring and Evaluation of Restorative Justice

Joanna Shapland
School of Law, University of Sheffield,
Sheffield, UK

Overview

As restorative justice programs spread throughout the world, it has become more and more important to have adequate evaluations of such programs upon which policymakers, practitioners, and academics can rely. This entry distinguishes between *monitoring*, which all programs and practitioners should do themselves, and *evaluation*, which requires more specialized knowledge and skills. Both monitoring and evaluation need to be appropriate to the aims and context of the program itself and should meet the needs of and be accountable to the stakeholders of the program, including funders, those referring cases to the program, participants, and staff. Evaluation is thus not just "measuring satisfaction" or answering the question "does it make offenders reoffend less?" but must consider all the outcomes desired for the program, whether they have been achieved and, preferably, whether the program is cost-effective, or value for money. The entry provides some guidance on how to set up and conduct evaluations of restorative justice programs, but each program needs to consider its own requirements and aims.

What Is Evaluation?

Evaluation itself is a contested topic and the subject of many academic papers in its own right. Within criminology, evaluation has been the subject of lively exchanges, for example, on whether outcome evaluation is the key or whether the contexts of programs and the theoretical mechanisms through which the outcomes might be expected to occur are equally important (Farrington 1997, 1998; Pawson and Tilley 1998).

Historically, the forms of restorative justice being developed have been highly attuned to their cultural environment. As a result, there are many different types of program or scheme, even when considering only those dealing with crimes and which remain within the sphere of criminal justice (this entry is restricted to this sector). There is victim-offender mediation, conferencing, indirect mediation, sentencing circles, community panels, and many others. There is even more diversity if one moves away from crime and considers the use of restorative justice in civil disputes, in schools and organizational settings, or in peace-making. It is also important to reflect as to whether the restorative justice program is concerned only with offences which have direct victims (people who are themselves injured or lose property) or whether it is also concerned with indirect victims (family members who are affected, neighbors, the community). The entry will use the term "scheme" to denote a program of work delivered by an organization within a defined geographical area in relation to criminal cases, such that the work is done within an agreed framework or process by one or more mediators or facilitators. It is possible for a scheme to have a national remit, as does the Youth Conference Service of Northern Ireland, which has statutory authority to deal with all cases referred by prosecutors or judges in youth justice cases (Campbell et al. 2006). More typically, however, restorative justice schemes have grown up locally, to serve one town, or one region, often specializing in particular types of referrals.

Within restorative justice schemes, there is considerable local diversity – and this may need to be so if participants (victims, offenders, those supporting each party) are to feel comfortable and safe in the restorative setting and so able to communicate with each other. However, it makes it much more difficult to say which forms of restorative justice are most suitable for whom or for what kind of dispute. We need to develop methods of evaluation which are sympathetic to the local aims and procedures of different restorative justice procedures but which are still rigorous enough to allow us to show whether there are differences in outcomes and to compare schemes.

Evaluation itself is a word which means different things to different people – which is usually the prerequisite for mutual misunderstanding, particularly in a comparative field. First, there is the need to distinguish what will be called "monitoring" from "evaluation."

Monitoring: A Basic Duty for Each Scheme and Practitioner

Monitoring is an activity which needs to be undertaken by all schemes and by all practitioners. It is the essence of the reflective practitioner: essentially considering at regular intervals what one has done and reflecting on what has worked and what might be changed.

The basic level of monitoring implies record keeping of what cases have been dealt with, from whom referrals have come, who the participants were (including basic demographic details such as age and gender), what happened in the case and the dates of contacts, and when the case was closed. Having such systems is the basis of accountability and a requirement in codes of practice for restorative justice practitioners (e.g., Restorative Justice Council 2011, in the UK). They are important in answering queries from participants (such as "I've lost my copy of the outcome agreement: could I have another one?"), from those referring cases and from funders. Without good data systems and monitoring, further evaluation is impossible. Nor is it possible for governments and funders to see whether funds are being used correctly.

Yet new schemes do find it very difficult to remember to set up such systems, which provide not just a case management tool but also allow reports to be derived easily to provide management information (Shapland et al. 2011). There is no "off-the-peg" software currently available for running restorative justice schemes, and it is strongly suggested that new schemes contact others (even others in different countries) to find out their experience in practice. Restorative justice is much more complicated than criminal justice processes, because it is voluntary for both victims and offenders – so there is a need to ensure all the participants, venue, etc., are in place before there is a direct meeting.

Monitoring implies that data will be available from each restorative justice scheme in terms of its activity and some agreed outcome measures. So it will be possible to know how many cases have been referred to the scheme from whom, how many facilitators/mediators dealt with them, when they were referred and when they were closed, and what the process outcome was (one party declined the service, indirect mediation, a meeting between parties, etc.). Some of the latent antipathy towards evaluation by some restorative justice workers seems to have stemmed from the feeling that restorative justice must never be bureaucratized as a product, to be achieved identically each time, and to be able to be counted like tins of beans. This is a valid concern: restorative justice must be flexible and able to meet each group of participants' needs. The very definition of restorative justice indicates this continuous democratic creation: "a process whereby parties with a stake in a specific offence collectively resolve how to deal with the aftermath of the offence and its implications for the future" (Marshall 1999). If the parties are collectively resolving, then necessarily the content of their discussions and any outcome agreement will be slightly different each time. With monitoring, however, it becomes possible to consider how restorative justice is faring across schemes or across countries (see Shapland et al. 2011, for a review of evaluation results; also Sherman and Strang 2007).

Understanding the Monitoring Figures: Providing a Description of the Scheme

Given the intrinsic plurality of restorative justice, bare statistics tend to be meaningless. What does it mean to say that one scheme had 30 referrals from prosecutors while another had 150? What does it mean for the participants that 80 % of cases were closed within four months? Monitoring is vital, but collection of figures needs to be amplified by a detailed description of the process of restorative justice being run by that scheme, including:

- What kinds of cases does the scheme take? What kinds of cases are referred? What processes are undertaken to see whether cases are suitable?
- Who is contacted by whom when a case starts? What is offered? Typically, how does the case proceed?
- Do participants meet face-to-face? Just victim and offender with a mediator (or two mediators?) Or with others? How many meetings?
- What are typical outcomes? Is there a written outcome agreement (agreed by all parties)?
- What happens after any meeting? Is there feedback to those referring cases? Is there feedback to participants about any criminal justice outcomes?

One of the most detailed but most helpful descriptions of what was done by a scheme was Justice Research Consortium Thames Valley (2004) "From soup to nuts" folder. The "from soup to nuts" title describes the typical pattern of an English dinner party – the idea of the folder was that new staff could find out from it how conferences were organized from first receiving the referral or data on the case (soup) all the way through the possible outcomes and processes, to the final feedback contacts with the parties (nuts).

Financial Cost Data

Alongside statistics of cases and this detailed description, it is also important that schemes keep details of their own scheme's financial operations. It will never be possible to see whether the scheme is value for money unless the financial cost of running the scheme over a certain period of time and undertaking a certain number of cases is known. Value for money, on the British definition of value for money in public services, is achieved if the cost of running the scheme is exceeded by the financial benefits of its work in terms of reoffending prevented or well-being created (if well-being can be measured in financial terms, as it is in health economics and, for example, by the English National Institute for Clinical Excellence). Details of the kinds of financial cost figures that need to be kept are given in Shapland et al. (2008), but essentially they include salaries or fees to personnel, buildings and premises costs, travel costs reimbursed to participants, publicity, insurance, training, and so forth. The costs need to be able to summed over a particular time period, which is the same as that used for case management summary reports, so that it is possible to calculate a cost per case (even though such an idea of an "average" case is difficult for restorative justice, where cases may stop at different stages) or a cost per facilitator.

Some might comment why bother undertaking the burden of keeping such cost and time data, when the scarce time of personnel could be used in undertaking more restorative justice work? The answer is that cost and time data are not just for the benefit of economists, hard-edged governments wanting value for money, or criminal justice practitioners who hold budgets but also for schemes themselves. They can help to answer questions such as the following: Does direct mediation take longer? Can one split it from the effort needed to be put in to undertake indirect mediation? What are the costs of recruiting, training, and managing volunteers compared to paying a fee per case or employing paid facilitators? All would agree that proper preparation of participants is vital, but over what length of contact should it be encouraged? How much more costly is work in prison (given the need to have security personnel present, get all participants to the prison, etc.) compared to work in the community? These are key questions for the setting up and development of any scheme – and for those funding restorative justice. It is important that new developments or new areas where referrals are taken are coded as such in the data. It can be very difficult to work back through financial data to undertake these costs analyses retrospectively. It is much easier to work out a simple system of codes to allocate to payments as they are made.

Evaluating What the Scheme Is Trying to Achieve: Specifying Aims and Outcomes

Some practitioners and academics tend to be referring to monitoring when they talk about evaluation. Evaluation, however, is a rather more long-term and fundamental exercise – looking at whether the scheme has achieved its desired outcomes. Monitoring is not sufficient. Any scheme also needs to know whether it is achieving its desired outcomes or aims. It also needs to know how its services are being perceived by participants and where it may need to make changes.

Specifying Aims: The First Key Step

In order to start on evaluation, the scheme needs to know what its aims are in sufficiently clear and precise terms so that it is possible to measure whether they have been achieved. Unless the scheme has spent time in working this out and in agreeing what the precise aims are, it is impossible to set out what its outcomes are supposed to be and so evaluation is close to impossible.

This would seem to be obvious. However, the history of crime reduction and criminal justice evaluation is a rather sorry one in this respect – and it is important restorative justice evaluation does not follow the same path. In England and Wales, for example, considerable amounts of money have been invested by government, police, and local authorities on crime reduction initiatives. Yet some of these initiatives have not been implemented as intended, and others have been almost impossible to evaluate (Hamilton-Smith 2004; Hope 2004). One of the reasons has been a lack of precision in the intended aims of the initiatives or a change in those aims during the initiative. The problem is that initiatives designed to reduce burglary may be intended just (a) to reduce recorded offences of burglary; and/or (b) to reduce other linked crime, such as criminal damage; and/or (c) to reduce fear of burglary; and/or (d) to reduce fear of crime more generally; and/or (e) to make residents feel the police or other local authorities are doing their job in the local area better. All these aims are possible; more than one may be desired – but each creates a different outcome measure. If the program does not specify exactly which aims are its priority, the evaluation has real problems.

Restorative justice has potentially as many aims as crime reduction programs. Is a particular restorative justice scheme aiming to:

- Achieve particular aims for participants (e.g., increase offenders' empathy, restore victims' hurt, provide a sense of closure for victims or offenders, reduce offenders' reoffending)
- Provide a process whereby participants may find their own solutions to situations/conflict (e.g., by allowing each to state the effects of the offence on themselves and ask questions, allowing each to have a fair say in resolution, encouraging a joint problem-solving agreement, providing a safe space for discussion)
- Provide a more civilized or cheaper or more participatory alternative to traditional criminal justice.
- Or more than one of these?

Each of these aims has been advocated as an aim of restorative justice. In our evaluation of three large restorative justice schemes in England and Wales, the schemes differed as to how the managers perceived their relation to criminal justice, for example, and so whether measuring reoffending was a relevant outcome measure (Shapland et al. 2006a). Facilitators within the same scheme put emphasis on different aims, because typically each scheme had multiple aims.

It is important to realize that each aim implies that specified people should judge whether it has been achieved. The first aim above, for example, is primarily about participants' perceptions, rather than schemes' or referrers' perceptions. It needs to be evaluated using data from participants or relating to participants. The second relies on participants as well but could also be measured by observers at restorative justice meetings and through questions to facilitators. The third could be judged by all of these, but it can be argued that if it is a publicly funded service, then criminal justice system professionals and policymakers should also be judging its worth against other alternative processes in criminal justice.

Exactly which aims are seen by the scheme as paramount will depend upon its history but also upon its ideology and the theoretical mechanisms through which it believes restorative justice is impinging on the participants and others. Aims are inseparable from theory. Many theoretical strands have combined to make up the rich tapestry of modern restorative justice, and they differ according to the key purposes they see for restorative justice (Shapland et al. 2006b). Zehr (1990), for example, stresses its healing and conflict-reduction potential and this is a dominant strand in victim-offender mediation, for example, in Nordic countries. Australasian restorative justice has stressed the democratic, participatory, emotional, and procedural potential of restorative justice conferencing (Braithwaite 1999; Harris et al. 2004). Recent schemes in England and Wales, following the dominant crime reductive imperative of national and local criminal justice agencies and government, have sought its potential in reducing offending, though our own evaluation has always stressed that both reducing offending and responding to victim needs must be equal aims (Shapland et al. 2011).

For restorative justice, specifying theoretical mechanisms is even more important than for crime reduction. This is because restorative justice is an intrinsically process-based initiative. It cannot be seen in evaluation terms as a black box model, where participants are put in one end, a mediator added, one shakes them all together, and outcomes come out at the other end. For restorative justice workers, it is precisely what happens in the middle, during the process, which is important. How exactly is it expected that victims will be reinstated or restored? What will be a sign of this? Are there mediations or conferences where this occurs more often or where conditions seem more fruitful? How can we make those occur more often? Is it something the mediators say? Or the surroundings? Or what? Similar questions can be asked in relation to offenders.

Setting Out Realistic Outcome Measures: The Difference Between Outcomes and Outputs

Evaluation is primarily about measuring outcomes – representing the final aims of the scheme. However, commonly, measuring outcomes takes some considerable time. If one aim of a scheme is to reduce reoffending, this is typically done by looking at reconviction rates or rearrest rates (in the USA). It is necessary to leave a period of time for reoffending to occur (1 year minimum currently in the UK and in the USA) and for official systems to record it (i.e., cases to reach conviction and sentence). It is important that reoffending be checked to see if it is being reduced in relevant ways (is it most relevant to measure likelihood of reoffending, or frequency, or seriousness, or all three?), but this tends to be a complex and costly business, because of the ways in which official conviction or arrest data are held. Would it then be sensible to measure intermediate goals called "outputs" more often, restricting evaluations looking at the final reconviction outcome to periodic sweeps every 5 years or so? Are there relevant outputs that could be measured? For reoffending or official conviction, it may be that successfully completing a release program from prison or a community program may be a proper output measure (though there is always the danger of contamination of the results if the criminal justice program workers know which offenders have been through restorative justice and are either favorable or very unhappy about it).

Restorative justice has been accused more recently of just relying on "satisfaction" measures (i.e., sending small questionnaires to participants immediately after closing the case asking if they were "satisfied" with the process and the result of the restorative justice). There is nothing wrong with sending out satisfaction questionnaires – they provide an opportunity for participants to feedback their experiences and some idea for supervisors as to whether any particular type of case or individual facilitator is providing problematic. They are a typical, simple output measure of participant perceptions. What is important, though, is that periodically it is checked that when an independent researcher does a more in-depth interview with participants at different times after the restorative justice is finished, it is considered whether there are different views about preparation, processes, outcomes, and feedback by the scheme about the result of the case and whether "satisfaction" immediately after the case ends continues for some months afterwards. Few restorative justice evaluations have been able to look in detail at all these elements, but Shapland et al.'s (2011) evaluation of victims' and offenders' views found that views on different aspects of the process and outcomes tended to be highly correlated and that there was not a big dip in positive views with time. They also found, though, that schemes might be regarded highly in terms of facilitator performance and outcome agreements but still fall down, for example, on feedback to participants about whether offenders had completed agreement items or what had happened to cases later in criminal justice.

Minimum Evaluation Is Not Optional

Some evaluation periodically is essential for all schemes. Without minimal evaluation which goes beyond monitoring, even a very major and potentially very successful program will leave nothing behind. It may have benefited the participants and criminal justice practitioners who have been involved, but their memories will fade in time and no one will be able to build on those useful foundations to develop or start new programs in the future. The minimum evaluation which is needed for all schemes and for all work funded through the public purse therefore seems to me to be:

- Monitoring.
- Process evaluation which provides a clear description of the scheme and its processes: a how to do it manual.
- Identification of clear outcome measures: what the scheme aimed to do and how it expected these outcomes to occur (its theoretical view).
- Evaluation using outcome measures periodically, supplemented as necessary by output measures (such as participants' feedback and satisfaction) regularly. Ideally, this evaluation will be conducted by independent researchers or data gathered by the scheme analyzed by researchers independent of the scheme and its funders.

Further Important Questions for Evaluation

Funders and developers of restorative justice, as well as schemes themselves, however, will have many further questions. Answering these will often, however, require more specialized help from different academic disciplines. They may be matters which each country or scheme will want to ask at intervals, in a planned program of developing restorative justice through evaluation. They are certainly elements on which countries trying to develop restorative justice will wish to try to acquire comparative data, so that it is possible to think about different forms of restorative justice and different procedures which provide the most suitable platforms for participants' particular needs.

Consideration of Human Rights and Legal Issues

The first specialist area relates to the fact that restorative justice done in connection with criminal justice will raise many legal and human rights issues. This is so whenever the action at the heart of the justice process involves behavior which is against the criminal law, though the precise issues will differ when the restorative justice is never dealt with formally by criminal justice (community restorative justice), when it is diversionary (i.e., the case no longer will be dealt with by criminal justice personnel), or when it feeds into criminal justice processes (e.g., presentence or prerelease restorative justice).

Some key issues are:

1. Examining the scheme's processes to ensure participants have adequate information and explanation about the process and its outcomes (including whether outcome agreements can be enforced and what happens if they are not completed) to be able to give informed consent on participation. This includes any likely effect on criminal justice proceedings (see Campbell et al. 2006; Daly 2003 for analyses of such effects in relation to young participants).
2. Considering power imbalances between participants not only in terms of the consequences of the offence but in criminal justice terms. This can be very complicated in terms of victims and offenders (Shapland et al. 2006b), even when the offence does not itself present unusual power issues (participants know each other well, live near each other, the offence involves interpersonal power).
3. Thinking how participants may be able to maximize communication within the restorative justice process (translators, dealing with disabilities, etc.). Communication is one of the key benefits both victims and offenders experience from restorative justice, compared to criminal justice (Shapland et al. 2011). Similarly, one of the reasons given for dissatisfaction in conferences, in the few cases in which this occurred in the same research, was when communication was difficult to achieve. If the aim of restorative justice is to facilitate communication and participation, then personal or situational difficulties need to be minimized.
4. If the case involves a serious offence or is still within criminal justice, then it may need to be ensured that offenders (sometimes others as well) can access legal representation in order to advise them on whether to participate in restorative justice.
5. The question of how open the restorative justice event itself is a key one. Normally, events (direct mediation meetings, conferences, circles) are private to the participants and facilitators. This has correlated with the dominant use of restorative justice allied to criminal justice for young offenders, for diverted cases, and for minor criminal cases where it is seen as similar to civil dispute resolution. The typical paradigm in these instances would have been a closed process if the case had been dealt with through normal criminal justice processes. However, often, these events are also open to observation by those training as facilitators and sometimes to other practitioners – though permission should be sought from the participants for this. Normally, they are not videoed or recorded, though a report is often prepared on the case to be sent to those referring it to the scheme. There are major questions about accountability in relation to

restorative justice, which has not often been considered (Dignan et al. 2007). If, for example, there were to be a disturbance during the event, or a complaint afterwards about the mediator/facilitator, what mechanisms exist to answer those questions? Is there a need to have some form of recording to ensure accountability to participants? Moreover, if restorative justice does increasingly deal with more serious offending, is there a need for recording to provide accountability to judges, referrers, those hearing appeals, etc.? Recording itself does not necessarily breach privacy, as long as that recording remains within the group of those properly concerned with that case.

Evaluation to Develop a Better Appreciation of What Restorative Justice Is Achieving

In order to discern whether restorative justice schemes are delivering their aims, there will need to be periodic investment in more in-depth and specialized evaluation. Just one research design may not suit all aims. For example, the current most stringent research design to measure decreases in reoffending is a randomized controlled trial (RCT) (see Sherman et al. 1997). In the evaluation of three large schemes in England and Wales, one of the schemes evaluated, Justice Research Consortium, used this design, and this enabled the evaluators to provide results on reoffending devoid of selection effects in participants volunteering to participate in restorative justice (Shapland et al. 2011). However, the use of RCT is rare in criminal justice research.

The use of an RCT is valuable in considering reoffending, but it does not by itself establish what it is about restorative justice which was found particularly beneficial by those victims (and offenders) who experienced it. An RCT can only look at whether victims who experienced restorative justice were more satisfied, or more helped, than victims who only experienced criminal justice, not the mechanisms by which this was occurring. Considering what elements of restorative justice were most helpful needed to be assessed by detailed interviewing of victims (and offenders) at different points after the process ended and comparison of their answers with observation of the conferences they attended (where this was possible) (Shapland et al. 2011).

Moreover, an RCT is unhelpful in determining cost value parameters, unless it is accompanied by accurate time measurements by schemes of the time taken on experimental group cases, compared to that on control group cases – and this was not always the case (Shapland et al. 2008). This is because the time taken on control group cases randomized out of the experiment after consent by victim and offender is obviously far less than that on experimental group cases – and one needs to know both in order to work out whether the financial cost of any decreases in reoffending attained by the experimental group over those achieved by the control group was greater than the cost of the scheme.

The choice of evaluation methods, therefore, depends very much on exactly which aim is being evaluated. Evaluations so far have concentrated upon participants' views, whether the restorative justice was completed and agreements made, whether outcome agreements were fulfilled, and reoffending (see Shapland et al. 2011 for a review of the findings in relation to youth and adult restorative justice). A concise summary of the results would be that, overall, participants tend to say they are highly satisfied with processes and usually with outcomes. Where outcome agreements were made, they were fulfilled at least to the same extent that similar criminal justice outcomes (e.g., financial penalties, community work) were occurring in that country at that time. There is some limited, but positive evidence on reoffending, particularly for direct meetings.

However, there are key remaining areas where evaluation in different countries is still lacking. They include:

- Why do some potential participants decline to take part? Most evaluations so far have been confined to those who do take part.
- What are participants' expectations of restorative justice – and were they fulfilled? Answering this question suggests interviewing participants before and after participation, which has rarely been done.

- What happens to those who do not agree to participation in restorative justice? Do they still obtain victim/offender support services?
- Which kind of procedure is most suitable for which kinds of cases and participants? There is some limited evidence that direct meetings (mediation or conferencing) produce greater satisfaction and greater drops in reoffending than indirect (shuttle) mediation (Shapland et al. 2011), and that conferencing is more effective in reducing power imbalances between participants, because the presence of victim and offender supporters is a mitigating one (Strang 2002; Shapland et al. 2011), but there have been very few direct comparisons between procedures.
- What would happen if there were no scheme – so to what extent is this scheme and its way of working better than none, or alternative methods available in that country?

In many ways, we are only at the beginning of thinking through the most effective ways of evaluating restorative justice and of exploring its potential for all its participants and the communities in which they live. As we accumulate more results of monitoring and more specialist evaluation results, hopefully that future may unfold. Continuing comparative ways of working, evaluating and discussing evaluation results will continue to play a crucial role.

Crimes without victims; Public order crimes

Overview

The study of moral crimes requires awareness of differences in the degree of moral condemnation of conduct. While a number of crimes seem to generate a consensus regarding their immoral character, there are some that do not. These crimes set the stage for conflict and to understand their nature one must be sensitive to the role of power in putting such acts within the criminal law.

What Are Moral Crimes?

In April 2009, the Supreme Court of the State of Iowa ruled unanimously to permit same-sex marriage. In November 2010, three of the judges, who were on the ballot for their job retention, were defeated and removed from office, largely because of their vote on same-sex marriage. One poll found that 41 % of Iowans said they would vote for a ban, while 40 % said they would not; the rest said they would not vote or were undecided (Clayworth and Beaumont 2009). And 92 % said the legalization of gay marriage had brought no real change to their lives. Clearly, the political drive to target the judges in November 2010 was well orchestrated and political in nature.

Chief Iowa Supreme Court Justice Mark Cady defended the 2009 decision based solely on the law and consistent with the Iowa Constitution; he said: "... the public should understand the important voice they have and be informed of the consequences of using that voice to remove judges for simply doing their jobs" (Nation 2011).

A similar scenario played out in New York when legislators there legalized same-sex marriage in 2011. There, four Republican legislators who backed gay marriage faced an uncertain future from their constituents in the next election, constituents who were very vocal in claiming their opposition to the votes of the legislators (Hakim et al. 2011).

What happened in Iowa and New York has been happening for a long time in this country. It was not long after the founding of this country that early settlers discovered that the law could be a resource and that law was not some independent, value-free force in social life. Groups learned that the law could be used to protect their interests and values. It unmistakably began in colonial times when the content of many statutes were lifted wholly from the Christian Bible (Erikson 1966). Even later statutes contained biblical phrases or intents.

It is not surprising that law should reflect moral values. Few people, including those who are not especially religious, would consider such crimes as murder, rape, and the theft of other people's property as immoral; rather, there are strong moral pronouncements against such behavior and a strong consensus that such acts violate both law and moral sentiments. Murder, rape, and robbery are condemned everywhere, even if there are exceptions to the degree of these acts' wrongfulness and therefore the offender's legal responsibility. One traditional argument about the role of law is the reinforcement and protection of the mores, those strongly held beliefs of a people. And, by extension one could ask: “If behavior isn’t immoral, why would there be a law against it?”

But there are other crimes about which there is no consensus as to their morality. There are disagreements, some strong, others weaker, about the immorality of the use of certain drugs, consensual sexual acts among adults such as prostitution, and pornography. Many disagreements also exist with respect to abortion. To some abortion is clearly immoral and condemnable; others disagree. In these so-called moral crimes, the law has come to be used to side with those who are offended by such acts. Some observers have claimed that such conflicts are the result of shifts of “moral time” (Black 2011), while others express the dynamic in terms of shifting power arrangements (Quinney 1970). Regardless of how it is characterized, shifts in opinions, disputes, claims, or differences in moral evaluations mark the border of moral crimes.

To say that there is general agreement about the immorality of many common crimes should not suggest that every single person shares that evaluation. Nor should it suggest that conceptions of immorality alone will prevent such crimes. In spite of strong condemnation of murder, there are murders every year. So too are there robberies, burglaries, and assaults. Yet, there is strong consensus that such acts ought not to happen.

If prostitutes and other sex workers are “moral criminals,” sex offenders are not, regardless of what they actually did. The term “sex offender” conjures horrific images of adults physically harming children. But many of the people on sex offender registries have not engaged in that behavior. Not all registrants are child molesters (Lancaster 2011a). Statutory rapists, who commit an offense involving neither coercion nor violence, are registrants in some states. Some states require “Peeping Toms” and exhibitionists to be on sex offender registries. Louisiana forced some prostitutes to register, and two-thirds of those on the North Carolina registry had been convicted of the nonviolent crime of “indecent liberties with a minor,” a crime which does not necessarily involve physical contact (Lancaster 2011b). In some states, indecent exposure can land an offender on a sex offender registry. There are also other issues with sex offender registries that warrant extensive discussion but are beyond this entry (Sample and Evans, 2009).

There are, to be sure, offenders who do physical and emotional harm to children, as alleged in the case at Penn State University. Such offenders should be dealt with harshly but we should not be guided in our reaction even to these serious offenders by stereotypes that all such offenders are likely to be recidivists. One federal study found that only 5 % of released sex offenders (those who committed forcible rape or sexual assault) were rearrested for a sex crime 3 years after their release from prison (Durose et al. 2003). This recidivism rate is below that of many other offenders, such as those convicted of burglary and robbery.

The Narrowing of Morality

Gay and lesbian behavior is not illegal in the United States but this does not mean that there are no legal issues surrounding the lesbian, gay, bisexual, and transgendered (LGBT) community. These issues include the status of gay marriage, the adoption of children by LGBT couples, the extent to which legal restrictions offend equal protection standards, and the presence of gays in the military, among others. Lesbian and gay rights continue to be problematic in the United States because of different evaluations of these people, their conduct, and perceptions of the origins of homosexuality.

That said, it seems clear that gay men and lesbians have made much progress, even if the gay people do not still enjoy the same privileges and rights as straight people. In 1986, the US Supreme Court upheld a sodomy law in Georgia (Bowers v. Hardwick), but an opposing decision made in 2003, which also dealt with a sodomy law (Lawrence v. Texas), left little doubt that courts were acting more positively toward gay issues. In the Lawrence decision, the justices believed that such laws “demeaned the very existence of gay people” (Carpenter 2011).

In 1998, four Harris (Houston) County Sheriff’s deputies, responding to a false report of someone waving a gun, entered an apartment to find John Lawrence and Tyron Garner allegedly (Lawrence and Garner denied they were having sex) violating the Texas law against sodomy. Lawrence was said to be belligerent, which was apparently a major factor in the arrest of the two men.

Lawrence and Garner were unlikely people to have figured too strongly in this major US Supreme Court case (see Carpenter 2012). Both had criminal records and with Lawrence, being white, and Garner, a black man, the relationship had a racial dimension to the case. Texas had a long history of making sodomy criminal. Legislation was refined over time to reflect different examples of possible homosexual behavior, and in 1943 oral sex was added to those acts made illegal. But the law stipulated that oral and anal sex would be prohibited only with another individual of the same gender. One observer said: “Put bluntly, it was now legal in Texas to have sex with a farm animal but not with someone of the same gender” (Oshinsky 2012: 10).

In other developments, the prestigious Washington, D. C., law firm of King and Spalding informed the United States Justice Department in 2011 that it would no longer assist Congress in defending the law that forbids the federal recognition of recognizing gay marriage (Carpenter 2011). The law, called the Defense of Marriage Act, was passed in 1996.

As of early 2012, seven states had legislation to give same-sex couples the right to marry. Those states – Connecticut, Iowa, Massachusetts, New Hampshire, New York, Vermont, and Washington State (and the District of Columbia) – are likely to be joined shortly by other states. The New Jersey Senate voted in February 2012 to legalize same-sex marriage, a shift from 2 years previously when a similar measure failed.

But while progress has been made, the history of homosexual rights has been a rocky one and progress has sometimes been slowed, perhaps because the cause of gay rights has not had a national figure to serve as champion. Black civil rights had Martin Luther King and feminism had Gloria Steinem, both of whom championed their causes very successfully. But gay rights activists have been more local figures, such as Harvey Milk in San Francisco, and it is difficult to think of gay activists who have captured a national stage. As a result, most progress toward equal protection of gays has been slow and sporadic.

The victories have been small but not meaningless. The Bureau of Labor Statistics, for example, examined the extent to which domestic partner benefits were enjoyed by all workers. Thirty-three percent of state and local government employees had access to health benefits for same-sex couples, slightly higher than the 29 % of employees in the private sector (Tavernise 2011a). In addition, California became the first state to require public schools to teach gay and lesbian history in 2012. The legislation followed a strongly publicized series of suicides among gay teenagers (Lovett 2011).

The result of local battles suggests that the stigma of being gay is still strong but weakening as people are becoming more accepting. For example, San Francisco is still considered a stronghold for gays but there are other places that are ranked higher than San Francisco in same-sex couples per 1,000 population (Tavernise 2011b).

Perhaps more compellingly, the repeal of “don’t ask, don’t tell” in the United States military set an official tone of increased tolerance. Signed into law in December 2010, the act repealed the discriminatory policy that forced American military men and women to serve with anxiety and isolation. The repeal of don’t ask, don’t tell was an affirmation that even in the military, sexual preference is irrelevant.

The Politics of Moral Crimes

Early forms of criminal law came about when the state replaced the tribal unit as the dispenser of justice. In so doing, the state (usually in the form of a monarchy) became the unit that administered procedures and sanctions; the blood feud was replaced by the king's punishment. Since collective responsibility of the tribe or clan no longer existed, the individual offender was punished and restitution for a large number of offenses disappeared (Pennington 1993). Offenses for which there was no compensation were considered crimes, while tort actions were those for which compensation was available. Over time, the number of crimes increased.

Criminal law was used to combat social problems associated with increased industrialization and urbanization both in Europe and the United States. With the manufacture of inexpensive alcoholic beverages, drinking – and drunkenness – was democratized to the lower classes. About the same time, increased industrialization witnessed the increased need for labor to run the factories. The Gin Act of 1736 and the Vagrancy Act of 1744 were designed to address these specific problems in England.

Clearly, some law is the result of processes other than a collective move to reinforce or amplify group mores. The creation of "Sunday laws" which make illegal some activities on Sunday, such as the sale of alcohol and the prohibition of certain kinds of labor, reflects the interests of religious groups who felt the need to protect that day as special from other days.

If there is, by definition, differences of moral opinion regarding these crimes, how has legislation been possible in defining these acts as illegal? Most explanations for offenses where we are all agreed on the wrongfulness of the act suggest that these laws simply grow out of our common conceptions of what is right and wrong. As noted earlier, the content of laws in colonial America was undeniably religious in nature. An analysis of these laws and their enforcement found that crimes brought before the Essex County (Massachusetts) court from 1636 to 1682 were, in order of their frequency, disturbing the congregation, absence from church, contempt of clergy, criticism of the government, and "delivering first child within too short a period of time after wedding" (Erikson 1966: 171).

But an explanation for the existence of laws where there is moral disagreement is lacking. In these instances, theories of law that recognize such conflict is an explicit characteristic of the legislative process are needed. Richard Quinney's (1970/2001) interest group theory of law serves as one example. Quinney begins with the observation that criminality is not determined by the nature of the behavior; rather, criminality is created and imposed by legitimate agents of social control. Crime is created politically. It is a judgment about the behavior of others who are perceived to be threatening to powerful, entrenched interests.

Conflict is an essential part of the law-making process. Law-making is unmistakably political – it was and is made by political entities (legislatures, Congress) and the judiciary, many of whom are elected officials. What is important is who has influence over those political entities and on what basis they are acting. The central concepts for Quinney are pluralism, power, and conflict.

Modern industrialized nations are pluralistic; they are composed of a multitude of groups who are defined by their interest structure. Some groups are defined solely by their interests and their pursuit of those interests in legislation. Consider the following interests: population control, labor issues, and gun rights. Each of these interests has groups organized with a particular position on the issue and, often, these positions are oppositional. Population control, such as the use of condoms and abortion, elicits strong and opposing views. The interest of the Roman Catholic Church and Planned Parenthood are discernibly different with respect to population control. Similarly, the interests of labor (e.g., unions) and management are often different, as are the interests of such groups as the National Rifle Association and the Brady Campaign to Prevent Gun Violence which seek different goals.

Regardless of the nature of group interests, another unmistakable fact is that there an unequal distribution of power among these groups. Not all groups have access to the same resource base. Some have more members than others; some have more money than others. As a result, some groups have more influence over the legislative process than do others.

As a result of differences in interests, implying conflict among groups, and power, it is inevitable that some interests will be protected in the legal system in the form of the content of laws and interpretation of public policy based on those laws. It is also inevitable, of course, that the content of law will change as some groups increase, and other groups decrease, the amount of power they can bring to bear on their interests.

Conclusion

The study of moral crimes requires awareness of differences in the degree of moral condemnation of conduct. While a number of crimes seem to generate a consensus regarding their immoral character, there are some that do not. These crimes set the stage for conflict and to understand their nature one must be sensitive to the role of power in putting such acts within the criminal law.

Mortality After Release from Prison

Overview

Studies from Europe, Australia, the United States and Taiwan have shown that the rate of mortality in ex-prisoners is elevated in the weeks immediately following release, compared with subsequent weeks. These studies have also shown that mortality rates in ex-prisoners remain elevated, compared with the non-institutionalized population, for many years post-release. Several mechanisms have been hypothesized to explain the elevated risk and a key debate relates to the relative contribution of incarceration itself and the high level of underlying risk among former inmates. Preventive efforts need further development and evaluation, and methodological limitations hinder synthesis of the literature.

Introduction

Correctional services have a duty of care to prisoners in their charge, and in most jurisdictions, deaths in custody are closely monitored (Curnow and Larsen 2009; Noonan 2010). In Australia for example, deaths in police custody and in prison are routinely monitored and reported annually through the National Deaths in Custody Program (NDICP). Similarly in the United States, deaths in custody are reported to the Bureau of Justice Statistics through the Deaths in Custody Reporting Program. Almost all prisoners return to the community eventually, most after a relatively short period of time in custody; however, it has only been relatively recently that researchers have turned their attention to deaths after release from custody. One of the first such studies examined mortality outcomes among persons released from a 300-bed prison in Geneva, Switzerland, from 1982 to 1986; the researchers identified 102 unnatural deaths in the cohort with a disproportionate number occurring in the first year following release, often due to opiate poisoning (Harding-Pink and Frye 1988). In a subsequent study, Seaman and colleagues used record linkage to examine mortality outcomes for a cohort of 238 HIV-infected injecting drug users after release from prison in Edinburgh, Scotland. The researchers found that the risk of death (the "crude mortality rate," or CMR) from overdose was 7.7 times higher in the 2 weeks after release, than in the subsequent 10 weeks, highlighting an acute period of vulnerability after release from prison (Seaman et al. 1998). Subsequent studies in Europe, North America, and Australia confirmed that this phenomenon was widespread, with a meta-analysis finding that the risk of drug-related death was between 3 and 8 times higher in the first 2 weeks following release from custody, than in the subsequent 10 weeks (Merrall et al. 2010). Some studies have also shown that the risk of death in recently released prisoners is higher than that of current prisoners (Binswanger et al. 2007; Kariminia et al. 2007; Kinner et al. 2011), and higher than that of age- and sex-matched members of the general community (the "standardized mortality ratio," or SMR) (Binswanger et al. 2007; Kariminia et al. 2007; Rosen et al. 2008; Stewart et al. 2004).

Although drug-related causes account for a large proportion of deaths in former prisoners, most studies report that the majority of deaths are not drug related. Another key cause of preventable death in this population is suicide, which may reflect the very high rates of mental illness in prisoners, particularly among women (Fazel and Danesh 2002). For example, in a study of almost 250,000 ex-prisoners in England and Wales, Pratt and colleagues found that the rate of suicide in the first year after release from prison was 8.3 times higher for males and 35.8 times higher for females, than for age- and sex-matched members of the community. Reflecting the concentration of risk in the immediate post-release period, 21 % of these deaths happened in the first 28 days post-release (Pratt et al. 2006). Similarly, in a cohort of male ex-prisoners in New South Wales, Australia, Kariminia and colleagues found that the rate of suicide was 3.9 times higher in the first 2 weeks post-release, than after 6 months post-release (Karaminia et al. 2007). Although the risk of suicide is greatest in the immediate post-release period, there is some evidence that it remains elevated for much longer. In a study of 168,001 ex-prisoners in North Carolina followed for a median of 10.3 years, Rosen and colleagues found that the rate of death from suicide was significantly elevated for white ex-prisoners (compared with age- and sex-matched white people in the community), although not for black ex-prisoners (compared with age- and sex-matched black people in the community) (Rosen et al. 2008).

Drug overdose and suicide are the leading causes of death in ex-prisoners; however, other key causes of unnatural death in this population include motor vehicle accidents (MVAs) and drowning and, in some countries, homicide. One study of 9,381 ex-prisoners in Western Australia found that of 326 observed deaths, 29 % were drug related, 20 % were due to suicide, and 12 % due to motor vehicle accidents (Stewart et al. 2004). Similarly, in the Australian study by Kariminia and colleagues, 33 % of deaths were drug related, 16 % were suicides, 8 % were transport related, and 4 % were due to homicide (Kariminia et al. 2007). By contrast, in the Rosen study in North Carolina, only 12 % of deaths were drug related, 5 % were due to suicide, 11 % due to homicide, and 9 % due to motor vehicle accidents (Rosen et al. 2008). Understanding patterns in mortality in ex-prisoners is complicated by the fact that most deaths have multiple contributing causes, and coronial processes may differ between jurisdictions and over time. For example, suicides involving drugs may be classified as a suicide or a drug-related death; accidental deaths such as MVAs may be related to intoxication from alcohol or other drugs; homicides may be related to substance use, involvement in the drug trade, and criminal subculture or, particularly for women, the return to violent relationships.

Although the majority of deaths in ex-prisoners are due to unnatural causes, ex-prisoners are also at increased risk of death from natural causes such as cancer; liver, cardiovascular, and respiratory disease; and infectious diseases such as HIV and hepatitis C (Kariminia et al. 2007; Rosen et al. 2008), reflecting the high prevalence of health risk behaviors such as injecting drug use, unprotected sex, and tobacco use in this population (Binswanger et al. 2007; WHO 2007). Furthermore, although the risk of death is greatest in the period immediately following release from custody, this risk remains elevated relative to the sex- and age-adjusted non-institutionalized population for at least a decade (Karaminia et al. 2007; Rosen et al. 2008). To date, no studies have examined whether the key causes of death or risk factors for death in ex-prisoners vary over this time.

Not all ex-prisoners are at equal risk of death following release from custody. Using survival analysis, some studies have charted the probability of "surviving" (i.e., remaining alive) over time, from the point of release from prison, for different subgroups. These studies provide a graphic illustration of the precipitous drop in survival in the immediate post-release period, and show that different subgroups of ex-prisoners (for example, defined by sex, age and race) have a different probability of "survival" after release from prison. Record linkage studies have also been used to identify risk factors for death in ex-prisoners. Although findings have not always have been consistent, most studies find that each additional episode of imprisonment (and subsequent release) increases the risk of death; not surprisingly, a history of substance abuse and mental illness is also associated with increased risk of death (Singleton et al. 2003; WHO 2010). Findings regarding age have been mixed, with some studies finding that younger people are at greater risk of death, while others find the converse (Binswanger et al. 2007; Chen et al. 2010; Larney 2010). One study of drug-using ex-prisoners in Taiwan found that HIV infection was associated with increased risk of death while retention in methadone maintenance treatment (MMT) post-release was protective (Chen et al. 2010). In another study of drug-related death among ex-prisoners in the United Kingdom, a history of relationship breakdown and limited social support post-release were associated with death (Singleton et al. 2003), highlighting the importance of post-release support mechanisms. Many studies find that ethnic and racial minority groups are at greater absolute risk of death (Stewart et al. 2004), although when compared with race-matched peers in the community, this difference is usually attenuated (Rosen et al. 2008; Stewart et al. 2004). Conversely, although most studies find that the *absolute* risk of death is lower for women than men, the *elevation* in risk of death for women, compared with age- and sex-matched peers in the community, is consistently greater for women than for men (Larney 2010; Stewart et al. 2004). This apparent paradox is explained by the fact that women in the community have a lower age-adjusted rate of death than men, but this difference is smaller among ex-prisoners. This may be due to the greater underlying risk among women who get incarcerated than men (differential selection).

Hypothesized Mechanisms

Several mechanisms have been proposed to explain the elevated risk of death among former inmates, depending on the cause of death and the time since release. Early studies focused on an acute elevation in risk of drug-related death (Seaman et al. 1998). The presumed mechanism was diminished physiologic tolerance, with opioid (usually heroin) dependent individuals ceasing or reducing their drug use while incarcerated, and upon release relapsing to substance use and experiencing an accidental poisoning (overdose). Accordingly, the main response to prevent such deaths was to educate soon-to-be-released prisoners about drug tolerance, and counsel them to avoid drug use or at least consume smaller quantities. This approach remains central to many correctional authorities' response to mortality prevention in ex-prisoners. In some jurisdictions, opioid tolerance is maintained throughout the period of incarceration via opioid substitution therapy, such as methadone or buprenorphine. Although it is clear that a substantial proportion of preventable deaths in ex-prisoners is due to drug-related causes, it remains unclear what proportion of these deaths is attributable to reduced drug tolerance. Furthermore, while former inmates may have knowledge gaps about tolerance to drugs and its potential ramifications (Adams et al. 2011), it is not clear whether education alone is sufficient to reduce drug-related mortality.

In addition to reduced drug tolerance, researchers have identified a range of other factors that may help explain the acute elevation in risk of drug-related death among recently released prisoners. Key among these is poly-substance use, and in particular the combined use of multiple central nervous system depressants such as opioids, benzodiazepines, and alcohol. Poly-substance use is a contributing factor in many drug-related deaths among former prisoners (WHO 2010); however, in order to explain the acute elevation in risk of drug-related death in the immediate post-release period, poly-substance use would need to be more common or more intense during this time. There is some indirect evidence for this, with some researchers describing an acute period of injecting risk behavior in the immediate post-release period (Seal et al. 2001). Another potential risk factor is single-room occupancy: Many recently released prisoners experience difficulty finding accommodation and may resort to living alone in single-room dwellings; drug overdoses in such settings are more likely to be fatal because the victim is unlikely to receive assistance from other users or passersby. Another potential contributing factor relates to the transition from the predictability of the prison environment to an ever-changing and unfamiliar outside world. Due to the process of classical conditioning, it appears that drug effects are attenuated in familiar environments and potentiated in novel environments, such that drug use in a novel environment may produce greater intoxication (Siegel 2001). Finally, some authors have argued that risk of fatal overdose may be increased by systemic disease, in particular lung and hepatic dysfunction (Warner-Smith et al. 2001). Consistent with this, the prevalence of both tobacco smoking and hepatitis C infection is very high among prisoners (WHO 2007).

Although the majority of deaths in former prisoners are not drug related, there has been less consideration of the mechanisms underpinning other causes of death in this population. One contributing factor in suicide deaths is likely to be mental illness, which is highly prevalent in prisoners (Fazel and Danesh 2002). Given that many prisoners experience mental illness and only a small minority commit suicide post-release, mental illness may be better conceived of as a predisposing factor than a direct cause. Given the concentration of suicide deaths in the immediate post-release period, at least part of the explanation for these deaths must be related to the transition from prison to community. For vulnerable prisoners, particularly those with a mental illness, the transition to the community is likely to be a highly stressful time characterized by uncertainty, frustration, and disappointment (Binswanger et al. 2011b). Many ex-prisoners experience homelessness, poverty, and discrimination, and may have difficulty reestablishing relationships with family and friends. These challenges may be compounded by a sudden reduction in access to healthcare and other support services, which are more readily accessible in prison environments (Adams et al. 2011; Levy 2005). For those experiencing mental illness, one consequence of this may be reduced access to and adherence to medication, and a subsequent relapse to decompensated mental illness. In this context, intentional overdose and suicide have been perceived by some former inmates as a "way out" for intolerable conditions in the community (Binswanger et al. 2011b).

Poor access to health care may also be an important factor in other causes of death in ex-prisoners, particularly given the high prevalence of chronic and infectious disease in this population. For example, there is evidence that among HIV-infected injecting drug users, release from prison is associated with reduced adherence to antiretroviral medications and subsequent increase in viral load (Palepu et al. 2004). Even if appropriate health services are available in the community, unless recently released prisoners are connected with these services before release, they may "fall through the cracks" after release, failing to access appropriate health care until an acute health issue arises. Increased support during the transition from prison to community, and improved access to healthcare for recently released prisoners, may reduce the risk of death from both unnatural and natural causes; however, the links between transitional health services and mortality outcomes are poorly understood (Kinner 2010).

Prison as a Cause or Marker of Underlying Risk

Although there is clearly a strong association between release from prison and death, this does not necessarily imply that the release "caused" the death. As discussed above, the reasons for death after release from prison are likely to be complex and variable over time. One view is that prison is a "marker" for underlying risk and that death may even be delayed by imprisonment. That is, populations who move through prison systems are already at increased risk of death, because the factors predisposing to death, such as substance abuse, mental illness, impulsivity, and poverty, also predispose to crime and incarceration. Epidemiological studies consistently reveal a high prevalence of disadvantage, poor health, and health risk behaviors such as injecting drug use among prison samples (Fazel and Danesh 2002; WHO 2007). Also consistent with the view that imprisonment is a "marker" for mortality risk is evidence that ex-prisoners remain at elevated risk of death for many years after release from custody (Kariminia et al. 2007; Rosen et al. 2008). Although it is possible that the experience of imprisonment and release has a long-term impact on mortality risk (for example, through promoting marginalization and disadvantage, initiation into risky behaviors such as injecting drug use, and/or exposure to chronic infections such as hepatitis C or HIV), it is clear that many people entering prisons for the first time are already characterized by a number of risk factors for mortality.

Despite this some authors, pointing to the acute elevation in risk of death immediately after release from custody, have implicated correctional authorities, implying a causal relationship between incarceration and death. In this view, correctional authorities are responsible for the deaths of recently released prisoners. Not surprisingly, most correctional authorities reject this view, arguing that deaths occurring in the community are, by definition, a community responsibility. While this may be true in some cases, the situation is less clear for those ex-prisoners subject to some sort of post-release supervision. At least one study has examined mortality outcomes according to post-release supervision and found no relationship, suggesting that involvement with correctional services after release may not be protective against mortality (Binswanger 2011a). Whether or not correctional authorities are in any way "responsible" for the deaths of recently released prisoners, the well-established association between release from prison and death suggests some sort of causal relationship between release from custody and death.

Given the acute elevation in risk of death in the first few weeks after release from custody, and evidence of ongoing elevation in risk of death for years after release, prison may be both a risk marker and a cause of mortality in ex-prisoners. That is, release from prison precipitates a period of particularly elevated risk of death, but given the preexisting risk factors that characterize many ex-prisoners, this risk never returns to that of non-incarcerated community peers. From a public health perspective, assigning blame for the deaths of ex-prisoners is less important than preventing these deaths. Although the majority of deaths in ex-prisoners do not occur in the weeks immediately following release, a disproportionate number of deaths do occur in this period and in the context of limited resources, it is probably prudent to target preventive interventions in the immediate post-release period.

Prevention

A growing body of literature has described patterns of mortality in ex-prisoners, but to date, there have been few attempts to evaluate interventions designed to prevent these deaths. Based on a review of largely descriptive evidence, the World Health Organization (WHO) proposed strategies to prevent drug-related death in recently released prisoners at the policy and program level (WHO 2010). Although oriented to the prevention of acute drug-related deaths, many of these recommendations are also relevant to the prevention of death due to other causes. Among the key policy responses recommended by WHO is the adoption of an evidence-based drug treatment framework that diverts individuals with a substance use disorder into treatment rather than prison wherever possible, and the integration of prison and community services so that gaps in service and accountability are minimized. Given persuasive evidence that the criminalization of drug use and dependence has driven rapid increases in prison populations internationally (Pettit and Western 2004), the recommendation to minimize the incarceration of drug users seems well grounded. Efforts to improve service continuity and integration for ex-prisoners, and to reduce financing silos, may also prove beneficial, although evaluation findings to date have been mixed.

At the program level, WHO advocates for evidence-based practices including opiate substitution treatment (OST) in custody and post-release. Recent evidence suggests that in-prison OST is associated with reduced drug-related mortality in ex-prisoners (Larney 2010), although it remains unclear whether this is a direct effect due to the maintenance of opioid tolerance in prison, or an indirect effect whereby those on OST in prison are more likely to transition to OST post-release, with the latter providing the protective effect. WHO also endorses education for prisoners, prison staff and support workers to make all stakeholders aware of the increased risk of death post-release, strategies for the prevention of drug use, the risks posed by reduced drug tolerance and poly-substance use, and strategies for overdose prevention. Although there is little evidence that education alone can prevent deaths, education is appropriate as part of a broader prevention strategy, supported by pharmacotherapy in prison and post-release for high-risk individuals.

Consistent with a growing body of evidence, WHO (2010) joins a chorus of researchers specifically advocating for training the families and peers of at-risk prisoners in first aid, including the administration of naloxone, an overdose reversal drug used routinely by paramedics. There is growing evidence that with appropriate training, naloxone can be safely administered by peers and is effective in reversing overdoses, almost certainly saving lives (Lenton et al. 2009). In Scotland, naloxone kits and training are currently being provided to friends and family of soon-to-be-released prisoners, on a trial basis. If the evaluation of this initiative is favorable, it is likely that the same approach will be adopted elsewhere; however, naloxone is not a panacea. Naloxone is only effective if the overdose victim used opioids, and if the medication is administered by a bystander early and with at least basic knowledge of its use.

Given the complexity of the post-release experience, the broad range of causes of death, and the high degree of marginalization and stigma experienced by former inmates, effective prevention will likely require a combination of behavioral, environmental, service-based, and pharmacologic interventions. Financing mechanisms that support continuity and integration of care during the transition from prison to the community may also help ameliorate transitional risk, although few such initiatives have been rigorously evaluated. Similarly, diversion initiatives (e.g., drug and mental health courts) designed to reduce the imprisonment (and subsequent release) of drug-dependent and mentally ill individuals, by providing appropriate community-based treatment and supervision, may reduce mortality risk. Under-investment in these programs has limited their impact and rigorous evaluations have been scarce.

Despite the dearth of evidence regarding "what works" to improve health outcomes and reduce mortality in ex-prisoners, correctional authorities in many countries are embracing a "through-care" model, implementing policies and programs designed to facilitate a successful reentry. Although this is rarely the intention and has yet to be demonstrated empirically, such programs may also reduce mortality. Whereas deaths in prison are routinely monitored in some countries, the same cannot be said for deaths after release from prison. A recent Australian study estimated that the annual number of deaths among adult ex-prisoners in Australia, within a year of release from custody, is about ten times the number of deaths in custody over the same period (Kinner et al. 2011). Highlighting this largely forgotten group, the authors advocated for routine monitoring of ex-prisoner mortality through record linkage, which is both feasible and cost-effective in many developed countries. In the Australian context, monitoring of deaths in recently released prisoners will feature in a "national minimum dataset for prisoner health" (AIHW 2011) in the near future, allowing policy makers and researchers to examine annual trends in mortality in this group.

Many questions remain about the most effective way to prevent deaths in ex-prisoners, and there remains a need for further research (Kinner 2010; WHO 2010): First, to identify who among ex-prisoners is most at risk of death, when and why, so that preventive interventions can be appropriately targeted and tailored. And second, to rigorously evaluate both targeted and broad-based interventions designed to improve health outcomes for ex-prisoners, to reduce untimely deaths in this profoundly marginalized population.

Methodological Issues

Evidence-based prevention requires sound evidence; however, methodological limitations of existing studies have made interpretation of the evidence complex and quantitative synthesis of the evidence difficult. Methodological limitations of the existing literature can be grouped into four categories: sampling, data quality, analysis and reporting. Early studies typically included a single prison and/or selected a subgroup of prisoners thought to be at high risk: for example, HIV-infected injecting drug users (Seaman et al. 1998). Although these studies were the first to identify a period of acute risk immediately post-release, the incidence of mortality observed in these cohorts would be a poor estimate of population-wide mortality rates, and the risk factors for mortality may also differ at the (prisoner) population level. A related problem is that imprisonment may be defined differently in different countries. In the United States, jails are differentiated from prisons on the basis of several factors including conviction, sentencing status, and length of stay; it is likely that patterns of mortality will differ for those released from jails and prisons. The definition of a release can also be complex. For instance, at least one study has excluded release for extraordinary medical placement (medical parole) from the definition of release (Binswanger et al. 2007), on the premise that inclusion of persons released on the basis of imminent death will inflate the numerator. Work release, transfer to low-security facilities or to locked half-way houses all pose additional methodological challenges. Furthermore, in countries with a number of discrete, State-based correctional systems, such as the United States and Australia, it is unclear whether the findings from one State can be generalized to other States. More broadly, despite the fact that the majority of the world's prisoners are in low- and middle-income countries, almost all studies of mortality in ex-prisoners have been conducted in wealthy, western countries.

Studies of mortality in ex-prisoners rely on linkage of prisoner data with death data. Limitations of the quality and scope of source data, and of the linkage process, can compromise the findings and thus the accuracy of the conclusions drawn. Studies that involve linkage to a national death register will potentially identify all deaths in the cohort, except for those who are deported or otherwise leave the country before death. However, some studies have relied on State-based registers, missing those who move interstate and die. Others have relied on coronial databases to identify deaths, thereby excluding all deaths that have not been brought to the attention or a coroner. The linkage process itself is imperfect, as it relies on probabilistic matching of prisoner and death data on the basis of identifying information such as sex, date of birth, and name, often including multiple aliases. This introduces uncertainty into the linkage process and in the United States, there is likely to be greater uncertainty for individuals of Latino ethnicity and African-Americans (Boyle and Decoufle 1990), who are more highly represented among former inmates. As a consequence, there may be selective underestimation of mortality in these groups.

Key analysis issues include numerator bias, correction for reincarceration, and selection of reference population. Examination of the association between release from prison and death is complicated by the fact that many ex-prisoners return to custody and are subsequently released again, requiring the researcher to decide which release to consider for the purposes of analysis. For example, if a prisoner is released from custody and is reimprisoned 6 months later, spends a further 3 months in custody, is released again and dies 1 month later, what is the time between release and death: 10 months or 1 month? When examining the link between release from prison and death, the latter approach biases toward releases that are followed by death, introducing "numerator bias." Studies adopting this approach overestimate the link between release and death, and were excluded in a recent meta-analysis of this literature (Merrall et al. 2010). A related analysis issue is that in calculating crude mortality rates, some studies fail to exclude subsequent time in custody, despite the fact that the risk of death in custody is considerably lower than the risk in the community (Binswanger et al. 2007; Kariminia et al. 2007). Where this occurs, the rate of mortality may be substantially underestimated.

A final analysis issue relates to the calculation of standardized mortality ratios (SMRs), which compare the observed number of deaths in the study population with the expected number of deaths based on a reference population (usually the general population), adjusting for key demographic differences. SMRs show how much the rate of death is elevated in the study population compared with the general population: For example, in a cohort of Australian ex-prisoners followed for a median of 7.7 years, Kariminia and colleagues (2007) found that the all-cause SMR was 3.7 for men and 7.8 for women, indicating that male ex-prisoners were 3.7 times more likely to die than age-matched males in the general population, while female ex-prisoners were 7.8 times more likely to die than age-matched females in the general population. In another study, Rosen (Rosen et al. 2008) followed a cohort of male ex-prisoners in North Carolina for an average of 10.3 years and calculated an

SMR of 2.08 for white ex-prisoners (vs. white males in the community, adjusted for age) and 1.03 for black ex-prisoners (vs. black males in the community, adjusted for age). Although these findings indicate that the rate of mortality was elevated to a greater degree for white than black ex-prisoners, compared with age- and race-matched members of the community, they mask the fact that the mortality rate in the community is higher for blacks than for whites. Another Australian study (Stewart et al. 2004) has illustrated this in a cohort of 9,381 ex-prisoners followed for a median of 3.3 years: Among Aboriginal males, the SMR was 9.4 when the reference population was all age-matched males in the community, but fell to 2.9 when the reference population was restricted to age-matched Aboriginal males. The reason for this dramatic change is that in the Australian community, the rate of mortality among Aboriginal males is considerably higher than among non-Aboriginal males. Whether or not adjustment for race is appropriate is a matter of debate.

Interpretation and synthesis of the literature is also made challenging by heterogeneity in reporting of study findings. For example, while some studies report crude mortality rates (CMRs) and/or standardized mortality ratios (SMRs), others compare the rate of mortality across two different time periods (e.g., the first 2 weeks post-release vs. the subsequent 10 weeks). Different studies report CMRs and SMRs across different time periods (e.g., 1 year post-release, 5 years post-release), and some do not indicate the time period, making their findings difficult to interpret. While some studies report findings disaggregated by key demographic variables (e.g., sex, race), others present whole-population findings; only a minority have reported both. A number of studies have examined only drug-related mortality, while others have considered all-cause mortality, suicide deaths, or some other grouping of death codes. This heterogeneity makes both narrative and quantitative synthesis of the literature challenging.

In order to inform evidence-based policy and practice, a more sophisticated understanding of the incidence and risk factors for mortality in ex-prisoners is required. Most studies to date have used record linkage methods which, by definition, rely exclusively on routinely collected data. Such data are usually not collected for research purposes and as such, they tend to provide only limited information about potential risk factors for death, or circumstances surrounding death (Kinner 2010). Until electronic records completely supersede paper-based correctional and coronial records, novel research designs will be required to complement the knowledge already gleaned from record linkage studies, and advance the evidence base to inform preventive efforts. Such methods may also allow examination of mortality outcomes for ex-prisoners in resource-poor settings.

Conclusions and Recommendations

Prior research has suggested an elevated risk of death among former inmates relative to incarcerated populations and non-institutionalized, general populations. Additionally, it has demonstrated significant time trends, suggesting an early peak in mortality after release from custody. We recommend the inclusion of diverse countries, including resource-poor countries, in future research efforts. In terms of surveillance, we recommend systematic monitoring of mortality in this population, particularly given increasing rates of incarceration that have been observed worldwide and in certain countries (e.g., the United States) over the past 20 years. To enhance efforts at data synthesis, we suggest improvements to the design, analysis, and reporting of research findings. Furthermore, more intervention research across a broad range of outcomes and populations is needed. Intervention efforts, which may include policy changes, should be supported by rigorous data. Collaborative efforts between public health, corrections and advocates are most likely to be successful. Policy efforts should address structural problems such as financing silos. Special attention to physiologic changes, medical comorbidity, poly-substance abuse, environmental factors and health service barriers should be routinely included in transitional interventions, as purely educational or individual behavioral interventions are unlikely to be effective in isolation, given the complexity of the physiologic, structural and policy issues.

Overview

According to the National Crime Victimization Survey (NCVS), motor vehicle theft has been on a decline in the United States during the last decade. Since 2001, the number of motor vehicle theft victimizations has decreased from just over one million to 606,990 per year. This is nearly a 40 % change in the last 10 years, with an average annual decrease of about 3.5 % (Truman 2011). The Uniform Crime Report (US Department of Justice 2011a) indicates a similar decline, with the motor vehicle theft rate decreasing from 430.5 per 100,000 people in 2001 to 258.8 per 100,000 people in 2009. Europe joins the United States in a reprieve from the inconvenience associated with higher rates of motor vehicle theft. Europe has also seen a 5.7 % decrease in motor vehicle theft between 2000 and 2007 (European Commission 2010).

Although these rates are representative of both regions as a whole, certain areas of the United States are still experiencing a disproportionate amount of stolen vehicles. In the United States, large cities are experiencing higher rates of motor vehicle theft (286 per 100,000 people), while smaller cities and rural areas experience much lower rates (142.5 and 105.3 per 100,000 people, respectively). The western and southern coasts of the United States experience disproportionately higher rates of motor vehicle theft. Cities in California close to the United States-Mexican border report that motor vehicle thefts account for 44 % of the total crime index. Cities experiencing such a high level of motor vehicle theft victimization are certainly inconvenienced by this type of crime.

Fundamentals of Motor Vehicle Theft

Definition of Motor Vehicle Theft

The Bureau of Justice Statistics (US Department of Justice 2011b) defines motor vehicle theft as the stealing or unauthorized taking of a motor vehicle. *Completed thefts* are those in which the vehicle is successfully taken by an unauthorized person. *Attempted thefts* are those in which the vehicle is unsuccessfully taken by an unauthorized person.

Sometimes motor vehicle theft and theft from motor vehicles are misunderstood. *Motor vehicle thefts* take place when a motor vehicle is removed from the location where it was left by the owner or a person who was authorized by the owner to drive the vehicle. Motor vehicle thefts are sometimes reported by the owner of the motor vehicle or a representative of the owner. Sometimes the reports are truly accurate in that the vehicle has been stolen by a person both *unauthorized* and *unknown* to the owner. Other times vehicles are reported stolen, but it is later determined that the owner's child or relative was the thief. In this case, the thief was *unauthorized* but not unknown.

Thefts from motor vehicles are those thefts which occur when items are taken from on or within the vehicle. Items stolen from within the vehicle can include items that are stolen from inside a locked or unlocked vehicle. These items can have monetary value, personal value, or no value at all. Items that may be stolen off of the vehicle include things such as hubcaps, pendants, magnetic signs, or other memorabilia on the vehicle for either functional or decorative purposes.

The number of both *motor vehicle thefts* and *thefts from motor vehicles* varies greatly dependent upon the type of vehicle and the location of the vehicle when it is parked. In the United States, foreign motor vehicles suffer more thefts than those made domestically. Location of the vehicle is also an important consideration. Location variables include aspects of physical space (garage, lot, driveway, curb) and city structure (urban, suburban, rural) to become part of the risk calculation.

Thefts of and from motor vehicles typically occur as a result of two types of thieves: opportunistic or purposive. *Opportunistic thieves* are more likely to strike when the vehicle is unlocked or able to be unlocked easily (e.g., through an open window or sunroof). *Purposive thieves* are more likely to steal from a vehicle or the vehicle itself, whether locked or unlocked, if they want a specific vehicle or something specific from the vehicle. These thieves are not deterred by locked windows or doors.

History of Motor Vehicle Theft

In 1919, the National Motor Vehicle Theft Act, or Dyer Act (18 USCS § 2311 et seq.), became federal law. The purpose of the Dyer Act was to obstruct and control vehicles stolen by organized thieves. According to the Dyer Act, the following must be established beyond a reasonable doubt: the vehicle must have been stolen, the stolen vehicle operator must be a person who knows the vehicle was stolen, and the stolen vehicle must have been transported interstate. The punishment for committing these acts is a fine, up to 10 years imprisonment, or both. According to the Dyer Act, a motor vehicle is defined as including "an automobile, automobile truck, automobile wagon, motor cycle, or any other self-propelled vehicle not designated for running on rails."

In 1931 the US Supreme Court debated the definition of a *motor vehicle* as described by the Dyer Act. The question before the court was whether or not the definition outlined above applies to aircraft. In McBoyle v. United States, 283 U.S. 25, the Court found that the language should be more specific if it wanted to include aircraft. Since the word "aircraft" was not mentioned in the language of the law, aircrafts were not to be considered motor vehicles. More recently the term *motor vehicle* is thought to include automobiles (vans, cars, trucks) as well motorcycles, scooters, and mopeds.

In 1984 Congress enacted the Motor Vehicle Theft Law Enforcement Act in response to the growing problem of motor vehicle theft in the 1980s. This Act led to the Federal Motor Vehicle Theft Prevention Standard, which mandated manufacturers to etch Vehicle Identification Numbers (VIN) into various parts of the motor vehicle. Despite the recommendations in 1984, motor vehicle theft was still on the rise in the 1990s. In response, Congress enacted the Anti-Car Theft Act of 1992. The 1992 Act added federal penalties to motor vehicle theft, provided grant money to law enforcement to combat motor vehicle theft, and improved vehicle titles, registration, and salvage requirements.

Since the mid-1990s, motor vehicle theft has been decreasing nationwide. This translated into a significant shift of the top 10 cities for motor vehicle theft in the last decade. In 2000, the National Insurance Crime Bureau (NICB) indicated that cities with major port facilities or those near international borders recorded the greatest number of thefts: Los Angeles, New York, and Philadelphia occupied the top three slots (National Insurance Crime Bureau 2000). In 2007, Las Vegas was ranked #1 (NICB 2008). In 2010, however, eight of the worst 10 cities for motor vehicle theft were in California with Fresno, Modesto, and Bakersfield in the top three (NICB 2011). This indicates a recent shift in motor vehicle thefts from coastal regions to inland areas and also demonstrates that California has been hit hardest by motor vehicle thieves.

Clearance Rates and the Impact of Technology

Historically, clearance rates have shown that it is difficult for police to track and arrest offenders. Modern cities provide outsiders with easier access to target vehicles via better road networks, more anonymity, and increased awareness of city routes and pathways during everyday travel. Until about 10 years ago, the battle between the owner and thief was that of one-upmanship. An advance in technology would provide the owner with the option of buying anti-theft devices, and the thief would find a way around such technology. One example of such a product is the steering wheel lock. The vehicle owner could purchase a steering wheel lock that would prevent the steering wheel from being turned until the lock was removed. Since the steering wheel locks were made of durable metal, they were difficult to cut. The thief could, however, cut the steering wheel so that the device would slide off. Once cut, the steering wheel still functions, at least well enough to drive the vehicle.

In the past 10 years, we have seen an increase in technology that has been more difficult for offenders to circumvent. Recent advances in technology, including ignition kill devices, smart keys, and GPS, make vehicles more difficult to steal. Ignition kill devices work to prevent motor vehicle theft because a switch is inserted into the ignition circuit. The offender would need to know where the switch is located in order to flip it and steal the vehicle. Smart keys contain a coded computer chip or radio frequency. If the smart key is not located inside the vehicle, the vehicle will not start. Both ignition kill devices and smart keys make the vehicle hard to steal because it is difficult or impossible to start the vehicle without them working properly.

Global Positioning Systems (GPS) locator devices make the vehicle easier to find once it has been stolen. The deterrent effect with GPS is that once the police or GPS service providers are notified that the vehicle was stolen, the vehicle can be easily tracked and recovered. This may be one reason why, overall, the number of motor vehicle thefts is on the decline.

Research on Motor Vehicle Thefts

Current research suggests that motor vehicle thieves find certain types of locations more suitable than others. In general thieves are concerned with not getting caught, so all things being equal, they will target areas that provide adequate cover (including poor lighting, low visibility, and obstructed view), a selection of targets, and adequate time needed for the theft to take place. Parking facilities, transportation hubs, hotel and motel parking lots, shopping centers, and motor vehicle repair and parking lots provide unique opportunities for motor vehicle thieves.

Parking Facilities

The physical structure of a parking facility can greatly impact the ability of residents and store owners to provide guardianship and informal surveillance over the vehicles. Several criminologists (Jacobs 1961; Newman 1972; Clarke and Harris 1992; Tilley 1993; Poyner 1997) acknowledge that the way the environment is built impacts perceptions of safety and can send cues to the criminal that one area is more suitable for the commission of a crime than another. Parking lots that are properly built can maintain the positive aspects of natural surveillance and encourage thieves to look elsewhere. Parking lots that are enclosed or located too far from residences or businesses reduce levels of natural surveillance and provide thieves with targets that are ripe for theft. Poor surveillance combined with a condensed number of vehicles in close proximity greatly increases the chance of motor vehicle theft. Research findings support the idea that parking lots should be created with increased surveillance both inside and outside the lots.

Current research has found that the layout of parking lots, level of lighting, presence of closed-circuit television (CCTV), and controlled vehicular access are also important factors utilized to enhance surveillance and on-site security. Lots with on-site security and personnel to monitor exits have better surveillance and report fewer thefts. Webb et al. (1992) found that parking lots, referred to as "surface car parks" (p. 15), have better attendant visibility; attendants can be seen from the entire lot and, also, can see all of the vehicles in the lot. Lots open in the evening and those with "pay and display" methods of payment are more likely to be victimized. Facilities that park the vehicles in the block method and keep the keys for owners tended to have fewer motor vehicle thefts. The block method prevents any vehicle from being stolen without moving at least one other vehicle. Parking in such a manner is one technique used to reduce motor vehicle theft in parking lots, decks, and garages.

Transportation Hubs

Transportation hubs provide a suitable environment for motor vehicle theft. This is related to both the concentration of people and the criminal's expectation that the owner will be away from the vehicle for a long period of time while watching a movie, shopping, working, or taking public transportation to another destination.

Transportation hubs impact the risk for motor vehicle theft in three ways: by increasing the number of offenders who can easily access an area, by decreasing the number of capable guardians who can provide surveillance over these areas, and by increasing the number of suitable targets. The transportation hubs, themselves, provide easy access for *offenders* to travel to the location from which the motor vehicle will be stolen. For an offender to steal a motor vehicle, he first needs to arrive on the scene. If he takes his own vehicle, it will be left at the scene while he is committing the crime. Therefore, parking facilities that are within walking distance from transportation hubs are attractive to motor vehicle thieves. They provide transportation to the crime scene.

Parking facilities near transportation hubs such as airports, train stations, and bus terminals may have fewer opportunities for *guardians* to provide informal surveillance since these large parking areas are not usually in city centers or residential areas where citizens would recognize the vehicles and their owners. Those who may be traveling through the parking facilities do not know the vehicle owner and could mistake a thief for the owner. Pedestrians in these areas may not observe with the same critical eye as they would if the vehicle were parked on a street in their own neighborhoods.

The number of *targets* in large parking facilities provides increased opportunities for motor vehicle thieves. A large quantity of vehicles provides greater selection and an increased chance that some vehicles will be unlocked or easy to access. The close proximity of vehicles in the parking facility, such as a deck or garage, makes seeing between vehicles more difficult. This obstructed view provides increased cover for offenders and provides thieves with more time to open the door and access the vehicle without suspicion. Therefore, more vehicles provide more opportunities, and these opportunities provide a greater chance of success.

Overall, residential and commercial locations near transit stops and hubs experience an increased amount of crime as compared to similar establishments not located near transportation stops. Huang et al. (1998) found that hotels with easy access to public transportation tend to have a greater amount of motor vehicle thefts than hotels without transportation stops. Brantingham and Brantingham (1999) and Levine and Wachs (1986) identified transportation hubs as types of environmental gatherings that present a greater risk for victimization. In addition to crime within the transportation hub, the vehicle parked in a lot, without residents or interested consumers to play the role of capable guardian, is at great risk.

Accommodations

Motor vehicles create an increasing amount of opportunity. Most people who travel long distances in the United States travel by vehicle. Travelers going long distances stop at hotels or motels for evening accommodations. Offenders anticipate that vehicle owners will not return to their vehicles until at least the early morning hours, providing offenders with hours of uninterrupted time to steal vehicles or items from them.

Hotels and motels create an increased risk for all types of crime, especially motor vehicle theft, since they provide a great number of opportunities for motor vehicle thieves. Guests who are staying at hotels or motels are often transient individuals, if not all of the time, certainly at the time in which they are staying at the hotel or motel. Often these individuals drive out of state vehicles. When out of state vehicles are stolen, local police have a more difficult time tracking down the owners and maintaining contact. Hotel guests and other travelers also tend to have more items in their possession since they are going to be away from home for longer periods (Huang et al. 1998). Travelers do not see the harm in leaving items in the vehicle instead of carrying them in and out of the hotel room. When high-priced items such as cameras, video equipment, computers, tablets, or other portable devices are visible, they increase the chance that the vehicle will be targeted for both motor vehicle theft and theft from the motor vehicle.

Shopping Centers

Similar to transportation hubs, shopping centers provide thieves with a large number of targets in a condensed area. Thieves also have easy access to the vehicles and are fairly certain that individuals will be away from their vehicles for a significant amount of time once they park and enter the shopping center. Engstad (1975) believed that parking lots provide opportunities for theft from vehicles and vehicle theft because massive parking lots with thousands of spots present increased opportunities for motor vehicle victimization. Like transportation hub parking facilities, the legitimate users do not know each other and are unable to spot thieves approaching a vehicle.

Supermarket parking lots also provide additional incentives for motor vehicle thieves. Supermarkets are often located off major roadways or adjacent to highways. They can be considered ideal targets since they are open late hours and have access to roadways which can make escape fast and detection impossible. By the time the motor vehicle is reported stolen, the thief can be in another county or state.

Motor Vehicle Repair Shops and Auto Parts

Year after year, vehicles that are reported stolen most often are older and foreign. In 2010, according to the National Crime Insurance Bureau, the top five stolen vehicles were the 1994 Honda Accord, 1995 Honda Civic, 1991 Toyota Camry, 1999 Chevrolet Pickup (full size), and the 1997 Ford F150 Series/Pickup. The top three stolen vehicles are older Hondas and Toyotas, which have made the top of the list for a decade. These motor vehicles are stolen for their parts; vehicle parts for many models are worth much more than the vehicle's street value.

Research in this area has supported these popular beliefs. Gant and Grabosky (2002) interviewed a snowball sample of motor vehicle thieves. Thieves in this sample indicated that professionals in search of parts to repair vehicles actually steal vehicles (especially older vehicles) and dismantle the vehicle for parts to sell them to motor vehicle repair businesses. Thieves steal for a number of reasons such as profit, transportation, or recreation. Those who steal vehicles to profit are thought to be more “professional offenders” and do not steal for reasons such as quick transportation and/or recreation. These professional offenders are often driven by the demand for certain makes and models of motor vehicles and their parts. Professional offenders may spend more time searching than offenders who are simply looking to joyride or find transportation home. La Vigne, Fleury and Szakas (2000) studied motor vehicle thieves and their travel patterns to chop shop locations. According to research by La Vigne et al., police or researchers can estimate the offender's journey to crime by considering the average distance from the location of the theft to the location of the chop shop. Lu (2003) also found that travel distances between the location of the stolen vehicle and vehicle dump sites were short. Research by both La Vigne et al. (2000) and Lu (2003) indicate that the search for thieves can be narrowed if the locations of the theft and dump site are known.

Current Issues and Controversies

The current debate over motor vehicle theft presents three key environmental factors that influence the likelihood of a motor vehicle to be stolen: location, lighting, and security. Surely motor vehicles that are parked in locations that have poor environmental characteristics, poor lighting, and poor security are more likely to be victimized, but current research has found that each characteristic varies in its level of contribution to victimization.

Locations

The location of the potential motor vehicle target is an important factor that offenders consider before they offend. The characteristics of the motor vehicle theft location help the offenders determine if it is a "good" target to select. Offenders will use landscape and design features to determine if their crime will be concealed and if the layout of the area will impede their escape after the vehicle is stolen (Keister 2007). Jeffery (1971) noted that there is a decision model that offenders use during the actual commission of a criminal act. "The decision to commit a crime involves the past experience of the subject, the immediate opportunity for a crime, plus the chances of apprehension or injury" (Jeffery 1971, p. 251). The last part of the decision, the likelihood of apprehension, is discussed with regard to the layout of the location to be targeted. All other things being equal, offenders will choose locations that provide an easy get away and enhance the chance of escaping apprehension. Nichols (1980) suggests that after offenders decide to commit a crime they engage in a search pattern of potential sites. This is conducted by using a "mental map" (Nichols 1980, p. 156) of known locations to help offenders evaluate their options. Lu (2006) also addressed the importance of escape routes for motor vehicle thieves. Major roads and those connected to major roads had disproportionately more motor vehicle thefts than less traveled roadways.

The safest place to park a vehicle is a residential garage. The best places to park, in order from most safe to least safe, are residential garage, residential driveway, residential street parking, then parking lots/garages/decks. Clarke and Mayhew found that "parking in a domestic garage at night is safer by a factor of 20 than parking in a driveway or other private place, and safer by a factor of 50 than parking in a street near home" (1994, p. 91). This indicates an increased risk for victimization when a person parks in the street instead of in a personal garage located at the residence. Street parking provides reduced surveillance and, in high density locations, a similarly plentiful group of targets as do parking garages.

Many cities prefer garage parking since it takes up less ground space and is more cost-effective for those who own the facilities. However, due to decreased surveillance opportunities, parking garages are less safe than parking lots. Parking garages that are either partially or fully enclosed and elevated above ground offer less natural surveillance than parking lots. This problem is enhanced by sloping ramps and multiple floors which further cut surveillance from other individuals inside the garages.

Lighting

Poor lighting can provide cover for offenders. Just as offenders use hedges and walls to prevent their detection when breaking into a home or business, dark alleys and dimly lit streets hinder residents and other watchers from their important involvement in informal surveillance. It is critical that lighting is both provided in adequate levels and is aimed in the proper direction. Historically, lighting has been a problem with regard to many types of crime and public safety issues. Government organizations (such as police) and private organizations (such as residents' associations) must work together to increase lighting.

Lighting is most important in parking lots and garages (Smith 1996; Webb et al. 1992) when garages are either partially or fully enclosed, limiting natural light from entering and prohibiting natural surveillance from the street (Tseng et al. 2004; Poyner 1997). Illuminance (the intensity of light) and vertical illuminance are important traits that must be considered when installing lighting. In addition to the intensity of light, placing white stain on the ceiling can reflect light and increase uniformity in the parking garages (La Vigne 1997; Painter 1994). Garages that can minimize ramps and utilize flat surfaces for parking areas will maximize the positive effects of light and reflected light and enhance natural surveillance from outside of the garage.

The presence and quality of lighting is an important site-level factor considered before the commission of a motor vehicle theft (Levy 2009; Levy and Tartaro 2010). Both the amount of lighting that is properly working and the intensity of that lighting are important in the overall lighting of streets at night. Street lighting is just one part of the lighting requirement of specific sites. Most businesses and residential areas obtain evening lighting from the streetlights and lights located on the store or residential property. Both the number of lights on the street and the property and the intensity of the light in these locations, are needed to determine if the lighting is adequate.

Farrington and Welsh (2002) conducted a meta-analysis of studies where street lighting was measured with regard to its impact on crime. Studies eligible for inclusion in the meta-analysis had to meet the following criteria: the study utilized improved street lighting as the intervention, the outcome measure was crime, the methodology was sound with both pre- and post-measures of lighting in experimental and control groups, and the experimental and control had at least 20 crimes in each group prior to the intervention. Farrington and Welsh (2002, 2004) concluded that improving street lighting decreased crime by roughly 20 %. This and other recent literature indicate that increasing lighting is an economical and effective way to reduce crime.

Security and Technology

Almost every kind of location employs some method of security in order to protect goods. For locations such as parking lots, controlling entrances and exits is an important security feature (Hunter and Jeffery, 1992). Webb et al. (1992) noted that the layout of the parking structure is a factor considered in motor vehicle theft. Parking structures with manned exits have the lowest risk for both motor vehicle theft and theft from motor vehicles. Manned exits not only provide increased surveillance, but bars or mechanical arms on the exits also provide a physical barrier to prevent vehicles from leaving the structures.

Owners of motor vehicles have their own set of precautions and security devices. Alarms are frequently installed by the manufacturer or are installed after market if the vehicle was not sold with an alarm. Research on motor vehicle alarms is mixed. Light et al. (1993) found that 35 % of motor vehicle thieves interviewed indicated that they would be deterred by alarms, 18 % said it would depend on the make of the alarm, while 9 % said it depended on the model of the alarm (p. 50). Conversely, Fleming, Brantingham, and Brantingham (1994) found that nearly 75 % of offenders would be deterred by an alarm. Many thieves also indicated that audio equipment "pull outs," radio faces that are designed to be detached and taken with the driver, are usually left in the vehicle and therefore are not a major deterrent to thieves. Research on steering column locks is similarly mixed with steering column locks working better on some makes and models of motor vehicles and not as well on others.

More recently, LoJack and OnStar have shown to be very effective tools used to locate vehicles after they are stolen. Arrest rates for vehicles with LoJack and similar GPS locator systems are three times greater than for vehicles without the devices. The LoJack company states that 90 % of vehicles with LoJack are recovered (LoJack 2011). GPS devices have been the most effective tool available to date, but often do not prevent vehicles from being stolen; such devices only aid in motor vehicle recovery.

The presence of security hardware, especially in the case of motor vehicle theft, is only effective if the hardware is installed and maintained properly. Motor vehicle owners who leave doors unlocked or leave the radio face in place are not going to deter a thief from stealing the vehicle or even the radio. Similarly, parking lots with gated access and egress are most effective in preventing motor vehicle theft, but only if these gates are working properly all of the time. Technology can play a major role in decreasing motor vehicle theft, but it can only work if used properly. And, sometimes, despite proper use, crime prevention techniques may not thwart the skilled offender.

Repercussions of Motor Vehicle Theft on Society

When compared to criminal homicide, forcible rape, and robbery, some of the other Part I offenses recorded in the *Uniform Crime Report*, motor vehicle theft typically has less of a direct personal impact on the victim. Despite this, victims of motor vehicle theft report crippling effects associated with the loss of a motor vehicle. Some of these effects include problems with insurance coverage or response times, the emotional impact of losing one's possessions, and the increase in policy premiums for all motorists living in areas that have high motor vehicle theft rates.

When a motor vehicle theft occurs, the owner is left to report the loss to the police department and to file an insurance claim. Many insurance carriers do not provide replacement vehicles while the claim is being settled, so – even if temporary – the owner does not have a motor vehicle. If the vehicle is not recovered, the owner may be compensated for the current value of the motor vehicle. In many cases this does not cover the full amount owed on the vehicle nor allow the owner to purchase a replacement vehicle of similar style or value. If the vehicle is recovered, it may have sustained serious damage during the time that it was missing. What is returned may not be the same as what was stolen. This can create more complicated interactions between the owner and the insurance company, often resulting in little or no compensation for the loss.

In addition to the loss of the vehicle, owners may suffer emotional distress in a variety of ways. The owners may have lost items of personal significance or sentiment which were in the vehicle when it was stolen. These items may have been irreplaceable but not of great financial value. Other items that were in the vehicle may not be replaced unless receipts and proof of purchase are provided. Owners may also suffer a fear of future victimization. They may fear that the replacement vehicle will also be stolen and that they will have suffer greater insurance premiums if future motor vehicles are stolen.

Finally, motorists living in areas with high rates of motor vehicle theft will have similarly high motor vehicle insurance premiums. As thefts continue to increase, so too will the premiums. Motor vehicle thefts impact the entire city because insurance companies base premiums on the location of the policy holder's home, the distance the policy holder travels, and the locations most frequented by the policy holder (work or school locations), in addition to the rate of motor vehicle theft in those areas. Motor vehicle insurance premiums are calculated based on all of these factors and are higher in areas with higher motor vehicle theft rates.

The Complicated Nature of Repeat Victimization

Motor vehicle theft presents researchers with a challenge when defining the role of "victim" in the motor vehicle theft event. Technically, there are three ways in which a victim of motor vehicle theft can be defined: address, vehicle, and owner.

An address can be a repeat victim. Motor vehicles parked in the same lot, same driveway, or same street segment can suffer multiple motor vehicle victimizations. In this example the address or location has been victimized. Criminologists can study the characteristics of these addresses or locations to better understand why the area may be suffering repeat victimization. Some potential causes of repeat victimization in these settings are reduced visibility by residents or business owners, little or no lighting in the evening, and poor security devices. Security devices that can be used to protect addresses or locations are gates, fences, security alarms on residential or commercial garages, and surveillance equipment.

A vehicle can also be a repeat victim. The same motor vehicle can be stolen from the same owner, or the same vehicle can be stolen from a different owner or renter. In this situation, the vehicle is likely to have certain features that make it more likely to be stolen. These features can be parts that were installed by the manufacturer such as engines and catalytic converters. Vehicles can also be repeatedly stolen or have parts repeatedly stolen, which were added after market. Items added after market that have high theft rates include portable GPS units, entertainment systems, rims, and tires. Security devices that can be used by vehicles in order to prevent repeat victimization are alarms, ignition devices, smart keys, and vehicle locator devices such as LoJack and OnStar.

Finally, an owner can be a repeat victim. The same owner can have many vehicles stolen at one or many points in time. Owners who find that they have many stolen motor vehicles likely have behaviors which put them at increased risk of victimization. Owners may continually purchase foreign-made vehicles which are more likely to be stolen. They may live in or routinely travel to an area that has a high motor vehicle theft rate. Finally, they may fail to lock vehicle doors, set alarms, or leave valuable items in plain sight. Any of these behaviors may put vehicle owners at an increased risk for repeat motor vehicle victimization.

Looking Forward

It appears that motor vehicle theft victimization is following a downward trend. However, that does not mean that motor vehicle theft is no longer a problem worthy of study. Over 737,000 motor vehicles were stolen in the United States in 2010. With each motor vehicle that is stolen, the costs to the owner, insurance company, and all motorists increase. With that said, it seems that advances in technology have created a significant obstacle for motor vehicle thieves to overcome. It may be that the risk has now met or exceeded the reward.

1%ers; Biker clubs/gangs; Motorcycle clubs; Motorcycle gangs; One percent clubs/gangs; Outlaw motorcycle clubs/gangs

Overview

Motorcycle clubs, that is, voluntary social organizations based on a common love of motorcycles and riding together, formed in the early 1900s. However, by the 1930s groups of displaced young men riding motorcycle grouped together in what were nascent gangs. These nascent gangs evolved into outlaw bikers and then into a subculture of bikers known as One Percenters aka Outlaw Motorcycle Gangs. The One Percenters evolved into motorcycle gangs more into crime for profit than a common love of motorcycles and riding together. Today, these Outlaw Motorcycle Gangs are national and international criminal organizations.

Are motorcycle clubs really clubs, that is, voluntary social organization built around the love of motorcycles, or criminal gangs whose members happen to ride motorcycles? There is no easy answer: some are and some are not. Some well-known criminal gangs, such as the Hells Angels Motorcycle Club (HAMC) and other Outlaw Motorcycle Gangs (OMGs) aka one percent clubs (1 %ers), vehemently argue that they are clubs and not gangs. Their behavior and the criminal history of their members do not support their argument. Therefore, we must examine the differences between conventional motorcycle clubs and criminal motorcycle clubs and how the 1 % outlaw motorcycle clubs/gangs fit in the motorcycle club grouping.

Motorcycle Clubs: Conventional and Criminal

Since the first American "motor-driven cycle," the Indian, was built in 1901 Springfield, Massachusetts, motorcycle riders have formed clubs based on their common interest in riding the iron machines (Hayes 2010). The first clubs were composed of foolhardy men racing these dangerous and unwieldy machines, then; in 1903 the fledgling American motorcycle scene changed dramatically. In 1903, the Harley-Davidson Company in Milwaukee, Wisconsin began building a motorized bicycle that changed the machines, the way the machines were used, and brought about a change in the riders and how they grouped together. Harleys began dominating sport motorcycle racing and then in the 1920s Harley's became more a means of transportation and pleasure rather than racing (Davidson 2002). At the time, individual travelers had a limited range of transportation options; they could ride a horse or a horse drawn buggy, ride a bicycle, or walk. The adventurous of that day who desired to travel between cities or farther had to take the train. There were few highways and coast-to-coast was a challenge. Motorcycles made it possible to ride within cities, between cities, and across the country for transportation or pleasure. The sidecar also allowed for the entire family to share the motorcycle experience.

Motorcycle riders changed as women and other family members began riding motorcycles. The clubs they formed also changed. In 1924, the American Motorcycle Association (AMA) was formed and provided the main motorcycling racing sanctioning body and soon began promoting what was known as Gypsy Tours that were "statewide, good-clean-fun, jamboree-picnic soirees, which proved to be the ground-seed for events like the Sturgis Rally (Hayes 2010, 43)." The AMA would play a huge role in the definition of outlaw motorcycle clubs. Following the formation of the AMA, groups of motorcycle riders organized clubs that are broadly classified as either conventional or outlaw clubs (Barker 2007). By the 1930s, the AMA had chartered 300 conventional motorcycle clubs (Fuglsang 1997). These clubs represented the "responsible" motorcycle riders and often had strict dress codes. Clubs that obtained a charter from the AMA were considered legal clubs; the others were classified as "outlaws" (Wolf 1999). The "outlaw" label in this case meant non-AMA, not criminal. However, the deviant label had consequences: outlaw clubs were not allowed to participate in AMA-sanctioned events.

The conventional clubs began a tradition of sponsoring mixers, charity events, and hill-climbing contests and promoting responsible motorcycling as a family activity that still exists. Historically, the members of conventional clubs came from different social strata and dressed and acted differently from deviant club members.

At about the same time, groups of motorcyclists began to appear in the motorcycle-friendly weather of Southern California in the early 1930s (Barker 2007). Depression stricken "Okies" looking for work and riding motorcycles because they were cheap transportation, appeared on the scene. Although most were loners who rarely stayed in one town for long, some banded together in the squalid Southern California industrial districts and formed loose-knit "outlaw" motorcycle clubs. Riding together in groups, these outsiders worked menial jobs and lived a deviant lifestyle of drinking and rowdy behavior, with some dealing in stolen motorcycle parts and other criminal pursuits (Yates 1999). Harley-Davidson motorcycles were the most popular and abundant bikes at that time, so Harleys became the motorcycles of choice for these groups – for both possession and theft. These outlaw clubs were more gangs than clubs and different in dress and behavior from the AMA clubs. Their appearance and behavior foreshadowed the development of Outlaw Motorcycle Gangs and the one percent biker.

At first, outlaw clubs were not much of a threat to conventional motorcycle clubs or the image of motorcycle riders in general, but this changed in the late 1940s. Following World War II, outlaw clubs began disrupting AMA-sanctioned events and the label "outlaw" motorcycle clubs took on a new meaning and changed the public image of motorcycle riders. "Wino Willie" Forkner has come to be representative of the change and the men who brought it about.

A hard-drinking young motorcyclist "Wino Willie" Forkner joined the 13 Rebels Motorcycle Club, an AMA conventional club, and rode with them for 2 years before the attack on Pearl Harbor. After Pearl Harbor, the dipsomaniac Forkner joined the Army Air Corps and was soon manning a 0.50 caliber machine gun on a B-24 Liberator for the next 30 months (Reynolds 2000). In the summer of 1945, the hell-raising Wino Willie returned to California and rejoined the 13 Rebels. It was not long before Wino Willie's hell-raising behavior, possibly intensified by his wartime experiences, and the conventional behavior of the 13 Rebels clashed.

Forkner, according to his widow, Teri, was like many of the returning veterans "back from the war and letting off steam (Bill Hayes Video Interview: The Original Wild Ones, 2003)." "Letting off steam" for these veterans meant riding their bikes and drinking together. In the summer of 1946, Forkner and his drinking buddy and fellow 13 Rebels' member, Blackie, were "letting off steam" in their favorite watering hole, the All-American Bar, when they decided to show up at 13 Rebels sponsored quarter-mile race in San Diego after an all-night drinking session (Reynolds 2000, 34–36). Thoroughly plastered and frustrated, Wino Willie decided to liven up a boring race. Forkner drove his bike through the wooden gate leading from the parking lot onto the track. The drunken Forkner burst onto the track in a shower of shattered wood and loud applause from the audience who shared his view of the race. Forkner roared down the straightaway and made four laps around the track before losing control and turning his bike over. The subdued whirling dervish was promptly arrested and hauled off to jail. After a weekend in jail, Forkner pleaded guilty to trespassing and being drunk and disorderly. He hitchhiked back to Los Angeles and faced an enraged group of 13 Rebels members. The club members demanded his 13 Rebels sweater and threw him out of the club. The unrepentant Forkner reportedly returned the sweater after defecating on it (Reynolds 2000, 36). The evolution to one percent biker clubs/gangs had begun.

The angry Wino Willie decided to put the 13 Rebels and the raceway fiasco behind him by drinking and sulking at the All-American Bar (Reynolds 2000, 36–38; Barker 2007). Forkner began drinking with three former servicemen. The four inebriated bikers decided to form a new motorcycle club but could not come up with a name. Overhearing the animated discussion, an All-American regular named Walt Porter lifted his head off the bar and called out "Call it the Boozefighters." The four inebriated bikers thought that was a perfect name. During the following weeks, Wino Willie and his fellow Boozefighters recruited 16 other members. The Boozefighters even applied for AMA membership but were turned down by the AMA president, who allegedly said: “No goddamn way I am giving a name like that a charter (Forkner 1987).” By 1947, three charters of the Boozefighters MC had formed in Los Angeles, San Pedro, and San Francisco.

The Boozefighters MC was not the only outlaw club formed by ex-servicemen “letting off steam.” World War II veterans joined outlaw clubs and called themselves the Galloping Gooses, the Pissed Off Bastards of Bloomington, Satan’s Sinners, and the Market Street Commandoes. Conventional clubs used simple and innocent-sounding names like the Road Runners, the Glendale Stokers, and the Side Winders. On occasion, these conventional clubs engaged in reckless street races, but their behavior was harmless compared to the sometimes violence-prone behavior of the new outlaw clubs (Yates 1999). To further distinguish themselves from AMA clubs members who wore ties and racing caps, the outlaw veterans were unkempt in appearance and rowdy in behavior. The stage was set for the creation of a new label – Outlaw Motorcycle Gangs. One event is considered to be the incident that changed the social definition of outlaw clubs: The Hollister Motorcycle Incident/Riot in 1947.

The events, real, imagined, and contrived of the Hollister Incident “riot”, that took place in the small California town of Hollister during the 1947 July 4th weekend led to a staged photograph, which inspired a short story that led to a movie, which influenced a genre of biker movies and media publicity that ultimately constructed a new social definition of outlaw bikers. The West Coast town of Hollister, California was chosen as the site for a gypsy tour and would draw in bikers from across the country. Hollister was [and still is] a big motorcycle town in the 1940s, with 27 bars and 21 gas stations. However, the town had only six police officers. Hollister held its first gypsy tour in 1936 and held regular motorcycle races and hill climbs. The residents were not expecting any trouble at the 1947 rally.

Members of all three Boozefighters MC chapters made plans to attend the motorcycle rally. The Los Angeles members, including Wino Willie, met on Thursday evening at the All-American to prepare for the ride to Hollister. Preparation included drinking at the All-American, riding to Santa Barbara for more drinks, and then riding to San Luis Obispo, where they became too drunk to go on. The Los Angeles Boozefighters “slept it off” in a bus terminal for 3 h and roared off to King City, where they stopped at a liquor store to finish “preparing” for the ride into Hollister. By the time they arrived in Hollister, several thousand motorcyclists were already there and thoroughly “prepared.” It wasn’t long before intoxicated bikers turned the blocked-off main thoroughfares into drag racing strips and stunt-riding exhibitions.

Conventional club members were at the nearby Bolado Racetrack, which was filled to capacity for the scheduled races. The hard core bikers of Wino Willie’s new club, the Boozefighters, and the other hell-raising outlaw clubs were driving the town’s six police officer’s crazy. Soon the jail was filled to capacity with drunken motorcyclists, including Wino Willie. While the commotion was going on, a photographer for the *San Francisco Chronicle* decided to take a picture of a drunken motorcyclist. For some reason, he staged a photograph even though there were plenty of drunken motorcyclists available. The photographer sat a Harley-Davidson motorcycle on top of a pile of beer bottles and persuaded an intoxicated biker in a leather jacket to sit astride the bike. The picture never appeared in the *San Francisco Chronicle*, but it would become one of the most famous pictures in motorcycle history after the Associated Press picked it up and printed it in *Life* magazine.

On Sunday night the Hollister police officers called for help from the California Highway Patrol (CHP). Forty CHP officers arrived at dusk. The CHP lieutenant in charge began moving the compliant bikers toward the end of town. The lieutenant spotted a group of musicians unloading their instruments for a dance and ordered them to set up in the street on a flatbed truck and play for the crowd. The crowd started dancing and continued dancing into the night under the watchful eyes of the CHP. While the drunken bikers danced, the local Chief of Police went to all the bars and had them closed at midnight, 2 h early. The "riot" was over, but the exaggerated and distorted publicity of the incident was just beginning. The media blitz that followed the alleged Hollister "riot" would create a new moral panic and "folk devil" – the outlaw biker. The next motorcycle "riot" would forever solidify outlaw bikers as folk devils.

A 1948 Memorial Day weekend gypsy tour rally in Riverside, California, attended by more than 1,000 drunken motorcyclists recreated the scene that had occurred at Hollister – this time with violent consequences. While they were drag racing and partying, an Air Force officer and his wife, trying to get through, honked at the pack of drunks blocking the street. The mob smashed the car windows, punched the driver, and manhandled his frightened wife (Reynolds 2000, 60). While this was occurring, one of the drunken riders wiped out on his bike, killing his girlfriend, who was riding with him. Boozefighters were in the area but not involved in the incident. However, local newspapers reporting the incident carried pictures of two Boozefighter members drinking beer and sitting on their bikes. The caption under the picture read that they were members of the same group who "started the Hollister Riot the previous year (Reynolds 2000, 60)." The national story coming on the heels of the Hollister "riot" led to a motorcycle short story that created a genre of low-budget exploitation biker films that would cement outlaw bikers as folk devils and a part of modern pop culture.

In 1951, *Harper's Magazine* published a short story by Frank Rooney entitled "Cyclists Raid." The story an exaggerated account of the Hollister incident would have been forgotten except for the movie it inspired – *The Wild One*. The short story's plot is about an unnamed motorcycle gang taking over and terrorizing a small town somewhere on the West Coast. Filmmaker Stanley Kramer read "Cyclist Raid" and decided to make a movie based on the story. He, writer Ben Maddow and film star Marlon Brando spent 3 weeks interviewing ex-Boozefighters before filming started (Stidworthy 2003). The resulting screen adaptation ushered in a new genre of biker movies. The 1954 movie *The Wild One*, starring Marlon Brando became a cult movie and solidified the image of outlaw bikers as folk devils and spread their cultural lifestyle and dress throughout the world. After the film's release, hundreds of American bikers would emulate Brando and costar Lee Marvin in dress and behavior. Biker expert Arthur Veno asserts that motorcyclists across the Western world "saw the Hollywood version of an outlaw motorcycle rebel" and copied their attitudes, clothes, disrespect for society, and the way they treated women (Veno 2002, 30). According to Veno, motorcycle clubs in England, Australia, Canada, South Africa, New Zealand, Germany, Denmark, and Italy mimicked the screen outlaw bikers. The next evolution of Outlaw Motorcycle Gangs comes with the Hells Angels Motorcycle Club.

Hells Angels Motorcycle Club and the One Percenters

After the Hollister incident, the World War II veterans outlaw motorcycle club, the Pissed Off Bastards of Bloomington, had disbanded, partly because of the bad publicity spin-off from the sensationalized Hollister "riot." Reynolds (2000) contends that Arvid Olsen, a former squadron leader with the WWII "Flying Tigers," of China suggested the name "Hell's Angels" for a new motorcycle club that he, Otto Friedl, and several other former Pissed Off Bastards of Bloomington decided to form in 1948 in San Bernardino, California. The new members chose as a logo a grinning skull wearing a pilot's helmet with attached wings. A decade later the name and logo would be adopted by a group of motorcycle-riding young toughs and thugs in Oakland, completing the one percent bikers aka Outlaw Motorcycle Gangs' progression.

During the next decade, Hells Angels Motorcycle Club chapters formed throughout California as nomadic members moved from one city to the next. The 1957 Sacramento Hells Angels chapter was formed out of the Hell Bent for Glory Motorcycle Club started by two teenage toughs, James "Mother" Miles and his younger brother Pat, breaking the connection between World War II veterans and the establishment of outlaw motorcycle clubs. These Hells Angels chapters were more like separate clubs operating autonomously and independent of each other, often not knowing of the others. One man, Ralph "Sonny" Barger is credited with bringing the chapters together and creating the largest outlaw motorcycle club in the world.

Barger grew up in the blue-collar jungle of Oakland, California, and joined the Army in 1955 with an altered birth certificate (Barger & Zimmerman 2000). Less than a year later, the Army discovered his actual age and discharged him. When he returned to Oakland, there were numerous motorcycle clubs, like the Oakland Motorcycle Clubs, that were conventional clubs, and there were also "freewheeling clubs" like the Oakland Panthers. Barger joined the Panthers but soon left because they did not provide enough action.

Barger found a new wild bunch of motorcyclists with whom to ride. The wild group had no name but was searching for a common identifier. One of Barger's riding buddies "wore a modified Air Force-like patch he'd found in Sacramento, a small skull wearing an aviator cap inside a set of wings (Barger & Zimmerman 2000, 30)." The young "outlaws" thought the patch was cool and decided to name their club Nomad Hells Angels after the patch. In April 1957, the club had patches made based on the design (which later became the easily recognizable copyrighted HAMC death's head). Sometime later Barger met another biker wearing the very same Hells Angel patch. This Angel filled Barger in on the history of the club formed in San Bernardino in 1948, including the other chapters and the rules, regulations, and procedures for becoming a Hells Angel chapter. Angels from the SoCal (Southern California) chapter visited the quasi-Hells Angels in Oakland. A series of meeting later and the Oakland Hells Angels Chapter came into being. In 1958, Sonny Barger became president of the Oakland Chapter; he then became President of the National Hells Angels Motorcycle Club and changed the HAMC forever. Although the basic organization was in place when Barger took over as Oakland president, under his leadership and guidance new rules were added pertaining to new members, club officials, and induction of new charters/chapters. With Barger at the helm, the HAMC would expand into the largest and most well-known outlaw motorcycle club in history. They would also become a criminal gang rather than a motorcycle club and spread its criminal tendrils all over the world.

Early outlaw clubs like the Boozefighters were formed by veterans, later outlaw clubs, particularly the one percent clubs, would not be veteran centered and would be in the tradition of the Sacramento Hells Angels chapter formed by young toughs and criminals or those with criminal tendencies.

George Wethern, the Oakland Hells Angels Vice President, describes a historic meeting that was "sort of like the Yalta conference" in 1960, held at the home of Frank Sadilek, the president of the San Francisco Hells Angels chapter (Wethern and Colnett 1978). At the meeting were Hells Angels leaders from across the state and former warring California biker club leaders – of the Gypsy Jokers, Road Rats, Galloping Gooses, Satan's Slaves, the Presidents, and the Mofos. The purpose of the meeting was to discuss police harassment, but discussion soon turned to recent hostile comments by the AMA.

"To draw a distinction between its members and us renegades, the AMA had characterized 99 % of the country's motorcyclists as clean-living folks enjoying pure sport. But it condemned the other one percent as antisocial barbarians who'd be scum riding horses or surfboards too (Wethern and Colnett 1978, 54)." The clubs decided to accept the one percent label (1 %) as a tribute and not as insult and adopt the "1 %" patch to identify themselves as righteous outlaws. Wethern and Sonny Barger were the first to get the "1 %" tattoos. From this day forward Outlaw Motorcycle Gangs would also be known as one percent (1 %) clubs/gangs.

Outlaw Motorcycle Gangs: The One Percenters (1 %ers)

In the 1960s, the formerly hell-raising and nonconforming outlaw motorcycle clubs such as the Hells Angels moved into criminal activity, particularly drug dealing, and became more like gangs (organized for crime as profit) than clubs of motorcycle enthusiasts (Barker 2007). There is no accurate count of the number of 1 % clubs/gangs. However, Outlaw Motorcycle Gangs (1 %er clubs) can be categorized into the Big Five Outlaw Motorcycle Gangs (OMGs), Puppet/Support OMGs, Independent OMGs, and Black/Interracial Gangs.

Big Five Outlaw Motorcycle Gangs

The designation of Big Five Outlaw Motorcycle Gangs is, in many ways, an arbitrary judgment, first made by law enforcement authorities in the form of the Big Four (Hells Angels, Bandidos, Outlaws and Pagans) to designate the criminal potential of the gangs. The Sons of Silence were added later becoming the Big Five Outlaw Motorcycle Gangs – the Hells Angels, Bandidos, Outlaws, Pagans and the Sons of Silence.

Hells Angels – Barger, in his autobiography, admits that he sold drugs and got into a "lot of shit" in what he describes as the "gangster era" of the Hells Angels (Barger & Zimmerman 2000). It appears that the Hells Angels are still in their "gangster era." The US Department of Justice (DOJ 2011) estimates that the HAMC has between 2,000 and 2,500 members in 27 US states and 26 foreign countries. Internationally, the HAMC is a criminal threat on six different continents. The DOJ reports that the OMG is involved in the production, transportation, and distribution of marijuana and methamphetamine. The international criminal gang is also involved in the transportation and distribution of cocaine, hashish, heroin, LSD, ecstasy PCP, and diverted pharmaceuticals.

Bandidos MC – As a testament to the criminal nature of the Bandidos Motorcycle Gang, starting with the founder, Donald Chambers, every national president of the Bandidos MC has been convicted of a felony, usually drug trafficking, and sentenced to prison. Since its founding in 1966, the Bandidos have expanded throughout the USA and internationally. The gang's first European expansion was in 1989 when the Bandidos "patched over" [assimilated] the Club de Clichy Marseille, France, igniting a war with the Hells Angels. The DOJ (2011) estimates that there are 2,000–2,500 Bandido members in the US and 13 other countries. According to law enforcement authorities, the Bandido MC is involved in transporting and distribution of cocaine and marijuana and the production, transportation, and distribution of methamphetamine.

Outlaws MC – According to their national website, http://www.outlawsmc.com/, the Outlaws MC is the oldest Outlaw Motorcycle Club, having been established in 1935 as the McCook Outlaws Motorcycle Club "out of Matilda's Bar on old Route 66 in McCook, Illinois just outside of Chicago." This motorcycle club was quite different from the Outlaws Motorcycle Gang of today. The DOJ (2011) estimates that this OMG has an estimated 1,700 members in 20 US states and 12 foreign countries. As is common with all OMGs, the Outlaws are involved in the production, transportation, and distribution of methamphetamine. They are also involved in the transportation and distribution of cocaine, marijuana, and to a lesser extent, ecstasy. The HAMC and the Outlaws MC are bitter enemies and have a long history of violence toward each other.

Pagans MC – The Pagans MC, a fierce 1 % biker gang with ties to organized crime groups in Philadelphia, Pittsburg, and New York, did not start out as a 1 % club. Lou Dobkins, a biochemist at the National Institute of Health, established the club in 1959 in Prince George's County, Maryland. Tradition says that the original 13 members wore white denim jackets with Surt the pagan Fire Giant carrying a flaming sword, logo on the back. The original members rode Triumph motorcycles. Their benign beginning did not foreshadow what the club would evolve into. During the 1970s, the fierce fighting club became an extremely violent criminal organization under the leadership of John Vernon “Satan” Marron. The Department of Justice reports that the Pagans are involved in the distribution of cocaine, methamphetamine, and PCP (DOJ 2011). The Pagans MC are the only Big 5 Outlaw Motorcycle Gang that does not have any chapters outside the United States, although there are rumors that they are attempting to establish a presence in Canada.

Sons of Silence MC – The Sons of Silence MC (SOSMC) also did not start out as a 1 % biker gang. The club was founded by Bruce, “The Dude Ruchardson” in Niwot, Colorado, in 1966. The club appears to have been formed as a “drinking” social club. As the club evolved into a gang, Richardson left the club. Today, the DOJ (2011) reports that the SOSMC is an Outlaw Motorcycle Gang with 30 US chapters and 5 chapters in Germany. Club members, according to the DOJ, have been involved in a wide range of criminal activities, including drug and weapons trafficking.

Puppet/Support 1 % Clubs

Puppet/Support Clubs are Outlaw Motorcycle Gangs affiliated with a dominant OMG. The puppet/support clubs do the biding of dominant clubs, serve as potential recruiting sources, and provide cannon fodder in the club wars. The OMG puppet/support clubs give a portion of their illegal gains to the dominant OMG. The larger OMGs will handle the wholesale distribution of the drugs and the puppet clubs will handle the more dangerous retail sale, thereby insulating the dominant club members from prosecution. On occasion if the subordinate club member is caught committing a crime and demonstrates that he “has class” [keeps his mouth shut and takes the fall], he will be rewarded by becoming a “prospect” for the dominant club.

The Red Devils MC is a well-known puppet/support club for the HAMC, and the Black Pistons MC and Forsaken Few are puppet clubs for the Outlaws MC. The Outlaws MC and the Bandidos MC list their puppet/support clubs on their national websites.

Independent Outlaw Motorcycle Gangs

Independent Outlaw Motorcycle Gangs are considered to be those who are not listed in the Big 5 and are not a puppet/support club of a Big 5 club. Because of the jealously of their territory by Big 5 clubs, it is not easy to be an independent club. Independent clubs operate in areas where there are no Big 5 Clubs or in the same area with permission of the dominant club. They are on friendly or tolerated terms with the larger club but remain independent of them.

Other independent clubs, such as the Mongols MC (national and international), operate in the same areas due to their ferocity and willingness to use violence. The Mongols MC and the HAMC fought a 17-year war over the wearing of the California bottom rocker. Other major independent clubs include the Vagos MC (national and international), Warlocks MC (national and international), and the Iron Horsemen MC (regional and national) and the smaller independents such as the Avengers MC, the Breed MC, and the Renegades MC who operate in limited geographical areas.

Black or Interracial One Percent OMGs

There are numerous one percent bikers that vehemently insist that there are no black 1 % bikers, insisting that like women, blacks are not welcome in the one percent subculture. It is true that the one percent subculture is basically sexist (women cannot be patch-holders in any 1 % club) and racist, with some clubs/gangs being more racist than others; however, it is not true that there are no black 1 % bikers or clubs. The Oakland, California, Eastbay Dragons MC is an all black 1 % club (Levington & Zimmerman 2003). The Wheels of Soul MC’s website says that they are “an Outlaw Motorcycle Club, founded in 1976 and is the only one of its kind. . ..we have a make-up of black white, Latino and Asian members (www.wosmc-trenton.com/history.html).” The Ching-a-Lings MC in Queens, New York City, are also interracial. Winterhalder reports there is a black, nationwide one percent club, the Hell's Lovers (Winterhalder 2005).

Chronic victims; Multi-victims; Serial victims

Overview

The plight of multiple victims of crime is identified, with the observation that their needs are often ill-served by police and other agencies. Reasons for this are identified. These include the often inadequate information provided to officers attending the homes of such victims, together with their failure to recognize the cumulative effects on victims of crimes which taken individually may not be of great seriousness. The typical failure of victimization surveys to reflect the extent of chronic victimization is bewailed and remedies suggested.

Fundamentals

Let us start with an appeal to your personal experience. Please bring to mind a fellow pupil at school, a fellow student at college, a colleague at work, or someone in your neighborhood who is or was subjected to repeated verbal or physical attack, practical jokes, or theft or damage to their property. Everyone whom the first author has approached with this modest task has been prompt in their nomination of such a person and often very voluble and detailed in their description of what the person nominated has suffered. The case which most embarrassed British police in recent years was that of Fiona Pilkington, who killed herself and her disabled daughter rather than suffer continued victimization at the hands of young people living near her, about which she had called police 33 times without effective action being taken. The Independent Police Complaints Commission concluded:

> Police missed several opportunities to take robust action, inadequately investigated criminal allegations on some occasions and failed to record information on their own intelligence system.(http://www.bbc.co.uk/news/uk-england-leicestershire-13504618 accessed August 16th 2012)

The Chief Constable of the force concerned, Leicestershire, apologized unreservedly for police shortcomings in the case, mention of which ever since has sent a frisson of anxiety through senior police officers who are all too aware that chance rather than professionalism has saved them from similar embarrassment. When Fiona Pilkington died, the Home Secretary of the day said that there were “some hard lessons to learn about past failures, which will be the subject of further investigations.” The shadow Home Secretary concurred, “This case has horrified the nation” (http://www.guardian.co.uk/uk/2009/sep/28/fiona-pilkington-suicide-mother-police accessed August 16th 2012).

The Pilkington case was far from the only occasion when senior police officers have been called on to apologize for cases of chronic victimization which failed to “get above the radar” and trigger official action. On recent case was that of a pedophile ring which organized sexual abuse of children (http://menmedia.co.uk/manchestereveningnews/news/s/1493200_police-council-and-cps-apologise-for-failures-that-allowed-rochdale-sex-grooming-gang-to-abuse-girls-for-2-years-after-crime-was-first-reported accessed August 16th 2012), where one of the victims “was being driven to different houses or flats where there would be other men waiting. The abuse continued for months, until one evening she was arrested by police for smashing the counter at a takeaway where some of the men met the girls.” “Towards the end,” she asserted, “it could be up to five men in a day, sometimes every day, at least four or five times a week” (http://www.bbc.co.uk/news/uk-england-manchester-17914138 accessed August 16th 2012).

Mark Dyche murdered Tanya Moore. The pair had met at a Young Farmers’ ball and was soon engaged. But in February 2003, Miss Moore, tired of Dyche’s jealous and threatening behavior, ended the relationship. For a year Dyche waged a hate campaign against Moore, which included repeated threats to kill her. In June 2003, he even paid three men armed with baseball bats to rob and beat her at her family’s farmhouse home in Alkmonton, near Ashbourne, Derbyshire. Nottingham Crown Court heard that Dyche, who had a history of terrorizing women, “wanted her hurting, wanted her legs breaking, wanted her eyes gouging out, wanted to be in control.” He offered criminal associates £50,000 to kill her, but when no one came forward, he did it himself, lying in wait on a country road in March 2004 and blasting her in the face with a shotgun. A few days before she was murdered, Miss Moore presented officers with a bundle of threatening text messages from Dyche. Derbyshire Police Federation said that the incidents leading up to Tanya Moore's death were not properly examined due to systemic failures and overwork (http://news.bbc.co.uk/1/hi/england/derbyshire/6109108.stm accessed August 16th 2012).

Sadly the whole of this entry could consist of cases of this kind, but we must move on to some of the relevant research on the topic which satisfied that chronic victimization, serious in itself, can have ultimately fatal consequences.

Why Super Targets?

The use of aggression to establish dominance hierarchies is a commonplace among nonhuman primates and has long been a standard explanation for child behavior (Strayer and Strayer 1976), with sexual aggression among normally heterosexual prisoners also being interpreted in dominance hierarchical terms (Fagan et al. 1996). The stability of dominance hierarchies over time is consistent with such analyses (see Perry et al. 2001). These authors note that aggressive children selectively target their peers, with individual victimization rates becoming stable by the later elementary school years. The consequence is a set of serious adjustment problems being manifested, including depression, anxiety, social withdrawal, low self-esteem, suicidal tendency, avoidance by mainstream peers, and poor school performance. The problems were evident into adulthood (Olweus 1978).

In the classic Milgram studies of obedience, the willingness to inflict pain diminished as the distance from the "victim" increased (Milgram 1974). It is therefore no surprise to find that Internet "trolling" and cyberbullying now feature prominently in the suffering of the multiply victimized (McQuade et al. 2009). Googling "cyberbullying" at the time of writing in August 2012 yields over 53 million hits. As with the multiple victimization of Fiona Pilkington, some cases result in the suicide of the victim (http://www.truecrimereport.com/2010/01/phoebe_prince_15_commits_suici.php accessed August 18th 2012).

As for multiple victimization by offenses against property, a number of studies have reported offender accounts of why they return (Ashton et al. 1998; Shaw and Pease 2000). Most such reasons are self-evident, along the lines of "it was easy," with some laconic explanations as "Big house, small van" and some a little more subtle, as below:

> He went into a house and got a good haul. Two months later, walking by, he saw new stuff so did it again . . . took the same stuff (the replacements). 'If I do a place and its got good stuff in it – I think to myself "I'll come back 2 months later". Guaranteed – y'know what I mean, If it's good I'll come back. I did this geezer once three times before he got a [security] system up there . . . alarm bell. After I saw the alarm I thought . . . ah I'll leave it now.

While the most tragic climaxes to chronic victimization, such as the suicide of Fiona Pilkington and Phoebe Prince, are thankfully rare, the evidence of the long-term effects of school bullying suggests possible widespread sub-fatal effects of chronic victimization by crime.

The central practical issue besetting a police response proportional to harm suffered concerns the dilemma which an attending police office faces in gearing her response to the presenting situation. If the response is geared to the seriousness of the most recent presenting event, it will not be appropriate to the cumulative harm suffered as a consequence of a series of similar events. Unless the officer is apprised of the event history, the response will be too meager. Stated another way, the perennial problem is that sequences of events, none of which individually gets over the threshold of seriousness which demands police action, is often cumulative in its impact on victims. Mandy Shaw (2001) draws a parallel with the classic five stages of bereavement, denial, anger, bargaining, depression, and acceptance. In Shaw's view, chronic victims of crime cannot work through the stages to acceptance because new victimizations overtake them and they return to the initial stage. They never complete the recovery sequence because the offense (or a variant of it) is repeated. Mandy Shaw and Sylvia Chenery (2007) note the particular distress of men whose families are repeatedly targeted since it challenges their self-perceived role as family protector.

Certain crime types almost always render their victims chronically disadvantaged in their everyday life. Such offenses include intrafamilial violence, incest, stalking, and hate crimes, especially when the prevalence of hating is high and the prevalence of victims with a particular attribute (e.g., a particular ethnicity or sexual orientation) is locally low. Lest the tone of this entry seems unremittingly grim, it must be noted that there has been an astonishing change for the better in the perception of such offenses in the last 40 years or so, though we should not delude ourselves that the situation is as yet satisfactory. On BBC Radio's archive channel, warnings about possible offense being caused by dated "humor" are not infrequent. Two examples can be taken from the work of Eric Morecambe and Ernie Wise, British comedians whose material was at the time (1970s–1980s) deemed entirely uncontroversial and would still be judged as such by those who were around at the time. It would still be judged so, that is, *until it was heard again* with current sensibilities in place. When heard 35 years later in 2012, the impression is shocking.

In the radio program *The Morecambe and Wise Show* aired on December 4, 1977, a sketch depicts a couple seeking marriage guidance. One exchange goes as follows:

> *Wife: He put the boot in on me last week.*
> *Husband: A man needs a hobby.*

And the studio audience laughed.

A song whose lyrics now sound like a stalker's anthem passed without comment when first featured by Morecambe and Wise. They are reproduced in full here as a reflection of how far we have progressed since 1970 when the song was written.

> *Anywhere, I will find you,*
> *Don't care where, look behind you,*
> *I'll be there, following you around.*
> *Rain or shine, you won't shake me,*
> *I don't mind, where you take me,*
> *Spend my time following you around.*
> *Now listen, don't you know,*
> *Hiding from me does no good,*
> *Where ever you may go, I'll be in the neighbourhood.*
> *If you fly, I will follow,*
> *I don't care about tomorrow,*
> *As long as I'm, following you around.*
> *If you run, I'll run faster,*
> *Gonna stick, like a piece of plaster,*
> *Get my kicks, following you around.*
> *Get my kicks, following you around.*

Attempts at theoretical explanation of super targets within conventional criminology have been sparse and provisional (Farrell et al. 2005; Tseloni et al. 2010) and will not be dealt with here. Rather, the more important issue is addressed of how super-targeted people fail to come to official notice.

Key Issues/Controversies

Until the last third of the twentieth century, the sole measure of crime was a count of crime known to and/or recorded by the police. This remains, for the purposes of effective police intervention, the key index. A police officer cannot be expected to respond to something of which she remains unaware. Many, sometimes most, crimes are not reported to the police. Let us assume that there is a 50 % chance (0.5 probability) that any household burglary is reported to and recorded by the police. For a household which has been burgled twice, there is thus only a 25 % chance that both burglaries will be reported to the police (because $0.5 \times 0.5 = 0.25$). If three burglaries have been suffered, the probability that all three have been recorded is 0.125, and so on. (This makes the unrealistic assumption that the decision of any householder to report to the police is 50 % for every burglary suffered. This assumption is clearly unrealistic, but alternative assumptions, while they make the arithmetic more complicated, leave the central point untouched). The attrition is even greater if repeat crimes are less likely to be recorded by the police, as found by Mukherjee and Carcach (1998). So multiple victimizations will be diminished in police awareness by dint of non-report or non-recording, if for no other reason. We will never know how many times Fiona Pilkington suffered "low-level" criminality which she did not report to the police. All we know is that on 33 occasions she did report events, and the police recorded the fact. There are other reasons why a police officer responding to a call for service from a multiple victim fails to recognize the fact and extent of prior victimization. Historically, an inability to trace the same people or addresses in police data systems has been a further way in which multiple victimizations has been underrepresented in police data, although this may be declining with improvements in police information technologies. However, we should contrast the experience of those calling the police with the experience of calling large commercial concerns. Over the last 30 years, citizens calling commercial concerns have come to expect the person responding to the call to be able quickly to bring up on screen the caller's address, history as a client, and possibly the brand of toothpaste they use! During this same period of 30 years, however, it seems that the experience of someone calling the police has changed far less.

Police awareness of victimization history remains the key practical information. In a wider sense, knowledge of how chronic victims contribute to the extent and shape of the "crime problem" is equally important as providing a motivation to act. For this purpose, the victimization survey has come to take center stage. It provides a measure gleaned from asking representative samples of the adult population what they have experienced by way of crime over a specified recall period (usually 6 months or 1 year). A key aim of such crime victimization surveys has been to reveal the extent and nature of unrecorded crime. It would reasonably be concluded that victimization surveys would provide a good idea of the extent and nature of levels of chronic victimization. Analyzed in one way, they do. Analyzed in the conventional way, they do not.

In the writers' view, the central obstacle to putting in place routinely a mode of analysis of victimization surveys that adequately represents levels and distribution of multiple victimization has been the central concern of state funders of (expensive) victimization surveys, to see how and where statistics of crime known to the police coincide and where they diverge from statistics of crime which citizens say they have suffered. To do this, certain conventions are adopted which, taken together, have the effect of air-brushing chronic victims from the picture. The one described below is probably the most important and is described fully elsewhere (Farrell and Pease 2007). The example is taken from the British Crime Survey (BCS), but the practice is standard and accounts of the situation in the USA (together with a recent recognition of how the conventions distort the resulting picture of victimization) can be found elsewhere. It should be explained that series crimes are repeated crimes of the same type, committed in the same circumstances, and probably by the same person. It will be obvious to the reader that crimes of violence will be more solidly attributed to the same perpetrator. The BCS Training Notes (Budd and Mattinson 2000) comprise the principal reference point for present purposes. Pages 59–65 of the Training Notes contain the exact SPSS syntax (the software commands) used. The syntax contains the line:

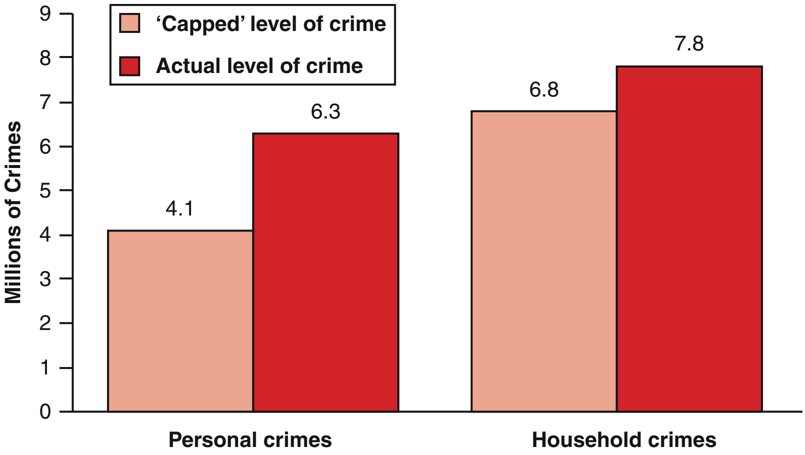
$$\text{If (nseries ge 5) number} = 5.$$

which, translated, means: If there are five or more incidents in a series of crimes reported on a victim form, only five of them are included in the calculation of the crime rates. Simply put, nobody in the UK is allowed to experience more than five crimes in any one series. A woman beaten daily by her partner is counted as having suffered five assaults. Why is this apparently bizarre de-emphasis of multiple victimizations chosen? The BCS Training Guide explains capping as follows:

> For 'series' incidents the number of incidents is capped at 5. Therefore if someone reports 10 incidents in a 'series' only 5 are counted. The limit is to avoid extreme cases distorting the rates. (Budd and Mattinson 2000, p. 32)

Let us consider the interesting use of the word "distortion" here. Does it mean that chronic victims are presumed to be lying? If so, the belief

Multiple Victims and Super Targets, Fig. 1 'Capped' vs actual England and Wales crime (British Crime Survey 2005–2006)



remains unstated although hinted at. When frequency distributions are examined for particular types of crime, the frequency of crimes said to have been suffered clusters around easy decimal system reference points: 10, 20, 30, 40 incidents, and so on, a phenomenon found elsewhere (Rand and Rennison 2005). There is also some indication of clustering around monthly reference points: 12, 24, and 36. These patterns are to be expected, and almost certainly reflect a tendency of respondents and interviewers to round, or approximate, to easy reference points (Rand and Rennison 2005). If interviewers suggest they were victimized "about" once per month, then an interviewer who is encouraged to report precise numbers would record 12 incidents. Analytically, such clustering is not a problem as discrepancies would be expected to be normally distributed around the cluster values. Any suggestion that this use of easy reference points compromises the veracity of victims is offensive. If you have been assaulted 47 times, rounding to 50 does not make you a bad person. So what is the "distortion" alleged to result from taking crime victims at their word? What it really means is that the overall incidence of crime would be more variable if it allowed chronic victims to be represented properly. Chronic victims being (thankfully) relatively uncommon, the crime incidence yielded by the survey would depend substantially on how many chronic victims were sampled. This would make the comparison with police statistics more problematic.

In short, the capping of series crimes at five events is a flagrant example of statistical convenience taking precedence over an accurate understanding of the distribution of human distress. As noted above, there are alternative approaches, for example the use of the Gini coefficient, which measures inequality and has been applied to crime victimization (Tseloni and Pease 2005). There has been a recent modest attempt to move toward the position advocated above by the US Bureau of Justice Statistics (BJS) (Lauritsen et al. 2012). It states the Bureau's intention as follows.

> Given the findings from this research, BJS will enumerate series victimizations using the victim's estimates of the number of times the victimizations occurred over the past 6 months, capping the number of victimizations within each series at a maximum of 10. This strategy for counting series victimizations balances the desire to estimate national rates and account for the experiences of persons with repeated victimizations while noting that some estimation errors exist. (p. 3)

While applauding the direction of movement, the objection in principle remains, with the stability of national estimation being given equal status with the facts about people whose lives are blighted by suffering multiple crimes, thereby becoming "super targets." The extent of the resulting difference in estimates of national crime incidence, particularly for crimes against the person, is evident from Fig. 1 below.

The "fat" tail of the victimization distribution arguably contains the bulk of the problem of crime and of the suffering inflicted upon its victims. There is an unanswerable case for crime counts and policing responses to reflect this. In fact, and to our collective shame, statistical and methodological convention has hitherto served to deflect attention from this fundamental truth.

Overview

This entry describes the issues associated with conducting multisite trials in criminal justice settings, including how to determine the interventions to be tested, the selection of control groups, and the potential threats to internal validity of the trial, and gives two real-world examples of trials conducted and how they were managed and analyzed.

Introduction

Researchers conducting an experiment must decide on the type of design and the number of sites to include. The latter decision is one that receives little attention. As previously argued by

Weisburd and Taxman (2000), multicenter trials have many advantages, including the opportunity to test a new protocol or innovation within various settings. Single-site trials provide a starting point to test out the feasibility of a new innovation, but multisite trials have a clear advantage in testing the innovation under varied conditions. The multisite trial may offer the potential to accumulate knowledge more quickly by using each site as a laboratory for assessing the characteristics or factors that affect the question of "value-added" or improved outcomes. It creates the opportunity to simultaneously test the innovation as well as learn from the sites about the parameters that affect outcomes. Multisite trials provide insights about areas where "drift" may occur, whether it is in the innovation, the management of the study, external factors that affect the innovation, or the inability of the environment to align to the innovation.

This entry provides insight into the complexity of a multisite trial and how different design, site preparation, and research management characteristics can affect the integrity of the experiment. Case studies of two recently completed multisite trials that involve complex innovations or innovations that involve more than one operating agency are used. In these case studies, the various types of threats to internal validity of the trial are used as a conceptual framework to illustrate the decisions that researchers must make in a study.

The Multisite Trial

While randomized control trials are the "gold standard" of research, they are often challenged by design and implementation issues. Adding diverse sites complicates matters, particularly when the goal is to develop a standardized protocol across sites and the study sites have a wide range of expertise and resources. These issues can be even more pronounced in criminal justice settings, where design considerations are often impacted by the structure and administration of local, state, and federal agencies. While there has been a push for more randomized trials in the criminal justice field (Weisburd 2003), the number of randomized studies remains relatively low to the field of medicine, substance abuse, education, and other similar disciplines.

The first step of a multisite trial is to develop a study procedure detailing the intervention for the study sites and research team. The protocol should have (1) the rationale for the study, (2) a description of the intervention, (3) a list of the procedures to implement the study, (4) a copy of the instruments and key measures, and (5) human subject procedures including consent forms and certificates of confidentiality. This protocol is needed to provide the guidance in terms of implementation of the study in real-world settings. The protocol should consider the unique characteristics of the sites involved, particularly if these characteristics are likely to impact findings or influence the fidelity of the intervention. Up-front analyses of these issues, through pipeline or feasibility analyses or piloting of procedures, will increase the likelihood that the trial is uniformly conducted across study sites. The goal is to mitigate differences, which reduces the need to control for these issues during the analytic stage. The issues to be addressed in the protocol are:

Rationale for the Study. Every trial has a purpose that should be specified in study aims and hypotheses. The rationale provides a guidebook as to why the trial is necessary and what will be learned from the trial.

Theoretical Foundation. Trials are about innovations, either the introduction of a new idea or a change in existing procedure or process. The innovation should be guided by theory which explains why the new procedure or process is likely to result in improvements in the desired outcomes. It is important to ensure that each component of the procedure is theory-based to provide an explanation of why the component is needed as part of the innovation.

Defining the Study Population. Based on the study aims, the criteria for inclusion and exclusion should be specified to ensure that the innovation reaches the appropriate target population. Generally inclusion criteria relate to traits of the individual or setting. But in real-world criminal justice settings, other selection forces may be present that are a function of the process or environment. Researchers may not have access to the full base population, which can potentially bias results. Wardens or correctional officers may decide that offenders under certain security restrictions are ineligible for study participation. Selection forces can vary between study sites because of factors that are often not evident. Also, sites may operationalize selection criteria differently. A recent article on multisite trials in health services research recommended that the lead center develops selection criteria but allows each site to operationally define these criteria given the local environment (Weinberger et al. 2001).

Defining the Intervention: The innovation that is being tested should, by definition, be different than traditional practice. As discussed above, the intervention needs to be outlined in detail, including theoretical rationale, dosage and duration, procedures essential to implementation, and core components that will be tracked using fidelity measures (Bond et al. 2000). Most interventions consist of different components that are combined to produce the innovation. It is important to specify who will implement the intervention and how they will become proficient in the skills needed to deliver the intervention. Clear delineation of how the innovation will be integrated into the existing infrastructure of an organization and what potential issues are expected to occur and how these will be handled is also needed.

Defining the Control Group(s) or Practice as Usual: The main purpose of the control group is to serve as a contrast to the innovation. The control group represents practice as usual. This group is expected to have the same distribution of other factors that could potentially affect outcomes as the treatment group, which avoids the possibility of confounding. Randomization gives each eligible subject an equal chance of being assigned to either group in a two-armed design. Blinding, in conjunction with randomization, ensures equal treatment of study groups. In general, the services received by the control group should follow the principle of equipoise, meaning that there should be uncertainty about whether the control or the experimental condition is a better option (Djulbegovic et al. 2003). It is important for the hypotheses to be concerned about how alternative strategies (including treatment as usual) impact outcomes.

Measurement and Observations: Another important component of a study is how effects what instruments that is, will be used to measure outcomes and how and when these instruments will be used. Dennis and colleagues (2000) outline four types of variables to be collected: design variables (sites, study condition, weights, etc.), other covariates (demographics, diagnoses, etc.), pre- and post-randomization intervention exposure, and pre- and post-dependent variables. Most experiments have multiple waves of data collection. Outcome measurements are subject to a number of potential biases, including recall bias (self-report), sensitivity and specificity issues (biomedical tests), and rater error (file reviews). The types of data to be collected should be based on the hypotheses to be tested and the availability and cost of data. Multiple sources of measurement are recommended for the main outcomes, such as self-report and urine testing for drug outcomes.

Quantitative Analysis: The analysis of multisite trial data is dependent on the types of measures collected and the format of the variables. While the trial is ongoing, interim analyses may be conducted, mainly for data monitoring purposes. Some trials in the justice system require oversight from a data and safety monitoring board (DSMB). A DSMB reports on a regular basis to determine if subject flow and follow-up are adequate and if treatment effects are evident in the data. These interim data runs often utilize t-tests, ANOVAs, or effect sizes

(Cohen 1988). For more formal analyses, multivariate models are used to account for the repeated measures and multisite designs. With repeated measures data, hierarchical models can be used, which nest observations within person over time (Raudenbush 2001). Different types of these models are available including latent growth models (LGM), which capture individual differences in change trajectories over time (Meredith and Tisak 1990).

A multisite trial allows for the ability to pool the overall and specific impacts of treatment within separate sites in the context of a single statistical model. The sites in a multicenter trial can be seen in this context as building blocks that can be combined in different ways by the researchers. The randomization procedures allow each center to be analyzed as a separate experiment as well as combined into an overall experimental evaluation where the researcher is able to identify direct and interaction effects in a statistically powerful experimental context.

A multisite study is not a multicenter study where there is a random sample of sites themselves. Without a random sample of sites, a number of restrictions must be placed on the generalizations that can be made and the type of statistical models that can be estimated. Site must be defined as a fixed factor in the statistical models employed, because of the possible variations in the context of the sites. It is important to consider that the generalizability of these effects is limited and cannot be applied to the larger population.

Weisburd and Taxman (2000) recommend a statistical process for using mixed-effects models in analyzing multisite studies. A model for this example is presented in Eq. 1 below.

$$Y = \mu + S_i + T_j + ST_{ij} + O_{k(i,j)} + e_{k(i,j)} \qquad (1)$$

Tj is the treatment effects averaged across sites to obtain larger population of centers for the mixed-effects model.

S_i is the average impact of a site (or center) on outcomes, averaged over treatments.

ST_{ij} is the interaction effect between treatment and site, once the average impacts of site variation and treatment variation have been taken into account.

$O_{k(i,j)}$ is nested within a site by treatment combination.

Tools to Monitor Implementation: CONSORT Flow Charts in CJ Settings

Understanding the flow of subjects through the different phases of an experiment is important to manage the quality and integrity of the experiment. In multisite trials, subject flow may be influenced by facets of the particular criminal justice system, the behavior of study subjects, and/or factors that are difficult to identify. In 2001, the Consolidated Standards of Reporting Trials (CONSORT) statement was issued as a way to improve the reporting of information from experiments in healthcare (Moher et al. 2001), and it has now become a standard that experimenters strive for in social policy areas like criminal justice. The CONSORT flow chart illustrates how to report subjects through each trial phase; it was amended in 2008 to specifically address issues related to non-pharmacologic treatments (such as different types of therapy or different modes of sanctions). A copy of the amended chart is in Fig. 1 (Boutron et al. 2008). The CONSORT chart provides documentation for each phase of the experiment and provides sufficient information to assess the quality of the implementation of the experiment. The CONSORT chart is a standardized reporting format that clarifies the steps in the study and the attention to recruitment and retention issues.

This section describes the CONSORT flow chart for non-pharmacologic treatments (Fig. 1) as it relates to implementing trials in criminal justice settings. The unique challenges presented by these settings not only include the target population as potentially vulnerable to coercion and exploitation but also reflect the difficulties of work in settings that are, by their nature, authoritarian and often not amenable to the rigors of randomized trials.

Multisite Trials in Criminal Justice Settings, Fig. 1 Sample CONSORT flowchart for non-pharmacologic treatments

The first section concerns eligibility. Most trials involve decisions about specific inclusion and exclusion criteria that should be in place for the trial so that the results can be generalizable to the appropriate population. The identification of people that fit the desired criteria may involve a multistep process. For example, a specific protocol may require the exclusion of sex offenders. This will require the research project to define the term "sex offenders" and then develop specific criteria to meet this term. In practice, researchers will generally need to conduct a prior chart review of offenders to make a determination of which offenders might meet the eligibility criteria. This screening often occurs before the consent process and baseline research interview. Other types of eligibility criteria are offense or location specifics, age or gender, language, or other characteristics. In general, screening criteria should be geared toward obtaining a study population that would be appropriate for the intervention. The questions for the CONSORT chart are how many subjects meet the criteria and what process is used to identify the target population. This defines the intent to treat group.

Prior to randomization, subjects may be dropped from the study because they fail to meet screening criteria or refuse to participate in the study. Once they are randomized, they may either receive their allocated intervention or they may not receive it for a variety of reasons including not meeting the eligibility criteria when they are interviewed, dropping out of the study, transferring to another CJ facility, or having a change in criminal justice status. All of these are examples of post-randomization factors that may affect participation in a study. The randomization process is such that once a subject is assigned to a condition, they are eligible for follow-up even if they only receive a partial dosage of the intervention or they did not complete the period of time devoted to the intervention.

The provider allocation section of the CONSORT chart was added in 2008 and characterizes the settings where the treatment(s) takes place. The researcher needs to identify all of the potential settings that might be involved in the experiment. These could be treatment facilities, jails, prisons, probation offices, courts, or other areas. Included are the number of providers, teams, and/or centers and the number of subjects in each area. Each organization will have different characteristics, and these require documentation.

A key issue is the follow-up rates for subjects in each arm of the study. The documentation should include the number that has been followed up and the reasons for missed follow-ups. Reasons for attrition from a study are critical to ensure sufficient power for the analyses. It is important to document follow-up rates at each wave, along with reasons for exclusions of any cases.

The last component of the CONSORT documentation is the results from the final outcome variables that relate to the study aims and the timing of all variables. The researcher is also required to document any assumptions that were made about the data.

Some criticisms have been made of the lack of detail present in the CONSORT chart, specifically the lack of information on implementation details. As our case studies demonstrate, the CONSORT chart does not capture a number of issues that can present threats to the internal validity of a multisite trial. Other scales and checklists have been developed to measure the quality of randomized trials, including the Balas scale for health services research (Balas et al. 1995) and the Downs scale for public health research (Downs and Black 1998). A review of these scales found little widespread use of them and also found that most had not been tested for construct validity or internal consistency (Olivo et al. 2008).

Case Studies of RCTs in Criminal Justice Settings

The following section present case studies of two RCTs that were implemented in settings covered in the Criminal Justice Drug Abuse Treatment Studies (CJDATS), a ten-center research cooperative sponsored by the National Institute on Drug Abuse from 2002 to 2008. Part of the objective of CJDATS was to use rigorous scientific methods to conduct studies in criminal justice settings. The purpose of the studies was to conduct trials at the point where offenders transition from incarceration to the community, referred to as the structured release or reentry process. The studies involved numerous agencies including prisons, probation/parole departments, prison or community treatment providers, and nonprofit organizations.

The case studies illustrate the issues regarding study design and management.

The conceptual framework for this analysis is the threats to internal validity that are specified in many textbooks on conducting social experiments (Campbell and Stanley 1966). By examining these issues, as well as looking at how the investigators managed the study, researchers can learn about the issues inherent in implementing multisite trials.

Threats to Internal Validity

- *Confounding*: The degree to which a third variable, which is related to the manipulated variable, is detected. The presence of spurious relations might result in a rival hypothesis to the original causal hypothesis that the researcher may develop.
- *Selection (bias)*: Both researchers and study participants bring to the experiment many different characteristics. Some of these characteristics that may not have been included in the eligibility criteria but may influence who participates in an experiment. These factors may influence the observed outcomes. The subjects in both groups may not be alike in regard to independent variables.
- *History*: Study participants may be influenced by events outside of the experiment either at the onset of the study or between measurement periods. These events may influence attitudes and behaviors in such a way that it might be detectable.
- *Maturation*: During the experiment, subjects may change and this change may result in how the study participant's reacts to the dependent variable.
- *Repeated testing*: Conducting multiple measures over period of time may result in bias on the part of the study participants. These impacts may occur from the failure to recall correct answers, or the prospects of being tested.
- *Instrument change*: An instrument used during the experimental period could be altered.
- *Mortality/differential attrition*: Study dropouts may be the result of the person, the experiment, or the situation. An understanding of reasons for the attrition and the differential rates of attrition can address the issue of whether the attrition is natural or due to some other factors.
- *Diffusion*: The experimental category should be different than traditional practice and movement from the experimental to control group or vice versa may pollute the assigned conditions.
- *Compensatory rivalry/resentful demoralization*: The control group behavior could be tainted by the result of being in the study.
- *Experimenter bias*: The researcher or research team may inadvertently affect the experiment by their actions.

Step'N Out: An RCT at Six Parole Offices in Five States

Step'N Out tested an integrated system of establishing target behaviors for offenders on parole, known as collaborative behavioral management (CBM). CBM requires the parole officers and treatment counselors to work together with offenders over a 12-week period, using a system of graduated sanctions and incentives. A more detailed description of the study can be found elsewhere (Friedmann et al. 2008).

Theoretical Intervention. CBM has three major components. First, it articulates parole and treatment staff roles, as well as the offenders and also makes explicit the expectations of each party. The clarification of expectations is covered in role induction theory where the emphasis is on clients understanding the roles and responsibility of different functions of the process. Second, a behavioral contract defines the consequences if offenders fail to meet those expectations. The behavioral contract specifies concrete target behaviors in which the offender is expected to engage in on a weekly basis; these target behaviors include requirements of supervision and formal addiction treatment and involvement in targeted behaviors that compete with drug use (e.g., getting a job, enhancing nondrug social network). Third, it regularly monitors adherence to the behavioral contract and employs both reinforcers and sanctions to shape behavior. The motto is "Catching People Doing Things Right," which is to say, the intervention creates the conditions to notice and reward offenders for achieving incremental pro-social steps as part of normal supervision (covered in the research literature on contingency management).

The CBM contract specifies expectations in terms of concrete target behaviors that the offender must meet before the next weekly session. These target behaviors are managed using a computer program which prints out a contract with copies for all three parties to sign and keep for their records. The CBM contract is monitored weekly to expedite identification and reinforcement of compliance and sanction of noncompliance, and then the contract is renegotiated and printed for the following week. Compliance with the contract earns points and, when preestablished milestones are reached, material and social rewards.

Control Condition. Offenders were supervised by the assigned parole officer in the normal manner that was used by that jurisdiction ("treatment as usual"). As shown in Table 1, each site had different standards for parole visits and drug testing.

Study Sites. Five CJDATS centers participated in Step'N Out – the University of Delaware (Wilmington parole office), Brown University/ Lifespan Hospital (Providence parole office), UCLA (Portland, Oregon, parole office), Connecticut (Bridgeport and Hartford parole offices), and George Mason University (Richmond, Virginia, parole office). All sites except Connecticut had one parole officer and one treatment counselor assigned to the CBM condition at their sites. In Connecticut, two or three officers were trained in CBM at each site, with one counselor also trained at each office.

Site Preparation. The initial two-and-half-day training for the Step'N Out teams occurred in December 2004. This training brought together parole officer and addiction counselor teams and their supervisors. After an overview of the intervention, most of the training focused on having each team practice skills in case-based role-plays with reinforcement and corrective feedback. A checklist of the key elements for fidelity to the protocol guided the role-plays and feedback. The teams were encouraged to negotiate roles with regards to initiating the role induction discussion, establishing goals, and setting target behaviors, but the protocol recommends that the parole officer (PO) takes primary responsibility for rewards and sanctioning and the counselor oversees problem-solving.

Additional on-site trainings were also done due to the lag time between the initial training and the time that sites began recruitment, the addition of new sites, and staff turnover. A 2-day booster training session in September 2006 focused on enhancing both the fidelity and finesse with which teams delivered the intervention.

POs were also asked to tape selected sessions. Feedback on the sessions was to be given on a monthly basis to build the skills of the POs in using the contingency management procedure.

Study Implementation. Table 2 outlines the issues encountered in implementing the study across the five sites. One of the first challenges was the point of randomization. Because those who were randomized to the CBM condition had to be assigned to a specific officer (the one who had received the CBM training), randomization had to occur at a point where PO assignment had not yet happened. This point varied among sites, with some assigning POs prior to an offender's release from prison, while others assigned the officer once the offender appeared at the parole office. While the ideal situation was to randomize at the parole office where the intervention was occurring, this was not possible in Delaware and Rhode Island. At those sites, the agency practice was to assign the officer prior to an offender's release, so screening and randomization were done while the offender was still incarcerated; this allowed the offender who was randomized to CBM to be assigned to the CBM officer. In Oregon, randomization began at the parole office, but recruitment was very slow in the initial months of the study and it was determined that the research staff had a better working relationship at the prisons; thus, recruitment was moved to the prison after

Multisite Trials in Criminal Justice Settings, Table 1 RCT implementation issues for Step'N Out

Issue	BP/HT	DE	OR	RI	VA
Place of randomization	Parole office	Halfway house	Parole office, switched to prison	Prison	Parole office
Selection bias	BP – 2 persons randomized but did not make initial parole session (CBM = 1, control = 1); HT – 2 persons (CBM = 1, control = 1)	85 offenders were not released to parole (CBM = 42, control = 43)	3 offenders not released (all control)	1 offender not released in CBM	Gang members were excluded
History	An event occurred (a parolee committed homicide) that resulted in a crackdown on parolees which increased violations			Recruitment was suspended in 2005. All subjects recruited were dropped from the study. Recruitment began again in July 2006 with offenders placed on electronic monitoring	
Maturation – time to touch-base session	6.1 days (0–27 days)	68.3 days (0–470 days)	51.6 days (0–175 days)	17.1 days (5–69 days)	10.7 days (0–78 days)
	CBM = 5.9 vs. control = 6.2 for Bridgeport	CBM = 47 vs. control = 92.8	CBM = 51.2 vs. control = 52.1	CBM = 9.8 vs. control = 20.4	CBM = 10.4 vs. control = 10.9
	7.7 days (2–25) for Hartford				
	CBM = 7.4 vs. control = 12				
Mortality/ differential attrition – 3-month FU	3M FU BP:	3M FU:	3M FU:	3M FU	3M FU
	CBM = 100 %	CBM = 98.9 %	CBM = 79.4 %	CBM = 100 %	CBM = 79.5 %
	Control = 100 %	Control = 97.9	Control = 87.5 %	Control = 85.7 %	Control = 91.3 %
	3MFU HT:				
	CBM = 100 %				
	Control = 95.7 %				
Mortality/ differential attrition – 9 months	9M FU BP:	9M FU BP:	9M FU:	9M FU:	9M FU:
	CBM = 97.2 %	CBM = 97.2 %	CBM = 73.5 %	CBM = 88.2 %	CBM = 64.1 %
	Control = 97.2 %	Control = 97.2 %	Control = 90.6 %	Control = 78.6 %	Control = 78.3 %
	9M FU HT:	9M FU HT:			
	CBM = 92.3 %	CBM = 92.3 %			
	Control = 82.6 %	Control = 82.6 %			
Selection-maturation interaction (average)	Control group saw parole Officers once a month	Control group saw parole Officers once a week	Control group saw parole Officers two times a month	Control group saw parole Officers once a week	Control group saw parole Officers once a month
Diffusion		Possibly in group SA sessions since treatment sessions for control and CBM at parole office			Possibly in group SA sessions as treatment for both control and CBM was at parole office

(*continued*)

Multisite Trials in Criminal Justice Settings, Table 1 (continued)

Issue	BP/HT	DE	OR	RI	VA
Compensatory rivalry		Anecdotal stories of resentment by control subjects of material and social rewards given to CBM			
Experimenter bias	Had a number of POs implementing CBM at each site, may have been differential implementation by PO, POs also had none CBM clients, may have diluted effects	Changed CBM POs partway through the study, may have had different implementation styles	Changed CBM counselor partway through process, may have different implementation styles		CBM PO felt isolated, also had substantial non-CBM clients, may have diluted effects

Multisite Trials in Criminal Justice Settings, Table 2 RCT implementation issues in HIV/Hep C Study

Issue	DE	KY	VA
Place of randomization	Halfway house	Prisons (2 male, 1 female)	Local jail
Start of follow-up	Randomization	Release date	Release date
Selection bias	Unknown selection forces for initial groups – had 406 randomized but only 391 released (96.3 %)	Unknown selection forces for initial groups – had 184 randomized but only 125 released (67.9 %)	Unknown selection forces for initial groups – had 113 randomized but only 67 released (59.2 %)
History	A confidentiality breach in DE on a different project shut down interviewing and recruiting until new processes were put in place	KY was unable to recruit in the men's prisons	Jail staffing issues and changes in security procedures affected recruitment; suspended for 2 months
Maturation		Longer time between randomization and follow-up than DE because of release dates	Longer time between randomization and follow-up than DE because of release dates
Repeated testing			
Mortality/differential attrition	30-day FU: Std = 98 %; NIDA = 100 %; DVD = 99 %; 90-day FU: Std = 98 %; NIDA = 98 %; DVD = 96 %	30-day FU: Std = 100 %; NIDA = 76 %; DVD = 92 %; 90-day FU: Std = 100 %; NIDA = 85 %; DVD = 92 %	30-day FU: Std = 90 %; NIDA = 73 %; DVD = 94 %; 90-day FU: Std = 75 %; NIDA = 60 %; DVD = 88 %
Selection-maturation interaction			
Diffusion	All arms of the study were all housed in the same facility for a period of time. Those in the intervention arms could share information with those in the control arms	All arms of the study were all housed in the same facility for a period of time. Those in the intervention arms could share information with those in the control arms	All arms of the study were all housed in the same facility for a period of time. Those in the intervention arms could share information with those in the control arms
Experimenter bias	Changed DVD interventionist partway through the study, also changed NIDA standard interventionist. Occasionally had same person do both arms		

6 months. In the end, half of the sites were randomizing in prison and half were randomizing at the parole office.

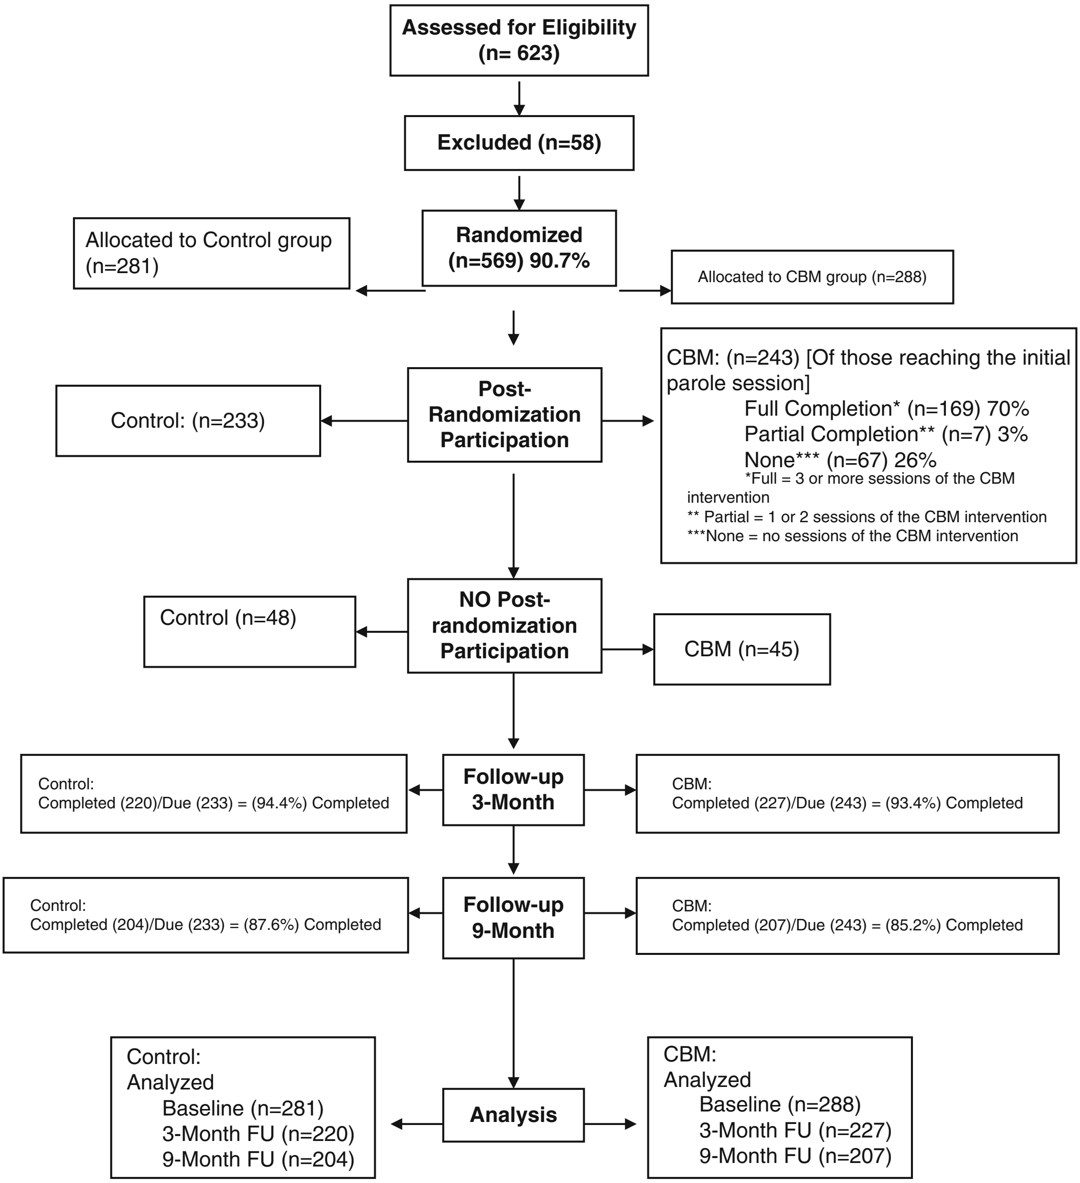
A consequence of the place of assignment is that not all randomly assigned participants were exposed to the intervention. A substantial portion of those who were randomized in prison never made it to the parole office. In Rhode Island, this was due to the fact that many offenders "flattened" in prison, or served out their parole sentences in prison, because of the unavailability of space in halfway houses where offenders were assigned upon release. In Delaware, many offenders committed violations in the halfway house that resulted in them being returned to prison before they could begin their parole sentence. This group of "post-randomization dropouts" was problematic, because they were technically part of the study population to be followed, yet they were not exposed to the intervention or any study activities. Many had no time in the community post-randomization. Rhode Island dropped their initial cases and changed their recruiting practices so that all of their cases were to be placed on electronic monitoring after release. Delaware also changed their recruiting to make their screening closer to the initial parole session. These measures drastically reduced post-randomization dropouts. The final CONSORT chart for Step'N Out is given in Fig. 2 (note that when the study was done, the revised CONSORT for non-pharmacologic interventions had not yet been published). There were a total of 93 post-randomization dropouts, with the majority (n = 85) from the Delaware site.

The "place of randomization" turned out to be a significant confounding variable in statistical analyses. Since the studies had different places of randomization (i.e., prior to release from prison, at the parole office, etc.), we were able to disentangle the impact of place of randomization on the study outcomes. Also, as is shown in Table 1, other selection forces also occurred during the study at different sites. In Virginia, gang members were never sent to the research interviewer for screening because a special program for gang members was being conducted with an assigned PO.

Another important site difference in implementation was the time it took for a person to begin the intervention after randomization. In some sites, those in the CBM group were able to begin parole services sooner than those in the control group, perhaps due to the availability of a dedicated PO for the CBM intervention who did not have the same large caseloads as other officers. In both Delaware and Rhode Island, it took about half the time for those in CBM to begin parole services as compared to those in the control group. This affects the outcomes which may be a function of the timing rather than the superiority of the CBM intervention attributes (MacKenzie et al. 1999).

The follow-up clock for Step'N Out began with the date of the first parole session (the "touch-base" session). Because the time to the touch-base session was longer for some subjects than for others, the time to the follow-up interviews also varied. In some cases, the 3-month follow-up occurred about 3 months after randomization (when randomization occurred close to the first parole session), but in other cases, there was over a year of time between randomization and the first parole session resulting in over 15 months between the baseline and the 3-month follow-up. While the follow-up was capturing the first 3 months on parole, there was a wide variation in how much time had elapsed since randomization for each subject. It was also complicated since some sites (Delaware) tended to have different timing between follow-up periods.

An attrition-related issue involved missed follow-ups. The Delaware center, which had the largest number of clients in Step'N Out, had staffing issues during the project and missed the 3-month follow-up window for a number of subjects. Because the main outcomes relied on data from the 3-month interview, provisions were made to obtain these data at a later date. At the 9-month interview, a full timeline follow back was completed for these subjects which included all time back to the initial parole session. The chances for historical and maturation issues were increased by this procedure, especially



Assessed for Eligibility (n= 623)

Multisite Trials in Criminal Justice Settings, Fig. 2 CONSORT flowchart of participants in Step'N Out study

with the different time frames for data collection across the various sites. This strategy allowed for the study to obtain needed outcome data, but it also created potential recall issues, where subjects were asked to self-report drug use, arrest, crime, and living situation data on a daily basis up to 18 months after it occurred. The varying lengths of the follow-up period may also have affected the integrity of the data.

An issue that was inherent to the specific criminal justice systems in each state was the status of the control group. Because this group received parole and treatment services "as usual" in each state, the services received by the control group were not uniform across all sites, as shown Table 1. In some sites, parole officers met with subjects once a month; in others, once a week. These were due to standard conditions of parole, but other variations could occur because individual offenders had different conditions which required different schedules. The same issues applied to substance abuse treatment. While the screening instrument used to assess eligibility ensured that those in the study had substance abuse dependency issues, it was not required that members of the control group would receive treatment since this decision depended upon the local parole systems. Not all parole officers recommended their clients for treatment. Thus, variations occurred in the conditions under which the control group was supervised both within a site and across sites.

The HIV/Hepatitis C (Hep C) Study: A Three-Armed RCT at Three Centers

This RCT was designed to test the efficacy of a criminal justice-based brief HIV/HCV intervention administered during the reentry period. Rates of both HIV and hepatitis C are disproportionately high for those involved in the criminal justice system, and the reentry period has been found to be a particularly risky time for offenders. This study was a three-group randomized design, with participants assigned to the following: (1) current practice, a group of transitional releases who saw an HIV awareness video shown as part of group sessions in the facilities in the prerelease process; (2) the NIDA Standard Version 3 HIV/Hep C prevention intervention delivered by a health educator via cue cards in a one-on-one didactic setting; and (3) the CJDATS Targeted, a near-peer facilitated intervention that used an interactive DVD format with gender/race congruent testimonials, also in one-on-one setting. Participants in all three groups were offered HIV and HCV testing. The full study design has been described elsewhere (Inciardi et al. 2007). The study was conducted by three CJDATS centers, the University of Delaware (lead center), the University of Kentucky, and George Mason University. The main purpose of the study was to test the interactive DVD method to determine if those who were exposed to a gender and culturally specific message had greater reductions in risky behaviors than those that receive the NIDA standard and current practice arms of the study. Follow-ups for this study were done at 30 and 90 days after either randomization or the date of release from prison.

Theoretically Driven Intervention. Based on focus groups with offenders, the study team developed a DVD that addressed issues related to reducing risky behaviors that involve the transmission of HIV/Hep C. The messages were then developed to be consistent with the gender and race (i.e., Caucasian, African American) of the offender. The theory was that the messages delivered in a gender- and culturally specific manner would result in greater compliance. The DVD arm of the study was administered by a near-peer, usually a former addict and/or someone with HIV or HCV. There were four separate DVDs, based on race/gender combinations (black male, black female, white male, white female), and they included testimonials from former offenders and persons infected with HIV and HCV discussing their situations.

Control Conditions. In this study, several treatment as usual conditions were used: (1) traditional practice where a group of offenders were shown an a HIV awareness video as part of group sessions in the facilities in the prerelease process and (2) the NIDA Standard Version 3 HIV/Hep C prevention intervention delivered by a health educator via cue cards in a one-on-one didactic setting (National Institute on Drug Abuse 2000). These represented two different conditions that reflected the "variety of practices" available in the field.

Study Recruitment. Potential participants were shown a video on HIV prevention in a group setting while still incarcerated (see section on setting by site) and were given information about the study and asked if they would like to participate. If they said yes, they were then screened individually to determine eligibility, and if eligible, they went through the informed consent process and were randomized into one of the three arms of the study. Testing for HIV and HCV was done at baseline and was voluntary.

Implementation. Table 2 presents some of the implementation issues of this study. Most of the challenges resulted from the varied settings where the intervention took place. For Delaware, the study was implemented in a halfway house facility, a place which ensured an adequate flow of, and continuous access to, participants. This site selection was convenient but in many ways altered the original intent of the study, as the offenders at this facility were already at risk in the community since they reside in the halfway house but still can spend time in the community. In Kentucky, the study was implemented at a men's prison and a women's prison, while in Virginia it was implemented at a local jail. Because the point of the follow-up period was to obtain information on risky behaviors in the community, the start of the follow-up clock was different according to site. In Delaware, because subjects were already at risk at the time of randomization, the follow-up clock started at the randomization date. In both Kentucky and Virginia, the follow-up clock did not start until the subject was released from the institution. This situation created a number of problems, including the fact that the type of site (prison, jail, halfway house) was completely nested within state and that the time at risk was not comparable among all subjects. Those in Delaware may have had some time at risk prior to being enrolled in the study. While baseline behavior data were gathered for the period prior to the last incarceration, the follow-up data collected may not reflect the same period of initial risk for those in Delaware as for those just released from incarceration in Kentucky and Virginia.

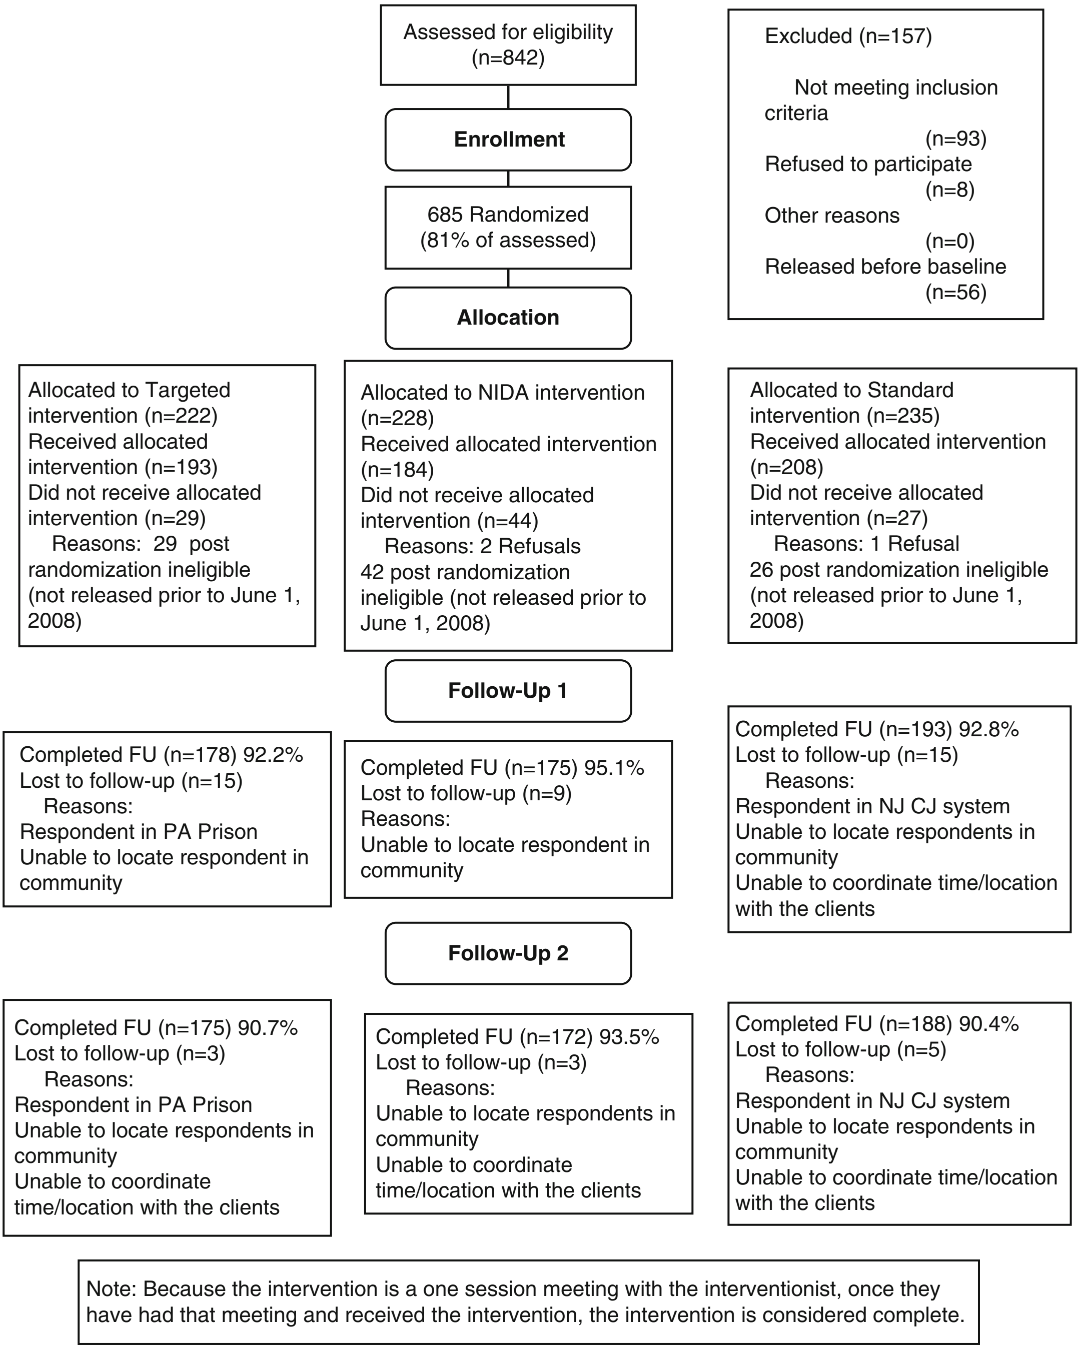
Another issue that may have affected implementation was the initial selection of the group of offenders to watch the video at each site. Generally, these groups were gathered by personnel at the facilities who were given the criteria for the study (offenders had to be within 60 days of release, speak English, and not have cognitive impairments). Researchers were not often privy to the decisions about the type of offenders that participated in the sessions. It may be that different types of groups were selected for inclusion at the different sites.

Since follow-up was dependent on release in both Kentucky and Virginia, a substantial percentage of those randomized were ineligible for follow-up because they were not released during the time frame of the study. While those randomized were initially scheduled for release within 60 days of recruitment, the release date often changed because of pending charges or other issues. In Kentucky, 33 % of the randomized population was never released, and in Virginia, 41 % of the randomized population was not released during the time frame of the study. This issue had the potential to create selection bias and differential attrition. The final CONSORT chart for this study is given in Fig. 3. A substantial number of those assessed were lost both prior to completing the baseline and also post-randomization, because of prison release issues.

Finally, in one site, the same interventionist, a peer counselor, administered the NIDA arm and DVD arm for a period of time. Bias should have been minimized since the interventionists could also do the testing for those in the control arm. There is a potential that the interventionists provided information to that group that was specific to their arm of the study. The interventionists were not blind to the study allocation of the subjects.

Discussion

Multisite trials are important tools to accomplish the scientific goals of (1) testing the efficacy of an innovation; (2) simultaneously "replicating" the study in multiple sites to determine the robustness of the innovation; and (3) allowing the unique characteristics of agencies, communities, and/or target populations to be concurrently examined in the test of an innovation to specify acceptable parameters. The trials represent the science of conducting field experiments but the process also reveals that there is an art in conducting randomized trials. It is the art – the crafting of the experiment, the mechanisms to conduct the experiment, and the daily decisions regarding the handling of "real-world" situations – that determines whether the experiment achieved the goal of testing the theoretically based innovation.



Assessed for eligibility (n=842)
Enrollment
685 Randomized (81% of assessed)
Allocation
Excluded (n=157)
Not meeting inclusion criteria (n=93)
Refused to participate (n=8)

Released before baseline (n=56)
Allocated to Targeted intervention (n=222)
Received allocated intervention (n=193)
Did not receive allocated intervention (n=29)
Reasons: 29 post randomization ineligible (not released prior to June 1, 2008)
Allocated to NIDA intervention (n=228)
Received allocated intervention (n=184)
Did not receive allocated intervention (n=44)
Reasons: 2 Refusals
42 post randomization ineligible (not released prior to June 1, 2008)
Allocated to Standard intervention (n=235)
Received allocated intervention (n=208)
Did not receive allocated intervention (n=27)
Reasons: 1 Refusal
26 post randomization ineligible (not released prior to June 1, 2008)
Follow-Up 1
Completed FU (n=178) 92.2%
Lost to follow-up (n=15)
Reasons:
Respondent in PA Prison
Unable to locate respondent in community
Completed FU (n=175) 95.1%
Lost to follow-up (n=9)
Reasons:
Unable to locate respondent in community
Completed FU (n=193) 92.8%
Lost to follow-up (n=15)
Reasons:
Respondent in NJ CJ system
Unable to locate respondents in community
Unable to coordinate time/location with the clients
Follow-Up 2
Completed FU (n=175) 90.7%
Lost to follow-up (n=3)
Reasons:
Respondent in PA Prison
Unable to locate respondents in community
Unable to coordinate time/location with the clients
Completed FU (n=172) 93.5%
Lost to follow-up (n=3)
Reasons:
Unable to locate respondents in community
Unable to coordinate time/location with the clients
Completed FU (n=188) 90.4%
Lost to follow-up (n=5)
Reasons:
Respondent in NJ CJ system
Unable to locate respondents in community
Unable to coordinate time/location with the clients
Note: Because the intervention is a one session meeting with the interventionist, once they have had that meeting and received the intervention, the intervention is considered complete.

Multisite Trials in Criminal Justice Settings, Fig. 3 CONSORT flowchart of participants in HIV/Hep C study

The analysis in this entry presented the art in terms of issues that have been identified as threats to internal validity (Dennis et al. 2000). We used these tests of internal validity to demonstrate how experimental processes and research designs affect the integrity of, and findings from, an experiment. These two experiments allow us to draw lessons about study management to reduce the degree to which the threats affect the dependent variables:

1. *Confounding*. An important step in reducing the influence of third variables is to conduct three pipeline flows: (1) the research process in each participating site, (2) the core components of the innovation should be outlined to determine what other factors affect the independent variable, and (3) the potential mediators or moderators that may affect the independent variables. All three of these preexperimental processes are important to minimize extraneous variables.
2. *Selection Bias*. The inclusion and exclusion criteria of an experiment are critical in assessing potential sources of bias. But more important than simply analyzing these a priori decisions is to map these criteria to the study population to ensure that the research processes are not affecting selection bias. For example, in the Step'N Out experiment, the researchers in one study site were unaware that the agency did not release offenders without the use of extra controls (e.g., electronic monitoring). Yet, in the early stages of the experiment, when this was discovered, it resulted in consideration of new eligibility criteria. Maps of the system would assist in this process.

   The two multisite trials analyzed here had other selection biases that crept into the study such as the use of different types of recruitment sites in the HIV/Hep C study. While this variation was useful in assessing the elasticity of the innovation across different correctional settings (prison, work release, jail), it introduced new problems, including a large population of post-randomization ineligibles who were not released from the prison/jail within the study period of 12 months. This created a potential bias because it affects the intent to treat group, and the differences in releasees versus detainees must be assessed to determine the degree to which the study protocol affected study outcomes. The use of a historical control group can mitigate issues with selection bias for this part of the population and can also reduce other biases, including diffusion, compensatory rivalry, and experimenter bias. The researcher must usually rely on records to obtain data for the historical group, but this strategy is useful, especially when the experimental condition appears to be clearly superior to the treatment as usual and denying it to a portion of the current population would be unethical. Another related issue is to have a historical control group that could define the base rates for the dependent variables which can assist with understanding whether there was a Hawthorne effect with the study or whether the inclusion and exclusion criteria affect the dependent variable(s).
3. *History*. The impact of events outside of the experiment, either at the onset of the study or between measurement periods, may influence measured outcomes or independent variables. In Step'N Out, a crackdown on parolees in Connecticut occurred during the follow-up period, resulting in a higher number of parole violations than would have otherwise occurred. While it was felt that this event did not differentially affect the study groups, it was presumed that the overall number of parole violations was higher in the study than it normally would have been. This information is important to know and to report with all analyses of the study, especially as parole violations were considered a main outcome and ended up being much lower for the CBM group than the control group.
4. *Maturation*. During the experiment, subjects may change, and this change may result in how the study participant reacts to the dependent variable. In both studies, some sites had longer times between randomization and the follow-ups because of timing and release issues and some subjects also had longer times until their follow-ups were completed. In these cases, it is difficult to determine if the intervention caused positive changes or if more time in the community and exposure to other factors could be a possible cause. Future studies could focus on ensuring that randomization and follow-up schedules are implemented so that there is little room for

variance and that research interviewers are trained to understand the importance of completing follow-ups in the given time windows. For example, studies that focus on the release period could delay randomization until an offender is released to avoid the uncertainty associated with release dates.

5. *Mortality/Differential Attrition*. Study dropouts may be the result of the person, the experiment, or the situation. In some Step'N Out sites, the CBM group had lower follow-up rates at both 3 and 9 months, indicating that offenders may have found it more difficult to complete the CBM intervention and to stay connected with the parole office. The implementation of the intervention at these sites should be explored to determine how it differed from other sites. In Oregon, for example, those participating in CBM had to attend parole sessions at a different office which may have been inconvenient for them. In another site, the CBM officer was required to also maintain a caseload of regular parole clients, and she often had scheduling conflicts with her CBM clients. These issues provide insight into how implementation can affect participation. One suggestion for future iterations of Step'N Out was to have it be an office-based, rather than officer-based intervention, where the entire parole office practiced CBM.
6. *Diffusion*. The experimental category should be different than traditional practice, and movement from the experimental to control group or vice versa may pollute the assigned conditions. While there was no known crossover from one study condition to another, there was potential in both studies for offenders from different conditions to mix with each other and share information. In Step'N Out, one site had a control group that was not dissimilar to the CBM group, as the study site had specialized parole services where POs met with their clients weekly. These POs often used novel methods of sanctions and rewards. In these cases, it is difficult to determine the explicit effects of the intervention under study, as (1) the control group may have been influenced by the intervention and (2) the control group may not reflect current practice accurately. For multisite trials, this variation among current practice at sites is an issue that is often raised. An initial feasibility study at each site should identify potential issues and provide insights on how each site works. Each study protocol should have some flexibility so that it can be adapted to multiple sites but also must specify minimum conditions for the control group that must be met in order for the site to participate.
7. *Compensatory Rivalry/Resentful Demoralization*. The control group behavior could be tainted by being in the study. This is more of a possibility in longer lasting interventions where the treatment under study appears as a "better" alternative to those who are targeted for treatment. In Step'N Out, there was some evidence that persons wanted to be in the CBM condition (often asking for this at randomization) and felt those in CBM were getting an "easy ride." This could lead to resentment from the control group, especially if they were aware that the CBM group would receive material rewards for good behavior and they would not. This could create a disincentive for good behavior for those in the control group, and study results could be biased upward, with results better than they should be under normal circumstances. Researchers should also be careful in using language to describe the study conditions to ensure that the experimental condition is not seen as highly preferable to the current practice and should also work with staff at the agencies to train them not to present the intervention as an improvement or something better, as staff attitudes are usually quickly conveyed to offenders.
8. *Experimenter Bias*. The researcher or research team may inadvertently affect the experiment by their actions. Both of the studies we examined here had interventionists on-site at justice agencies who were not blinded to the study condition assignment of the offenders. Blinding cannot be done for the interventionist in these types of studies as they must know

what condition a person is in so that they can deliver the correct intervention. While a number of measures were in place to ensure fidelity (tapes in Step'N Out, checklists in HIV), there were concerns that POs may have implemented CBM differently at different sites and even at the same site, based on the person involved. The same is true for the health educator and peer interventionist in HIV, especially the peer counselor who had less of a script to work with and used more of their own experience in working with their clients. While the tapes were a good idea in Step'N Out, they were not used effectively as a feedback tool, as there was a long delay in coding and providing feedback to the POs. Because delivery of the intervention is such a key component of the study, researchers should make provisions for ongoing and timely fidelity monitoring of the intervention, with a clear plan on how fidelity will be tracked, how feedback will be provided, and how corrective actions will be taken (Carroll et al. 2007).

As a researcher considers validity threats to a multisite experiment, they should ask themselves the following five questions and care fully consider how the decisions that are made affect the experiment:

1. How does the issue affect the flow of subjects on the CONSORT chart?
2. How does the issue affect inclusion and exclusion (selection forces)?
3. Does the issue disrupt the theory underlying the intervention? Or does it disrupt the treatment as usual?
4. How might the issue affect the dependent variable(s)?
5. How might the issue affect possible confounders?

Conclusion

Multisite field experiments can test an innovation as well as the environment where an innovation can be offered. In addition, the multisite field experiment requires the researcher and/or research team to be even more sensitive to the impact of design and implementation decisions on the integrity of the experiment, as well as the generalizability to the wider target population. This entry has been designed to help researchers think about the issues related to internal validity threats and how to make decisions about the target population, eligibility processes, intervention design and processes, and instruments. Managing one study site presents sufficient challenges, while managing more than one study site requires the researchers and investigator(s) to be cognizant of how each decision at each site might affect whether the goals of the study can be obtained. In both case studies, we have examples where practical realities crept into the experiment. More work will need to be done to determine the impact on the outcome variables. In the end, it is apparent that scientists must also be good research administrators to ensure the study sites uphold the experimental design and that each decision is weighed against the concern about the integrity of the design.

Naming and Shaming of Corporate Offenders

Judith van Erp
Erasmus School of Law, Criminology
Department, Rotterdam, The Netherlands

Synonyms

Disclosure; Publicity sanctions; Reputation sanctions

Overview

Pressure from the social environment of business is a major explanatory factor for corporate compliance. The threat of negative publicity, reputation damage, and social stigma may prevent business offenses or socially irresponsible or unethical business behavior. Therefore, both public and private regulatory actors attempt to activate social control by *naming and shaming* firms that offend legal or social norms. Exposing corporate misbehavior to the public may trigger stakeholders to impose "reputation sanctions" that largely exceed the impact of legal sanctions, such as fines. Public enforcement authorities therefore increasingly make use of publicity in their enforcement strategies, and disclose names of offenders in an attempt to increase the impact of regulatory sanctions. Similarly, NGOs actively "name and shame" firms involved in socially or environmentally harmful behavior to invoke extralegal pressure in the absence of strong formal legal enforcement. This entry addresses naming and shaming as a reaction to corporate crime. It discusses its form, the impact on various types of corporate offenders, and its potential and capacity to prevent corporate crime.

Naming and Shaming: Definition and Goals

A distinction should be made between naming offenders and subsequent shaming. Naming offenders can be a neutral activity when public enforcement agencies disclose names of offenders in the context of transparency about their enforcement results. In his standard work "*Crime, shame and reintegration*," the Australian criminologist John Braithwaite (1989, p. 100) defines shaming as follows:

> Shaming means all social processes of expressing disapproval which have the intention or effect of invoking remorse in the person being shamed and/or condemnation by others who become aware of the shaming.

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

Formal punishment can have a shaming effect, but shaming can also occur as an extralegal punishment: We often speak of shaming sanctions or publicity sanctions. The act of shaming can be performed both by the "naming" authority itself, or as a reaction to more neutral public disclosure of offenders by third parties such as media, consumer organizations, interest groups, or other NGOs. Because no clear demarcation line exists between disclosure of offenders' names and shaming them, it is relevant to conceptualize naming and shaming as continuing scale with more neutral disclosure intended to increase market transparency on the one end and shaming, intended to invoke a negative reaction, on the other end.

A few recent examples:

- The European Directive on public access to environmental information obliges member states to publish names of polluting companies in the European Pollutant Emission Register.
- In many countries, "scores on the doors" of restaurants show the extent to which the restaurant complies with hygiene standards.
- The British Department for Business, Innovation and Skills publicizes names of employers found in breach of minimum wage regulations.
- Financial market authorities, such as the US Security Exchange Commission, the British Financial Services Authority, and the Dutch Authority for Financial Markets, publish sanctions against offending financial market firms.
- Greenpeace campaigns for "greener electronics" by rating consumer electronics producers on an index of their performance regarding responsible for disposal of electronic waste as well as by shaming firms who fail to adequately prevent waste dumping.
- Amnesty International targets Shell for its oil spills in the Niger Delta.

Since naming and shaming comes in many different forms, a variety of goals can be identified. More or less neutral naming of offenders is often associated with the goal of transparency and accountability of regulatory agencies. Many public enforcement agencies systematically disclose offenders' names systematically in a repository of inspection reports, in a public sanction register, or in generic offenders' indices, with the aim of informing the public about their output. Enforcement decisions are visible results of market regulation, and their publication is one of the most direct ways of informing the public of the results of supervision. Transparency can also increase the democratic legitimacy and acceptance of supervision; public trust in market supervision may increase when the public and business become aware that bad practices are being addressed. Publication of sanctions may thus also contribute to the legitimacy of supervision through the creation of an image of "tough" enforcement. The purpose may also be to avoid blame in case of a disaster – publication confirms that the enforcement authority was aware of the problem and did not hide information about risks from the public.

In addition to the general purpose of government transparency, naming offenders may serve a more instrumental goal when it serves to repair information asymmetries in markets. Disclosure aims at contributing to the functioning of markets by providing consumers or other stakeholders with information that may be relevant to their choices. In the context of regulatory offenses, the goal is to enable consumers to include risks or unwanted side effects that result from regulatory noncompliance in their decisions.

Shaming adds a normative element to the publication of offenders' names. It serves to express and invoke public condemnation for the offender and the offense. Therefore, it not only involves the publication of offenders' names, but adds a negative evaluation, such as a press release announcing a regulatory fine or explaining an offense, or placing offenders on a blacklist. Shaming may also consist of more informal and incidental negative comments by public officials. President Obama's remark that BP CEO Tony Hayward "wouldn't be working for me" in the course of the Deepwater oil spill is a recent example. Shaming by NGOs may involve a whole array of advocacy strategies, such as negatively branding a product ("blood diamonds"); targeting a company (Greenpeace's attacks on Nestlé for producing Kitkat with palm oil from endangered tropical forests) to addressing the (ir)responsibility of individual CEOs.

How Does Shaming Work?

Again, a distinction should be made between consumer-oriented disclosure of names aiming at increased market transparency and shaming. In the case of disclosure in the context of market regulation, the audience may react to disclosure by avoiding the product or firm ("exit") or by voicing their concerns and exerting pressure on the company to change ("voice") (Hirschman 1970). Such a consumer-oriented disclosure policy explicitly or implicitly departs from the rational economic assumption that information allows consumers to protect themselves, instead of being protected by authorities. Moreover, the aggregate market pressure coming from consumers' individual actions can also result in third-party enforcement when they "punish" offending companies and "reward" firms with a good compliance status. It is because of this last mechanism that disclosure is considered such a powerful regulatory instrument. Fung et al. (2007, p. 6, 51) describe the process that is triggered by publication of offenses as a chain reaction:

- Information users perceive and understand newly disclosed information.
- They therefore choose safer, healthier, or better-quality goods and services.
- Firms perceive and understand users' changed choices.
- They therefore improve practices or products.
- That in turn reduces risks or improves services.

Theories about shaming generally identify two working mechanisms of shaming: deterrence and moral education (Braithwaite 1989; Ayres and Braithwaite 1992). Naming and shaming may deter firms from offending, because firms fear reputation damage in addition to the costs of the formal legal sanction. A good reputation pays out in terms of confidence of business partners and investors, consumer trust, and goodwill and support of the community and the political and bureaucratic environment. All these assets are necessary for the continuity and growth of a company (Gunningham et al. 2004). Publication of a firm's status as an offender may give rise to negative publicity that may result in reputation damage in the form of loss of clients, employees, business partners, or investors, that add up to the formal costs of sanctions. General deterrence theory has therefore expanded to include the cost of reputation damage in the cost-benefit equation (Williams and Hawkins 1986; Thornton et al. 2005).

Naming offenders may not only increase the cost of sanctions by adding the financial costs of stakeholder reactions, but also by adding nonfinancial reputation damage, such as loss of face, and being shamed in the eyes of colleagues, peers, and relatives. Convicted business people often feel the loss of their status and prestige, and the loss of trust in their authority as corporate executives, as their biggest punishment (Benson 1990). Although impossible to quantify, the threat of being publicly shamed probably deters more than financial reputation damage.

The "moral education" working mechanism in shaming is most prominently outlined in the theory of responsive regulation (Ayres and Braithwaite 1992), the paradigmatic current criminological theory of regulation of corporate compliance. Responsive regulation regards corporate compliance not primarily as a result of fear of legal sanctions, but as a result of a combination of an intrinsic motivation to behave responsibly, and external social pressures, such as fear of negative publicity, reputation damage, and, eventually, fear of legal sanctions. Responsive regulation aims to improve business compliance by connecting with firms' perceptions of appropriate and responsible behavior (Ayres and Braithwaite 1992). Firms are initially addressed with a cooperative, persuasive strategy, and only when firms do not respond, a regulator may escalate with a variety of interventions. A responsive regulatory approach is therefore visualized as a pyramid. The majority of regulatory action takes place at the bottom of the pyramid, where regulators use a variety of cooperative strategies, and enable third-party action. Pressure for compliance does not primarily come from legal sanctions, but from advocacy groups as watchdogs and informal regulators.

Adverse publicity is important as a catalyst for third-party action. But in addition to its function as a deterrent, shaming is essential in responsive regulation theory to communicate the harmfulness of corporate offenses and to strengthen communities' shared expectations about appropriate business behavior. Public exposure of the offender underlines the unacceptability of the conduct and is expected to evoke the normative disapproval of the general public or significant peers (Braithwaite 1989; Parker 2006). Adverse publicity may thus contribute to public awareness of the harmfulness of corporate crime and foster normative attitudes against corporate crimes both in the general public and business communities (Braithwaite 1989). Shaming is also less likely to result in neutralizing calculating behavior, and more likely to lead to a discussion about moral or normative aspects of business behavior. A higher awareness of the societal and environmental impact of business behavior may also increase firms' willingness to invest in "beyond-compliance" behavior.

Whereas formal punishment communicates that legal norms have been breached, shaming communicates the message that social or moral norms have been offended. It is an expressive instrument that works through emotions such as the wish to be respected and the fear of being humiliated (Murphy and Harris 2007), and addresses consciences by expressing to the offender that he did not take his responsibilities toward the community.

Shaming, however, can easily result in humiliation and stigmatization of the offender. Reintegrative shaming theory predicts that stigmatization will make crime worse, whereas reintegrative shaming will prevent it (Braithwaite 1989). Reintegrative shaming means that public disapproval of the offense is combined with communicating trust in the offender's willingness to improve (Makkai and Braithwaite 1994). The offender is addressed as a good person who committed a bad act. Shaming directed against the offender, instead of inviting him to show his better self, will be experienced as stigmatizing. Stigmatizing will result in defiance and resistance of the offender and often also of the business community in general (Braithwaite 1989). The offender will refuse to acknowledge shame he feels inside or attempt to reason away his part in the offense or to neutralize the offense (Harris 2001; Braithwaite and Drahos 2002; Braithwaite et al. 2006; Murphy and Harris 2007).

Empirical research in responsive regulation has shown that offenders will only perceive shaming as reintegrative when performed by direct and respected peers. Shaming by officials is often experienced as stigmatizing, even when officials do not intend this (Makkai and Braithwaite 1994; Ahmed et al. 2001). Effective shaming therefore works best in a normative community of conscience between regulators, third parties, and business executives. In the case of white collar crime, however, consensus about the harmfulness of offenses, or a community of conscience formed by regulators, interest groups, and businesses will frequently be lacking (Parker 2006). Therefore, governments or NGOs should engage in formal, but respectful shaming, encouraging business actors to become reengaged in the substantial goals of the law. Although these formal shaming statements will unavoidably be experienced as stigmatizing to some extent, chances are that they will be translated in reintegrative shaming by peers – friends, family members, or colleagues or, internal compliance departments who have the capacity for reintegrative shaming.

In sum, shaming may work as a market incentive, as a deterrent "big stick" and as a form of moral education. Empirical research has shown that formal legal sanctions such as fines often fail to fulfill these functions. Naming and shaming therefore appears to compensate for some of the shortcomings of "traditional" legal financial sanctions. It is therefore often expected that naming and shaming is more effective in promoting compliance. What empirical evidence is available to support this claim?

Is Shaming Effective?

Several factors complicate the answer to the question whether shaming is effective in combating corporate crime. The first is the interdisciplinary character of research. The question of shaming addresses the interplay between business, NGOs, media, regulatory and enforcement authorities, and consumers, shareholders, and other stakeholders. An understanding of this interplay requires contributions from a variety of disciplines. Research into the effects of shaming is conducted within management science, economic science, law and society scholarship, empirical legal studies, social psychology, corporate governance research, business law, regulatory governance research, criminology, and media studies. While all these approaches provide valuable insights about effects of shaming, they also each depart from a particular theoretical perspective and study different types of shaming, complicating the aggregation and integration of research results.

A second complication in effect studies is the measurement of effects and causality. Concepts such as "reputation" and "shame" are intangible values which are difficult to measure. Several studies have attempted to solve this problem by measuring quantifiable consumer or shareholder reactions to publicized sanctions, such as fluctuations in sales, stock rates, or revenue after publication of offenses. Also, corporate reputation indices or media monitors may generate sophisticated indicators of corporate reputations following scandals. But although these measures may generate insight into the height of reputation sanctions, they do not answer the key causal question how the threat of reputation damage prevents corporate crime. The preventive, deterrent, or educative effects of naming and shaming depend on perceptions. Qualitative case-studies or interviews may give more in-depth explanations of the relation between naming and shaming and compliance, but the findings of these studies are context-dependent.

Given these limitations, a selection of important results from different disciplines may be highlighted. They shed some light on the effects and effectiveness of shaming.

A first line of research addresses the assumption that publication of offenses creates a market incentive by generating consumer reactions. Behavioral economic research and cognitive psychology have shown that markets where consumers act as rational information-processing "econs" are rare. Consumers struggle with an overload of information and make decisions under influence of cognitive biases. In particular, they value the status quo, meaning that they are loyal to their existing choices even if negative information about a firm becomes available. In line with the changed perspective on consumer decision making, several empirical studies of regulatory disclosure initiatives show that most of them did not evoke strong or consistent consumer reactions (Fung et al. 2007; Weil et al. 2006; Pawson 2002; Van Erp 2010; Kraft et al. 2011). Information about offending firms or unsafe products plays a less prominent role in consumer decision making than a consumer-oriented disclosure logic expects. Consumers do not actively gather information from regulatory agencies' websites; fail to correctly understand the information; and, most importantly, do not act upon this information. They often remain loyal to firms despite their negative performance. In addition, firm's legal compliance or even its socially responsible behavior often does not play a prominent role in consumer choices. This is not to say that naming offenders has no effect on business behavior, but the incentive generally does not come from consumer reactions to disclosed inspection results directly.

Two types of circumstances are suggested that alter this equation. The first is the type of stakeholder. It is often expected that shareholders are more active in seeking and processing information and act more rationally than consumers. Disclosed offenses of companies traded on the stock exchange are therefore expected to generate severe reputation sanctions in the shape of stock rate devaluation. Stock reactions to disclosed corporate offenses are also one of the most concrete indicators for actual reputation damage. Several research projects have therefore measured stock rate reactions to (for an overview, Van Erp 2011a). Research by Karpoff, Lee, and Martin (2008) shows that the disclosure of financial misrepresentation can lead to reputation sanctions that multiply the size of legal sanctions. Although part of this loss can be explained as a correction for the misrepresentation of the value of the company, or anticipation of costs of legal procedures and fines, the majority of this loss is reputation loss. Comparable studies in other regulatory arenas, however, find much lower stock rate reactions than those for financial misrepresentation. The publication of environmental offenses also leads to a drop in stock value, but this loss can be entirely accounted for by the costs of legal fines and restoration of the damage (Karpoff et al. 2005). There is no additional reputation sanction, because stockholders do not value the company less for its failure to comply with environmental regulations. Karpoff et al. conclude that investors will sooner impose a reputation sanction for an offense that damaged the interests of a firms' contract partner, than for an offense that damages a third party or an intangible value such as the environment.

Second, active negative publicity, generated by public advocacy campaigns by NGOs, may trigger larger reputation sanctions than public disclosure of sanctions alone. Kagan, Gunningham, and Thornton (2011) summarize the combination of pressures on companies by describing how companies recognize three "licenses to operate": the economic license (the obligation to meet the expectations of financial stakeholders); the legal license (compliance to law and permit conditions); and the social license: expectations from neighbors, employees, community groups, news media, and advocacy groups. Their research on pulp mills showed that firm's environmental performance did not vary in relation to differences in their legal or economic license, but in relation to social license pressure. Naming and shaming corporate irresponsible actors may create large pressures on corporations to put an end to pollution and to improve their environmental policies. Indeed, many examples exist about successful campaigns that have forced corporations to withdraw from profitable, but damaging activities or even beyond-compliance behavior where companies voluntary exceed legal norms.

Adverse publicity may also have an implicit preventative effect in the sense that media exposure increases the visibility and public awareness of the damage of harmful corporate activities; thus increasing the legitimacy of public enforcement and creating support for new legislation. It may contribute to the development of self-regulation such as certification schemes and codes of conduct. In the absence of public enforcement, voluntary compliance of businesses to "soft law" can decrease damage to the environment and violations of human rights of laborers and local communities. This may provide an opportunity particularly for issues that exceed jurisdictions of individual countries, such as environmental harm, deforestation, and other extinctions of natural resources, or globalized production chains where Western producers produce goods in countries where public enforcement against businesses and legal protection of employees are weak. But is this more than a drop in the bucket? In an analysis of corporate social responsibility initiatives for working conditions in developing countries, for the environment, and for human rights; David Vogel (2005) concludes that the "market for virtue" is small. There is no business case for corporate social responsibility: Simply because consumers are not willing to pay higher prices and only a small proportion of investors are interested in CSR. For example, few industries have been as heavily shunned in the media as the tobacco industry; yet, investment in this industry has flourished and the stock rates of tobacco firms have outperformed other stock. Vogel therefore concludes that informal naming and shaming by NGOs cannot take the place of legally binding public law and strong enforcement.

It can be added that only a proportion of corporate offenses generate negative publicity because not all form attractive news stories. Likewise, a market reaction to negative publicity may not always occur. Firms invisible to the public and not known to end-consumers are unlikely to experience reputation sanctions, if they do not comply (Thornton et al. 2009). Likewise, companies facing bankruptcy, and monopoly actors do not depend on a good reputation. Finally, even when publicity causes significant reputational damage, this may not translate into better compliance because of large necessary investments in production technology or simply a lack of responsiveness of businesses (Kraft et al. 2011).

A last and entirely different line of research discussed here does not directly address firm's reactions, but regulatory authorities' shaming strategies and corporate reactions. Researchers in responsive regulation ask the question to what extent enforcement authorities are capable of powerful, yet reintegrative naming and shaming, as is expected in responsive regulation. Sometimes, regulators that lack powerful enforcement tools attempt to actively invoke negative publicity and publicly shame corporate officials by portraying them as irresponsible, greedy, or criminal. Case-studies have demonstrated that an active shaming strategy requires broad political and societal consensus about the harmfulness of the condemned behavior, and unquestioned authority of the regulatory agency as the messenger. Conversely, when regulators lack support and authority, their messages will invoke resistance and undermine business' intrinsic motivations for compliance in the long run. They will also undermine the political support for the regulatory agency itself and result in attacks on its political legitimacy by the business community (Parker 2006).

It should be added that corporate offenders do not passively undergo adverse publicity, but actively attempt to manage publicity about their involvement in offenses. The ambiguous nature of corporate crime presents an opportunity for corporate officials to deny its harm by presenting their side of the story and to neutralize the severity of the offense or their responsibility (Braithwaite and Drahos 2002; Levi 2006). Defendants may even try to present themselves as victims of abusive regulators or prosecutors. For the media, initial reports of corporate crime may be salient news facts, but the newsworthiness of disclosed inspection results may decline over the course of the years, as happened in the 25-year existence of the American Environmental Protection Agency's toxic release inventory (Kraft et al. 2011).

This illustrates the crucial role of the media in presenting the shaming message that regulatory actors attempt to broadcast. Media are no neutral intermediaries, reproducing the news as it is presented by legal authorities. By selecting, interpreting, and framing the news, they may reinforce the moral message that a punishing authority sends, but may also detach it of its shaming component. Thus, publicity can raise doubts about the rightfulness of enforcement and either remove the blame from, or even create sympathy for, business. Also, authorities' accusations of businesses may lead to further questioning of the supervision practices that enabled business offenses to occur in the first place, resulting in the shaming to backfire to the enforcement agency (Almond 2009).

Last, enforcement authorities fear that adverse publicity will lead to disproportional reputation damage for firms that may damage the interests of employees and other firms or even the economy or financial system stability in the case of corporations "too big to fail." Not surprisingly, then, many public regulators wish to avoid conflict, and revert to "naming without shaming": formalistic, technical, and generic offender's indexes or sanction registers using legal language rather than explicitly condemning corporate malpractice (Van Erp 2011b). As a result, shaming by enforcement agencies often does not contain the moral message, nor results in the negative publicity and reputation sanctions that would be required to trigger a broader debate about the harmfulness of the underlying behavior.

Future Developments and Directions for Research

The broad phrase "naming and shaming" may refer to a wide array of activities, aims and potential effects, and target groups addressed. Any naming and shaming policy or research should start by specifying the audience addressed and effects that are expected. Shaming may work as a market incentive, as a deterrent "big stick" and as a form of moral education. Often, these effects interact and reinforce each other. The impact of naming and shaming therefore often largely exceeds that of formal legal sanctions, and can be more effective in promoting compliance than "regular" enforcement. However, the effects of shaming cannot easily be predicted. The type of business and market; the existing reputation of the offender; the type of offense; the authority and legitimacy of the shaming actor; and the media all influence the amount and intensity of adverse publicity. It is clear that the process in which naming offenders and attempts to shame, translate to financial or immaterial reputation damage, and subsequently improves compliance of the offender and other firms, is a very complex process that is difficult to control. Case-studies of successful and failed shaming campaigns of both formal and informal regulators; media analyses of the nature of the media representation of corporate crime; and quantitative studies of the impact of disclosed offenses on business performance or compliance rates are necessary research strategies to contribute to theoretical understanding of the relations between naming, shaming, and corporate crime.

A few research topics in particular are relevant to mention here. First, a large part of enforcement against corporate offenses is performed by administrative regulatory agencies rather than criminal prosecutors. Disclosure of inspection results or sanctions in sanction registers, offenders indices or performance inventories, is more and more common for these administrative agencies in their quest for transparency and accountability. This may change the character of administrative enforcement, which is generally thought to generate less media attention and therefore to result in less stigma, less reputation damage, and less moral condemnation of white collar offenders. The increased powers of disclosure by administrative authorities may shift the balance between criminal and administrative enforcement regimes, because a publicized fine may result in more negative publicity than a criminal verdict, which is often anonymous. One of the few studies in this area reveals unexpected differences in press coverage of cartels in Germany. In Germany, cartel offenses of firms are regulated by federal administrative law, whereas cartel offenses of individuals are enforced under criminal law. The administrative cartel authority issues press releases, naming offending companies. Public prosecutors however do not systematically issue press releases and do not reveal the names of perpetrators. Accordingly, press coverage about bid-rigging prosecutions and convictions is much sparser than press coverage of administrative fines in Germany. “This is the opposite of the effect one would usually expect – that the increased saliency of criminal cases would lead to wider reporting” (Wagner 2011).

The effects of the rise of new and social media on corporate reputations are another important topic for future research. The impact of shaming is already highly dependent on crowd dynamics, but the new media may increase the unpredictability of the reactions to public disclosure of offenders’ names even more. Publication of offenses on the internet results in long-lasting blame for small offenders, whereas more professional or strategic firms may replace negative news by a proactive public relations strategy.

Intensified disclosure also increases the risk that firms manipulate performance scores as these become increasingly important. In other words, disclosure intended to prevent fraud, at the same time, creates new opportunities for fraud. It should also be taken into account that media are corporate actors themselves, who may be connected to corporations involved in illegal activities. Business interests may influence the way in which corporate crime is being reported. Corporate involvement in crimes could be less likely to generate negative publicity when the corporations it concerns are active advertisers on the news networks that report the crimes.

Last, the topic of shaming illustrates that state control of corporate and white collar crime does not operate in isolation from social control. In order to understand how external pressures are translated in firm’s actions, a multidisciplinary approach is required which combines criminology with governance studies and management science.

National and Local Policing

Barry Loveday
Institute of Criminal Justice Studies, University of Portsmouth, Portsmouth, UK

Overview

This entry considers the differing structures of policing particularly those pertaining to the Anglo-American and European policing tradition. It argues that both national and local experience of policing should be viewed as reflecting the differing purposes of the police within which protecting the state has preeminence within national systems and where protection of the community takes precedence within local policing arrangements. It looks in detail at the experience of national police in France and contrasts this with the policing traditions that have characterized the development of local policing in both America and the United Kingdom.

Key Controversies

There has been an ongoing debate among both practitioner and academic commentators as to the advantages and drawbacks of two competing models of police organization. It is fair to say that until recently, the commitment to local policing was one that very much reflected the Anglo-American approach to devolved police structures that were closely linked to systems of local government (Marshall 1965). On the other hand, the national and more centralized police model was linked to mainstream European models of policing where a highly centralized state exercised clear hegemony over national policing (Mawby 1990: see Mawby this volume). Indeed, historically, the division between the two very different types of policing models may have also reflected a much more refined definition of what constituted the primary role of the police in different states (Stead quoted in Loveday 1999).

Thus within many states in Europe, traditionally the central role of the police was – and remains – the protection of the state. Certainly within France which has remained committed to national policing over many centuries, the police system as constituted in the late seventeenth century exhibited a "state protection responsibility" which over the years has remained a crucial function for the national police and the gendarmerie. The Ministry of the Interior and the Minister of Defense continue to exercise immediate responsibility for all policing in urban and rural areas within France (Mouhanna 2011). Historically a very similar situation pertained in Spain where the public order function of the police gave it a paramilitary profile with state and public protection providing the overriding raison d'être for the paramilitary Guardia Civil (Mawby 1990).

In contrast, the Anglo-American approach was to place much more emphasis on local delivery, linked closely to local government (Mawby 1999). This system was to demonstrate its most extreme form in the United States where local policing was to prove to be, in its earliest manifestation, overwhelmingly local in terms of structure, recruitment, and direction (Conley 1995). But early nineteenth-century developments in policing in America only reflected to a greater degree the creation of the local policing system in the United Kingdom.

Following the Municipal Corporation Act of 1835 and the County and Borough Police Act of 1856, local authorities were encouraged [but not at this time required] to establish local police forces. The Municipal Corporations Act of 1835 led to the creation of municipal police forces based on local authority boundaries which were to survive until well into the mid-twentieth century. Locally financed and locally led, the municipal police were in effect under the direction and control of local Watch Committees made up primarily of locally elected councillors (Marshall 1965). In effect, outside London, the police system reflected a patchwork of local forces exercising duties that would be closely monitored by locally elected representatives [albeit based on a very limited franchise]. The primary point remains, however, that the "protection of the state" and centralized control of the police never appeared as a primary function or organizational characteristic of policing in either the UK or the US. Even in London where the Metropolitan Police was made accountable to the Home Secretary, there was to be little interference in policing which was made the immediate responsibility of the Metropolitan Police Commissioner (Marshall 1965).

In America the relationship between the local government and the police force was to prove to be even stronger both from the inception of the police in the early nineteenth century and later. Arguably this very close relationship was to provide the basis for later claims that the police were heavily politicized, a criticism that continues to be raised against local policing models today. It is fair to say that given the strength of local political engagement in America, it was always unlikely that any local public service could expect to evade the tentacles of local politics. Yet, as will be argued later, the development and professionalization of policing in both the US and UK was to create situations where police forces – particularly the bigger urban forces – exhibited a degree of professional autonomy that may have generated a significant democratic deficit (Marshall 1978).

Key Issues: National and Local Police Systems

While the historical background to the division of police models remains of interest, it is also the case that policing structures remain a matter of continuing concern to both public policy makers and chief police officials. This may be linked to either party political processes or the perception that structural change can be expected to improve police efficiency and effectiveness. Some current, and very contemporary, examples of this development can be identified within two distinct police jurisdictions.

In Scotland, for example, the decision has been made within the Scottish National Party that there are significant advantages to be gained from the amalgamation of the existing eight police forces to create one national police force for Scotland. Plans are now well advanced to initiate this major structural reform of policing which could provide a significant indicator of what benefits accrue from a "national police force" within mainland UK where traditionally local structures have been seen as a defense of policing. Interestingly one justification used by the Scottish assembly in defense of nationalization of the police has proved to be that other European states have embarked on a very similar pathway (Fyfe 2012). In Norway, Denmark, the Netherlands, and Finland, the respective governments have recently decided to move from local to national police systems.

Indeed within the Netherlands, a country which in the past has challenged the European stereotype of centralized policing (Jones 1995; Mawby 1990), the political process has resulted in a decision to effectively scrap the local policing system which differentiated it from mainstream Europe. It has instead opted for the introduction of a national policing system. Based on a perception that a national police model would prove both more efficient and less costly, the myriad local police forces that characterized the Netherlands will form part of a national Netherlands police service. Interestingly, in both cases the primary consequence of the reforms planned for the police service will be a change in police governance away from local government to national government within which the single chief officer will be made either directly or indirectly accountable and answerable to a national assembly which could prove to be highly political.

Developments in both Scotland and the Netherlands provide a remarkable contrast on the other hand to developments in England and Wales. Here the Coalition government within the 2011 Police Reform and Social Responsibility Act intends to move to strengthen local police systems by radically reforming local police governance to provide much greater local accountability of the police to their local communities. The 2011 Police Reform Act represents the most significant recommitment on the part of national government to local policing and local police governance (Loveday 2012). To the extent that the current Coalition government in England and Wales remains committed to entrenching the local policing dimension, this policy development reflects a common law Anglo-American approach to policing which highlights local police delivery along with a corresponding commitment to "low" rather than "high" policing.

Indeed the division of policing into "high" and "low" policing styles has accurately reflected the differing approaches to policing responsibilities.

Traditionally "high" policing was [and remains] closely associated with European systems where immediate police responsibilities centered upon the protection of the state. Within the Anglo-American approach far less importance is attached to state protection and far more is accorded to protecting the community. This may well reflect the common law basis upon which policing in England was established and upon which the "new" policing model of the early nineteenth century was based. Within the 1829 Act creating the London Metropolitan Police, the Home Secretary Robert Peel made much of the police being "citizens in uniform" and where it was an offense for a citizen not to assist a police officer in his duties if called upon to do so. While therefore the high policing model could remove the police from any immediate responsibility to the community, in contrast "low" policing aimed to cement the police system within the community.

International Perspectives: Typologies of Policing

Typologies of policing have been expanded to include a range of policing systems which provide for a better comparative evaluation of the structure and effectiveness of those systems (Mawby 1990; see Mawby this volume). While national and local police structures provide a description of police systems, there are a range of models that can be applied to current police jurisdictions and which go beyond this. One of the most useful typologies was developed by Stead in his influential study of the French police in the 1950s, which continues to have a ready application (Loveday 1999).

Stead was to develop three typologies of police systems which he classified as "fragmented," "combined," and "national centralized" police systems. In developing these typologies, Stead also provided in effect a heuristic device in approaching the analysis of policing systems. Thus, it might be argued that using these typologies, it is relatively easy to identify examples of each of the typologies developed by Stead. Traditionally the police systems of the USA and Britain would have been classified respectively as examples of fragmented and combined police systems: in the USA a large number of police forces operated in relative autonomy, whereas in the UK local and central government were made jointly responsible for the government of the police. Similarly France has traditionally been identified as a clear example of a national centralized police system fully established with the creation of the Police Nationale.

One evident feature of government of the police remains the degree to which a police force can be made accountable for what is does [or doesn't do]. This is not an esoteric matter as accountability can be closely linked, as will be argued later, to issues surrounding police effectiveness and police efficiency. However, it might be noted that each typology identified by Stead demonstrates a different form of accountability. Thus, national systems are theoretically made accountable at national political level usually by way of ministerial responsibility to a national parliament of assembly. In France, for example, the Minister of the Interior has traditionally been identified as the senior minister responsible for the National Police. Similarly the Minister of Defence has immediate responsibility for the gendarmerie, responsible for all policing outside of the larger urban areas.

Within fragmented police systems, the accountability mechanism is in contrast much more local and diffuse. Here as in the USA police forces will be viewed as being immediately accountable to the local electorate. As if to reinforce this within some jurisdictions, both the police chief and the local mayor may stand for election (Loveday and Reid 2003). Here, as with many police forces in the USA, the police will be viewed as being immediately accountable to the local electorate, as the sheriff or chief officer of police may well be an elected official or may hold the office of chief officer which is the gift of the locally elected mayor (Loveday and Reid 2003). In between the national centralized and fragmented models of policing lies the "combined" system where a mix of local and central government is designed to maximize the accountability and responsiveness of the police to the public interest.

Yet it is also the case that each model policing and police system may not provide the degree of accountability which the public may see as being appropriate. National police systems may have been the responsibility of ministers who as in France have shown until recently a strong desire to protect police interests from effective scrutiny by the national assembly (Loveday 1999). On the other hand, local fragmented police systems as demonstrated in America can be subject to local partisan interests, a feature which as Conley notes can be seen as being a reflection of the early development of police forces in that country. Fragmented systems may also be susceptible to central-federal government interference particularly where local units of policing are resource poor and may require assistance from external police forces or federal agencies.

Within "combined" systems, the very division of responsibility between local and central government may over time have allowed for the exercise of power without responsibility by central government. Given the interesting lacuna which may surround each typology of policing, it may be of use to explore examples of each typology and following on from that attempt to assess the overall accountability and effectiveness of each model of policing.

A National Police System

The recent decision on the part of a number of European states which had earlier supported local policing models to move to integrated national police systems suggests that some evaluation of existing national police structures would be of some value. In relation to this the best example of a state-led and national centralized police system would be the National Police of France.

Certainly the French policing system has traditionally been cited as the most extreme form of centralized police activity in Europe, where the collective interests of the state have often appeared to have overshadowed the rights of citizens. Over the years observers have often concluded that given its origin and raison d'être, the national police has been more concerned with protecting the interest of the state than with the rights of the individual (Loveday 1999). However, the role of the national police may provide some evidence of the potential gains and hazards which may be associated with a national police system.

While allowance must be made for differing domestic political cultures, it is evident that the history of the national police is not one that appears to place high value on either local accountability or responsiveness to the community. In the late 1950s some evaluation of the role of the national police was to be made by one commentator who argued in relation to the National Police of France that it was "not too sweeping a judgement to say that the French police system could be more easily fitted than that of any other Western countries into the pattern of totalitarian government. The political activities and the building up of dossiers of persons unconnected with crime which form so large a part of the work of the police of totalitarian countries has been among the activities of the French police since the days of the first Napoleon" (Coatman 1959:77–8 quoted in Loveday 1999).

Moreover, along with the highly dirigiste nature of policing in France has gone a willing acceptance of a very wide discretion accorded to the police in the exercise of their powers. As has been noted elsewhere, for example, "The French police are allowed a latitude – license would not be too strong a word, in their dealings not only with suspected and arrested persons which is probably unique in Western democratic countries" (Coatman 1959:75 quoted in Loveday 1999).

Despite police reforms, it remains the case that the national police continue to have, for example, uninterrupted access to suspects for the first 48 h of their arrest and when suspects may be at their most vulnerable. Under the system of "garde à vue," suspects for this period are denied access to legal representation. Within local fragmented policing systems where the potential danger of police abuse of their authority may arise, similar police freedom has been drastically curtailed by way of either statute or rulings handed down from the higher courts.

The lack of effective accountability at either local or central government level has been evidenced over the years and not the least of these proved to be the policing of an Algerian protest march through Paris in October 1961 which was to lead to numerous fatalities among the many Algerian protestors (Rudorff 1970:55). There was never to be any kind of investigation as to how those fatalities at the hands of the police had arisen. This proved to be largely the result of a decision made by the Minister of the Interior at that time who also intervened to ensure that there was a blanket ban on any media coverage of the police attacks during the course of the protest march (Rudorff 1970).

Some of the worst examples of police abuse of their authority arose while under the leadership of Maurice Papon, chief of Paris police, at this time. One commentator provides an interesting insight into the potential dangers of overt politicization of the police and the threat this can present to the rule of law, which can arise in relation to national police systems. Reflecting on the police violence exhibited at this time and supported by the French government, Rudorff notes that "No matter what crimes were committed by the police for whose behaviour Papon was responsible, he was untouchable and even after the end of the Algerian war he remained in office always protected by the government, never disavowed and never out of favour" (Rudorff 1970:55).

Yet while the national policing system of France is often identified as a model of national policing, it has never been a unified national police system. This is because of the dual system of policing within which two central departments exercise separate responsibilities for the national police and the gendarmerie. Interestingly, as is also to be found within the Italian national police system, the division of responsibilities between the two police forces has led to continuing conflicts between them over time (Gleizal quoted in Loveday 1999). There may be some suspicion that institutionalized conflict has been a characteristic which may have been encouraged by political elites in both Italy and France, to undermine the autonomy of national police forces and limit their potential influence.

The level of institutional dysfunction exhibited within the French national police system was to be best evidenced in the Jobic affair in 1987 when officers of the gendarmerie arrested a very senior officer of the National Police in Paris (Guyomarch 1991). This arrest served only to exacerbate an already deep antipathy between the two national police forces which was to be reflected in a continuing lack of cooperation between them. Indeed, it is evident that rather than seeking to allay such tension, national politicians have at times exploited it to encourage greater police responsiveness. In 1987, for example, the Minister of Defence was to allow the gendarmerie to operate in plain clothes. In the early 1980s the national police was to be publicly humiliated by the decision of the then President Mitterand to transfer responsibility for his personal protection to the gendarmerie (Guyomarch 1991:325).

While the institutionalized tension between the two forces has retarded the development of any unified professional policing strategy, it may, ironically, have encouraged greater political accountability of both services. This in itself might be seen as no small achievement where in the recent past the police had become "too powerful to criticize and where national politicians feared their hostility and whose support had to be courted" (Rudorff 1970:47). While it may exhibit characteristics that are specific to that country, it is however evident that there are potential dangers which may arise from national police systems.

These would include the danger of overt politicization at a national level as the police are seen as an extension of government rather than being independent of it along with the danger of operational dysfunctionality as the police role and mission is potentially subsumed within the realm of national politics. In effect the primary function of the police is reinforced within this political environment and becomes "public protection and public order," a role which in

France has been clearly evidenced in the policing style of the Compagnies Républicaines de Sécurité [CRS]. The public order role which has traditionally fallen to national police systems as a primary function is indeed best demonstrated in France by the CRS.

As has been noted by one commentator, the mobile units of the CRS were created and placed under the explicit command of the Minister of the Interior. While these units had to deal with natural disasters [floods, forest fires], their primary function was to provide "a weapon against strikers, rioters and political demonstrations which got out of hand or were judged to be dangerous by governments which made increasing use of this force in political affairs" (Rudorff 1970:49). A highly confrontational policing style developed by both the CRS and elements of the police national came at the expense of alienating the public and also of developing any form of policing by consent. This is a traditional policing advantage pursued by local police forces, not least because of the real and potential benefits to increasing police effectiveness which this approach can encourage.

The potential problems generated in France by way of national policing have been recently addressed by Body-Gendrot. In her analysis of policing Paris, she notes that rather than giving citizens a sense of safety with community policing, for the CRS maintaining order during street demonstrations and pursuing organized crime have long been seen as the national police mission (Body-Gendrot 2012:84). The same commentator also finds that while the national police have over recent years pursued a strategy of "proximity policing," police officers involved in this strategy are not "policing by consent or pursuing a public reassurance function" either. Rather they are merely required to be "visible," and in problematic suburbs, there is often a glaring difference between "proximity policing" during daylight hours and more brutal methods used by police forces at night or during street demonstrations (Body-Gendrot 2012:85). Significantly, some commentators, such as Mouhanna (2011), have concluded that the apparently more militaristic gendarmerie in fact has traditionally had a stronger community orientation than the national police.

Moreover, as with any established professional policing model, most officers within the national police will not be available for public patrol work as they can be expected to be engaged in "intelligence or investigation work" analyzing "cyber crimes, underworld and organised crime" (Body-Gendrot 2012:84). This commitment to specialization which may be encouraged within national police systems only provides further evidence that the larger the unit of policing, the more difficult it can become for the police organization to fulfill its most basic functions which engage it with the public and community (Loveday 1999). This is because the level and degree of specialization which is encouraged by the very number of police officers available siphons off police resources from the public domain to police professional priorities that may not be shared by the public. It is also the case that within the French National Police, a lack of leadership, the inertia of bureaucracy, and the limited accountability exhibited by the police together have served to weaken police efficiency.

It is interesting to note that in the absence of effective accountability, the national police remain committed, within the capital, to a more basic and highly political function. As Body-Gendrot succinctly argues, as the core of Paris remains a defensible space with numerous official buildings, public and private mansions, palaces, and banks, the police are required to protect them as well as provide for the safety of state VIPs. She adds that "Whenever it is anticipated that disorders could occur a strong paramilitary police deployment is placed in charge and made responsible for law and order" (Body-Gendrot 2012:87).

Nor is the paramilitary response to disorder by the police national confined to Paris. Most recently in August 2012, in response to disturbances in Amiens in Northern France, the police were to use rubber bullets and teargas "which some residents considered excessive" (Chrisafis 2012). It appeared that the rioting was sparked by resentment over "spot" checks conducted on residents by the police and also on a highly negative relationship between the police and some sections of the local community.

In response, President Hollande was to state that his government would mobilize all of its resources to combat the violence and that his priority was "security." It meant that the next budget would include "additional resources for both the gendarmerie and the police" (Chrisafis 2012). It is evident that in the situation that confronts the police in many French banlieues, increases in police resources alone are unlikely to resolve the underlying alienation experienced by many residents as a consequence of aggressive public order policing which remains the primary response and central characteristic of the national police.

Fundamentals: Local Policing

In contrast to national policing experience within the Anglo-American, police system has continued to emphasize the importance of local service and integration with the community. This is best exampled within America where there is a continuing commitment to a wide range and variety of police agencies which operate within it. Most recently, the total number of police agencies in America has been estimated to stand at just below 20,000. However, the very number of local agencies suggests that America continues to provide the best example of a fragmented police system. While the long-term goal of many police professionals may have been to consolidate smaller police agencies, the evidence from larger police departments suggests that these continue to experience greatest difficulty in sustaining public police patrol. It has also proved difficult to persuade local residents of the value of relinquishing their own local police department in the interest of any perceived future gain in police efficiency.

As was to be argued over 40 years ago in what proved to be the most revealing study and analysis of policing in America, the President's Commission on Crime found that the community service function of the police could not be underestimated (The Challenge of Crime 1967). This was because analysis of the role of the police highlighted how dependent they remained on information given to them by the public. In its evaluation of the investigation function, the evidence of such dependence was stark. Thus, in its analysis of crimes reported in Los Angeles in 1966, it was to discover that "where the police were furnished a suspect's name then the case was very likely to be resolved." It noted however that in "1,375 crimes where no suspect was named only 181 cases were cleared by the police," and that in the LAPD one of the largest police departments in America, of all reported serious crimes against property recorded by the department, "78 % were never solved" (The Challenge of Crime 1967:97).

All the evidence indicated that a primary indicator of police effectiveness was the degree to which the police enjoyed the support and confidence of the public. This was because police dependence on the public for information was the primary driver of most crime case clear-up. Nor was it evident that increased expenditure on police specialization could necessarily be expected to impact on the crime rate or the clearance rate. The Commission discovered that in "practically every department the caseloads carried by detectives were too heavy to allow them to follow up thoroughly more than a small percentage of cases assigned to them" (The Challenge of Crime 1967:96).

In this situation increased further investment in the detective specialism, however large, would be unlikely to significantly increase the clear-up rate. It concluded that in the great majority of cases, personal identification by a victim or witness remained the only clue to the identity of the criminal (The Challenge of Crime 1967:97). Thus, the critical issue became one of encouraging victims and members of the public to come forward to help the police resolve cases.

The landmark 1967 report remains the bedrock for any evaluation of police effectiveness, and its central discovery of police dependence on the public it serves continues to have an immediate relevance to any contemporary debate over the organizational structure of policing and policing systems. This is because the evidence suggests that where the police are removed from regular contact with the public and cease to be integrated into the community the police ostensibly serve, then the decline in police efficiency and effectiveness can be expected to be quite dramatic. This may be measured in fact by the level of non-reporting of crime by the public who fail to report incidents because they believe the police cannot or will not do anything about it (The Challenge of Crime 1967:96).

This may indeed have been the overall experience in the UK as a consequence of the major police amalgamation program embarked upon in the 1960s and early 1970s. Bigger police departments ended in the creation of bigger police bureaucracies and much greater specialization all of which came at the expense of contact with the public by way of visible police patrol (Loveday 1999). Experience of the growth of police departments in the UK provided clear support for the inverse relationship identified by Monkennon in the 1980s that existed between police size and effectiveness. He noted how as police departments grew in size police patrol activity could thereafter be expected to decline (Monkennon cited in Loveday 1999).

Devolving Police Services in Centralized Systems

It is interesting to note that within France, one of the most centralized police systems in Europe, there has been growing recognition of the need for local police service delivery and evident failure of the national police model. Ironically while representatives of Anglo-American policing have highlighted its benefits, the French have implemented change at a local level which has significantly strengthened local poling in many towns and cities in France.

This can be traced back to the early 1980s with the interesting discovery that under the Law of 1884 passed by the national assembly, the mayor was given responsibility for public order in his commune (Journes 1993 cited in Loveday 1999). Under the 1884 Law, the mayor was given responsibility for the appointment of all municipal employees including police constables and inspectors, although this responsibility is balanced by the authority of the prefect who has a greater role in the recruitment of police in towns with over 40,000 residents. Thus, from the early 1980s in response to the perceived failure of the national police to provide effective policing, particularly in relation to responding to crime and delinquency and the decline in public police patrol, there has been a steady increase in the number of municipal police forces in many French towns and cities. In 1986, it was estimated that 530 municipal police forces were in existence, and that of these, 107 competed with the national police in terms of duties and responsibilities (Guyomarch 1991:331). In 1993 it was computed that there were some 10,000 municipal police officers who worked in 2,860 localities.

This interesting development remains a continuing phenomenon in response primarily to the failure of the national police organization to deliver effective police services. One consequence of this has been the decision of an increasing number of local mayors to establish their own police forces where the police are made directly accountable to the mayor. In effect the vacuum created by the withdrawal of the national police from visible policing has led to the creation of a policing system that is closely allied to the local government structure.

It is, however, evident that in France the future expansion of municipal policing may be influenced by the political position adopted by police unions on what they may understandably view as a threat to their role and status. In relation to this it is interesting to note that as identified by Body-Gendrot, one of the factors explaining the current malaise of policing in France is "a general lack of leadership to confront police unions' resistance to necessary change" (Body-Gendrot 2012:85). Yet in relation to this, it might be relevant to note that in terms of devolved policing, the experience of post-Franco Spain has demonstrated a similar movement to devolved policing with the creation of municipal police forces which in most towns and cities now act as an integral element to local municipal administration. With this has gone the part demilitarization of the Guardia Civil and closer engagement by it with local communities.

The realignment of policing with local government has also been demonstrated in England and Wales. Following the introduction of local partnership arrangements under the Crime and Disorder Act 1998, police forces now have a shared responsibility with the local authority to reduce crime within their areas. Formal arrangements under the 1998 Act mean that the local authority and other local partners are required to develop on an annual basis a strategy to reduce crime in their area. The strategy document is preceded by a local audit of crime and criminal damage and since the introduction of the 1998 Act has served to provide a far more comprehensive picture of the extent and nature of criminal activity than existed before.

The same legislation requires the partnership to consult with the local community about what should be the local strategic priorities before determining what they will be. Interestingly in this context has been the discovery that one of the highest priorities identified by the public is not in fact crime but antisocial behavior [ASB]. This has proved to have been [and remains] a significant factor in sustaining high rates of "fear of crime" in England and Wales despite the near-record fall in recorded crime. It is also evident that although ASB has long been a matter of concern to many residents, it was not one that, unfortunately, appeared to be shared by the police (Loveday 2012). Over the period of the partnership, one primary objective has been to realign police priorities with community priorities where in the past a commitment to a professional policing approach has often created a lacuna that has put local communities at risk.

Experience in England and Wales suggests that there is much to be gained from establishing close links between the police and the local authority. This is because while the police may be able to identify problems that may generate crime and disorder, unlike the local authority, they do not have the resources to respond to them. In an era of significant reductions in public spending, it is of interest to note in this context that in England and Wales, the Coalition government remains committed to increasing local accountability of the police by way of directly elected police and Crime Commissioners [PCCs].

While there may some argument over the mechanism surrounding the planned PCCs, created to achieve this, there can be little dispute about the principle that drives this reform which is to ensure that communities are in future better able to influence what kind of police service is locally delivered. To encourage greater public engagement, all police forces are now required to provide communities with local crime maps to enable them to make a more-informed judgement about how effective the local police force is proving to be in relation to the incidence of crime and disorder in their area.

Moreover, to assist local police forces in achieving greater responsiveness to local demand, the Coalition government is also in the process of establishing a National Crime Agency that can be expected to relieve local police forces from responding to serious, organized crime and terrorism as this new body is given a much higher status and role than has been accorded before to "national" agencies in the past.

Future Directions

The evidence from experience suggests that "local" policing only becomes meaningful when it is linked closely to local government structures. Moreover, even where local policing is in operation, there will be a continuing requirement for a national arm of policing to respond to the challenges of international crime and the terrorist threat. This is perhaps best evidenced in America where despite a plethora of local police departments, there are numerous federal agencies that exercise considerable power domestically. This federal responsibility cannot be ignored and has been substantially increased with the Patriot Act and the creation of the Department for Homeland Security [DHS] which now employs around 200,000 personnel and has a budget of $98.8 billion.

As in England and Wales the commitment to local policing is underpinned by a significant role accorded to national or federal agencies and reflects a reality that in the contemporary world there is a role for both local and national police capabilities and that neither can be expected to operate in isolation from the other. As the national police structures roll out in the Netherlands, Scandinavia, and Scotland, it will be of interest to discover how successful reliance on a single national force proves to be. Already in the Netherlands, local mayors are challenging the surrender of their responsibilities for the police and their removal to a national forum at The Hague.

In Scotland the argument for the introduction of a national force has been in part predicated on the need to protect existing police establishment [17,234 officers] by saving on overheads generated by the current eight forces (Fyfe 2012). Unfortunately no activity analysis of policing has been undertaken to assess whether current police establishment can be justified. In its absence the highly political nature of the Scottish governments' reform program becomes more apparent.

While local police commands will be aligned with Scotland's 32 local councils, it is noticeable that there will be limited influence accorded to the local council in the determination of policing priorities identified by the local police commander. Nor will the "partnership structure" developed in England and Wales be replicated in Scotland. It is also of some interest that in a public consultation on options for police reform, undertaken in 2011, less than 10 % of respondents supported the national police option, with most respondents preferring, in fact, a regional structure (Fyfe 2012).

In this analysis of types of policing structures, it is evident that national and local policing cannot be addressed in terms of simple alternatives. Within most advanced states, there is a perceived need for a mix of police structures which can respond to differing demands and challenges at differing levels. The degree of interdependence might be best evidenced in America where a continuing and strong commitment to local policing and community engagement is balanced by significant responsibilities given to an increasingly important federal arm.

It is also clear that national political cultures are significant in determining both domestic police structure and public expectation of policing styles. This of course is reinforced by the significance of the political context within which policing is delivered. The highly dirigiste approach to policing exhibited in France is replicated to a high degree in the Russian Federation where there may also be lower public concern about potential abuse by police of their authority and a greater indifference to the importance of legal procedures. These may, in fact, be seen by the public as impeding the work of the police (Kelly 2005:xxix).

It is also evident that as with many other areas of public service delivery there is very little evaluation of how police structures might impact on performance and general service delivery. Nor has any effective analysis has undertaken to demonstrate with any clarity whether in moving from local to national police systems the long-term cost savings which are claimed in defense of it are ever actually achieved. Additionally such savings may come at the expense of reducing public satisfaction with the police by encouraging specialization and reducing visible policing. As a result, it might then be concluded that any immediate financial savings could be more than outweighed by significant costs to police service delivery to the public.

Overview

The aim of this entry is to trace the development and the expansion of general victimization surveys across the world. The description focuses on national general victimization surveys, although references to international surveys cannot be avoided because many countries use the International Crime Victims Survey (ICVS) as their national measure of victimization. Specific surveys, such as those focused on businesses, domestic violence, or minority victimizations, are excluded. The entry begins with a historical note, continues with a description of the main surveys already carried out – and those currently conducted periodically – across the five continents, and concludes with a summary of the main findings and a brief mention of known methodological issues in comparative cross-national research based on national victimization surveys.

Historical Development of Crime Victim Surveys

In 1730, following a series of citizens' complaints about an increase of property offences, the City Council of Aarhus, Denmark, sent six persons throughout the households of the city to ask whether they had been victims of domestic burglary (Sparks 1981). This study has often been considered as the first victimization survey.

Two hundred years later, on 20 October 1935, George Gallup published his first survey of public opinion (Newport 2010). In 1945, Gallup established an agency in Finland and conducted a general survey that included a question that can be translated from Sweden – one of the Finnish national languages – as "Do you have this year personally suffered from a crime?" In case of an affirmative answer, respondents were asked to specify whether it was theft, burglary, robbery, assault, trespassing, fraud, or something else. A search in Gallup's database (http://brain.gallup.com) shows that similar questions were not asked in the United States until 1972, when the survey included the following question: "During the last 12 months, have any of these happened to you?- A) My home was broken into or an attempt was made to do so; B) I was mugged or assaulted; C) Money or property was stolen from me or some other member of my household; D) My home, or car, or other personal property was vandalized; or E) My car, or a car owned by a member of my household was stolen?" According to our search, before 1972, Gallup polls included some questions on crime – for example, in 1954, the public considered that comic books, TV, and radio crime programs were partly to blame for teenage violence; in 1957, it considered that parents were mainly to blame for that; and, since 1965, polls included a question on fear of crime while walking alone in their own neighborhood at night – but not phrased as a typical victimization question. Thus, the 1945 Finish Gallup Poll seems to be the first major public survey to have asked a question on victimization. The Nordic experience with these questions is reflected in the fact that it is precisely a Finish criminologist, Inkeri Anttila, who is often quoted as one of the main promoters of victimization surveys. However, the publication that is usually quoted refers to self-reported delinquency survey and includes only this sentence about victim surveys: "By Gallup investigations it is also possible to establish how many of the general public have been made objects of a certain crime, and how many of these have reported the crime to the authorities" (Anttila 1964: 413).

The rising public worries about crime in the United States by the mid-1960s – sometimes qualified as a "moral panic" but at least partially supported by a 1965 Gallup Poll (Chambliss 1994) – combined with the increased use of surveys and the inclusion of questions such as the ones mentioned below attracted the interest of criminologists. Thus, the President's Commission on Law Enforcement and Administration of Justice (1967) sponsored three surveys in the United States, conducted by Biderman et al. (1967), Reiss (1967), and Ennis (1967). Between 1969 and 1972, several surveys were conducted in cities across the United States (Sparks 1981, with references) and in the Nordic countries, starting in Finland in 1970 (Aromaa 1971) and then in Denmark, Norway, and Sweden in 1971 and 1972. Also in 1972, the United States launched the National Crime Surveys (NCS) program which led to the first national survey being conducted in 1973 and annually since then (Rand 2006). Australia carried out a survey in 1974 (Congalton and Najman 1974). In the same year, the Dutch Ministry of Justice commissioned Gallup/NIPO to carry out a pilot survey following the format of the Gallup US survey of 1972 (Buikhuisen 1975). Building on this experience, the Ministry of Justice of the Netherlands launched in 1975 its series of national surveys which has been repeated annually – first by the Ministry of Justice and, from 1980 on, by the Central Bureau of Statistics – ever since (Van Dijk and Steinmetz 1979). Following a series of local surveys that started in the city of London in the early 1970s, the United Kingdom launched the British Crime Survey (BCS) in 1982, which has been carried out periodically since then. In the 1980s, Finland and Norway also introduced a periodical survey, as did the city of Barcelona/Spain in 1983 and Australia in 1975. Around the same time, Clinard (1977) noted that victimization surveys could be especially useful in developing countries, in which police statistics of crime were sometimes unavailable. However, the breaking point for the development of these surveys across the world is undoubtedly the first International Crime Victim Survey (ICVS), conducted in 1989 and published in 1990 (Van Dijk et al. 1990), largely building on the experiences of the Dutch, British, and Swiss national surveys. Thus, in the 1990s, roughly 70 countries participated in at least one of the waves of the

ICVS or, at least, used its questionnaire for conducting victimization surveys. Also in the 1990s, regional Latin Americans victimization surveys were developed and countries such as Italy, France, and the Autonomous Region of Catalonia introduced periodical victim surveys. Since the beginning of the twenty-first century, some Latin American (Argentina, Chile, and Mexico) and European countries (Denmark and Sweden) have also introduced national periodical victimization surveys.

National Victimization Surveys by Continent

The following sections present the development of national general victimization surveys by continent. The information available does not always allow a differentiation between the year in which the survey was conducted, the year of reference of the survey, and the year of publication. For example, in most European Union countries, the EU ICS was conducted in 2005, using 2004 as the year of reference, but the results were published in 2007 and 2008. In principle, the dates indicated in this entry refer to the date of publication of the results. This review draws on the ones conducted for Latin America by Dammert et al. (2010), for Asia by Chan (2008) and for Europe by Aebi and Linde (2010).

America

In the American continent, there are three regional multipurpose surveys that include victimization modules: the *Latinobarómetro*, conducted by a nonprofit NGO (Latinobarómetro Corporation); the *Ecosocial* (Encuesta de Cohesión Social en América Latina), conducted by another nonprofit NGO (Corporación de Estudios para Latinoamérica – CIEPLAN); and the *AmericasBarometer* of the Latin American Public Opinion Project (LAPOP) of the Vanderbilt University. The questions included in these surveys are sometimes too broad – for example, the Latinobarómetro asks: Have you or a relative been robbed, aggressed, or victim of a crime during the last 12 months? (Lagos and Dammert 2012) – and, as a consequence, they only provide a rough estimate of the extent of victimization.

The *Latinobarómetro* is conducted annually since 1995 in Latin America. Eight countries participated in 1995, 17 from 1996 to 2003, and 18 since 2004. Currently, Cuba is the only Latin American country that does not participate in the survey (see Table 1). The *Ecosocial* survey was conducted in 2007 in seven Latin American countries (see Table 1). The *AmericasBarometer* is conducted every second year since 2004 in the whole American continent. Eleven nations participated in the first survey in 2004, 20 in 2006, 23 in 2008, and 26 in 2010 (see Table 1). Thus, Cuba is the only country not covered by the survey.

In the following country-by-country analysis, it can be seen that victimization surveys became a standard measure of crime in the United States in the 1970s, in Canada in the 1980s, and in most Latin American countries in the 1990s. The latter introduced such dedicated surveys mainly through their participation in the ICVS with city samples. In particular, in 1992, Argentina, Brazil, and Costa Rica took part in the second wave of the ICVS. The same countries participated in the third wave, in 1996/1997, in which Bolivia, Colombia, and Paraguay also took part, and the number of participating countries continued to increase in the following years. In the 2000s, the UNDP sponsored some victimization surveys in collaboration with governments of countries of the Americas, such as the one conducted in 2004 in Costa Rica and El Salvador and the IDHAC survey, conducted in 2009–2010 in seven Central American countries (Belize, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama).

In **Argentina**, the first victimization survey was conducted in the capital, Buenos Aires, in 1989, with the support of a private foundation. Always with samples from the capital, the country participated in the ICVS in 1992, 1996, and 2004. From 1997 to 2003, the Ministry of Justice used a slightly adapted version of the ICVS to conduct an annual victimization survey in the city of Buenos Aires and its surroundings, including also in some of its waves the cities of Rosario,

Mendoza, and Cordoba. Since 2006, some local governments (city of Buenos Aires, province of Santa Fe) started conducting their own surveys with the scientific support of universities. Also, since 2006, the Di Tella University conducts a monthly victimization survey in the main 40 urban centers of the country.

In **Barbados**, the Victimization Survey of Barbados was conducted in 2002 using the ICVS questionnaire and in 2009–2010 including also a business victimization section. In **Bolivia**, three victimization surveys were conducted in 2006. One of these surveys was conducted by IPSOS and covered the cities of La Paz, El Alto, Cochabamba, and Santa Cruz. Another one was sponsored by the UNDP and covered cities with more than 2,000 inhabitants. The third one was conducted by the Observatory of Democracy and Security and covered the cities of La Paz and El Alto. Bolivia conducted the ICVS in 1996 with a sample of the capital, La Paz.

Brazil conducted four national victimization surveys. The ones of 1988 (PNAD) and 2002 (PESB) were multipurpose surveys that included a module on victimization and were conducted by the Brazilian Institute of Geography and Statistics (IBGE) and the Universidade Federal Fluminense, respectively. The IBGE conducted also in 2009 a national victimization survey, while, in 2010, the UNDP sponsored a survey which used an adapted version of the ICVS questionnaire. Indeed, Brazil participated in the ICVS in 2002 and 2005 with samples of the cities of Rio de Janeiro, Sao Paulo, Recife, and Vitoria. Apart from that, many local surveys were conducted throughout the country. That was the case in Rio de Janeiro at the level of the city (1992, 1996, 2002, 2005, and 2006), some of its neighborhoods (2001), the metropolitan region (1996, 2000, and 2006), and one of the municipalities of that region (2000). In Sao Paulo, victimization surveys were conducted at the level of the city (1997 and 2003), the metropolitan region (1999), and the state (1998). In Belo Horizonte, surveys were conducted at the level of the city (2002 and 2003) and the metropolitan region (2006). Finally, other victimization surveys were conducted in the cities of Marilia (2003) and Alvorada (2004).

In **Canada**, a national victimization survey is conducted roughly every 5 years as part of the General Social Survey program. The survey took place in 1988, 1993, 1999, 2004, and 2009. Before that, a national victimization survey had been conducted in 1981. Canada participated also in the five waves of the ICVS (1989, 1992, 1996, 2000, and 2004) with national samples and in the ICVS-2 pilots of 2009 and 2010.

In **Chile**, the National Urban Survey on Citizens Security (ENUSC) was conducted in 2003 by the Ministry of Interior, and it became annual since 2005. Apart from that, since 1999, an ONG (Fundación Paz Ciudadana en Chile) conducts surveys every 6 months in different municipalities of the main cities of the country.

In **Colombia**, the first victimization survey was conducted in the city of Cali in 1978 by a researcher of the University of Wales (United Kingdom) with the support of the Colombian Statistical Institute (DANE). Between 1978 and 1980, the National Association of Financial Institutions (ANIF) carried out short victimization surveys in several cities, but no scientific publications were produced out of them. The Cisalva Institute of the University del Valle conducted also a victimization survey in six cities in 1996 and in Pasto in 2008. Since 2006, the Foundation *Seguridad y Democracia* carried out some victimization survey in the six main urban centers of Colombia. In the capital city of Bogota, the Chamber of Commerce has created a Security Observatory that, since 1996, conducts periodically a victimization survey. Bogota provided also the sample for the participation of Colombia in the ICVS in 1997 and 2000. In 2003, a victimization survey sponsored by the World Bank and the DANE took place in the cities of Cali, Medellin, and Bogota, while in 2009, a pilot survey took place in Soacha. At a national level, a module on victimization was included in the National Households Survey in 1985, 1991, and 1995, and the first national victimization survey – sponsored by the Inter-American Development Bank (IDB) – should take place in 2013.

In **Costa Rica**, the United Nations Latin American Institute for the Prevention of Crime and the Treatment of Offenders (ILANUD) carried out a victimization survey in the capital city of San José in 1982. The same city provided the main sample for the participation of Costa Rica in the ICVS in 1992 and 1996, and the design of both surveys included also a small rural sample. National victimization surveys were conducted in 2006, 2008, and 2010. These three national surveys were sponsored by the UNDP, and the ones of 2008 and 2010 were cosponsored by the National Institute of Statistics. The **Dominican Republic** conducted in 2005, through its National Institute of Statistics, a national multipurpose survey (ENHOGAR) that included a module on victimization. In **Ecuador**, after some regional surveys conducted by NGOs, the government conducted the National Survey on Victimization and Perceptions of Insecurity in 2008 and 2010. In principle, this survey should be conducted every 2 years. In **El Salvador**, the University Institute of Public Opinion (IUDOP) conducted national victimization surveys in 1998, 2004, and 2009 and in the cities of Sonsonate and Cojutepeque in 1999. In **Guatemala**, since 2004, the UNDP conducts surveys on victimization and insecurity perception in Guatemala City every 6 months.

In **Mexico**, the first victimization survey was conducted in the city of Jalapa in 1976 by the Veracruzana University, using a questionnaire developed by the Texas Department of Public Safety (United States). A similar questionnaire was used for a survey carried out in 1983 in the Federal District and its surroundings, sponsored by the National Institute of Criminal Sciences (INACIPE). The Mexican National Institute of Statistics (INEGI) conducted victimization surveys in the Federal District and the State of Mexico in 1988, 1990, 1992, and 1994 and in Monterrey, Oaxaca, Veracruz, Cuernavaca, Ciudad Juárez, and the metropolitan area of the city of México in 1992, 1993, and 1997. In the Federal District and the State of Mexico, the Center for Research and Teaching in Economics (CIDE) has been carrying out every 6 months since 2005 a Survey on Victimization and Institutional Efficacy (ENVEI). At a national level, in 2002, the Citizen's Institute of Studies on Insecurity (ICESI) conducted for the first time the National Survey on Insecurity (ENSI), with an instrument inspired by the ICVS questionnaire and the one developed by the Autonomous University of Mexico (UNAM) for a national survey conducted in 2000. The ENSI was conducted again in 2003, 2005, 2006, and annually from 2008 to 2010, by the ICESI, sometimes in collaboration with the INEGI, and with some modifications of the questionnaire. Since 2011 the ENSI became the National Survey on Victimization and Perception of Public Security (ENVIPE) and was placed under the responsibility of the INEGI, which continues to carry it out annually with a revised questionnaire. INEGI also conducts since 2009 the Continuous Survey on the Perception of Public Security (ECOSEP) that generates a monthly index of public security perception. Finally, Mexico participated in the ICVS in 2004 with a national sample.

In **Panama**, within the framework of a project organized by the University of Santa Barbara (California), the University of Panama conducted in 1973, with a sample of the capital, the first Latin American victimization survey. **Paraguay** conducted a national victimization survey in 2009 through its Ministry of Interior using the ICVS questionnaire. The country also conducted the ICVS in 1996 with a sample of the capital, Asuncion. **Peru** participated in the 2005 ICVS with a sample of the city of Lima. The same year, the Ministry of Interior also conducted through a private enterprise a victimization survey in the main urban centers. The ONG *Ciudad Nuestra* conducted the First National Urban Victimization Survey in 2011. An annual survey on citizens' security conducted by an ONG (Grupo de Opinión Púbica) since 2004 includes some questions on victimization. In Lima, a local victimization survey was conducted in 2007.

As mentioned in the historical introduction, in the **United States of America**, three pilot victimization studies were sponsored by the President's Commission on Law Enforcement and Administration of Justice in 1967. They were followed by several city surveys, by the 1972 survey conducted by Gallup/USA (Gallup Poll Number 861) and, since 1973, by the annual *National Crime Victimization Survey* (NCVS, conducted under the name of National Crime Survey until 1990).

The Ministry of Interior of **Uruguay** conducted victimization surveys in the cities of Montevideo and Canelones in 1999, 2000, 2001, 2002, and 2004. A national survey was sponsored by the same ministry in 2007. In **Venezuela**, local victimization surveys were conducted in the city of Mérida (in 1980, 1983, and 1985), Maracaibo (1987, in the context of a comparison with the United States of America), and Caracas (2005). In 2001, 2006, and 2009, national victimization surveys were conducted for the Ministry of Interior and Justice by a private enterprise (2001) and by the Institute of Statistics (2006 and 2009). In 2007, another national survey was conducted by a consortium of institutes and universities.

Belize and **Nicaragua** do not have their own national victimization surveys, but victimization data on them for 2009–2010 can be found in the IDHAC survey and in the *AmericasBarometer* for 2008. Nicaragua also participated in the *AmericasBarometers* of 2004 and 2006.

Europe

In Europe, there are no genuine regional comparative *general* victimization surveys yet. The *Eurobarometer* 44.3 (1996), 54.1 (Autumn 2000), and 58.1 (Autumn 2002) included some questions on fear of crime and victimization, and the same is true for the *European Social Survey* of

2002, 2004, and 2006, but they cannot be compared to a victimization survey and not all European countries participated in them. Eurostat is currently preparing the *European Security Survey*, a full victimization survey which should take place in 2013 or 2014 (van Dijk et al. 2010).

Austria participated in the ICVS in 1996 and 2005 (EU ICS) with national representative samples and conducted the pilot study on the EU victimization survey module in 2009. Since 2006, the Austrian Safety Board conducts annually the Security Barometer (*Sicherheitsbarometer*).

Belgium participated in four sweeps of the ICVS – in 1989, 1992, 2000, and 2005 (EU ICS) – with national representative samples. Since 1997, the country conducts regularly a national victimization survey called Security Monitor (*Moniteur de Sécurité*). This survey has been conducted in 1997, 1998, 2000, 2002, 2004, 2006, and 2008–2009. Apart from that, since 1996, the Flanders Authority conducts annually the APS-SCV survey (*Administratie Planning en Statistiek – Sociaal Culturele Veranderingen*) among the Flemish-speaking population.

In **Bulgaria**, victimization questions were included in the monthly surveys led within the framework of the UNDP's Early Warning project in 1996–1997. The ICVS questionnaire was used, with a sample from the capital, Sofia, in 1997, and with national representative samples in 2002 and 2004 (EU ICS). Also in 2004, another national victimization survey was conducted with an ad hoc questionnaire. Since then, the ICVS questionnaire is being used for periodical national victimization surveys conducted in 2005, 2007, 2008, and 2009. **Cyprus** only conducted the pilot study on the EU victimization survey module in 2009 with a sample of two urban areas.

The **Czech Republic** participated, as part of Czechoslovakia, in the 1992 ICVS with a national representative sample. After the separation from Slovakia, the ICVS was conducted with a national representative sample in 1996 and with a sample from the capital, Prague, in 2000. Apart from that, between 2000 and 2003, four victimization surveys with national representative samples were conducted with an ad hoc questionnaire. The country also conducted the study Victimization of Citizens of the Czech Republic by Some Types of Criminality in the Year 2004. In 2006, an adapted version of the ICVS questionnaire was used for the survey Experiences of Czech Republic Citizens with Some Offences. The country also conducted the pilot study on the EU victimization survey module in 2008/2009.

Denmark is considered as the birthplace of victim surveys as, in 1730, the council of the city of Aarhus reacted to the complaints of the citizens by asking six persons to go through all the households of the town asking their inhabitants if they had been victims of burglary during the last 3 or 4 years. In September 1971, Denmark was the second European country to conduct a modern victimization survey, which was indeed a replication of the one conducted in Finland 1 year before. The country participated in the ICVS in 2000 and 2005 (EU ICS) with national representative samples and conducted both the pilot study on the EU victimization survey module in 2009 and the second ICVS-2 pilot study in 2010. Since 2005, Denmark has an annual victimization survey which is not based on the ICVS questionnaire but includes some comparable questions.

Estonia participated in four sweeps of the ICVS, in 1993, 1995, 2000, and 2004 (EU ICS) with national representative samples. The ICVS became then a sort of regular national victimization survey, and, as such, it was conducted again in 2009.

Finland conducted in 1970 the first contemporary European victimization survey. With the cooperation of the Scandinavian Research Council for Criminology, that survey was subsequently replicated in Denmark, Norway, and Sweden in 1971/1972. The Finnish government also financed a replication of that survey in Finland in 1973. Finland carries out a periodical victimization survey called the Finnish National Safety Survey. That survey has been conducted in 1980, 1988, 1993, 1997, 2003, 2006, and 2009. The country also participated in the five sweeps of the ICVS, in 1989, 1992, 1996, 2000, and 2005 (EU ICS) with national representative samples.

In **France**, the first nationwide victimization survey, covering the years 1984–1985, was conducted in 1986. The country participated in four sweeps of the ICVS, in 1989, 1996, 2000, and 2005 (EU ICS), with national representative samples. Between 1996 and 2006, France conducted 11 annual surveys on the Living Conditions of Households that contained a module on victimization loosely based on the ICVS questionnaire. Since 2005, the country launched an annual victimization survey called Framework of Life and Security, whose questionnaire is inspired by the one used in the British Crime Survey. Local victimization surveys were also conducted in Épinay and Toulouse in 1989, in Amiens in 1999, and in the Île-de-France (Paris) region in 2001, 2003, 2005, 2007, and 2009, as well as in five cities that are members of the French Forum for Urban Safety in 2005.

In **Germany**, the first victimization survey was conducted in Stuttgart, in 1973. Reflecting the federal structure of the country, most of the German victimization surveys took place at the local level, at an average rhythm of four surveys per decade until 1990 and up to five per year since then. Some of these surveys used a longitudinal design, such as the Victims of Crime in Bochum study, conducted in 1975, 1986, and 1998 in the city of Bochum. In 1989, the ICVS was conducted in Western Germany with a sample representative of the population of the Federal Republic of Germany. After the reunification of the country, victimization surveys with national representative samples were conducted by different researchers in 1991, 1992, 1993, 1995, and 1997–1998. In 2005, Germany took part in the EU ICS. The country also participated in the pilot of the EU victimization survey module in 2009 with a sample of four states and in the ICVS-2 pilots of 2009 and 2010.

In **Greece**, in 1991, a pilot study of the ICVS was conducted in the city of Athens. In the same city, surveys on fear of crime were conducted in 1998 and 2004. At the national level, only one victimization survey was conducted, in 2001.

Hungary participated in the ICVS in 1996 and 2005 (EU ICS). In 2003, the country also conducted the survey Victims and Opinions with a national representative sample and a questionnaire that was not based on the ICVS but included some comparable questions.

In **Ireland**, the first victimization survey was conducted in 1982–1983 with a national representative sample. In 1994, two victimization surveys were conducted. One used a national representative sample and the other a sample covering only Dublin. In 1996, the survey Victims of Recorded Crime in Ireland was conducted with a sample of victims drew from the records of the Ireland's National Police. Apart from that, Ireland participated in the 2005 EU ICS with a national representative sample. Finally, the Quarterly National Household Surveys (QNHS), introduced in 1997, include regularly a module on victimization and, as a consequence, can be considered as a sort of regular national victimization survey. The module on victimization was included in 1998, 2003, 2006, and 2009.

Italy participated in the ICVS in 1992 and 2005 (EU ICS) with national representative samples. In 1991 and 1994, national victimization surveys were conducted by UNICRI (with the support of the Ministry of the Interior) and the Cattaneo Institute, respectively. From 1993 to 2003, the national multipurpose survey called Everyday Life Aspects (*Aspetti della vita quotidiana*) included some questions on victimization, but, currently, only fear of crime in the area of residence is measured through this survey. At the same time, the Italian Citizens' Safety Survey (*Sicurezza dei cittadini*) is a multipurpose national study conducted every 5 years (1997/1998, 2002, and 2008/2009) that includes questions on victimization. This survey used oversampling for the Emilia-Romagna region in 1997/1998, for that region and another four in 2002, and for five provinces of the South in 2008/2009. Finally, in Bologna, a local victimization survey was conducted in 1994.

Luxembourg participated in the 2005 EU ICS with a national representative sample. Apart from that, the police services of Luxembourg conducted in 2007 a survey on feelings of insecurity with a national representative sample.

National annual victimization surveys started in the **Netherlands** in 1974 under the responsibility of the Ministry of Justice, initially out-contracted to Gallup/NIPO. These surveys were later adopted by Statistics Netherlands (CBS) that has been carrying out national victimization surveys since 1980. The Permanent Survey on Living Conditions (POLS – *Permanent Onderzoek Leefsituatie*) including the Justice and Security Module was conducted from 1980 to 2005 (from 1980 to 1985 every year and from 1986 to 1992 every 2 years). At the same time, from 1980 to 1992, the Crime Victim Survey (ESM) was held first annually and, from 1984 to 1992, biannually. From 1992 onwards, the ESM was succeeded by the Justice and Security Survey (ERV – *Enquête Rechtsbescherming en Veiligheid*). Since 2005, the ERV was replaced by the National Security Monitor, which integrated elements from the former POLS Justice Module and from the Police Monitor (PMB). The latter is conducted in every police region since 1993, and it was conducted every second year until 2001 and annually since then. The National Security Monitor was stopped in 2008 and replaced by the annual Integral Security Monitor. Apart from that, the Netherlands participated in the five sweeps of the ICVS in 1989, 1992, 1996, 2000, and 2005 (EU ICS) with national representative samples and in the second ICVS-2 pilot study in 2010.

In **Norway**, by the end of 1971, the Scandinavian Research Council for Criminology supported the replication of the victimization survey conducted in Finland in 1970. Currently, the Survey of Living Conditions includes periodically a module on victimization. That module was used in 1983, 1987, 1991, 1995, 1997, 2001, 2004, and 2007. Norway participated in the ICVS in 1989 and 2004 (EU ICS).

Poland participated in the five sweeps of the ICVS and in the pilot study on the EU victimization survey module in 2009. In 1989, the survey was conducted in the city of Warsaw only, and in 1992, 1996, 2000, and 2004 (EU ICS), it was based on national representative samples. In 2000 and 2004, the country used an adapted form of the ICVS questionnaire. The ICVS questionnaire was also used for a survey conducted in Warsaw in 2005.

Portugal participated in the ICVS in 2000 and 2004 (EU ICS) with national representative samples and conducted the pilot study on the EU victimization survey module in 2009. Portugal also conducted national victimization surveys with an ad hoc questionnaire in 1991, 1992, and 1994.

Romania participated in the ICVS in 1996 and 2000. In 1996 the country combined an urban sample from the capital city, Bucharest, and a small rural sample. In 2000, the country used a sample from Bucharest only. From 2001 to 2006, the National Institute of Statistics (Institutul Naţional de Statistică, INS) conducted annually the multipurpose Living Conditions Survey (*Condiţiile de viaţă ale populaţiei din România*, ACOVI), which included questions on victimization, with national representative samples.

Russia participated in the ICVS in 1992, 1996, and 2000 with a sample of the capital, Moscow. In 2001, a victimization survey was conducted in the cities of Smolensk, Omsk, and Volgograd. The **Slovak Republic** participated, as part of Czechoslovakia, in the 1992 ICVS with a national representative sample. After the separation from the Czech Republic, the ICVS was conducted in Slovakia in 1997. The country also conducted the pilot study on the EU victimization survey module in 2008/2009. **Slovenia** conducted the ICVS in 1992, 1996, and 2001 and participated in the pilot study on the EU victimization survey module in 2009. In 1992, the sample was restricted to the capital, Ljubljana; in 1996, it combined an urban (Ljubljana) and a rural subsample; and, in 2000, it was representative at the national level.

Spain participated in the ICVS in 1989 and 2005 (EU ICS) with national representative samples and conducted the pilot study on the EU victimization survey module in 2008/2009. The Centre for Sociological Research (CIS – *Centro de Investigaciones Sociológicas*) conducted six victimization surveys with national representative samples (in 1978, 1980, 1991, and 1995), one in Madrid in 1980, and one with a sample of several cities in 1982. The CIS also conducted in 1987 a study on terrorism and citizens' security. Finally, the barometer conducted periodically by the CIS includes a few questions on citizens' concerns, among which delinquency is often included. The Andalusian Institute of Criminology has also carried out a series of surveys in different cities of the Autonomous Community of Andalusia in 1994, 2005, 2006, and 2007, as well as a national survey in 2009, using the successive versions of the ICVS questionnaire, adapted to the Spanish case. The Autonomous Community of Catalonia participated in the ICVS in 1996 and 2000 and conducted the pilot study on the EU victimization survey module in 2009. From 1983 to 2001, the Survey on Public Security in Barcelona was conducted annually in the city of Barcelona. This victimization survey inspired the Survey on Public Security in Catalonia, which is conducted annually with a sample representative of the population of Catalonia since 1999.

Sweden conducted its first victimization survey in 1972 as part of a project sponsored by the Scandinavian Research Council for Criminology in Nordic countries. Since 1978, the country conducts annually the multipurpose survey called Living Conditions Survey (ULF), which includes a module on victimization. Since 2006, the country also carries out a national annual victimization survey called the Swedish Crime Survey (NTU). Sweden participated also in four sweeps of the ICVS in 1992, 1996, 2000, and 2005 (EU ICS) with national representative samples. The country also conducted the pilot study on the EU victimization survey module in 2009 and the first and second pilot studies of the ICVS-2 in 2008/2009 and 2010, respectively.

Switzerland conducted seven national victimization surveys, of which four were placed under the umbrella of the ICVS. These surveys took place in 1984/1987, 1989 (ICVS), 1996 (ICVS), 1998, 2000 (ICVS), 2005 (ICVS), and 2011. Since 1989, the survey is always based on the ICVS questionnaire.

In the **United Kingdom**, the General Household Survey was the first survey that covered victimization issues. This multipurpose survey, conducted during the 1970s, included some questions about domestic burglary victimizations. Since 1982, the United Kingdom has carried out periodically the British Crime Survey (BCS) which, as explained below, took different forms in England and Wales, Scotland, and Northern Ireland. In **England and Wales**, the first victimization survey was the London survey, conducted in the early 1970s. Other local surveys took place in Sheffield (1975), London (1983 and 2002), the county of Nottingham (1985), Merseyside (1984), and in the London Borough of Islington (1986). In the 1980s, the BCS was conducted three times in England and Wales (in 1982, 1984, and 1988). From 1992 to 2000, it was conducted every other year, and, since 2001, it became a continuous survey with monthly interviews. From 2012, the survey's name was changed from BCS into the Crime Survey for England and Wales. England and Wales participated also in the five sweeps of the ICVS, in 1989, 1992, 1996, 2000, and 2005 (EU ICS) and in the ICVS-2 pilots of 2009 and 2010. **Northern Ireland** participated four times in the ICVS, in 1989, 1996, 2000, and 2005 (EU ICS) with national representative samples. The country also conducts periodically the Northern Ireland National Crime Survey (NICS). This survey was conducted in 1994/1995, 1998, 2001, and 2003/2004, and, since 2005, it became a continuous survey with monthly interviews that follows closely the model of the BCS. **Scotland** conducts periodically a national victimization survey since 1982. In 1982 and 1988, the country used the BCS. The first independent Scottish Crime Survey was conducted in 1993 and repeated in 1996, 2000, and 2003. That survey was replaced by the Scottish Crime and Victimization Survey (SCVS), which took place in 2004 and 2006. In 2008, the SCVS was replaced by the Scottish Crime and Justice Survey (SCJS) which is a continuous survey with monthly interviews, inspired by the methodology of the BCS, but with a slightly different questionnaire. Scotland also participated in four sweeps of the ICVS, in 1989, 1996, 2000, and 2005 (EU ICS).

The following European countries do not have a national victimization survey but have conducted the ICVS, usually with samples of their capital city complemented in some cases with a small rural sample (the year and the name of the city from where the main sample was extracted are indicated between brackets): **Albania** (Tirana, 1996 and 2000), **Belarus** (Minsk, 1996 and 2000), **Croatia** (Zagreb, 1996 and 2000), the **Former Yugoslav Republic of Macedonia** (Skopje, 1996), **Latvia** (1995 and 1998, with multiple-city samples and 2000 with a national representative sample), **Lithuania** (1996/2007, with a multiple-city sample, 2000 with a sample from Vilnius, and 2005 with a national representative sample), **Malta** (1997, unpublished, except in ICVS reports), **Serbia** (Belgrade, 1996), and **Ukraine** (Kiev, 1996 and 2000).

Oceania

In **Australia**, the Australian Bureau of Statistics (ABS) conducted national victimization surveys in 1975 (except the Northern Territory), 1983, 1993, 1998, 2002, 2005, and, annually, since 2008–2009 (as part of the Multipurpose Household Survey – MPHS). Questions on fear of crime and perception of security were also covered in other surveys, such as the General Social Survey (conducted in 2002, 2006, and 2010, which includes also some questions on crime victimization) and the Personal Safety Survey (2005) and in the Southern Australia Health Omnibus Survey, conducted regularly in that region of the country. Apart from that, the ABS conducted regional surveys in Adelaida (1985); Victoria and Queensland (1987); Tasmania (1989); New South Wales (1990); Queensland, Southern Australia, New South Wales, and Western Australia (1991); New South Wales (1992); and Victoria and New South Wales (1995). Australia also participated in the ICVS in 1989 with a sample of New South Wales and Victoria and, with national samples, in 1992, 2000, and 2004. In **New Zealand**, the Ministry of Justice conducted national surveys in 1996 and 2001 (New Zealand National Survey of Crime Victims) as well as in 2006 and 2009 (New Zealand Crime and Safety Survey). The country also participated in the ICVS in 1992 and 2004 with national samples. In **Papua New Guinea**, the ICVS was conducted in 1992. The Safer Cities Programme of UN-HABITAT, with the financial support of the UNDP, launched a project in 2002 that allowed carrying out a victimization survey in the capital, Port Moresby. In 2004 and 2005, victimization surveys were conducted in the cities of Arawa and Buka.

Africa

Egypt participated in the ICVS in 1992 with a sample of the capital, Cairo. In 2006, a national victimization survey was carried out by the National Center for Social and Criminological Research (NCSCR) with a random sample of 6 governorates including Al Fayoum, Assiut, Behera, Cairo, Dakahlia, and Port Said. **Nigeria** conducted the ICVS in 1998 with a sample of the capital, Lagos. In 2010, the MacArthur Foundation supported a national victimization survey with a representative sample drawn from the 36 states of Nigeria and the Federal Capital Territory. **South Africa** conducted the ICVS in 1993, 1996, and 2000 with samples of the capital, Johannesburg. Since 1998, the country has a periodical national victimization survey. It was conducted in 1998, 2003, and 2007 under the name of South Africa National Victims of Crime Survey (NCVS), and in 2011, it became the Victims of Crime Survey (VOCS). In 2005, South Africa conducted a youth victimization survey, with a sample of youths aged 12–22. The Safer Cities Programme of UN-HABITAT, with the financial support of the Dutch government sponsored since 1997 victimization surveys in several cities, including Johannesburg, Durban, Pretoria, Port Elizabeth, and Cape Town. **Tanzania** conducted the ICVS in 1992 with a sample of the main urban center, Dar es Salaam. The Safer Cities Programme of UN-HABITAT, with the financial support of the Dutch and the Swedish government, sponsored victimization surveys in 2000 (Dar es Salaam), 2004 (Dar es Salaam, Arusha and Mtwara), and, in collaboration with the UNODC, 2008 (Dodoma, Mbeya, Moshi, Mwanza, and Tanga). **Uganda** conducted the ICVS in 1992, 1996, and 2000 with samples of the capital, Kampala. The UNODC sponsored a national victimization survey in 2008.

The following African countries do not have a national victimization survey but have conducted the ICVS, usually with samples of their capital city complemented in some cases with a small rural sample (the year and the city from where the main sample was extracted are indicated between brackets): **Botswana** (1997 and 2000, Gaborone), **Lesotho** (2000, Maseru), **Mozambique** (2002, with a sample of the city of Maputo and the regions of Nampula, Sofala and Zambézia), **Namibia** (2000, Windhoek), **Swaziland** (2000, Mbabane), **Tunisia** (1992, Tunis), **Zambia** (2000, Lusaka), and **Zimbabwe** (1996, Harare).

Different bodies of United Nations, namely, the UN-HABITAT through its Safer Cities Programme, the United Nations Office on Drugs and Crime (UNODC), and United Nations Development Programme (UNDP), have sponsored victimization surveys – sometimes with the support of the Dutch, the Belgium, or the Swedish government – in the following African countries, which do not have a national victimization survey (year and city from where the main sample was extracted are indicated between brackets): **Cameroon** (2002, Yaoundé; 2003, Douala), **Ghana** (2009, in the metropolitan areas of Sekondi-Takoradi, Accra, Kumasi and Tamale), **Ivory Coast** (1999, Abidjan), **Kenya** (2003, Nairobi; 2010, national representative sample), and **Rwanda** (2008, national representative sample).

Asia

Cambodia participated in the ICVS in 2000 with a sample of the capital, Phnom Phen, and a small rural sample. In 2011, the Survey of Cambodian Public Opinion, conducted by the International Republican Institute with a national representative sample, included a module on victimization. **Georgia** participated in the ICVS in 1992 and 1996 with national samples. The country also participated in the 2000 ICVS with a sample of the capital, Tbilisi. In 2010, 2011, and 2012, the Gorbi Institute carried out, with the financial support of the European Union, national victimization surveys using the questionnaire of the ICVS with some adjustments from the future European Union Security Survey. In **Hong Kong**, ICVS-based victimization surveys were conducted in 1990, 1995, and 1999. In **India**, the ICVS was conducted in 1992 and 1996 with samples of the capital, Mumbai. In 1996 a small rural sample was also included. In 2003, a victimization survey was conducted in four cities (Madurai, Coimbatore, Trichy, and Chennai) of the State of Tamil Nadu. The survey was funded by the University Grants Commission, New Delhi. In **Indonesia**, national victimization surveys were conducted in 1982, 1991, and 1994, as a part of its National Economic and Social Survey. The ICVS was conducted in 1989 with a sample of the city of Surabaya. In 1992 and 1996, the ICVS was repeated with a multiple-city sample accompanied by a small rural sample. **Japan** participated in the ICVS in 1989, 1992, 2000, and 2004 with national samples, and, since then, it has been using the ICVS questionnaire for national surveys every 4 years. In 2006, an independent victimization survey was conducted by Kyoto's Ryukoku University with a national random sample and a questionnaire based on the ICVS and British Crime Survey questionnaire. Surveys with samples of crimes victims were conducted in 1991–1992, 2000, and 2003. In South **Korea**, the Korean Institute of Criminology participated in the ICVS in 2000 and carries out a national victimization survey every 3 years since 1994. In **Taiwan**, victimization surveys were conducted in 2000 by the Prevention Institute of the Central Police University and in 2005 by the National Taiwan University. A survey with a sample of crime victims was conducted in 2005. In **Thailand**, a victimization survey was conducted in 1983 with a sample of the city of Bangkok.

The following Asian countries do not have a national victimization survey but have conducted the ICVS, usually with samples of their capital city complemented in some cases with a small rural sample (the year and the city from where the main sample was extracted are indicated between brackets): **Azerbaijan** (2000, Baku), **China** (1992, Beijing), **Kyrgyzstan** (1996, with a multiple-city sample), and **the Philippines** (1992 and 1996, Manila).

Conclusion

The first victimization question in a major public opinion survey seems to be the one included in a Gallup survey carried out in Finland in 1945. By the end of the 1960s, national victimization surveys were developed in the USA and the Nordic countries. The first ICVS in 1989 gave a major impulse to these surveys across the world. Currently, they are carried out regularly in the five continents, and many countries have their own national survey, conducted regularly. In particular, the regions of the world where national victimization surveys have become a systematic measure of delinquency are North America, the Nordic countries, Oceania, as well as some countries of Latin America and Western Europe.

Cross-national comparisons of independent national surveys can be performed – see, for example, the ones conducted by Langan and Farrington (1998) on the basis of the NCVS and the BCS and the studies compiled by Farrington et al. (2004) and Tonry and Farrington (2005) – but are usually problematic as the methodology of the surveys vary from country to country. The main methodological problems have been pointed out by Lynch (2006). In particular, differences in the labelling of the questions cannot be easily overcome. In this context, the increased use of the ICVS questionnaire – which was inspired by the victimization surveys conducted in the United States (namely, the one conducted by Gallup in 1972), the Netherlands, and the United Kingdom – has introduced a relative homogeneity that simplifies to some extent the task. However, the use of different methods of interviewing introduces a supplementary bias. Currently, participants in a survey can be contacted personally, by letter, by telephone, or by e-mail, and then give their answers to the questionnaire orally (by telephone or during a face-to-face interview) or in a written form (by filling a paper or an electronic questionnaire). Across the world, the technique most commonly used is the face-to-face interview, which can lead to PAPI (paper and pencil interview that can be filled by the respondent or the interviewer), CASI (computer-assisted self-interview), or, most frequently, CAPI (computer-assisted personal interview, in which the interviewer introduces the answers directly in a computer). Face-to-face interviewing has always been the preferred methodology in nonindustrialized countries, usually because their telephone and computer penetration rate are relatively low. On the contrary, in industrialized countries, the 1990s provided apparently the perfect window of opportunity for surveys conducted through CATI (computer-assisted telephone interview), as most of the households disposed of a fixed telephone line and the costs of such surveys were relatively low. Thus, during the first five waves of the ICVS (1989, 1992, 1996, 2000, and 2004/2005), most industrialized countries used this methodology.

The increased use of mobile phones instead of landlines and the growth of unwanted telephone marketing led to a fall of the response rates of victimization surveys conducted with the CATI methodology in industrialized countries, especially since the 2000s. For example, for the five countries that participated in the five waves of the ICVS (Canada, England and Wales, Finland, the Netherlands, USA), the rates increased from 52 % in 1989 to 64 % in 1996 but decreased to 63 % in 2000 and fell to 48 % in 2004, when up to seven attempts were made to reach the potential respondents. It is worth noting that response rates decreased also in some of the Central and Eastern European countries that used face-to-face interviews. For example, Poland registered a response rate of 96 % in 1992, but this rate decreased constantly and reached 72 % in 2004. Such decrease could be related to interview fatigue but also to an increased insecurity feeling that produced mistrust of strangers knocking at one's door, even if some countries announced the survey by letter. However, in Latin American countries, response rates are extremely high (e.g., 85 % in Mexico in 2011).

In order to improve response rates, some industrialized countries are currently testing CATI with samples that include mobile phones, and they are also introducing CAWI (computer-assisted web interview) as a new method. CAWI is sometimes combined with PAPI by inviting the persons, usually through a letter – a method that was seldom used due to its lower response rate – to fill the questionnaire either through the Internet or in a written form. Taken into account that the number of Internet users is growing constantly worldwide, there can be no doubt that the CAWI technique offers the promise of a new generation of affordable comparative crime surveys not only in industrialized nations but also in the rest of the countries. However, the results, in terms of differential nonresponse biases and pure mode effects of the few pilot surveys conducted until now with CAWI, are not satisfactory for its full implementation at the present time.

Another major problem faced by victimization surveys is related to the temporal localization of the events. Experimental research (Scherpenzeel 1992) has shown that higher annual victimization rates are found when respondents are asked directly about the victimizations suffered during the last 12 months (like in the BCS) than when they are first asked about victimizations suffered during the last 5 years and then are asked to indicate whether the event took place during the last year or before that (like in the ICVS). The NCVS, with its method of multiple interviews, also produces more accurate estimates of victimization rates and, compared to surveys conducted in other countries with a different methodology, should usually show lower levels of victimization in the USA.

Finally, small samples – as the ones usually used in Europe for the ICVS and in Latin America for the LAPOP and the Latinobarometro, which ranged between 1,000 and 2,000 households – can produce instable rates, especially for infrequent offences, which are usually the most violent ones (e.g., rape). Currently, the biggest samples are the ones used in The Netherlands (220,000 households in 2011), Mexico (90,000 households in 2011) followed by the United States (the NCVS used samples of roughly 40,000 households representing 70,000 interviews by the end of the 2000s), England and Wales (in 2010/2011, 51,000 people – including 4,000 children aged 10–15 – were interviewed for the BCS), Australia (29,000 households for the 2008–2009 MPHS), Chile (that since 2008 use a sample of 26,000 households for its annual ENUSC), and Canada (19,500 respondents for the GSS in 2009).

The best solution for all these problems is, evidently, to use the same questionnaire and the same methodology in different countries. At a continental level, the three regional victimization surveys applied in Latin America (Ecosocial, Latinobarómetro, and AmericasBarometer) use the same questionnaire but include only a few questions. In Western Europe, the ICVS has been applied usually with the same methodology of CATI in several countries. However, at the international level, the methodology used for carrying out the ICVS has not been homogeneous. Whenever the questionnaires or the methodology are fundamentally different, the best solution for comparative researchers is to concentrate on the trends shown by the surveys and not on the differences in victimization rates across countries.

Overview

It has been recognized for some time that crime clusters at a range of spatial scales. It is also well established that offenses cluster in time such that crime occurrence is more likely at particular times of the day, week, month, or year. More recently, a growing body of evidence has started to accumulate that indicates that crime also clusters in time *and* space, such that when an event occurs at one location, there is a temporary elevation in the probability that other events will occur nearby. Where crimes occur at the exact same location, this is referred to as repeat victimization, and where they occur at nearby locations, *near-repeat victimization*. Finding that the risk of crime diffuses in space has implications for crime forecasting. However, this type of work is in its infancy and naturally, many questions remain unanswered. For example, there is something of a disconnect in methodological terms between those techniques that are used to detect crime patterns and those that are, or should be, used to generate predictive crime maps. Moreover, approaches to calibrating predictive maps so that a range of factors can be incorporated, and so that the extent to which crime risk might be diffused varies across areas, are things that have received little or no attention. Similarly, the extent to which patterns of one type of crime might affect those of another largely remains unexplored in the literature. A final point is that while crime is known to cluster in space, analyses of crime at the street segment level suggest that there exist sharp discontinuities in risk from one street to another. As most methods of crime forecasting use some form of smoothing algorithm, this issue is not accounted for in these models. The above issues and how thinking about methods of crime forecasting might be developed to accommodate them are discussed in this entry.

Introduction

Many things in life are random. Patterns of crime are not. Crime clusters at places, where places represent neighborhoods, street segments, or individual properties (for a review, see Johnson 2010). For many crimes, it is also evident that the timing of victimization is not random, with there being seasonal variation in the frequency of occurrence of offenses (Farrell and Pease 1994), and variation throughout the day (Ratcliffe 2002). Moreover, for burglary events, the elapsed time between events at the same home is typically short (Johnson et al. 1997). More recently, using (for example) techniques originally developed to detect disease contagion, research (see Table 1) has examined the association between the timing and location of crimes committed not just against the same target but also those nearby. The finding so far consistently observed is that when a crime occurs at one location, others are more likely to take place swiftly nearby. This finding applies to volume crime such as burglary, but also extends to other event types such as shootings (Ratcliffe and Rengert 2008) and insurgent activity (Townsley et al. 2008). In this entry, research concerned with this phenomenon – referred to as *near-repeat* victimization – is reviewed and consideration is given as to how this area of investigation informs methods of crime forecasting, and how it might usefully evolve. The entry is organized as follows. It begins with a discussion of methods of quantifying repeat and near-repeat victimization. Next, theoretical explanations as to why such patterns might emerge are considered. In the subsequent section, a number of unanswered research questions that might inform future work are identified. And, finally, there is a discussion of how what is already known has informed methods of crime forecasting and how such methods might be developed.

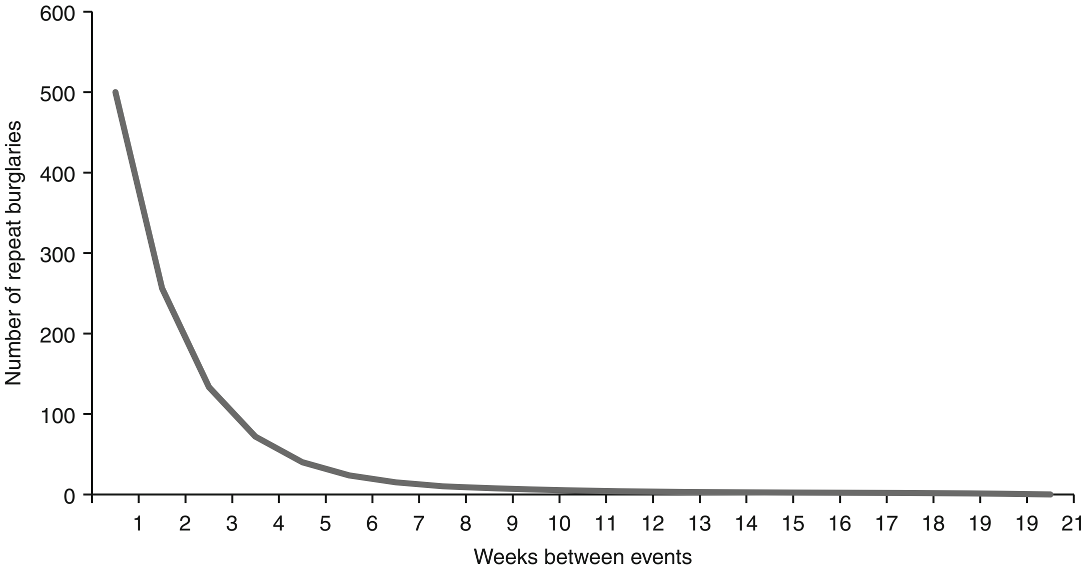
Fundamentals: Identifying and Quantifying Patterns of Near Repeats

A number of techniques have been used to examine patterns of repeat victimization of the same home (in the case of burglary) and near-repeat victimization. In the case of the former, the approach to analysis is somewhat simple. For repeat victimization proper, an incident of repeat victimization is defined simply as an offense where the victim has previously experienced an incident of the same type (or, crime more generally depending upon the researcher's interest). For this type of analysis, one may calculate the time elapsed between events and summarize this inter-event distribution. A typical finding is that the time elapsed between offenses is short, with the count of events declining logarithmically as a function of time. Figure 1 gives an example of such a time course (in this case, using fictional data).

One may also estimate whether the number of homes that were observed to have been victimized one, two, three, or more times differs from chance expectation, assuming that events are independent. The approach to analysis typically used is to estimate the number of homes that would be expected to be victimized 1 to N times, assuming the observed distribution can be explained by a Poisson process (the null hypothesis in this case). This type of analysis can be conducted assuming that the overall risk to homes

Near Repeats and Crime Forecasting, Table 1 Findings from selected studies of "near repeats" (studies in which a new method was introduced are highlighted with an asterisk)

Offense type	Study authors	City (Country)	Statistical technique	Time period	Space-time interval of effect
Burglary	Townsley et al. (2003)	Beenleigh (Australia)	Knox*	34 months	Clear effect but precise pattern unreported
	Johnson and Bowers (2004)	Liverpool (UK)	Knox, Mantel*	12 months	400 m and 28 days
	Bowers and Johnson (2005)	Liverpool (UK)	Descriptive, Mantel*	60 months	Neighbor effect, 1 week
	Johnson et al. (2007)	5 countries (AUS, NDL, NZ, UK, USA)	Monte Carlo Knox*	24 months	Varied, but always apparent for 200 m and 14 days
	Mohler et al. (2011)	Los Angeles, USA	Self-exciting point process*	24 months	100 m and 7–10 days
	Rey et al. (2011)	Mesa, USA	Markov Chains*	51 months	Adjacent locations and 1 month
Bike theft	Johnson et al. (2008)	Bournemouth (UK)	Monte Carlo Knox	12 months	300 m and 3 weeks
IED attacks	Townsley et al. (2009)	Iraq	Knox	3 months	1 km and 2 days
	Behelendorf et al. (2011)	Spain	Knox	144 months	5 miles and 2 weeks
IED attacks and counterinsurgency	Braithwaite and Johnson (2011)	Iraq	Bivariate Monte Carlo Knox*	6 months	Varied across event types
Shootings	Ratcliffe and Rengert (2008)	Philadelphia, USA	Monte Carlo Knox	13 months	400 ft and 14 days
Theft from vehicle	Johnson et al. (2009)	Bournemouth (UK)	Monte Carlo Knox	60 months	800 m and 14 days
Theft of motor vehicle	Lockwood (2010)	Lincoln, USA	Monte Carlo Knox	48 months	700 ft and 28 days



Near Repeats and Crime Forecasting, Fig. 1 Stylized illustration of the change in the risk of re-victimization risk over time is homogeneous or that there will be variation at the area (Trickett et al. 1992), neighborhood or house-level (Johnson 2008). A similar approach can also be used to estimate the expected time course of repeat victimization (Johnson 2008). In the case of burglary, what the available evidence – conducted across a variety of countries – suggests is that, relative to the pattern expected, the risk of victimization is temporarily elevated following an offense.

In terms of near-repeat victimization, the approach to analysis is slightly more complicated in that the analysis is extended to an examination of any regularity in the patterning of crimes that occur not just at the same locations, but also nearby. A number of approaches to analysis have been adopted. In one study (Bowers and Johnson 2005), using data recorded by the police (Merseyside, UK) that covered an interval of 5 years, the authors identified every street on which two or more burglaries had occurred. For each burglary, they then calculated how many doors apart that burglary had occurred from the most recent burglary that had also taken place on the same street. A distribution was then derived to indicate how many sequential burglaries had occurred one-door apart, two-doors apart, and so on. This distribution was standardized to account for the fact that because roads are not infinite in length, there would be more opportunities for burglaries to occur (say) one-door apart from each other than (say) 30 doors apart. The results clearly indicated a pattern of distance decay, such that when burglaries occurred on the same street as each other, they were most likely to occur near to each other. Further analyses also indicated that burglaries that occurred on the same street were also more likely to occur on the same side of the street as each other and near to each other in time. Thus, when a neighbor of a victimized home was burgled, this was more likely to occur within 1 week of the first offense than (say) 7–14 days apart.

Such analysis examines patterns observed on the same street, but does not consider those offenses that occur near to each other but on a different road. For this reason, other methods of analysis, originally developed to detect disease contagion, have also been used. A number of studies have used a technique developed by Mantel (1967). This test is used to see whether crimes that occur closest to each other in space are also more likely to occur close to each other in time. This particular test provides a single index of space-time clustering for a particular area, and while it has useful diagnostic value, it is a relative measure which means that what is defined as near (in time or space) is not actually specified. That is, space-time clustering would be detected even if it were the case that the events that were closest to each other were (say) two miles apart, if that is, relative to events that occurred further apart, these crimes also tended to occur closest to each other in time.

A test developed by (Knox 1964) provides an alternative approach. In this case, each event of interest is compared with every other and the absolute distance and time elapsed between them is computed. In the original formulation, a 2 × 2 contingency table was populated to enumerate how many pairs of events had occurred close to each other in space and time; close in space but not in time; close in time but not space; and neither close in space nor time. This test allows the researcher to define what is meant by "close" in both dimensions and hence provides more precise insight into observed patterns. To determine whether the latter differ from chance expectation, assuming the timing and location of events are independent, the expected counts are calculated for each cell by multiplying the total counts for the relevant row and column and then dividing by the total across all cells of the table (the same approach used to compute expected counts for a Chi-Square statistic).

Such an analytic strategy may be sufficient for estimating the extent to which a disease is contagious, and for examining general patterns in the space-time dynamics of crime, but it does not provide a particularly precise picture of crime patterns. This is so because only two categories of near and far are defined. For this reason, in recent work (Johnson and Bowers 2004a), the approach has been extended so as to include numerous categories. In general, around 10–20 different spatial and temporal bandwidths have been used. For example, Johnson and Bowers (2004a) used spatial bandwidths of 100 m and temporal intervals of 7-day periods. Patterns observed across these relatively finely resolved categories can then be compared with each other and with a more general “distant” category.

One potential weakness with the approach to statistical inference used for this test is that the test statistics are based on parametric assumptions that might not be met. For this reason, Johnson et al. (2007a) developed a nonparametric version of the test that uses a Monte Carlo simulation to estimate the statistical significance of observed patterns. As was the case for previous work, the authors found that burglary clustered in time and space more than would be expected if the timing and location of events were independent. Importantly, in that study, the authors found consistent patterns within each of two cities in each of five different countries, suggesting that the patterns are not specific to a particular locality.

A further refinement in the existing research involves a more precise study of the distribution of space-time clusters. To elaborate, for the techniques discussed above, the approach to analysis involves counting the number of pairs of events that occur within particular spatial and temporal intervals of each other and comparing these counts to expectation, assuming that the timing and location of events are independent. In an early study, Johnson and Bowers (2004b) extended the approach by examining whether pairs of events that occur close to each other in both space and time also cluster. They did this by computing the number of event pairs (hereafter, close pairs) that occurred within a given space and time interval (100 m and 1-month) of each other for a series of 151 neighborhoods, for each month of a 1-year period. Their analyses showed that in general, the number of close pairs that occurred in a neighborhood was similar for sequential monthly intervals, but that the correlation was lower and typically nonsignificant where the counts for intervals that were more than one month apart were compared. Similarly, it was evident that if a neighborhood had a high count of close pairs in a particular month, those nearby also tended to also have a high count of close pairs around the same time. There was no systematic association between the count of close pairs in neighborhoods that were a fair distance apart, regardless of whether comparisons were made for the same month or other intervals.

A slightly different approach was adopted in other work (Johnson et al. 2007b). In that study, for each burglary event, the authors calculated how many other burglaries had previously occurred nearby in the recent past. The idea of doing so was to estimate the number of events that might typically make up a *spate* (or *poly-order chain*) of burglary events. In a further study, this time concerned with Improvised Explosive Device (IED) attacks in Iraq, Johnson and Braithwaite (2009) used a Monte Carlo method to compare the observed length of spates with those expected, assuming that the timing and location of events were unrelated. In this study, relative to expectation, it was apparent that while there were significantly more spates that comprised six or more IED attacks, there were actually significantly fewer spates with seven or more offenses. That is, after six IED attacks had occurred at or near to a location shortly after each other, others were actually less likely to occur than would be expected if the timing and location of attacks were independent. Collectively, these findings suggest that when a crime occurs at a location, others are more likely to occur nearby in the near future. However, as time elapses, this increase in risk decays.

Following the development of methods to quantify patterns of near repeats, a number of studies have been conducted and Table 1 provides a summary of some of the most salient findings to date. Between the period 2003 and 2011, more than 30 studies of which the authors are aware have so far been published on this topic and so what should be apparent is that while the analysis of this type of patterning for crime events is relatively new, there now exists a considerable body of research for a range of different types of event and for different countries.

Possible Explanations for Near-Repeat Patterns

Much of the research concerned with spatial patterns of crime ignores the dimension of time, focusing exclusively on spatial patterns aggregated over some interval. Such analysis might be described as examining the stable or slow dynamics of crime. In contrast, research concerned with near repeats explicitly examines both spatial and temporal patterns, and does so at a fairly fine level of resolution. As such, this kind of analysis might be described as examining the fast dynamics of crime.

One question that remains unanswered is how the fast and slow dynamics of crime influence each other. For instance, do the fast dynamics give rise to the slow ones, or vice versa, or, is the association more complex? Given that many hotspots endure it would seem unlikely that the fast dynamics entirely define the slow ones, and so disentangling this issue is of clear importance. Controversies such as this will be discussed in a later section.

Apropos why repeat and near-repeat victimization occur, two theories have been proposed to explain observed patterns. According to the first, variation in enduring characteristics that makes targets vulnerable to crime explains the patterns described. This concept of *risk heterogeneity* (see Johnson 2008) assumes that – other than the target involved – there is no association between one offense and another. The risk of victimization across targets is seen as being time-stable and a function of a set of characteristics that many or all offenders would find appealing.

Considering offender spatial decision making, research has generally focused on the types of place that offenders might display preferences for. Underlying such models is the idea that offenders, like the rest of the population, are rational decision makers (Clarke and Cornish 1985) who weigh up the benefits, costs, and effort associated with possible courses of action. Such decision making is not seen as involving a comprehensive evaluation but is regarded as being more heuristic in nature, with offenders using “rules of thumb” to assess opportunities perceived. Of course, offenders will rarely be aware of the true costs, benefits, and rewards of any particular decision made, and so their decision making is instead considered to be bounded by the information of which they are aware, cognitive biases, and so on. However, the point of central importance is that in most of the research literature, offender decision making is typically considered in terms of spatial choices. These may be hierarchical, insofar as certain types of areas may first be selected, after which particular targets – which may confirm to cognitive templates – are selected, but they are nonetheless spatial.

Research on near repeats draws more explicit attention to the dynamic nature of offender spatial decision making. For example, the offender as forager hypothesis (Johnson and Bowers 2004b; Johnson et al. 2009b) borrows from concepts regarding animal foraging, ideas that are well established within the field of ecology. The obvious reason for the comparison being that the activities considered, be they animal foraging or offender decision making, share common underlying goals. Both seek to maximize benefits, while minimizing expended effort and the associated risks (be it detection or being eaten). Moreover, both forms of activity are subject to constraints. The actor, be it animal or offender, can only move so far and so fast per unit time, and both expend effort in doing so. In neither case would it seem to be efficient to make future choices without reference to previous ones, particularly those made most recently. Where recent choices have been rewarded, their repetition would seem reasonable, albeit up to a certain point. In the case of the offender, returning to the same location repeatedly would likely ultimately either lead to arrest or little reward – as little would be left to take. The targeting of locations near to successfully exploited targets may represent an efficient strategy as the first law of geography (Tobler 1970) states that things that are close to each other are more similar than are those that are far apart. Thus, nearby targets are likely to share important features (e.g., levels of natural surveillance, escape routes, etc.) of those previously successfully targeted that will make them good opportunities for crime, at least in the short term. The latter point is important as things may be subject to change, and memory fades.

Thus, in contrast to theories of risk heterogeneity, those concerned with *event dependency*

(Pease 1998) assume that victimization influences future risk. In the case of crimes such as burglary, where the conditions at already targeted locations are conducive to crime, it is hypothesized that the same offender (or group of offenders) will return and that they will do so swiftly.

A number of research methods have been used to test the two types of theory. The analysis of crimes detected by the police (Bernasco 2008; Johnson et al. 2009b) indicates that, relative to burglaries that occur close in space *or* time to each other, those that occur nearest to each other in both dimensions are massively more likely to be the work of the same offender(s). The same is true for theft from motor vehicles (Johnson et al. 2009b). Such patterns would be predicted by the offender as forager hypothesis but are inconsistent with theories of risk heterogeneity.

Interviews with offenders also suggest that offenders return to the same locations (Ashton et al. 1998) and those nearby (Summers et al. 2010) for reasons compatible with the offender as forager hypothesis. Of course, such research also indicates that target attractiveness plays a role; an offender can only return to an area or street they have already targeted, and so as a minimum, risk heterogeneity will play a role in determining where offenders commit initial offenses. Moreover, not all offenders will adopt foraging strategies and for such offenders, target attractiveness may be the primary factor that they consider when selecting targets.

In the case of repeat burglary victimization, it is apparent that relative to low frequency offenders, prolific offenders who are more established in their criminal careers appear to be more likely to return to the exact same properties (Everson and Pease 2001). It is unclear whether the same applies to those who commit near repeats, but this would seem to be plausible. If this is the case, then it would suggest that target attractiveness (risk heterogeneity) alone may explain the targeting strategies of those burglars who infrequently commit crime, but that those who routinely engage in such offenses, the experiences associated with the burglaries they have recently committed will significantly inform their subsequent choices.

A different approach to theory testing and falsification than has been discussed hitherto uses mathematical models or computer simulation. The detail is not important, but the central idea is to see if models that describe a particular data-generating process – such as event dependency or risk heterogeneity – are sufficient to generate space-time patterns of events that resemble those observed in crime data. This research indicates that models that include only – or completely exclude – risk heterogeneity are incapable of generating the time course of repeat victimization (Johnson 2008) or near-repeat victimization (e.g., Pitcher and Johnson 2011). However, those that include both processes generate patterns much like those observed in the research described above.

Mohler et al. (2011) have also used a class of statistical model, originally developed to examine patterns of earthquakes, to examine patterns observed for the crime of burglary. The aim of this type of statistical model, known as a *self-exciting point process*, is to estimate the contribution of (unobserved) time-stable factors that vary across space (e.g., the location and size of unknown fault lines in the case of earthquakes) and the effects of after-shocks that follow each quake. Using data for burglaries recorded by the police in Los Angeles, Mohler et al. (2011) find that for this event type at least, both types of process are important. Thus, it would seem that both types of explanation – risk heterogeneity and event dependency – have a part to play.

Before leaving this discussion, it is worth noting that one methodological issue that is sometimes discussed with respect to patterns of repeat or near-repeat victimization is that these might be explained by an artifact associated with the data. It is widely acknowledged that police-recorded crime data is by no means a perfect measure of crime, as much crime goes unreported. Moreover, from the perspective of when crimes occur, it is often difficult to pinpoint the exact time of a burglary as this will be unknown and so estimation procedures are often necessary. However, these issues are unlikely to influence the results of the types of analysis discussed unless there is a systematic pattern (in space and time) associated with them, and there is no reason to suspect that there is.

A potentially greater concern involves edge effects. In the case of near-repeat victimization, burglaries that occur at or near the boundary of a study area have more opportunity to be further away from other burglaries than do those in the middle; likewise, burglaries that occur at the start of a time period have more potential to be further apart in time from other crimes than do those that occur at the end. However, because the expected distribution of events is established using the observed data and methods such as the Monte Carlo procedure discussed above, we suggest that the approach to analysis accounts for edge effects (and other issues).

What Don't We Know About Near-Repeat Patterns?

Although much has been learned about near repeats over the last 8 years, a number of things are currently unclear. For example, while the research to date suggests that both theories of risk heterogeneity and event dependency have a part to play in explaining space-time patterns of crime, the precise contributions of each process are not well understood. For instance, as discussed, in the case of burglary, it could be that some burglars tend to select targets purely on the basis of their perceived attractiveness, whereas others select targets in a way that is consistent with the optimal foraging theory discussed above. Others still may adopt a more even mix of strategies. An alternative explanation is that all offenders adopt the same strategy, but that some burglary events encourage a swift return to the same property or those nearby, whereas in other cases, the reverse is true. For instance, if an offender is challenged by a resident while attempting to burgle a home, that offender is likely to be discouraged from returning to the same neighborhood for some time. To put it another way, at what unit of analysis – the offender or the event – do these two types or processes (risk heterogeneity and event dependency) operate?

The preceding discussion focused on the crime of burglary, but as is evident in the introduction to this entry, near repeats are observed for a range of event types and it is likely that different mechanisms will be responsible for observed patterns for some of these. In the case of similar crimes, common explanations may suffice but is the same true for very different types of events?

While this seems unlikely, there may be some commonalities associated with human mobility dynamics. For instance, most actors are subject to constraints that limit how far they can travel per unit of time and how fast they can do so. It may also be reasonable to assume that actors are more likely to engage in activities at locations with which they are familiar than those that they are not, regardless of the event type. However, while there may be some commonalities in the explanations for different event types, understanding the differences will be important if the patterns are to be truly understood.

Little research has considered how patterns, and the contribution of the two theoretical processes (risk heterogeneity and event dependency) discussed, might vary across space and/or time, but there are two exceptions. Townsley, Homel, and Chaseling (2003) found differences in patterns of repeat and near-repeat victimization across a sample of five different suburbs and found that near-repeat victimization was more likely in those suburbs with more homogeneous types of housing. They interpret this as suggesting that where replicas of a previously victimized home exist, offenders will be more likely to commit near repeats. Bowers and Johnson (2005) examined patterns of repeat and near-repeat burglary victimization for a larger sample of 118 areas in one county in the UK. They found the former to be accentuated in deprived areas, but that patterns of the latter were clearer in affluent ones. However, other than these two early studies, little research has examined how patterns vary across spatial units, or if they are stable over time. It is possible, for example, that in one hotspot of criminal activity, there may be a strong pattern of near repeats, whereas in another, there will be no such pattern. Moreover, patterns of near repeats may ebb and flow over time, perhaps with the seasons (Johnson and Bowers 2004b) or perhaps as a consequence of certain types of offenders moving into or out of an area. Studying such dynamics is likely to inform understanding and assist in efforts of crime forecasting.

Given previously well-documented offender versatility, it may be expected that the space-time distribution of different types of offense would be correlated. Only one study (Johnson et al. 2009b) has so far examined near-repeat patterns across offense types. In that study, patterns of burglary and theft from vehicle were considered and it was found that for the two types of event, patterns of victimization were *not* correlated in space and time. Further analyses of crimes detected by the police for the same area indicated that offenders who committed one type of offense typically did not commit offenses of the other kind. This latter finding explains why the space-time distributions of the two types of offenses were not found to be correlated, but are at odds with other research concerned with offender versatility. Thus, it is not yet clear whether the finding regarding space-time clustering across offense types is typical across other localities or if it holds true for other combinations of offense types.

Another issue which requires attention is how co-offending or offender cooperation might contribute to (or interfere with) patterns of repeat or near-repeat patterns. Empirical research on co-offending more generally is in its infancy (Andresen and Felson 2010) and so this may be a particularly useful area to consider. For example, it is possible that offenders may share information regarding good opportunities, or (for example) work streets together in some cases. If this is the case, then the "boost" hypothesis would still explain observed patterns, but establishing the extent to which offenders cooperate in this way would inform criminological understanding and have implications for police practice. An alternative is that where offenders work together, the patterns are quite different to when they offend alone. Those that co-offend may adopt quite different strategies to the foraging approaches discussed above. Regardless of the reality, it would be beneficial to examine this.

A point that is discussed below concerns what the appropriate units of analysis for research of this kind should be. For the Knox and similar forms of analysis, the distance between events is measured using either the Euclidian (straight-line distance) or Manhattan (the sum of the difference between two points in the horizontal and vertical dimensions) distance between them. Given that many offenses occur along a street, this may be inappropriate or it may mask important variation. For example, two homes may be (say) 100 m from each other in Euclidian space, but be separated by a much more substantial distance along the street network. Thus, a further question that has not been addressed to date is how risk spreads along the street network as opposed to within streets or across Euclidian space. Researchers might ask if risk spreads preferentially from streets that are connected to each other, if such a diffusion of risk is more likely along similar types of streets, and if there are other regularities associated with when risk spreads from one street to another and when it does not.

Predicting Future Crime Locations

While there is still much that is unknown about space-time patterns of crime, current findings have practical application and inform criminological theory. The finding that following one crime at a particular location, the risk of others occurring nearby is temporarily elevated has obvious implications for crime prevention and crime forecasting. In this regard, recent work has examined the forecasting accuracy of simple mathematical models that take account of both the timing and location of historic events, and compared this with methods that consider only where historic events occurred (regardless of when they took place). For both types of model, the risk of crime is assumed to be a function of how much crime previously occurred at that location and nearby. In the case of models that take account of when and where crimes occurred, the reason is that the risk of crime is assumed to diffuse in space much like a contagious disease. And, consequently, more recent events are seen as more important and thus given a larger mathematical weighting in the models. In the case of those models that do not consider the timing of events, the theoretical rationale for considering the location of events that occurred near to, as well as at, each location has not been explicitly articulated, but the research concerned with near-repeat victimization at least provides a justification for this.

A typical method of contrasting the accuracy of such models may be described as follows. First, a study area is represented by a grid of regular sized cells (say 50 m by 50 m in dimension). Second, predictions are generated for each cell using data for a training interval. To calculate the expected risk in each cell, a mathematical formula is used which considers how much crime occurs in each cell and within some (usually) fixed distance from it. What that distance or *bandwidth* is often is selected for atheoretical reasons, such as the visual elegance of the resulting map. However, the research concerned with near repeats provides a theoretically meaningful way of determining the bandwidth. For example, the Knox analysis can be used to determine the distance and time over which the risk of crime appears to diffuse in space and time, and hence, the distance and time over which each crime might be expected to affect the risk of crime at nearby locations. Regardless of the approach to selecting the bandwidth, all of the methods typically apply a weighting to each event that is inversely related to the distance the event occurs from the center of the cell. Methods that take account of the timing of events additionally apply a weighting that considers when the events occurred. In this case too, a bandwidth is selected and the weighting applied to events within that bandwidth is usually inversely related to the time elapsed between that event and the period for which the forecast is generated.

After generating predictions for a particular model, these are compared with observed outcomes for a series of subsequent forecast intervals. In the analyses so far conducted (e.g., Bowers et al. 2004; Johnson et al. 2007b, 2009a) for the crime of burglary, those models that take account of both the timing and location of burglary outperform those that consider only the location of previous events. In a recent study, Mohler et al. (2011) show that statistical methods that explicitly estimate the likely contributions of time-stable (estimated using crime data alone) and event-dependent processes improve the forecast accuracy of such methods.

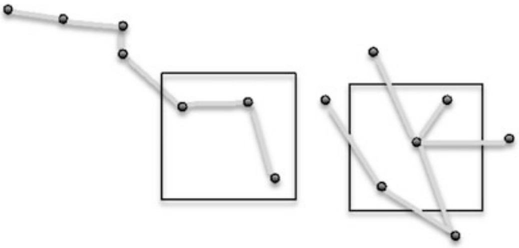
Other work (e.g., Johnson 2008) has examined how forecasting models can be improved by considering time-stable characteristics of the environment in a different way. In that study, the researchers incorporated simple data regarding the distribution of potential targets (houses) of burglary and the street network. Again, improvements in forecast accuracy were observed relative to models that exclude such information.

Future Developments in Prediction

Work on predictive analysis is, however, embryonic. For example, information on the street network has so far been limited to an indication of where roads are physically located. As discussed above, the risk of crime may diffuse along the street network in particular ways. Even in the most basic sense, if risk diffuses along the street network rather than through geographical space, then the topology (the ways in which segments of the street network are or are not connected to each other) of the network may significantly affect how the risk of crime spreads. For example, if two cells in an area were near to each other but not connected by the street network, then it is possible that risk may not diffuse between them, or that any propagation is impeded relative to two homes that are the same distance apart but connected (all other things being equal). In addition, even if two cells are connected via the street network, while they might be close in Euclidian space, they may be far apart in topological terms. The extent to which a consideration of topology might play a role in improving the accuracy of crime forecasting is currently unknown but amenable to mathematical analysis.

As discussed above, the way in which crime risk might spread in space *and* time might well vary across different neighborhoods. In the analyses so far conducted, patterns are modeled in the same way across areas and so gains in predictive accuracy might be achieved by systematically studying how patterns vary across areas and incorporating such findings into predictive models. Similarly, patterns might vary in time. For example, near repeats might be more likely at certain times of the day or even the year. Such variation is plausible as the risk of crime more generally is known to fluctuate throughout the day (Ratcliffe 2002) and year, presumably reflecting (amongst other things) variations in people's routine activities and hence their availability to act as capable guardians against crime. In line with this suggestion, Johnson et al. (2007) find that when pairs of events occur near to each other in both space and time, they are more likely to occur during the same interval of the day than chance expectation. However, with the exception of this study, no research of which of the authors are aware has examined how the risk of near-repeat victimization might vary over the course of the day and how predictable patterns might be.

One issue not so far discussed is that the types of analyses generally conducted to detect patterns of space-time clustering focus on point patterns (the precise locations of crime events), whereas the methods used to generate predictions do so with reference to a fixed grid. The potentially important issue is that for point patterns, space-time clustering may be generated in a number of ways. For example, space-time clustering might occur if many pairs of events happen close to each other in space and time and are all located in an area surrounding a single cell – let us refer to this as cell A. Space-time clustering might also occur if sequential pairs of events happen near to each other but if, over time, the pairs of events generally move away from cell A. Figure 2 represents these possibilities. It should be clear that the risk to cell A should be modeled differently if the first type of pattern were typical than if the second type were dominant. However, it is not possible to differentiate between these two types of directional pattern using the kinds of analyses that have been traditionally used.



Near Repeats and Crime Forecasting, Fig. 2 Potential near-repeat point patterns surrounding a grid cell

There appears to be value in matching units of analysis used to determine space-time patterns with those used in prediction. In two recent papers (Mohler et al. 2011; Rey et al. 2011) concerned with space-time clustering, the units of analysis were grid cells rather than point locations. For example, Rey et al. (2011) divided their study area into ¼ by ¼ mile grid cells and calculated how many burglaries occurred in every cell each month for a period of 51 months. Next, using a discrete Markov Chain framework, for each month, they examined the probability with which each cell would transition from a state of experiencing no burglaries or a state of experiencing at least one to the same or the alternate state. Consistent with research that has examined point patterns, their findings clearly showed that the *state* of a cell (whether crimes occurred in it or not) at any interval was positively associated with the state of that cell and those adjacent in the previous period. Moreover, that this pattern could not be explained by risk heterogeneity alone. This, or similar approaches, may help to more precisely calibrate methods of crime forecasting that take account of both the timing and location of events.

In addition to the issue of matching units of analysis for description and prediction, there is still the underlying question of what the relevant unit of analysis should be in crime forecasting of this kind. Grid-based predictions are largely used because of computational convenience. That is, constructing a grid of regular sized cells is straightforward and the spatial relationship between each cell and every other is simple to establish. However, crimes do not occur on a grid (except where the street network is of that geometric configuration), and offenders are unlikely to engage in decision making with reference to such a representation of the world. Moreover, research suggests that there are sharp discontinuities in the distribution of crime risk, such that (for example) two roads that are very near to each other (even directly connected) may experience very different risks (Groff et al. 2010). Possible reasons for this variation are numerous but the point of central importance is that – whatever the explanation – something about the way those street segments differ is associated with variation in crime risk. This is also true of block faces in a US context which in essence are equivalent to street segments in Europe. Where risk is modeled on a grid surface, this variation is ignored as the grid cells are unlikely to reflect the geometry of the street network. Thus, the risk for the cell represents the average risk across those street segments within it, even though the places within the cell may differ considerably in factors including crime risk. Moreover, the smoothing algorithms used to derive grid-based predictions will mean that risk is assumed to diffuse from one location to any another nearby location, irrespective of the characteristics of the type of location, something that may be unreasonable.

Thus, it is suggested that future research should explore methods of crime forecasting using street networks or block faces rather than grid cells. Methods of describing and representing street networks are possible using basic techniques from a branch of mathematics known as graph theory, and that exploring this type of approach is an obvious next step in the research agenda.

In closing, a further question to consider as yet unasked in the research literature is precisely what does one want to predict with forecasting models? To make things concrete, consider those forecasting models developed to predict patterns of burglary. As discussed, the available evidence suggests that observed patterns are most likely the result of two data-generating processes: risk heterogeneity and event dependency. If, as has been tentatively suggested, these two processes reflect the dominant targeting strategies of two different types of offender, the patterns and locations of offenses generated by one group of offenders might differ from those of the other. If so, should the accuracy of forecasting models be evaluated with respect to the total amount of offenses correctly predicted, or should such assessment also consider what types of events (e.g., near-repeat victimizations) are accurately identified? One reason for asking such a question is that the types of crime reduction action that might be triggered by the two types of prediction – those that might forecast the locations of events most likely committed by those who adopt foraging strategies as opposed to those who adopt more opportunistic strategies – may well differ. If this proves to be the case, for events that may be considered most likely the result of the consequence of enduring characteristics of places (assuming such a distinction is possible), situational crime prevention interventions will likely represent the most productive approaches to crime reduction. In contrast, where events predicted are more likely to be the work of offenders who adopt optimal foraging strategies, efforts directed toward detecting (or preventing) future offenses will likely prove more fruitful. In operational terms, the development of methods of forecasting that are specifically tailored to these two types of policing may be more helpful than are those models that predict more offenses (of any kind). The extent to which this is true is, of course, an empirical question.

Overview

Features of neighborhood social networks are central to many of the most prominent theories of crime. Empirical tests of a number of criminological theories underscore the importance of neighbor networks in both facilitating and deterring crime, both at the individual and community levels. However, most studies that focus on the link between neighborhoods and crime are limited by the use of "perceptual" and other proxy measures that aim to capture neighbor cohesion, social capital, and other social processes thought to mediate the association between neighborhood structural characteristics (e.g., concentrated disadvantage, residential instability) and offending. Exactly which features of neighborhood social organization are the most consequential for crime remains unknown due to the paucity of relational data that capture theoretically relevant features of actual neighborhood network structures. Furthermore, the mechanisms through which social networks influence neighborhood crime remain underexplored.

Despite the significant challenges associated with collecting neighborhood-based social network data, great strides have been made in the study of neighborhood networks in recent years. This entry provides a brief overview of past research on neighborhood networks and crime and highlights notable recent advances in the conceptualization and measurement of neighborhood-based social networks in empirical research.

Whether explicit or implied, several of the most prominent criminological theories focus on the link between social networks and individual and aggregate offending patterns. For instance, theoretical constructs such as bonding, cohesion, social control, and peer influence are all central correlates of crime in criminological research (Papachristos 2010). These constructs in turn are commonly thought to represent emergent properties of the structure of affiliations among social groupings at various levels of aggregation (e.g., peer groups, neighborhoods, cities).

A number of macro- and multilevel theories also specifically focus on the direct and indirect effects of neighborhood and community networks on aggregate and individual rates of offending. Unfortunately, despite the centrality of social networks in criminological theory and empirical research, criminologists rarely employ social network analysis in research, especially when compared to researchers from other disciplines (e.g., public health and sociology; see Papachristos 2010). The use of social network analysis in community and neighborhood studies of crime occurs even less frequently. This neglect is quite noteworthy considering social processes related to neighborhood-based affiliations are central in explanations of neighborhood "effects" on crime (Sampson et al. 2002).

The disjuncture between the conceptual significance of social networks and the relatively infrequent use of network data and analysis in research on crime highlights the need for more effective integration of social network analysis into the criminological toolkit. Initial efforts toward this end have resulted in significant advances in the articulation and testing of classical and contemporary theories of crime. For instance, researchers focusing on "peer effects" (Haynie 2001) and gangs (Papachristos 2009; Radil et al. 2010) are increasingly employing network designs to test and expand upon criminological theories of diffusion, group conflict, and influence. Research on the implications of neighborhood social networks has also integrated more conceptually sophisticated social network insights into their explanations of criminal behavior. Despite the inherent difficulty of collecting data on neighborhood social networks, neighborhood scholars are developing innovative methods of data collection and analysis that may be used to study the association between neighborhood network structures and crime.

This entry presents an overview of recent advancements in the study of neighborhood social networks and crime focusing on neighborhood networks as they pertain to the dominant macro- and multilevel theories of crime and community. Those primarily interested in the association between individual level or ego networks and crime may wish to read Haynie and Soller's (this volume) chapter on "peer effects" research in criminology.

This entry proceeds as follows. First, a brief overview of classical and contemporary theories of neighborhoods and crime is presented, highlighting the theoretical associations between the structure of social relations and crime. Attending to these theoretical associations will help identify which properties of social networks are most consequential to crime. This entry then highlights the unique properties of network data while focusing on the potential application of social network analysis to the study of neighborhoods and crime. Finally, this entry describes recent studies that have employed innovative social network approaches to understanding the association between neighborhoods and crime.

Neighborhood Networks in Theory: From Yesterday to Today

Durkheim (1951) provides one of the first attempts to empirically examine the association between the structure of social relations and aggregate social problems. Durkheim proposed high levels of communal social integration promote social control over individual members, constraining individuals' natural tendency to obviate social rules in the pursuit of self-interested ends. Thus, strong affiliations among members control crime and maintain social order through social control processes.

Early Chicago School scholars such as Wirth (1938) suggested increasing urban development and division of labor has deleterious effects on the community structure and solidarity characteristic of nonindustrial societies. The linear model of development has been characterized as a prototypical example of the "community lost" paradigm, which suggests pervasive division of labor in society disrupts solidary communities, leading to the formation of fragmented networks consisting of "impersonal, transitory, and segmental ties" (Wirth 1938, p. 12). Such patterns of community organization are thought to hinder neighborhood residents' capacity to collectively organize to deal with social problems (e.g., crime and delinquency) within local communities.

Around the same time, Shaw and McKay (1942) proposed their theoretical model of community social organizational influences on crime. In this view, neighborhood structural characteristics, such as concentrated poverty, racial and ethnic heterogeneity, and residential stability, determine the extent of social interaction among neighbors and their corresponding capacity to maintain informal social control over local youth, with consequences for the prevalence of crime in the community. Building on the work of Shaw and McKay, Kornhauser (1978) developed a community control model of neighborhood social disorganization, which more precisely articulates how concentrated disadvantage, population turnover, and racial/ethnic heterogeneity shape consequential neighborhood social networks. For instance, residential instability, or the frequency with which residents move in and out in a neighborhood, is thought to limit opportunities to form trusting relations among neighbors. Racial/ethnic heterogeneity is hypothesized to limit interaction among members of different racial groups, which hinders the formation of "weak ties" (Granovetter 1973) within neighborhood settings. One potential outcome of social and cultural heterogeneity is a fragmented neighborhood network structure that hinders the collective capacity to maintain informal social control. This systemic model of crime thus proposes exogenous neighborhood structural characteristics indirectly lead to crime through shaping neighbor networks, which determine more proximate causes of crime, such as informal social control.

While Kornhauser extracted a pure control model from Shaw and McKay's theory of social disorganization, other theorists (Cloward and Ohlin 1960) propose that the criminological consequences of community social organization are dependent upon the types of individuals and cultural models that are present in the community. From this perspective, deviant "value systems" represent emergent properties of neighborhood social organization. Accordingly, structures of social ties among neighborhood residents take on additional criminological consequences by fostering the formation and maintenance of delinquent subcultures conducive to crime.

From an individual standpoint, neighborhood contexts are important in shaping peer associations, especially among youth and adolescents. Peer delinquency in turn is one of the most robust predictors of offending (Haynie 2001). Different features of neighborhood social organization also more directly influence individual offending. For instance, routine activity perspectives suggest adolescent offending is in large part a function of the time adolescents spend engaging in unstructured socializing with peers in the absence of adult authority figures (Osgood et al. 1996). Other prominent theories, such as collective efficacy theory (Sampson et al. 1997), also point to the importance of intergenerational closure (i.e., adult embeddedness in neighborhood social networks) in promoting pro-social behavioral norms, which in turn fosters adolescent development and desistence from crime.

Finally, studies on the criminological consequences of residential segregation point to the importance of intra-neighborhood social ties in determining neighborhood- and city-level crime rates. As Krivo et al. (2009, p. 1792) suggest, "city segregation contributes to neighborhood violent crime indirectly, through the way it produces isolation and structural disadvantage in predominantly minority areas, and directly, by making it difficult for separate and unequal groups to work together to foster common goals and solve shared problems." From a network perspective, racial segregation hinders social integration across neighborhoods, which in turn obstructs the formation of ties between political institutions and community investors and members of disadvantaged and isolated communities. Low levels of city-level social integration limit intergroup contact, which has deleterious effects on efforts at collective organizing to realize both the formal and informal controls over crime (Hunter 1985).

Empirical Tests of Neighborhood Theories of Crime

The aforementioned theoretical approaches present different, and at times, competing mechanisms with regard to the role neighborhood social networks play in shaping individual and aggregate rates of offending. While empirical support mounts for a number of these criminological theories, to date, few studies have tested these theoretical models with social network data.

The vast majority of studies focusing on neighborhood networks and crime instead utilize “perceptual measures” to capture aspects of neighborhood social networks. Most typically, researchers ask neighborhood residents a series of questions regarding perceptions of neighborhood social organization (e.g., intergenerational closure, friendship ties) or the extent of neighbor interactions (e.g., see Bellair and Browning 2010). Unfortunately, such measures are unable to capture features of the *structure* of neighborhood social networks (e.g., cohesion, network closure) that are most consequential for crime in the aforementioned theories. As few studies have attempted to directly measure the structure of social ties at the neighborhood level, “the structural features of locally based social networks have been inferred from the reports of individual respondents, measured indirectly, or simply presumed to operate” (Entwisle et al. 2007, pp. 1500–1501). As demonstrated below, social network data (i.e., actual relational data linking nodes in a network) better capture the social phenomena that are at the heart of many theories of community and crime.

The dearth of research that employs social network designs in the study of neighborhoods and crime is in no small part due to the significant (but not insurmountable) challenges associated with collecting data on neighborhood networks. In the following section, a brief overview of social network analysis is provided, highlighting the unique features of social network data. At the same time, the inherent difficulties associated with collecting network data across several neighborhoods that is necessary for the statistical analysis of “neighborhood effects” are discussed. However, this section also presents examples of certain forms of social network data (e.g., affiliation or two-mode network data) and network analytical techniques (e.g., network-based simulations) that may be used to enrich the understanding of the association between neighborhood networks and crime.

Some Unique Properties of Social Network Data

From a theoretical standpoint, social network analysts stress the importance of interdependence among actors (e.g., individuals, institutions, nations) to explain both individual and collective outcomes. From this standpoint, individual and collective behaviors represent emergent properties of identifiable patterns of ties between actors and institutions and other units of interaction (Papachristos 2010). At the same time, the processes that explain variation in the structural characteristics of social networks (e.g., density, clustering) are also of interest to sociologists (Entwisle et al. 2007) and criminologists (Young 2011). In this latter case, social networks themselves serve as dependent variables. As the effects of neighborhood networks on crime itself are of primary interest in this entry, networks as dependent variables are not discussed in this entry.

While an extensive review of the various types of social network data is beyond the scope of this entry, this section provides a brief overview of the constitutive elements of network data that are most relevant to research on neighborhood networks.

All forms of social network data consist of *actors*, which may be conceptualized as individuals, organizations, or any other unit of analysis that are thought be related to one another, and *ties*, which refer to specific types of relationships that link actors within the population of interest. Just as actors may be defined in any number of ways, there are several different types of ties that link actors. One of the most common types of tie that is studied among criminologists is friendship. Friendship networks are relevant to a number of criminological questions, such as, “Is adolescent delinquency related to the delinquency of one’s friends?” and “Do dense neighborhood-based friendship networks protect against crime?”

Ties need not be limited to those capturing friendship relations. Indeed, a number of different types of ties have also been considered in criminological research. For example, Papachristos (2009) used official police records to reconstruct a network consisting of Chicago gangs. In this network, two gangs were linked through a directed tie if a member of one gang killed a member of another gang. Schaefer (2012) used official police data to construct a neighborhood-based co-offending network in Maricopa County, AZ. In this network, two census tracts were linked if juvenile delinquents from two different tracts were arrested during the commission of the same crime. An emerging approach to studying neighborhood effects on delinquency and adolescent development focuses on overlap in "routine activity spaces" among neighbors to measure network structural characteristics of neighborhoods. Integrating insights from activity space approaches (which is given more attention near the end of this entry) and social network analysis, an emerging approach to measuring neighbor networks focuses on residents' overlap in routine activities. Demonstrating the utility of this approach, Browning and colleagues (2011) recently used data from Los Angeles Family and Neighborhood study (LAFANS) to construct 65 "actor-location" neighborhood networks consisting of individuals tied to block groups in which residents' routine activities took place. Findings indicate various structural features of actor-setting networks (e.g., density, clustering) vary across the census tracts in the study. The exact types of tie that can link actors in a network that are considered are determined by particular research questions.

Ties may be further distinguished by their directionality. In network terminology, directed ties are referred to as *arcs*, while ties that are undirected are referred to as *edges*. Such a distinction is important, as some relationships are inherently directional, as in the case of resource exchange between actors. Other ties may not entail directionality. One prime example of non-directed ties is ties between spouses.

Social network data are most often collected through the use of two primary research designs. *Ego network data* most typically focus on the direct ties and associates of an individual "focal" node. Ego network data are typically collected through random samples by asking subjects to identify all, or a subset, of the actors to whom they have some form of connection (e.g., friendship, economic exchanges). Respondents then report any existing ties among the identified "alters" or actors to whom the focal respondent is tied. However, ego network data cannot typically be used to measure aggregate features of social networks, which are of primary interest to neighborhood theories of crime. However, through the use of snowball sampling techniques (Sampson and Graif 2009) and respondent-driven sampling (Papachristos et al. 2012), researchers have constructed relatively complete network data from ego network data.

Whereas ego network designs focus on the structure of ties that surround single actors, *full* or *complete network* designs collect information regarding every actor's ties within a population or multiple populations of actors. For instance, the groundbreaking National Longitudinal Study of Adolescent Health or Add Health attempted to collect information on every adolescents' school-based friendship ties within several middle and high schools in the United States. Complete network data allow for the examination of a number of topics of criminological interest. For instance, as with ego network data, complete network data allow for the examination of the association between peer delinquency and individual offending. However, complete network data also allow researchers to examine how features of the larger network (e.g., cohesion) and individuals' positions within larger networks (e.g., centrality) influence offending. For instance, Haynie (2001) found that peer delinquency is more strongly associated with individual offending among adolescents who are tied to others who are also well connected in school network.

Network data are also comprised of radically different data structures. For example, bipartite networks (also known as affiliation or two-mode networks) consist of two different sets of actors that can only be linked to members of the opposite set. Browning and colleagues' (2011) actor-location network represents a bipartite network, given neighborhood residents (the first node set) are indirectly linked through sharing common activity spaces (the second node set). The data structure of bipartite networks differs from that of one-mode networks, which consist of single sets of actors and the direct ties between them. While one-mode networks are more commonplace in network research, as this entry will illustrate, certain features of bipartite network data open up new and exciting avenues for future research on neighborhood networks.

Network data capture simplified versions of the social relations between actors. However, in reality, actors are tied to one another in any number of different ways. For example, students within a school network may be tied to one another through friendships, romantic relationships, overlap in their courses, participation in extracurricular activities, neighborhood residence, or bullying relations. *Multiplex networks*, consisting of actors who are connected by two or more different types of relations, explicitly take into account the different ways in which actors are connected to one another. Importantly, multiplex networks allow for the simultaneous examination of how different types of ties overlap and create specific relational structures within networks. While most techniques of network analysis are designed for networks consisting of one type of tie, network analysts are increasingly focusing on designing methods for multiplex networks.

In sum, social network data provide unique opportunities to examine the influence of social relations on individual and collective outcomes. This property of network data is particularly attractive to researchers focused on the association between neighborhoods and crime, as the structure of social relationships among neighbors is fundamental to all of the prominent theories of neighborhoods crime.

Unfortunately, there are a number of methodological barriers to gathering network data among neighbors. For example, constructing a one-mode network consisting of friendships among neighbors within just one neighborhood would require every resident to identify each of their friends from a neighborhood roster. The likely nontrivial amount of survey nonresponse in such a study would impede reliable estimation of structural properties of the neighborhood network.

Another problem with measuring neighborhood networks with survey data stems from the "boundary specification" problem that afflicts both social network research and conventional (i.e., nonnetworked) research on neighborhoods and crime. With regard to the latter, a number of different levels of community aggregation have been considered in research on neighborhoods and crime. For example, studies have (in order of their typical size in area) examined crime and disorder at the census block level, the block group level (which in the United States typically consists of 39 blocks), the census tract level, neighborhood cluster level (i.e., two or three contiguous census tracts), and zip codes. There are two significant limitations related to all of these forms of aggregation. First, certain neighborhood boundaries are based on administrative definitions, as in the cases of census tracts and zip codes. Despite the plethora of research that identifies associations between the characteristics of neighborhoods, as defined by administrated boundaries, and individual and aggregate outcomes (see Sampson et al. 2002 for a review), there is no guarantee that administrative boundaries encompass the actual "neighborhoods" that neighborhood researchers aim to study. Second, the association between neighborhood characteristics and crime has been shown to depend on the level of aggregation. For example, Hipp (2007) demonstrates that economic resources are most strongly associated with neighborhood crime and disorder among neighborhoods that are defined at the block level, while racial heterogeneity is most strongly associated with crime and disorder when measured at the census tract level.

A similar problem of boundary specification exists in social network research. In social network analysis, the issue of boundary specification pertains in large part to both the inclusion of certain actors and types of affiliations. With regard to the latter, a researcher must decide upon which types of ties are to be measured. Decisions regarding the measurement of ties are most often driven by research questions prior to execution of the study. Conversely, identifying which actors comprise a network in question takes considerably more thought in certain situations. As Laumann et al. (1983, p.18) explain:

> because individual behavior is viewed as at least partially contingent on the nature of an actor's social relationships to certain key others. . .care must be given to specifying rules of inclusion. Such rules pertain both to the selection of actors or notes for the network *and* to the choice of types of relationships among those actors to be studied.

Accordingly, much thought must be put into identifying both the actors as types of ties that are to be included in the empirical network, as noninclusion of relevant actors may have severe consequences for the measurement of the structural properties of networks.

While researchers employing network methods and concepts continue to make novel contributions to the understanding of crime, difficulties associated with collecting network data among neighborhood samples have contributed to the relative paucity of network-based studies of neighborhood effects. In the following section, four recent alternatives to studying neighborhood networks are discussed. Each takes a distinct approach to the conceptualization and measurement of neighborhood networks. It is our contention that these approaches hold promise for advancing the understanding of how neighborhood-based social network processes shape individual and aggregate offending patterns.

New Directions

Despite the challenges facing investigation of network effects on crime, emerging directions in the conceptualization and measurement of neighborhood networks offer the potential to significantly advance the understanding neighborhood effects on crime. The remainder of this entry focuses on recent studies that have attempted to capture the structure of social relations among residents and other important actors (e.g., community organizers) in neighborhood networks. While to date, no known published studies stemming from these projects have applied social network data to examine the association between neighborhood or community networks and crime itself, studies have focused on processes that are thought to mediate the association between neighborhood networks and crime, such as trust, cohesion, and informal social control. The described approaches attempt to capture consequential neighborhood networks through innovative efforts to reconstruct the pattern of actual ties among actors (Sampson and Graif 2009) or by integrating spatial and social network information to arrive at alternative conceptualizations and measures of neighborhood networks (Butts et al. 2012; Radil et al. 2010; Browning et al. 2011).

A large share of recent research on neighborhood effects on crime has utilized data from the Project on Human Development in Chicago Neighborhoods (PHDCN). A lesser-known component of the PHDCN, the key informant (KI) study, utilized a snowball sampling design to collect information on dimensions of relationships among community leaders across religious, educational, business, law enforcement, political, and community organization domains within several of Chicago's community areas. As part of initial interviews, key informants were asked to identify up to five people they went to in order to "get things done" in the community. From these nominations, Sampson and Graif (2009) constructed community leadership networks for a subsample of the community areas, measured a number of their structural properties (e.g., density, leadership inequality, and path distance). The authors also found that network centralization in the leadership network captures the extent to which nominations from all community leaders are sent to a few key leaders to be positively associated with community residents' trust in law enforcement and trusting relations among community leaders. The authors suggest that the presence of highly central leaders may foster working trust among leaders and residents by making leaders more visible and accountable to the community. Thus, leaders and community residents may be better able to exercise social control over central leaders, creating a multilayered "enforceable trust" (Sampson and Graif 2009, p. 207) within the neighborhood network.

A number of recent studies have integrated spatial and social network approaches to arrive at theoretically relevant conceptualizations and measures of neighborhood networks. For instance, Radil et al. (2010) build on insights from geography and network perspectives to highlight the roles that the geographic distribution of gangs and the network structure of gang rivalries play in shaping patterns of gang violence within a larger community. The authors suggest that space is socially constructed in large part through processes related to geographic and network embeddedness of actors. One important feature of network embeddedness is spatialized network structural equivalence, which captures the extent to which two or more geographic areas are similarly situated in terms of positions within "spatialized" social networks.

Relying on information from gang informants and the Los Angeles Police Department, the authors reconstructed a spatialized community network for which actors represent collections of census block groups that comprise gang territories. Gang territories are in turn tied to one another through rivalries with other local gangs. Through a network analytic technique called *convergence of iterated correlations* (CONCOR), the authors identify geographic subsets that are comprised of gang territories that are similarly situated within the rivalry network. Upon mapping the territorial subsets, the authors demonstrate that the geographic distribution of the gang territories has a distinct spatial pattern and that the spatialized patterning is meaningfully related to the distribution of gang violence across the larger community. Results from Radil et al. (2010) study illustrate the importance of the structure of social relations among actors across different geographic spaces in shaping crime rates across different communities.

Butts and colleagues (2012) present an alternative, simulation-based approach to measuring community networks that relies on assumptions about the spatial organization of social ties. The authors ground their analysis on the well-established notion that the probability of a social tie between individuals increases with their geographic proximity to one another (McPherson et al. 2001). Using data on geographic distributions of individuals from the US Census, Butts and colleagues constructed simulated networks for several metropolitan (i.e., an area that includes at least one city with a population greater than 50,000 individuals) and micropolitan (areas that contain at least one city with a population between 10,000 and 50,000) areas in the USA. Through specifying and applying a spatial interaction function (SIF), which captures the "marginal probability of a tie between two randomly selected individuals at some given distance" (Butts et al. 2012, p. 83), to data on geographic location of actors, the authors constructed simulated metropolitan and micropolitan networks comprised of friendship relations and face-to-face interactions. Butts and colleagues also identified associations between the spatial distribution of actors across the units of aggregation and various structural properties of the networks. This simulation process can also incorporate several other nongeographic processes that are known to influence tie formation, such as selective mixing on race, age, and socioeconomic status (McPherson et al. 2001) to potentially simulate networks that more accurately reflect actual networks of distinct areas. While this innovative method holds much promise for understanding neighborhood network processes and crime, future research that compares the simulated networks with actual networks constructed from network-based studies will help to assess how well-simulated networks reflect neighborhood social networks.

One of the most attractive qualities of the network simulation approach of Butts and colleagues is that it enables researchers to construct social networks with readily available data across several cities and neighborhoods. This is particularly useful, as collecting data on every individual's ties across a single, let alone, several neighborhoods through conventional survey approaches is a daunting, if not impossible, task.

However, individuals may be connected to other persons through any number of ways. For instance, neighborhood residents may be indirectly tied to one another through shared participation in activity spaces. Activity spaces may be understood to encompass all of the locations individuals come into contact with as a result of their routine activities (Golledge and Stimson 1997). Incorporating activity space data into a social network analytic framework may help address the challenges facing research on neighborhood networks and crime in two primary ways. First, activity space data enable the measurement of individual exposure to specific places and settings that vary in their criminogenic properties (i.e., extent of disorder and crime). Activity space data can also capture exposure to certain types of individuals and allow for the measurement of the extent of overlap in individuals' routine activities. Finally, as illustrated below, network structural characteristics describing patterns of overlapping routine activities among neighborhood residents are likely important in the functioning of neighborhood social processes that are relevant to crime (e.g., collective efficacy, individuals' access to social capital, participation in neighborhood organizations).

Apart from capturing individuals' place-based exposures, sampling activity spaces among geographically contained populations may allow investigators to measure the extent to which neighborhood residents share activity locations within given boundaries or larger areas (e.g., entire metropolitan areas). Consistent with Jacobs (1961), the structural patterns of activity overlap may capture important features of the social organization of a neighborhood. For instance, "co-location networks" may impact a number of neighborhood processes such as social network formation as well as trust and shared expectations for informal social control. While these factors have been linked to individual offending and neighborhood crime rates, the social and ecological dynamics that are associated with such features of neighborhood organization remain elusive. Moreover, by measuring the co-location network more precisely, researchers may apply a continuously developing catalogue of network analytic techniques to characterize routine activity patterns using sophisticated global network measures (e.g., density) and characterize individuals' locations in the network (e.g., centrality). Additionally, through the use of panel and other longitudinal study designs, one may examine how co-location networks evolve over time with stochastic actor models (Ripley et al. 2012).

Browning and colleagues (2011) recently examined the association between structural features of actor-location networks among neighborhoods in Los Angeles and a number central processes in neighborhood-based studies of crime and delinquency. The authors find that triadic closure, or "clustering" (Opsahl Forthcoming), in the actor-setting network is positively associated with access to social capital as well as perceptions of network exchange (i.e., frequency of exchange of favors among neighbors), intergenerational closure among neighborhood residents, and collective efficacy. Future research that builds upon the approach of Browning and colleagues may help further identify the association between structural features of neighborhood actor-setting networks and offending patterns.

Conclusion

The primary objective of this entry was to provide an overview of network approaches to studying the association between neighborhood social organization and crime. Importantly, the approaches highlighted in this entry were situated within prominent theoretical approaches to neighborhood networks and crime. After outlining central network processes of neighborhood-based theories of crime, this entry highlighted the limitations of "perceptual" measures of community organization that are most commonly used to assess structural features of neighborhood networks. The limitations of perpetual measures were further illustrated by highlighting how relational properties of social network data allow for a more complete understanding of neighborhood social organization as it relates to individual and aggregate offending patterns.

Most importantly, this entry detailed emerging approaches to measuring structural properties of neighborhood social networks. Through the use of network simulations, snowball sampling, spatialized gang networks, and two-mode actor-location affiliation network data, recent studies have made great strides in measuring structural properties of neighborhood and community networks. Perhaps as importantly, these techniques circumvent a number of the inherent difficulties and cost restrictions of collecting neighborhood-based social network data. Future research that builds on these and similar network analytic techniques may advance the understanding of the association between neighborhood social organization and offending rates by identifying which structural properties of neighborhood networks (e.g., network density, closure) are most strongly associated with crime. In addition, considering different types of ties (e.g., friendship tie versus gang rivalry) may further demonstrate the criminological consequences of differential social organization and advance the understanding of the neighborhood context of crime.

Overview

Criminological theories have focused on different aspects of social relationships to explain the role peers play in shaping delinquency. Control theory, as presented by Hirschi (1969), focuses on the strength of attachment between individuals to explain variation in delinquent outcomes. Conversely, influence theories, such as differential association theory (Sutherland and Cressey 1960), propose that delinquency is learned within intimate relationships that expose individuals to definitions favorable to law and norm violation. Unfortunately, most empirical tests of these competing perspectives rely on data from random samples that do not allow for the direct measurement of peer characteristics (e.g., peer delinquency) or the assessment of the structural characteristics (e.g., cohesion) of peer and friendship groups. Overcoming these limitations, a network approach to crime/delinquency takes into account the structure of social relations, as well as the characteristics of actors comprising the network, to explain peer influence processes. This entry outlines contemporary approaches to understanding the peer-delinquency association, focusing primarily on the ways that researchers operationalize key elements of influence and control theories, such as exposure to delinquent peers and peer group cohesion, with social network data. The entry also describes how criminologists are advancing the understanding of peer influence by studying behavioral development and network dynamics over time and by expanding the study of peer influence to include romantic partners, those to whom actors are indirectly tied, as well as associations occurring outside of school contexts.

Friend and peer influence has long been central to explanations of crime, delinquency, and other problem behaviors. Compared to children and adults, adolescents attribute greater importance to friends, spend more time socializing with friends, and are more strongly influenced by the behaviors and attitudes of their friends. While peer relationships have been less central in explaining adult offending, research documents the role of social influence from friends and romantic partners throughout the life course (Giordano et al. 2003). Not surprisingly then, the finding that individuals with delinquent friends are likely to be delinquent/criminal themselves is one of the most consistent and strongest findings in the criminological literature. Consistently robust associations between peer and individual delinquency have led some to argue that peer influence is one of the most important processes in explaining delinquent outcomes, regardless of whether the focus is on substance use, minor property offenses, status offenses, or violent crimes.

Prominent explanations of crime and delinquency disagree with regard to the mechanisms through which peers influence individual offending. While some of the debate is informed by theoretical concerns (e.g., "selection" versus "influence" as the driving mechanism), debate also stems from inadequate and inconsistent measurement of peer characteristics across research designs. In order to advance the understanding of peers' impact on delinquent outcomes, this entry provides a broad overview of past, present, and emerging techniques for measuring peer characteristics in criminological research. Particular attention is directed at social network processes and methods.

This entry begins with a discussion of two prominent theoretical perspectives on delinquency, namely, control and influence theories. Close attention is paid to the manner in which peers are purported to influence crime and delinquency in these theoretical models. Next, social network approaches to peer influence on delinquency are discussed. The Section "Measuring Peer Influence: Past and Present" describes past and current methods of measuring peer characteristics in criminological research. This section first focuses on *perceptual* or self-report measures of peer characteristics, highlighting the methodological shortcomings of this approach. Next, network approaches to measuring the *content* (e.g., peer delinquency) and *form* (i.e., structural characteristics) of adolescent peer networks are identified. In addition, this section discusses manners in which network analysis has been used to help resolve competing claims regarding the role of peers in delinquent behavior in criminological theories. In section "New Directions in Peer Influence", more recent innovations in social network approaches to peer influence are reviewed, highlighting how these methodological advancements can promote the understanding of peer influence processes. Finally, a conclusion provides a discussion of future directions in the study of peer influence that have great potential for advancing the current understanding of network processes as they relate to crime and delinquency.

Theoretical Explanations of "Peer Effects"

Control theories, such as those presented by Hirschi (1969) and Gottfredson and Hirschi (1990), and influence theories, such as those presented by Sutherland (Sutherland and Cressey 1960) and Akers (2009), are prevailing perspectives that explain the importance of peers for adolescent delinquency. These perspectives offer opposing explanations with regard to the ways in which peers influence individual delinquency. Accordingly, criminologists have focused on different features of peer contexts in order to assess the plausibility of the theoretical mechanisms in empirical research. This section briefly outlines the predominant control and influence theories of crime, and makes note of the relative importance of the *form* and *content* of peer networks in each perspective and then discusses the network approach to peer influence, and identifies how it helps advance the understanding of peer selection and influence processes.

Control Explanations of Crime

Hirschi's (1969) social control theory proposes that connections to others serve as the primary constraints against delinquent impulses and actions. With regard to peer networks, social control theory predicts that strong friendship bonds are invariably and negatively associated with adolescent delinquency. This is because strong friendships entail attachment to conventional peers that would be weak or absent among more selfish and delinquent individuals. Hirschi explains the peer-delinquency association by suggesting that delinquent youth cannot form genuine friendships with peers. This implies that social ties among delinquent youth lack high levels of attachment.

Gottfredson and Hirschi (1990) general theory of crime elaborates the process through which individuals self-select into delinquent peer groups. Gottfredson and Hirschi argue that peers have no direct influence on individual offending. Rather, individual self-control (i.e., the ability to control impulsive behavior), which is relatively stable by early adolescence, shapes how adolescents cluster together in peer settings. Delinquent adolescents with low self-control are likely to befriend other delinquents as a result of their similar levels of self-control. Apart from determining the types of friends one makes, low self-control is also a primary cause of delinquent behavior; thus delinquency and associations with delinquent others are both directly caused by low self-control.

Importantly, Hirschi and Gottfredson and Hirschi's control models propose that the association between delinquent peers and individual offending is spurious. Delinquency is instead explained by other processes such as inadequate social control caused by weak attachment to others or low self-control. These models explain any peer-delinquency association resulting from selection processes, and not because friends influence individual delinquency.

With regard to measuring peer effects on individual offending, social control theory primarily focuses on attachment within adolescent networks. Both control models also predict that delinquent peer groups will be less cohesive than those consisting of nondelinquent individuals with high self-control. Accordingly, measures that capture the strength of friendship ties, as well as the configuration of ties linking individuals within friendship groups, are crucial elements in tests of control theories. Such measures include subjective assessments of peer attachment, which capture mutual trust and involvement among friends, and network density, which measures the probability that a tie will exist between two members of friendship groups. Conversely, measures of peer characteristics, such as delinquency, are less central because the peer-delinquency association is believed to be spurious in these models. In support of both variants of control theory, weak attachments and low self-control are consistently associated with delinquency in research (Pratt and Cullen 2000).

However, research has also found that delinquent adolescents are no less attached to friends than their nondelinquent counterparts (Giordano et al. 1986). Additionally, Young et al. (2011) found self-control has a negligible impact on adolescent friendship formation after triad closure, or the tendency for individuals who share friends to become friends themselves, and other individual characteristics are taken into account. Similarly, Kreager et al. (2011), found group-level delinquency has no impact on the structural characteristics of friendship groups when group composition (i.e., average socioeconomic status and proportion male) is taken into account. Perhaps most importantly, friendships with delinquent peers is positively, and consistently, associated with delinquent behavior in criminological research (Haynie 2001), even after controlling for self-control and peer attachment (Pratt and Cullen 2000). Although friendship selection and social and self-control most likely shape delinquent behavior, peer influence continues to play an important part in explaining delinquent outcomes.

In contrast to control theories, influence theories argue that peer characteristics are consequential for individual offending. Accordingly, empirical tests of these theories have in turn largely focused on the content of social networks to explain individual offending.

Influence Perspectives

Influence theories argue that criminal and other “antisocial” behaviors are learned from intimate social relationships with others where attitudes or “definitions” favorable to law violation are acquired. The social transmission of crime/delinquency primarily occurs within peer networks through the transference of favorable attitudes and definitions that encourage criminal behavior. Akers’ (2009) extension to differential reinforcement theory emphasizes behavioral modeling and operant conditioning processes. This model assumes that the adoption of criminal behavior occurs through the imitation of friends’ behavior and the observation of its consequences, either positive or negative. Sutherland and Akers’ theories represent prototypical influence theories in that they argue that crime and delinquency, like any behavior, are learned in intimate relationships, including peer friendships.

The characteristics of peers within adolescent friendship groups have been at the forefront of empirical tests of differential association and social learning theories. For example, the principle of differential association states, “A person becomes delinquent because of an excess of definitions favorable to violation of law over definitions unfavorable to violation of law” (Sutherland and Cressey 1960, p. 78). In empirical research, differential association has been most commonly operationalized by asking respondents how many or what proportion of their friends commit deviant acts. These “perceptual” measures of peer delinquency have been remarkably strong and consistent predictors of individual offending in delinquency research (Pratt et al. 2010). Both the consistency and robustness of the association between peer and individual offending attest to the validity of peer influence theories.

While perceptual measures of peers’ criminal involvement are some of the most robust predictors of individual offending, tests of social learning and differential association theories have been hindered by oft-used self-report measures of delinquency in criminological research. Perceptual measures of peer delinquency are susceptible to report bias, which likely results from delinquent individuals ascribing their own behaviors to their friends (Gottfredson and Hirschi 1990). Indeed, recent research indicates that perceptual measures of peer delinquency both *overestimate* (Haynie and Osgood 2005) and *underestimate* (Weerman and Smeenk 2005) the actual level of delinquency among peers.

One drawback of social learning and differential association perspectives is that they offer little theoretical and empirical attention towards understanding how the form, or structural characteristics, of social networks factors into peer influence processes. These oversights are significant, given that exposure to and circulation of norms and behaviors conducive to offending are central features of the theories. For example, Sutherland proposes that differential associations vary in their “frequency, duration, priority, and intensity” (Sutherland and Cressey 1960, p. 78). Unfortunately, the exact meaning of frequency, duration, and intensity of differential associations has been underdeveloped and left largely unmeasured in empirical tests of influence theories (Haynie 2001). In contrast, the social network perspective more fully explains the mechanisms through which social relations shape the peer-delinquency relationship. Social network data, in turn, more fully capture both the form and content of peer groups than non-relational data, which enable more thorough examinations of peer influence processes.

A Social Network Perspective

The social network perspective offers a unique view of humans in its basic premise that individuals are interdependent and, more importantly, that these interdependencies have important consequences for behavior. Therefore, it emphasizes both the configuration of ties connecting individuals in a social structure and the characteristics of actors in that structure to explain delinquent outcomes. Scholars interested in applying a social network perspective to understand individual offending require data on the ties or connections among individuals within a particular setting. While these ties can take on different forms, researchers interested in adolescent behavior most often examine the form of friendship ties among adolescents. This suggests that the behavior and structure of adolescent networks offer powerful explanatory power for delinquency and other social behaviors. Network perspectives also allow researchers to test competing theoretical hypotheses of control and influence theories, while also advancing new concepts – such as centrality and density – and methods that expand our knowledge of delinquent contexts.

Friendship networks are particularly important for understanding adolescent involvement in crime/delinquency for a number of reasons. Integration into friendship groups where adolescents form bonds and spend time with peers may facilitate or inhibit delinquent behavior depending upon the norms, values, and behaviors within the network. Also, while adolescents may discount a friends' evaluation, they are less likely to discount a group evaluation. This suggests that embeddedness within friendship networks takes on additional influence as it generates expectations for behavior while reinforcing group social norms and beliefs. Adherence to group norms is especially likely during adolescence because acquiring peer acceptance is of central importance during this stage of the life course. Furthermore, friendships are crucial in establishing role identity throughout adolescence. As a result, adolescent peer networks are especially effective at directing and constraining individual members' behavior.

While a social network perspective offers a particularly useful tool for understanding peer influence, it is only recently that the full benefit of a network approach for crime/delinquency research has been revealed. The following section describes past and recent methods of measuring peer characteristics. Although conventional, non-networked, "perceptual" methods are discussed, this section primarily focuses on network approaches to assessing peer influence.

Measuring Peer Influence: Past and Present

Prior studies examining the effect of peer influence on delinquency generally ask adolescents to think about their friends and to report whether their friends have participated in a particular illegal behavior or set of illegal behaviors. Respondents usually report that "none," "some," or "all" of their friends participated in the behavior being discussed. Studies relying on such perceptual measures have found robust associations between peer delinquency and respondent offending (Pratt et al. 2010). However, the consistent association between perceived peer deviance and respondent delinquency provides only limited support for influence theories such as differential association theory for a number of reasons. First, social psychologists refer to the tendency to assume that friends behave as do you, as assumed similarity or projection. Therefore, the perceptual approach to measuring peer characteristics contains a same-source bias that inflates similarity in behavior between peers. In fact, prior research demonstrates self-report measures of peer delinquency tend to be not only inaccurate but are systematically biased (Young et al. 2011). Findings such as these support Gottfredson and Hirschi's claim that individual characteristics, such as self-control, bias perceptual measures of peer delinquency and other behaviors. Accordingly, the extent to which perceptual studies of peer delinquency can actually support influence theories is limited by the extent to which they are unbiased by individual characteristics. Furthermore, misspecification of peer delinquency is especially problematic in studies that test competing claims of influence and control theories, as biased measures of peer delinquency likely results in the upwardly biased estimates of peer effects and downwardly biased estimates of self-control effects (Meldrum et al. 2009).

Apart from mounting evidence indicating systematic misspecification of peer delinquency, perceptual measures of peer characteristics are limited in a number of other ways. For example, past research employs imprecise definitions of the friendship group in which behavioral influence is thought to occur. As a result, the number of friends considered by the adolescent when responding to questions regarding peer delinquency is often unspecified. Accordingly, the structure and composition of an adolescent's delinquent friendship network remains relatively unclear.

Perhaps as importantly, perpetual studies of peer influence fail to consider how structural properties of network – that is, how adolescents are connected to one another via friendship ties – condition peer influence processes. In doing so, past research assumes that everyone in the friendship network is affected by friends' behavior in the same manner. Non network approaches overlook individual position within the network (e.g., central versus peripheral), the cohesiveness of the network (i.e., the interconnections among network members), and the adolescent's status (e.g., popularity) within the network. These structural characteristics likely shape the degree to which adolescents are influenced by group behavior (Haynie 2001). A network perspective is guided by the assumption that both behaviors exhibited by network members and the structure of the network have important consequences for understanding subsequent behavior. With regard to delinquency, this suggests that exposure to pro- or anti-delinquent behaviors will depend upon the structure of the network, the adolescent's position within the network, and the behaviors exhibited in the network.

Measuring Peer Delinquency with Network Data

Recent data collection efforts, such as the National Longitudinal Study of Adolescent Health (Add Health), have made relational data available to criminologists interested in applying network theories and methods to the understanding of peer influence. The Add Health data are unique in that they provide an opportunity to analyze complete social networks of adolescents attending a representative sample of schools in the United States. To achieve this, researchers collected data on every student attending school on the day the questionnaire was administered. As part of this data collection effort, respondents were asked to nominate up to ten of their closest friends (five male and five female friends) from school rosters listing all schoolmates. Because every student present completed the questionnaire, it is possible to observe almost all friendship ties among students in the school. Add Health provides the largest and most comprehensive portrayal of adolescents' school-based friendship networks to date. Other smaller-scale efforts, such as the Netherlands Institute for the Study of Crime and Law Enforcement (NSCR) "School Study," the Context of Adolescent Substance Use Study, and the Promoting School-Community-University Partnerships to Enhance Resilience (PROSPER) study have utilized similar data collection techniques to directly measure peer and network structural characteristics.

With regard to the peer-delinquency association, criminologists have operationalized peer delinquency in a number of ways. Theoretical concerns should be, and for the most part, are primary in informing approaches to measuring peer delinquency. For example, the principle of differential association theory maintains that individuals become delinquent because they experience excess of definitions favorable to law violation, compared to definitions that favor observing law. In testing this claim, Haynie (2002) constructed a "relative" measure of peer delinquency which consisted of the proportion of friends that are delinquent within individuals' peer networks. Results indicated adolescents' delinquent behavior most resembled that of their peer groups when they were enmeshed in friendship networks with greatest behavioral consensus (i.e., all friends are either delinquent or nondelinquent). Another more common way of operationalizing peer delinquency is to measure the average amount of delinquency across one's peer group (Haynie 2001). This operationalization allows researchers to focus more on the consequences of total exposure, rather than relative exposure, to delinquent peers.

Recently, McGloin (2009) expanded the operationalization of peer delinquency by considering how peer deviance relative to one's own, rather than simply exposure to delinquent peers, shapes individual delinquency. McGloin points out that one aim of interactive relationships is to achieve behavioral congruence, or homeostasis with one's close associations. One hypothesis that stems from this perspective is that adolescents will seek behavioral congruence with their closest friends. In order to test this assertion, McGloin constructed a measure of *delinquency balance*, which consisted of the difference between respondents' delinquency and that of their best friends. Results indicate adolescents tend to commit less delinquency over time when their delinquency was previously higher than their best friend; conversely, respondents tend to become more delinquent when they were initially less delinquent than their best friend.

Influence theories in large part emphasize the importance of learning that takes place within intimate peer groups. Accordingly, most empirical tests and influence theories have primarily focused on the influence of peers to whom one is directly tied. However, influence theories stipulate that peer influence also takes place through vicarious learning, in which individuals observe certain behavior and others' reactions to that behavior. Individuals are more likely to perform observed behavior that is positively reinforced by others throughout social interactions. This suggests that peer influence processes likely also occur between individuals who are only indirectly tied.

Network approaches to peer influence allow for the testing of processes that extend beyond those to whom individuals are directly connected. For example, Payne and Cornwell (2007) found that the delinquency of indirect associates (i.e., friends of a friend who are not my friends) is positively associated with respondent delinquency, even after taking into account the delinquency of those to whom one is directly tied. However, the authors also found that the influence of indirect associations diminished according to the extent to which the overall delinquency of one's indirect ties diverges from that of the immediate friendship group. Similarly, Kreager and Haynie (2011), demonstrate that behavior among those to whom one is indirectly tied through a dating partner (i.e., friends of my partner who are not my friends) influence individual behavior. Interestingly, the authors find evidence that the drinking of friends of partners have stronger associations with a dater's future behavior than do his or her own friends or the romantic partner.

Social proximity to delinquent individuals also factors into peer influence processes. In their examination of peer and social network influences on adolescent substance use, Ennett et al. (2006) found that the shortest distance to the nearest substance user, as measured by the number of ties needed to link respondents to the nearest substance user within a school, is negatively associated with substance use after controlling for the substance use within friendship networks.

Recently developed methods for identifying peer "clusters" allow researchers to further examine peer influence occurring at multiple levels and between individuals who are only indirectly tied. Peer clusters consist of densely connected groups in which ties are more likely to occur between members of the same group than members of different groups. Peer clusters also represent "meso levels" of social organization, which are larger in size than micro level friendship groups, but smaller in scale than other levels of aggregation, such as schools (Magino 2009). These conglomerations of friendship ties, which have discernable boundaries, may be used to capture larger social circles or "cliques," within which peer influence likely occurs.

Clustering algorithms, such as Moody's (1999) CROWDS or Frank's (Frank et al. 2008) *Kliquefinder*, allow researchers to detect dense friendship groups in social networks. Resulting subgroups in turn may be used as distinct levels of analysis in the study of peer influence processes. For example, Frank et al. (2008) used the *Kliquefinder* algorithm to identify "local positions," represented by clusters of adolescents based on their shared academic course taking among Add Health respondents. The authors found that girls were more likely to subsequently take higher-level courses when they were previously embedded in peer group clusters that include girls who also took advanced math courses. While this finding does not directly pertain to delinquency, it nevertheless points to the likelihood that peer influence processes extend beyond individual ties. Although peer group clustering techniques have not been widely employed in delinquency research (see Kreager et al. 2011; Ennett et al. 2006 for notable exceptions), the study of peer influence processes occurring within larger peer groups represents an interesting future direction for research to pursue.

Exactly how structural characteristics of peer networks condition the peer-delinquency association has also been largely overlooked in prior delinquency research. This oversight is unfortunate, as differential association theory proposes that while criminal behavior is in large part shaped by exposure to delinquent peers, differential associations vary in their "frequency, duration, priority, and intensity" (Sutherland and Cressey 1960, p. 78). Additionally, the form, or structural characteristics of peer networks, likely shapes peer influence processes by facilitating, among other things, behavioral reinforcement, circulation of definitions of behavior and attitudes conducive to offending, and exposure to nonredundant information (Granovetter 1973), which may facilitate co-offending opportunities and contagion of delinquent behavior.

Recognizing that the form of adolescent networks likely shapes the relationship between the content of peer networks and delinquent outcomes, Haynie (2001) evaluated whether network characteristics condition the effect of peer delinquency on individual offending. Results indicated that network centrality, density, and popularity accentuated the positive association between delinquent peers and individual delinquency. Further research examining how structural features of social networks shape the association between peer characteristics and risk behavior will help advance the understanding of how the effects of differential associations on individual outcomes vary according to network characteristics.

New Directions in Peer Influence

Emerging and exciting areas related to social networks and adolescent offending have accompanied increased access to high-quality social network data. For instance, actor-based models have recently been introduced to analyze behavioral development and network dynamics over time. Developed by Snijders and colleagues (Steglich et al. 2010), the SIENA statistical package uses simulation and Markov chain models to estimate changes in friendship ties and behavior over multiple waves of network cross sections or panels. Recent applications of SIENA in criminological research are advancing the understanding of peer influence by distinguishing selection from influence effects, while also adjusting for the structural characteristics of the network.

Researchers interested in peer influence are also expanding their empirical focus to associations other than friends. Increased inter-gender contact in mid-to-late adolescence entails increased opportunities for forming romantic relationships (Warr 2002). Recognizing the potential for romantic partners to impact offending, Haynie et al. (2005) demonstrate that romantic partner's delinquency exerts a unique effect on adolescents' delinquency, over and beyond the delinquency of one's friends. Giordano et al. (2010) revisit Hirschi's "cold and brittle" relationship hypothesis with regard to delinquents and romantic involvement. Using data from the Toledo Adolescent Relationships Study, they found little difference in the quality and longevity of delinquents' and nondelinquents' romantic relationships.

While this entry has largely focused on how peers influence individual delinquency, most criminological theories recognize that delinquency often occurs in groups. Accordingly, peers also impact individual delinquency by providing co-offending opportunities, the effect of which is analytically distinct from peer influence (Warr 2002). Unfortunately co-offending remains a relatively understudied topic in criminology. Notable exceptions (McCarthy et al. 1998) provide strong evidence that co-offending is an important mechanism through which peers impact individual crime deviance.

Innovative network studies continue to advance the understanding of peer influence processes. For example, the PROSPER Peers data, emanating from Pennsylvania State University under the supervision of Osgood and colleagues (Kreager et al. 2011) follows two successive sixth-grade cohorts in 28 rural Iowa and Pennsylvania communities. Social network data were collected yearly from the 6th to the 12th grade, resulting in an impressive number of complete school networks (∼400) over a 7-year span within each school cohort. With detailed delinquency and substance use measures and SIENA analyses, studies from PROSPER and similar longitudinal network datasets promise to expand our understanding of peer selection and influence processes.

One area that remains particularly underdeveloped in peer influence research relates to the impact of nonschool friends and peers. Out-of-school peers are likely important in shaping delinquency because they are more likely to be delinquent, older, and less connected to conventional institutions than school-based peers. Understanding the content and structural properties of nonschool friendship networks, may provide important clues for the etiology of delinquency. Collecting such data requires researchers to move beyond the bounds of schools and focus on communities, which is logistically more demanding and likely to be more costly, but capable of providing new insights into the peer-delinquency association.

Papachristos et al. (2012) present an innovative approach to measuring non-school-based networks among high-risk individuals in Cape Verdean, a low-income, predominately African-American community in Boston. To construct the network of high-risk individuals, the authors first identified the population of Cape Verdean gang members who were known by the Boston Police Department (BPD). Next, the authors generated a list of gang members' immediate associates from Field Intelligence Observation (FIO) data which were collected through observations conducted by the BPD. This respondent-driven approach resulted in a network in which ties between individuals occurred when they were observed in each other's presence by the police and recorded in the FIO data. This process was repeated for the associates of the gang members. From there, the authors constructed a network of high-risk individuals that consisted of gang members, their associates, and the associates of the non-gang members. Using matched data on fatal and nonfatal gunshot injuries, the authors demonstrate that the probability of experiencing gunshot injury was related to one's distance from other gunshot victims.

The limited availability of community-based network data is largely a result of the astronomical costs of obtaining population samples needed to construct network-based measures across several communities. One innovative approach to constructing nonschool social networks entails constructing affiliation, or "two-mode" networks, which, in the context of community research, consist of ties between individuals and activities or locations. Recently, Browning (2011) constructed two-mode networks among 65 neighborhoods with data from the Los Angeles Family and Neighborhood Study (LAFANS). Browning demonstrates that triad closure within networks based on individual overlap in respondents' routine "activity spaces" is negatively associated with adolescent risk taking. One primary advantage of two-mode approaches to community networks is that affiliation network data can be collected through clustered random samples. This lowers the cost of constructing measures of global network structure and individual embeddedness within community-based networks. Frank's *Kliquefinder* algorithm may also be applied to two-mode networks to construct adolescent group clusters, within which peer influence may also take place (Frank et al. 2008).

Summary

This entry aimed to provide an overview of network approaches to the measurement of peer effects in criminological research. After outlining the merits and limitations of control and influence theories, the entry advocated a social network approach to understanding the role of peers for two primary reasons. First, the network framework described in the entry emphasized the importance of the social connections among individuals within a social setting. Capturing the relations among actors within social contexts allows criminologists to assess the interconnectedness of actors, which is an important element of both influence and control perspectives. Second, the network perspective facilitates direct measurement of peer characteristics, which allows for more stringent tests of influence and control theories. In the end, the entry intended to demonstrate the value for a network approach to the study of the peer-delinquency association which incorporates characteristics of the friendship groups in which adolescents are enmeshed.

This entry also addressed emerging areas related to social networks and peer influence. Such areas include changes in friendship structure and composition, influence from actors to whom one is indirectly tied, romantic partner influence, and co-offending. Finally, the entry identified innovative approaches to capturing nonschool social networks, including a respondent-driven approach based on police observation data, and affiliation networks based on activity-location overlap.

The network approach to adolescent delinquency provides a coherent and promising framework for investigating the variety of ways that peers shape and influence involvement in delinquency and crime. This approach is consistent with the current emphasis on the significance of social contexts (e.g., neighborhood, school) and helps understand the intricate ways in which individuals' behavior is shaped by the social networks in which they are embedded.

Overview

Modern neuroscience has made significant and sometimes dramatic gains into understanding how the brain and central nervous system are implicated in a range of problematic, criminal, and addictive behaviors. Indeed, the growth of modern neuroscientific findings can only be described as explosive, with new discoveries being published almost daily. These findings are often produced by highly advanced technologies – technologies that, at a broad level, allow scientists to view the brain in action and under experimental conditions. This same technology also now allows scientists to directly measure brain cell activity and the strength and integrity of connections between brain cells. Never before in human history have scientists had these tools at their disposal.

Criminologists, once primarily wedded to sociological explanations of crime, are beginning to incorporate many of these findings into their understanding of the development of criminal conduct. They are also using these findings to understand the process of chemical addiction, how environmental experiences affect brain development, and how best to intervene with anti-social youths and adult criminals.

Apart from understanding brain structures and their functions, neuroscience has made tremendous progress in understanding how the chemicals in the brain, known as neurotransmitters, affect a range of personality traits and behaviors. This knowledge has led directly to the development of entire classes of psychopharmacological drugs. These drugs, known as selective-serotonin-reuptake-inhibitors (SSRI's), have been used to effectively treat a range of mood and psychological disorders. New stimulants, too, have been created that help individuals better regulate their own conduct, including those diagnosed with attention-deficit-disorder. The point is, what neuroscience reveals to us about behavior, including criminal and imprudent behavior, may lead to better, more effective interventions.

Evolutionary and Developmental Background

The human brain is the most complex computational device known to exist. It controls all necessary life functions, takes over 20 years to fully mature, and allows human beings to exercise tremendous control over their behavior and their environment. The human brain is a marvel of complexity and has been subject to evolutionary selection pressures for at least 250,000 years. Anthropological and genetic evidence indicates that the human brain has undergone at least two key evolutionary changes. The first is a mutation in the ASPD gene. The ASPD gene codes for the abnormal spindle protein homolog protein. Around 6,000 years ago a new allele of the ASPD gene emerged, resulting in progressively larger brains across humans of European, Asian, and Middle Eastern decent. Brain size is positively correlated with intelligence and is thought to allow for increases in the number of neurons and the number of connections between neurons. Growth in brain size, however, was not uniform. The area of the brain responsible for all higher-order thought processes, known as the cerebral cortex, expanded to the point where today it accounts for 77 % of total brain volume. Mutation in the ASPD gene corresponds with the advent of writing, agriculture, and science; although, it is unlikely to have directly caused them.

The second mutation also had a profound effect on human development and activity. Approximately 100,000 years ago a mutation in the FOXP2 gene occurred. Scientists believe that the mutation eventually allowed for the development of language. The mutation spread rapidly across ancestral populations, in large part because language provided early hominids a tremendous advantage in terms of survival. The area in the brain responsible for the production of language was discovered by a French physician, Paul Broca, and is known as Broca's area. The area of the brain that allows individuals to understand language was named after German psychiatrist Carl Wernicke, and is known as Wernicke's area. The development of language has allowed for tremendous advancements among human cultures. Interestingly, research has found that language deficiencies are positively correlated with antisocial behaviors.

Over 60 % of our genes code for the structure and function of the brain. In terms of nuclear material, the brain is the most expensive organ to create. The average adult brain weighs between 1,300 and 1,400 g, or about 3 lb. Because brain development is under strong genetic control, several regions of the brain appear to be strongly heritable, including regions that allow individuals to control their emotions, to plan for the future, and to engage in self-control. The heritability of brain structure and functioning necessarily means that the traits and characteristics of biological parents, both physical and behavioral, are likely to be shared and expressed by their offspring. Numerous behavioral genetic studies show that most traits, including self-control, intelligence, and specific personality features are modestly to strongly heritable. Part of the reason for the correlation between parent and offspring behavior and traits is likely to be due to similar brain architecture and functioning. Criminologists have known since the 1800s that criminal behavior and other social pathologies concentrate within some families and can show high degrees of inter-generational continuity.

The brain begins to develop almost immediately after conception. Research shows that during in-utero development the brain is forming over 250,000 connections per minute. While much of brain development is genetically controlled, evidence indicates that environmental factors can also be influential. Because the developing embryo is connected to the mother by the umbilical cord and placenta, maternal behavior can influence in-utero brain development of the fetus. Maternal nutritional intake is the clearest example. The fetus depends on receiving sufficient levels of nutrients from the mother. Insufficient nutritional intake can have devastating neurological consequences for the fetus. Moreover, maternal stress, and the accompanying release of stress hormones, has been shown to affect brain development of the fetus. While the brain of the developing fetus is protected by layers of fatty lipids, known as the blood–brain barrier, molecules from a variety of substances can pass from one side of the barrier into the developing central nervous system of the fetus. Maternal drug use and abuse, for example, has been found to potentially compromise the brain and central nervous system of the developing fetus. Cocaine molecules, as an example, easily pass across the blood–brain barrier. Moreover, lead (Pb), which can be stored in the bone of the mother, becomes bioavailable during pregnancy, passes through the blood–brain barrier, and may compromise healthy nervous system development. Prenatal lead exposure has been linked to a range of conduct problems, including delinquency in adolescence and criminal conduct in adulthood.

The rate of synaptogenesis, the creation of new nerve cell connections, corresponds directly to the increases in motor and cognitive abilities witnessed across childhood. Indeed, the brains of 2 year olds are about two-times as active as adult brains. Yet by late childhood the brain begins pruning unused and unnecessary synaptic connections. Reductions in the number of unnecessary connections eventually results in an increase in brain efficiency. The brain, in other words, does not have to use as much energy to do the same tasks in adulthood as it did in childhood. In part, this is due to the strengthening of connections through repetition; however, this is also due to the sculpting away of unused connections. While the sculpting begins in late childhood, it is accelerated during puberty when the brain undergoes a substantial period of reorganization. The onset of puberty also signals the myelination of the front part of the adolescent brain. Myelin is a fatty substance that will eventually cover axons. By covering axons in myelin the electrical impulse across the axon is accelerated by a factor of 10 over unmyelinated axons. The end result of these developmental changes is an energy efficient, highly integrated adult brain.

It is worth pointing out that although the brain undergoes substantial reorganization and pruning in the earlier stages of life, this does not mean that once one reaches adulthood the brain remains unchanged. On the contrary, the brain continues to change over time. Scientists do not yet know, however, how these changes are connected to criminal behavior.

Structures and Functions

The first part of the brain to develop is lower brain, which includes the brain stem and reticular activating system (RAS). The RAS contains a dense bundle of nerves that help direct sensory information to the correct parts of the brain. Psychologists have also linked variation in the RAS to certain personality characteristics, with some of these characteristics, such as neuroticism and extraversion, relating to offending. The lower brain controls all autonomic activities, such as breathing, that support basic life functions.

Sitting on top of the lower part of the brain is the midbrain, also known as the limbic system or the reptilian brain. The limbic system is commonly thought of as the alarm system of the brain in that it prepares the body for fight or flight when faced with a threatening situation. The limbic system controls overall neuroendocrine functioning, which regulates the release of hormones throughout the body. Containing a series of unique but highly inter-related structures, the limbic system is deeply implicated in crime and violence.

One of the more important structures, at least as it applies to understanding violence, is the amygdala. The amygdala is an almond-shaped structure responsible for human emotions and emotional memory. The term "emotion" comes from the early Greek word for motion. The Greeks understood the powerful influence of emotions in human motivation and behavior. Emotions are chemical states generated by the amygdala which can serve as powerful motivators. Several emotions have been implicated in crime and violence, such as fear, anger, disgust, and contempt. The amygdala is also implicated in social learning. Information, situations, and events that carry with them strong emotions are more likely to be stored by the brain and recalled in the future.

Other structures, such as the hippocampus, hypothalamus, thalamus, and cingulate gyrus, compose the limbic system and are also implicated in problem behavior. For example, the hypothalamus, with connections to the pituitary gland, helps to control endocrine functioning. The endocrine system regulates the flow of hormones and androgens, sex-specific hormones, in the bloodstream. Human sensations of bonding, for example, are produced by the release of vasopressin and oxytocin, while aggression has been linked to increased levels of testosterone in males and to estrogen in females. Moreover, the hippocampus is associated with the anticipation of consequences and the ability of individuals to learn from prior experience – known as conditioning. One of the hallmarks of adult criminals is their inability to learn from prior experience. Finally, the cingulate gyrus has been repeatedly linked to human aggression. The anterior cingulate gyrus influences attention, concentration, and focus. Reduced ACC volume and activity correlate with conduct disorder, obsessive thoughts, and compulsive behaviors.

Numerous studies have also implicated the hypothalamus-pituitary-adrenal (HPA) system in a range of emotional, psychiatric, and behavioral problems. The HPA axis is a complex network that regulates nervous system responses to stress. When the brain is under stress, the hypothalamus will release corticotropin-releasing hormone (CRH) and vasopressin. These molecules will be transported to the pituitary gland where they will cause the release of adrenocortictropic hormone (ACTH). ACTH will then stimulate the release of cortisol, a stress hormone, from the adrenal gland. These chemicals will then act on the hypothalamus and pituitary gland to eventually suppress CRH and ACTH production.

Extended exposure to stress can harm brain functioning and, in turn, can bring about a variety of non-adaptive stress responses. This may be why dysfunction in the HPA axis has been correlated with everything from aggression, to mood disorders, to drug-addiction and abuse. Indeed, prolonged exposure to intense stress appears capable of altering HPA axis functioning. This possibility has encouraged scholars and criminologists to examine how stress filled environments influence neurological activity. For example, some children of depressed, neglectful, or physically abusive mothers show dysregulation of the HPA axis. Blunted HPA responses to stress may occur because of repeated exposure to abuse and neglect. In turn, the affected child may be neurologically compromised in his response to threatening and difficult environmental circumstances.

The cerebral cortex sits atop the limbic structures and is divided into two hemispheres by the corpus collosum, which connects the two hemispheres through a dense bundle of fibers. The cortex has been called the key to civilization because all higher-order, uniquely human capacities are distributed across the cortex. There are approximately 10–20 billion neurons in the cerebral cortex generating between 60 and 240 trillion connections. The cortex is the last part of the brain to develop, taking approximately 20 years to fully mature, and is more susceptible to insult and injury in males than females. The limbic system, moreover, is intimately connected to the cerebral cortex.

The cortex is divided into the prefrontal cortex (PFC), the dorsolateral prefrontal cortex (DLPC) and the orbitalfrontal cortex (OFC). Collectively these areas are responsible for what are known as "executive functions." Executive functions include goal driven behavior, planning and execution of a plan, impulse control, delayed gratification, task switching, and emotional regulation. Deficits in executive functioning are of primary concern to criminologists. First, a large body of research evidence shows that criminal offenders are highly impulsive, frequently hedonistic, and have trouble delaying immediate gratification. A dominant theory in criminology refers to this syndrome as "low self-control" (Gottfredson and Hirschi 1990). Medical experts are able to assess brain function through a number of imaging techniques. A growing body of imaging evidence, including functional magnetic reasonance imaging (fMRI), positron emission tomography (PET), and single photon emission tomography (SPECT), reveals a pattern of under-activation in the in the left, but sometimes the right, PFC. The lack of activity is thought to correspond to deficits in the executive control functions of the brain. Self-control is known to be housed in the PFC, specifically the OFC. It is considered to be a relatively stable characteristic over long periods of the life-course. Activity levels in the OFC, however, can sometimes be adjusted with the use of prescribed stimulants.

Second, the PFC is the last part of the brain to fully develop, with myelination not complete until the start of the third decade of life. Because of this, adolescents appear to be more influenced by limbic impulses and emotional stimuli. Experimental studies have found that adolescents tend to over-estimate the potential emotional and social awards of a behavior, while they tend to under-estimate the actual risks associated with the behavior. Moreover, they appear to be more influenced by peer pressure than are adults. One of the developmental changes that takes place during adolescence is a shift from a reliance on initial limbic impulses to a reliance on the PFC as the primary brain mechanism used to solve problems. Interestingly, this evidence was used by the Supreme Court of the United States in *Roper v. Simmons*, 543 U.S. 551 (2005). The court held that the execution of individuals who were under the age of 18 years at the time of their capital crimes is prohibited by the Eighth and Fourteenth Amendments.

Contemporary neuroscience theorizes that aggressive and violent impulses originate in the deep limbic structures of the brain, primarily in the amygdala, where they stimulate an autonomic nervous system response that prepares the body for violence. Part of this response is an increase in the amount of hormones, such as testosterone, entering the blood stream, as well as an increase in muscle oxygenation, a loss of peripheral vision, and an increase in heart rate. Depending on the context, however, this impulse can be shunted by a sufficiently developed and interconnected PFC. The PFC causes a reduction in the initial limbic impulse and delays the behavioral actions that can accompany the impulse. This is why, for example, most people do not engage in violence even when they have been sufficiently provoked. Violent behavior can occur, however, when deficits in the PFC, either through a lack of active connectivity or insufficient connections to the limbic system, fail to filter the violent impulse.

Neurotransmission

Neurotransmission is the process by which electro-chemical messages are sent throughout the brain. Neurons are cells that facilitate this communication. There are approximately 100 billion neurons in the adult brain, and each neuron connects to between 1 and 10,000 other neurons. Neuronal activity is highly complex and is involved in every thought, emotion, and behavior engaged in by the human organism. Neuronal transmission occurs when a pre-synaptic neuron generates and sends an electrical charge down its axon, which is a tail-like extension emanating out of the cell. The electrical charge moves down the axon by passing through a series of positively and negatively charged sodium and potassium gates where it will eventually encounter the synaptic cleft. Electrical energy is then converted to chemical energy when the vesicle housing chemicals, known as neurotransmitters, releases molecules into synaptic space. Synapses, or the area between the axon of one cell and the dendrite of the another, is 1/600th the width of a human hair.

Neurotransmitters pass through synaptic space and bind to specialized receptors on the post-synaptic neuron. Once the neurotransmitters have bonded to the receptors, an electrical charge is sent back down the post-synaptic neuron and the transmission cycle is completed. The neurochemicals used in the process are reabsorbed by the neuron in a process called reuptake, or they are enzymatically degraded for future use.

Neuronal receptors are highly specialized and vary in number and sensitivity. The number of receptors located on a dendrite, and their efficiency and sensitivity, is genetically controlled and varies across individuals. Receptor sites are also specific to each neurotransmitter. For instance, dopamine receptors accept only dopamine molecules while serotonin receptors accept only serotonin molecules.

Neurotransmission frequently involves groups of neurons working collaboratively. These "neural networks" are responsible for a number of complex functions carried out within the brain. With repetitive stimulation, these networks become more efficient and send messages more quickly. In contrast, neurons that are not used or that are stimulated irregularly are pruned. This has led to the development of Hebb's rule: neurons that fire together, wire together.

Neurotransmitters can be classified as excitatory, causing an increase in cell firing, or inhibitory, which prevents cells from firing. Four neurotransmitters have been identified that are related to antisocial behavior. Dopamine is an excitatory neurotransmitter, which is involved with the reward and punishment systems in the brain, as well as cognitive functioning. Norepinephrine is another excitatory neurotransmitter. This chemical is tied to emotion and memory, and is involved in fight-or-flight responses. Gamma aminobutyric acid (GABA) and serotonin are inhibiting neurotransmitters. GABA is responsible for filtering stimulation from the environment to allow interpretation of experiences. Serotonin has been linked to mood and self-restraint. Each of these neurotransmitters has been found to be related to antisocial behavior.

Moderate levels of dopamine are associated with optimal cognitive functioning. It is known to enhance problem solving and to increase concentration. Dopamine is released in the brain when individuals participate in pleasurable activities, creating feelings of euphoria. This increases the likelihood that the behavior will be repeated. As dopamine is involved in the reward systems in the brain, it has been hypothesized that some individuals may experience reward deficiency syndrome (RDS). In these circumstances, individuals experience less neurological arousal from behaviors that would be experienced otherwise. For individuals suffering from RDS, behaviors such as eating or sex would not bring an optimal amount of pleasure. This condition is thought to lead individuals to be more impulsive, obsessive, or vulnerable to addiction. Commonly abused substances such as nicotine, caffeine, and a number of illicit drugs increase dopamine levels, and many substances such as cocaine, bind directly to dopamine receptors. As a result, dopamine is believed to play an important role in substance abuse and addiction.

Significantly high levels of dopamine have been associated with aggressive and criminal behaviors as well as reduced intelligence. A number of studies have shown that antipsychotic drugs known to reduce dopamine production have also reduced aggressive behaviors (Brizer 1988; Mollinger et al. 1962; Yudofsky et al. 1987). However, some studies have suggested that the effect of dopamine on aggressive behavior may be insignificant (Raine 1993).

Norepinephrine can be found in the cerebellum and hindbrain regions, as well as between the brain stem and cortex. It is distributed throughout the limbic system. During periods of heightened arousal norepinephrine is released, aiding individuals in responding to fright or anger. Provided that norepinephrine can be found in regions of the brain responsible for emotion and memory, these events are likely to remain in an individual's memory for a long period of time. Some drugs can block the reuptake of this neurotransmitter, resulting in an excess of this chemical in the brain. Generally, studies indicate that excessive amounts of norepinephrine are related to aggressive behavior (Brizer 1988; Fishbein 2001; Volavka 1999; Yudofsky et al. 1987); however, there is also evidence that lower levels of this neurotransmitter may be linked to antisocial behavior (Raine 1993). The available research indicates that the relationship between norepinephrine and maladaptive behaviors may be curvilinear; meaning both high and low levels of this neurotransmitter can increase problem behavior.

The most prevalent neurotransmitter is GABA (Wan et al. 1996). Primarily, GABA is used by the brain to regulate the functioning of the nervous system and cognitive functioning. This neurotransmitter works to balance excitation in the brain by inducing relaxation and sleep. Reduced levels of GABA can lead to increases in irritability, anxiety, and violent behavior. In contrast, excessive levels of this neurotransmitter depress cognitive functioning. Alcohol and the date rape drug gamma hydroxybutyrate (GHB) have effects on the brain similar to excessive amounts of GABA. The senses of the body are inhibited, and it becomes difficult to have a complete awareness of the immediate environment.

Serotonin is used by neurons found in the brain stem, the limbic system, and the frontal cortex. In addition to the influence genetics may have in the development of the serotonergic system, there are environmental factors such as seasonal changes that also seem to influence serotonin levels. This neurotransmitter has been found to play a large role in the regulation of behavior and mood. Low levels of this neurotransmitter have consistently been linked to criminal behavior among juveniles and adults (Brizer 1988; Fishbein 2001; Raine 1993). Recent research has indicated that serotonin is important in inhibiting impulsive behavior, and that impulsivity that is tied to strong emotion is more likely to result in violent outcomes (Krakowski 2003; Volavka 1999). Lower levels of serotonin have also been associated with violent forms of suicide. It has also been found to correspond with higher levels of substance abuse and a number of clinical disorders. There is even evidence that suggests that low serotonin, alcoholism, and violence may share an association.

There is clear evidence that an excess or deficiency in neurotransmitters can result in modifications in behavior. While the amount of these chemicals in the brain is influenced by the body's production of the chemical, it is also influenced by the regulation of the substance through its removal. One method of removing neurotransmitters that remain in the synaptic space after neurotransmission is through the process of enzymatic degradation. Monoamine oxidase-A (MAO-A) is an enzyme found within the brain which is responsible for metabolizing serotonin, norepinephrine, and dopamine. Having too little or too much MAO-A will interfere with neurotransmission. If an individual is deficient in MAO-A, an abundance of neurotransmitters may be left in the synaptic cleft after neurotransmission. In contrast, an overproduction of MAO-A may reduce the amount of a neurotransmitter in the transmission process. In either case, this interference can result in abnormal behavior.

Genes code for the level of MAO-A in individuals, and alleles for this enzyme are categorized as either high or low activity. Although research on the relationship between MAO-A and behavior is still in early stages, high and low levels of MAO-A have been associated with aggression and impulsivity among children and adults. There is also some evidence that suggests that varying levels of MAO-A may interact with environmental conditions producing maladaptive behavioral outcomes (Kim-Cohen et al. 2006). For example, those that possess the low activity allele and experience maltreatment during childhood may be more likely to engage in antisocial behaviors during adolescence or adulthood.

Controversies/Remaining Questions

While the available research indicates that various aspects of brain structure and function are implicated in the explanation of antisocial behavior, these relationships require further specification. For example, some studies have found that high concentrations of a neurotransmitter are related to maladaptive behaviors, but other studies demonstrate that lower concentrations of the same neurotransmitter also lead to maladaptive behaviors. The pattern of findings suggest that excesses and deficiencies result in behavior differences, but some scholars have also suggested that the relationship may be specific to types of offenses, such as property offenses, and to the nature of the offending, such as predatory or impulsive offending (Raine 1993). Either way, it is fair to say that while great advances have been made that much research is still necessary.

Neurological findings, in general, and those associated with human aggression and violence specifically, challenge many long held views about the nature of free will and choice in human action. Some scholars assume that accepting biological factors as contributing to human behavior eliminates the possibility of free will. They point, for example, to the neurological evidence showing brain deficiencies in the frontal cortex as evidence that behavior cannot be freely chosen. Moreover, other scholars have argued that since certain afflictions, such as alcoholism and drug-addiction, are highly heritable, that individual responsibility for conduct associated with these afflictions should be reduced. This is no small matter. The criminal justice system currently operates under the assumption that individual's make decisions based on free will. Neurological findings, however, have been used to question the extent to which free will exists and thus have been used to argue that the criminal justice system should more fully embrace a medical model – where the cause of criminal behavior is diagnosed and individual treatment, not punishment, provided.

Recent evidence adds to and expands this debate. Several studies have recently found that brain structure and function in the early life-course predicts brain structure and functioning in adulthood. The implications of these findings are not fully understood but they contrast with the images of rapid growth and change in brain functioning so prevalent in the research literature. It may be the case that the brain changes only within a limited range and that the changes detected in childhood through adulthood are bounded or restricted. If true, early brain activity may be a marker for problem behaviors later in life. While this information could be used to target youth for intervention, it could also be used to label youth as potential criminals. Hence, the ethics surrounding the use of neurological information in the identification and treatment of individual behavioral problems has yet to be sorted out. Do we, as a society, intervene in the lives of children and their families based on early neuro-scientific findings, or do we wait until problem behavior has emerged and someone has possibly been harmed? At this stage, the science is far ahead of our ethical understanding about the limits of the science.

New Penology

Michelle Brown
Department of Sociology, University of
Tennessee, Knoxville, TN, USA

Overview

The new penology is a perspective that plots the rise of actuarial justice in understandings of crime and criminal justice. This model views crime as now normal and no longer a site for social reformation. Instead, the best that can be expected is the control of crime through techniques based upon technology and statistical calculations that enhance the identification and management of "high-risk," "dangerous," or unruly groups. This approach marks the rise of technocratic forms of knowledge no longer concerned with the rehabilitation or transformation of individual offenders but rather with the production of aggregate categories and classification schemes that locate and track actual and potential offenders. Mass incarceration and the warehousing of offenders become primary ways of managing risk in criminal justice simply by removing potentially dangerous individuals from society for long periods of time. This logic is argued to be a major influence on criminal justice agents, institutions, and policies where risk management and actuarial discourses, its proponents argue, have diffused throughout the justice system and into the community.

Fundamentals, Critiques, and New Directions

Introduction

A reaction to the decline of rehabilitation and the rise of "nothing works" discourse in the late 1970s and 1980s, the new penology is configured as a radical break from the past at a moment of penal crisis. As David Garland writes in *The Culture of Control*:

> Within the brief time it takes to progress from basic training to mid-career, a whole generation of practitioners – probation officers, prison officials, prosecutors, judges, police officers, and criminological researchers – have looked on while their professional world was turned upside down. Hierarchies shifted precariously; settled routines were pulled apart; objectives and priorities were reformulated; standard working practices were altered; and professional expertise was subjected to challenge and viewed with increasing skepticism. The rapid emergence of new ways of thinking and acting on crime, and the concomitant discrediting of older assumptions and professional orientations, ensured that many penal practitioners and academics lived through the 1980s and 1990s with a chronic sense of crisis, and professional anomie. (2001: 4)

This context of crisis became the setting for fundamental paradigm shifts in understandings of crime and punishment. In the closing moments of the twentieth century, the United States, for the first time in world history, imprisoned more people for the purposes of crime control than any other society, with a total prison and jail population of over two million people. This kind of penal expansion was in keeping with the kind of growth taking place across various forms of punishment from prison to probation. This expansion continued even as crime rates decreased. In fact, historically, there is no significant correlation between crime rates and incarceration rates; rather, offenders are more likely to commit a crime after release from prison than previous to incarceration.

For these reasons, criminologists began to look closely at the latent functions of punishment, those reasons and motives that are less apparent in rhetoric but materialize in practice. Against this unprecedented transformation, scholars began to ask a new set of questions: If the prison's function cannot be found in perhaps its most rational and logical justifications, including crime reduction, public safety, and rehabilitation, then why does the institution persist and why did it expand exponentially in the late twentieth century? How has this transformation reconfigured the implementation of justice, notions of individual and collective identity, and modes of governance? They also produced a wave of new explanatory concepts and theories – terms like "penological crisis," "incarceration binge," "prison-industrial complex," and a "new penology." The new penology, then, as articulated by its main theorists, sociolegal scholars Malcolm Feeley and Jonathan Simon, represents perhaps most fundamentally the understanding shared across much of criminology that "a different kind of historical change is unfolding in our contemporary penal practices" (Simon 1988: 452).

Background and Foundations

The New Penology

The new penology represents one of the more powerful accounts that seek to add insight to these problems and predicaments by highlighting some of the potentially permanent effects contemporary patterns in punishment may have upon the configuration of criminal justice and social life. Feeley and Simon introduced the new penology in a widely read 1992 *Criminology* article which they then followed with a body of work dedicated to revising and further developing their propositions (Feeley and Simon 1992, 1998). Their claims continue to serve as a critical point of reaction within the field of criminology. For these authors, the predominant transformation in punishment is theorized to be centered upon a "change in conception – discourses, objectives, and techniques – in the penal process... shifts that have multiple and independent origins and are not reducible to any one reigning idea" (1992: 449). This change in conception centers upon three core assertions, which they describe as follows:

1. The emergence of new discourses: In particular, the language of probability and risk increasingly replaces earlier discourses of clinical diagnosis and retributive judgment.
2. The formation of new objectives for the system: The objectives we have in mind are not simply new to the system (some of them have old antecedents) but are in some sense newly "system." We are especially interested in the increasing primacy given to the efficient control of internal system processes in place of the traditional objectives of rehabilitation and crime control. Goals like reducing "recidivism" have always been internally shaped in important ways, but in the contemporary setting, the sense that any external social referent is intended at all is becoming attenuated.
3. The deployment of new techniques: These techniques target offenders as an aggregate in place of traditional techniques for individualizing or creating equity (Feeley and Simon 1992: 450).

The emergent discourse, objectives, and techniques of the new penology express a fundamental reorganization in contemporary understandings of crime and punishment, identified in such patterns and practices of surveillance and regulation as preventive detention, profiling, intensive supervision programs, the buy-busts and drug testing practices at the heart of the drug war, the targeting of subpopulations through policies centered upon selective incapacitation (habitual, career, and "three strikes" offenders), emergent statistical and software packages that track crime, and the increase in imprisonment alongside of the rising prominence of policy and crime experts. The primary contours of this reorganization, as marked by Simon, include a shift from the individual to the aggregate, from normalization to management, and from social norms to systems. This perspective privileges utilitarianism over moral reasoning, quantitative methods over qualitative analysis, and the notion of criminal justice as a series of operations and systems over individual-focused justice and rational actor theories.

Governmentality, Risk, and Actuarialism

> It is actuarial. It is concerned with techniques for identifying, classifying and managing groups assorted by levels of dangerousness. It takes crime for granted. It accepts deviance as normal. It is skeptical that liberal interventionist crime control strategies do or can make a difference. Thus its aim is not to intervene individuals' lives for the purpose of ascertaining responsibility, making the guilty 'pay for their crime' or changing them. Rather it seeks to regulate groups as part of a strategy of managing danger. (Feeley and Simon 1998: 375)

The new penology is squarely centered in larger frameworks of governmentality, risk, and actuarialism. Governmentality, with its implied rationalities, centers upon knowledge and practices that operate across and are shared between individuals, institutions, and the state. The new penology is most formidable in that its discourses, objectives, and techniques come to operate broadly across the social body as a form of governance. The new penology thus marks a move away from one of criminology's dominant frames in understanding punishment, a disciplinary model. Disciplinary modes of punishment are organized around an intense focusing upon the individual down to the most minute of details and habits. This kind of disciplinary focus, as exemplified by Foucault, is built around surveillance and normalization of the offender, inmate, delinquent, worker, and student, embodied in the closing of the gap between a norm and its deviation, the transformation of the individual self. The new penology, which privileges an actuarial model, is no longer concerned with closing this gap between individuals and society but rather seeks an accommodation of such variables through the management and mapping of distributions of populations. As Simon argues, in part, "the movement from normalization (closing the gap between distribution norm) to accommodation (responding to variations in distributions) increases the efficiency of power because changing people is difficult and expensive" (1988: 714). In contemporary social and political contexts, "it is cheaper to know and plan around people's failings than to normalize them" (Ibid). The new penology no longer seeks to normalize populations but rather to regulate them and their differences through segregation across abstract spaces, groupings, and social distributions that ironically culminate in even deeper exclusionary divisions, including the creation of a "functional" or permanent underclass. This phenomenon is noted in the governmentality literature as governing from or at a distance.

Within this new mode of governance, crime control efforts on the part of the state are defined by an abrogation of responsibilities by institutions that are already and historically under-sourced and under-trained. These justice agencies, envisioned originally as the last resort in the line against social problems, in many ways are now the first resort in the management of the mentally ill, homeless, economically disadvantaged, etc. Such a phenomenon also seeks to responsibilize individual actors even as it restricts the discretionary decision making of frontline justice actors and then implements unwieldy mechanisms of accountability through performance indicators. This mode of governance is most compelling in its ability to move out from political centers through dense, overlapping networks in which authorities, groups, institutions, and individuals all reflect a new emphasis no longer on production but the calculation of the activities and desires of others. Such entities will direct classification via an assessment of risk, including where it is most likely and how it might most efficiently be managed. Under the new penology, risk, in the form of "dangerous" populations, is most effectively managed, not through normalization, but spatialization marked by a well-mapped exclusion and isolation through mechanisms of classification rather than the more disciplinary mode of segregation through social control institutions. This pattern is most visible when social control is organized in a manner which extends beyond justice agencies into families, communities, schools, churches, and other primary social institutions as well as the fabric of social life. For instance, increasing attention and debate has centered upon the mapping of sex offenders in communities through social policy and legislation as groups who remain intractably in need of management, grounded in a fundamental public pessimism about the possibility of individual reformation or change. In the clinical and justice discourses surrounding that management, the vocabulary of actuarialism through risk management models is strongly apparent. These patterns are significant in the manner in which they invoke penality as a way in which to generate fundamental changes in political culture, generate regimes of truth, exercise power, differentiate groups, classify individuals, and thus, in general, reorder social life. In such a context, the material and institutional structures of the new penology have social and political effects with life organized around crime control and a perpetual search for security.

Such patterns are strikingly similar to other emergent sociological concepts, including Zygmunt Bauman's paradigm of exclusion, Jock Young's exclusive society, and Loïc Wacquant's urban outcasts and "deadly symbiosis" of community and prison. In such contexts, Foucauldian disciplinary modes, with their emphasis upon normalization – and the closing of a gap between a norm and its deviation – no longer dominate. Rather, these gaps are simply accommodated and regulated largely through exclusionary practices. In contemporary social and political contexts, Simon argues "it is cheaper to know and plan around people's failings than to normalize them" (1988: 771). This marks a critical site from which the study of punishment must carefully distance itself, they imply, in order not to reproduce these exclusions and normalizations through an institutionalized myopia in its own reports and research. Rather, the place of experts is one that calls direct and critical attention, like Feeley and Simon, to these dangerous convergences. This kind of engagement with governmentality speaks to a theoretical breadth in criminology that marks not only how emergent modes of governance shape the nature of crime and punishment but of what it means to be social. Risk and actuarial logics, which often omit sociological thinking, make it more difficult for groups and individuals to build solidarity and exercise political choice. At stake is the preservation and protection of human agency from forms of regulation and classification that may, at first glance, seem all too rational, logical, and "natural." In such contexts, the privileging of actuarial techniques risks denying the moral, political, and social significance of the historical markers of vulnerability – race, class, gender, and age – instead arguing these differences are no longer problematic, closing off significant social debates a priori. Beyond this, individual and group identities are rendered flat and sterile with little critical reflexivity. As Simon argues, "Rather than making people up, actuarial practices unmake them" (Ibid: 792). Out of this emerges a new and dangerous kind of social collectivity, one that is defined not by a deep sense of shared bonds or experiences but by exclusion. This is one of the larger implications of a new penology.

In such scenarios, the weakening of social welfare frameworks for governance has led to an expansion and exportation of punitive carceral strategies by the United States, a new mode from which to regulate minorities, the poor, and the socially abandoned across the planet. Importantly, these shifts are not hidden or invisible but rather prominent, naturalized features of emergent urban landscapes. Such transformations map the manner in which sovereignty is reconfigured in a broad social and global landscape with the imprint of a distinctly American mode of punishment. Importantly, citizenship in these contexts is experienced as hierarchical, determinedly and dangerously paternalistic, and punitive in its reliance and reproduction of social and cultural oppositions of race and class, all of which flow into and out of insecurities surrounding criminality and dangerousness. In this sense, the new penology is a distinctly dangerous way of understanding crime and punishment in its capacity to feed into social practices that extend globally and foundationally into social order and life. For these reasons, the defining contours of the new penology are built around broader notions of governmentality, risk, and actuarialism, practices that:

> are so familiar and banal that it is difficult to notice them at all, let alone see them as central components of a new regime of social ordering linked to myriad exercises of social control and power, e.g., hiring, admitting, campaigning, selling, sentencing, and educating. Yet these practices are generating fundamental changes in our political culture. (Simon 1988: 771)

These practices are argued to derive from actuarial techniques that "play a central role in a proliferating set of social practices. They are at the same time a regime of truth, a way of exercising power, and a method of ordering social life" (Ibid: 772). Actuarialist models emerge as complex mixtures of styles of thought, discourse, and vocabulary as well as sets of practices, strategies, and technologies. Grounded in efficiency, they value a certain technicism where system streamlining on the basis of cost-benefit analysis and risk assessments is foregrounded. They are driven by an economy of management centered upon the distribution of aggregate numbers of individuals across the justice system and an extension of these patterns of control across the everyday life of offenders and system professionals – "a fundamental respatialization of control mechanisms, from the enclosed spaces of carceral institutions to the dispersed territory of 'the community'" (Rose 2002: 212). Their primary tools are prediction instruments, classification schemes of "at-risk" populations, distribution grids, and technology, all of which are conducive to the production of emergent, wider networks of control.

These features reflect the manner in which actuarial understandings of the world are perceived as having the potential to fundamentally transform social life, playing pivotal roles in the organization of power, expertise, and social control. In this system-based focus, justice itself is reconfigured, and, as sociologist David Garland argues, "new performance indicators tend to measure 'outputs' rather than 'outcomes,' what the organization does, rather than what, if anything, it achieves" (1996: 458; See also Garland 2001). In this regard, the new penology marks a larger shift in the history of social control, the first grounded in a "crisis of penological modernism," devoid of philosophical underpinnings and organized instead around a collapse of faith and implicit sense of futility in deterrence and rehabilitation. Its power is in the implication of a particular form of logic that facilitates other kinds of penal aims, including incapacitation and retribution.

Centered upon the prevalence of uncertainty in the discretionary patterns of justice, the new penology offers a formula for control and the semblance of predictability in terrain that has systematically denied and subverted efforts and reform and control. The center of the new penology is consequently and, not surprisingly, a paradox:

> Across its various forms and calculative techniques, one feature stands out: risk thinking seeks to bring the future into the present and make it calculable. We could say that it tries to discipline uncertainty, in the sense of making uncertainty the topic of a branch of learning and instruction. It acts as well to discipline it in a second sense, by bringing uncertainty under control, making it orderly and docile. Risk thinking tames chance, fate, and uncertainty by a paradoxical move. (Rose 2002: 214)

Its attention to risk assessment through testing instruments and statistics serves as well to automatize and conceal a host of decision-making processes by practitioners and experts, instead often responsibilizing actors for their own risk classifications. In the end, justice actors, experts, subjects, and citizens all find themselves caught up in the tensions that define the new penology. And yet, Feeley and Simon argue that this very reality is concealed by the nature of the aggregate that actuarial practices exemplify, constituting a new kind of social collectivity, "one defined neither by internal bonds, nor external experiences, but by locations on a statistical distribution" (Simon 1988: 789). These classification schemes produce particular kinds of identities and individualities, but, as Simon argues, these techniques lack a distinctive sense of subjectivity and group identity itself is treated as "singularly sterile in [its] capacity for political empowerment"

(Ibid: 789). Thus, "actuarial techniques can be used to identify people who are more or less likely to be high-rate offenders, but these variables are not integrated into a conception of the underlying subject" (Ibid: 791).... "actuarial classification, with its de-centered subject, seems to eliminate, in advance, the possibility of identity, of critical self-consciousness and of intersubjectivity" (Ibid: 792). In that sense, the new penology is a symptom of a larger crisis within governance and thus apparent in punishment, one that seeks to regulate rather than explain or change contemporary social problems. In doing so, the meanings of the social and the self are argued to be fundamentally transformed.

Critiques and New Directions

Critiques

In Feeley and Simon's own words, their "thesis has sparked vigorous debate" (1998: 148). Many have critiqued the "newness" of the new penology and instead perceive it as a repackaging to some extent of preexisting theoretical frames. For some, the new penology represents an invocation of old penological and criminological themes with its emphasis upon classical Marxist terms like the "dangerous classes." Others argue that the new penology is unable to account for the rise of populist understandings of punishment centered upon retribution and an emotive turn in law and order politics. Others wonder to what degree frontline actors and professionals in the criminal justice system have internalized the actuarial logic of the new penology. Similarly, it is not entirely clear how the new penology marks a fundamental rupture from disciplinary to actuarial modes, or from modern punishment to something postmodern or otherwise, with critics pointing to the presence of actuarial logics historically in criminal justice as well as the persistence of individualistic, rational actor orientations that privilege retribution and expressive modes of populist sentiment in contemporary contexts.

Sociolegal scholar Mona Lynch writes, "One site for examining whether the new penology is indeed emerging as a distinct penological operating system is at the place where strategy is put into penal practice: at the level of implementation. There is reason to think that the contact point between the institution (and its new penological policies) and the outside world (with its old-fashioned "modern" take on criminality) is one battleground where the sustainability of the new penology may be tested" (1998: 842). Lynch models an empirical testing of the new penology through a rigorous ethnography of a California parole field office. Her findings point to the manner in which features of old and new penology meld in the everyday settings of criminal justice agencies, with actors reaffirming conventional law enforcement roles, including an individualistic focus, even as upper management developed policies framed by actuarial logics of risk management.

Criminologist Leonidas Cheliotis makes a case as well for the unpredictable aspects of human agency within institutional frameworks as a check upon the totalizing tendencies of a new penology. In an article where he examines the ways in which the defining boundaries of the new penology foreclose other possibilities, he writes:

> In so far as criminology aspires to influence the penal policy debate to any significant extent, analyses that fail to identify 'the real human stuff of disposition, choice and action – the stuff of which society and history are actually made'... cannot but be fatalistic and nihilistic, thereby inauspiciously (one could also say 'by way of benign neglect') contributing to the reproduction of the very crises they are supposed to pre-empt or combat.... Yet, in the dearth of convincing evidence that they signify a 'marked break with the past', and given that actuarialism is neither inevitable, nor necessarily undesirable in its entirety, the concept of new penology lacks interpretive adequacy and, consequently, remains a mere hypothesis. And this is a hypothesis which, in itself, Feeley and Simon would surely wish to see eventually disproved. (2009: 331)

New Directions

Aside from these critiques, the centerpiece of the new penology is found in Simon's introduction of the idea of "governing through crime" in the volume by the same name (2007). As crime becomes the primary way in which a broad variety of social problems and social action comes to be configured, Simon finds that the penal state itself becomes a framing logic not simply for the urban centers hard-hit by crime and violence through spiraling inequalities of race, class, gender, and ethnicity but for the sites and centers for the performance of middle-class life – work, education, family, and health. Crime and punishment become the larger context for shaping and regulating the conduct of others. The construction of issues related to work performance, education, divorce and child custody, etc. as "crime" issues allows for a host of regulatory mechanisms that would not otherwise be available: drug testing and other forms of surveillance; harsher, more punitive treatment; segregation; restriction of mobility; and forced movement, such as deportation. In Simon's estimate, governing through crime exceeds the conventional parameters of criminal justice and has seeped into the fabric of social life by way of other social institutions and everyday life frameworks. In this way, governing through crime is not really about crime but is instead a useful tactic or legitimation strategy that enables actors to manage other kinds of disputes, annoyances, social problems, or personal and public issues. Its rise includes an expansion of executive power, the privileging of a new and dangerous mode of political subjectivity – the victim, the weakening of courts and judges, and the rise of mass incarceration. In this manner, governing through crime produces citizens who are not victims themselves but live in fear of being victims across complex regulatory frameworks that deny the formation of other kinds of subjectivities – the kinds of informed citizen actors upon which democracy depends.

Finally, the new penology foreshadows a growing sense of pessimism and futility in criminology and criminal justice alike. Centered in correctional managerialism, actuarial justice, and the privileging of custody, the discourses, objectives, and techniques of the new penology share key elements with what works models. Grounded similarly in the crisis of the state, a heightened perception of high crime against the futility of punishment and a hardening of popular attitudes toward criminals, both discourses speak to the limits of science. However, the new penology is marked by an expansion and elaboration of exclusionary tactics through the convergence of scientific and bureaucratic mechanisms as managerial strategies, practiced and implemented through new technological possibilities in the realm of empirical classification and social control. More significantly, the new penology, through such public and private convergences, extends outward into the production of identities and subjectivities well beyond crime across the social fabric – governance at a distance and through crime. Such a perspective relates specifically to the despair and futility of nothing works in that, as an actuarial objective, it "does not offer an answer to this perceived hopelessness. Instead, it takes for granted that no answer exists, and offers the placating alternative of at least managing this hopelessness in a less burdensome and more efficient fashion... a chance to succeed, although only through a redefinition of goals" (Kempf-Leonard and Peterson 2000: 68).

The linkages between what works discourses and the new penology are complex, but importantly many of the aims, methods, and techniques of evidence-based research are potentially and aptly directed at new penology objectives with their privileging of techniques for identifying, classifying, and managing groups assorted by levels of dangerousness. In such worlds, science can collide again with familiar terms in a way that "takes crime for granted... accepts deviance as normal... is skeptical that liberal interventionist crime control strategies do or can make a difference. Thus its aim is not to intervene in individuals' lives for the purpose of ascertaining responsibility, making the guilty 'pay for their crime' or changing them. Rather it seeks to regulate groups as part of a strategy of managing danger" (Feeley and Simon 1998: 375). In keeping with new penology claims, much of the contemporary study of punishment has concerned itself with the absence of social vision and metanarratives that might anchor the practice of punishment in democratic, humane discussions. As Adrian Cherney argues, “Any form of social policy hinges on more than a rational analysis of ‘what works.’ Instituting change in how society responds to social problems depends also on the ability to articulate a vision – a public ideal around which reform can be mobilized....” (2002: 51), a collective possibility that is constrained by the objectives, discourses, and techniques of the new penology.

Conclusion

Feeley and Simon argue that the new penology might best be envisioned not “as a theory or program conceived in full by any particular actors in the system, but as an interpretive net that can help reveal in the present some of the directions the future may take” (1992: 460). In this future, they argue that the essential elements of a new penology are powerful enough to become “permanent features of the criminal justice system” (Ibid: 470). As knowledge concerning the features and qualities of particular groups grow more distinct in public records and classification schemes, “the ideological effects of actuarial practices... render more difficult the formation” of community organization and social movements where “the effect of actuarial practices is precisely to make it more difficult for groups to intensify their solidarity or exercise political choice” (Simon 1988: 786–787). One concern then of the critics of a new penology is the preservation and protection of human agency from forms of regulation and classification that may, at first glance, seem all too rational and logical. As Simon argues in early work:

> Today’s actuarial practices presage the development of a third model of politics where neither status nor class provides the basis for engagement. Indeed, we have no real models of what aggregate politics look like, but extrapolating from current conditions leads to a disturbing picture. Actuarial practices can mobilize segments of the population and form majorities that have no basis for understanding themselves as motivated by a common cause. (1988: 793)

Mapped into dramatic changes in law and administration, across such vast sociolegal landscapes as workplace regulation, sex offender registries, immigration practice, homeland security, and the war on terror, the new penology is a prescient and cogent reminder of the present and potential face of governance now and later.

Nuclear Weapons and State Crime

Ronald C. Kramer
Department of Sociology, Western Michigan University, Kalamazoo, MI, USA

Overview

Since the advent of the nuclear age, only a relatively small number of lawyers and criminologists have addressed the issue of nuclear weapons from anything resembling a criminological perspective. From 1945 on, questions concerning the legality or illegality of "the bomb" were raised, and over the years, a number of legal scholars and courts have analyzed the legal status of nuclear weapons under international law (Falk 1965, 2008a, b; Lawyers' Committee on Nuclear Policy 1990; International Court of Justice 1996; Boyle 2002). One legal analyst argues "that we need to recognize the intrinsic criminality of any threat or use of nuclear weapons" (Falk 2008a, p. 43). However, the number of criminologists who have advocated for or directly engaged in criminological inquiry concerning nuclear weapons is quite small (Friedrichs 1985, 2010a, b; Kauzlarich and Kramer 1998; Kramer and Kauzlarich 1999, 2011; Kramer and Bradshaw 2011). One prominent criminologist has observed: "It is quite remarkable that the vast criminal potential in the use of nuclear weapons has been neglected by criminologists" (Friedrichs 2010a, p. 132). And he also points out that the nuclear threat is a "monumentally important issue" that should be part of what he calls a "prospective criminology" of state crime (Friedrichs 2010b, p. 77).

This entry will address the topic of nuclear weapons and state crime. Three broad areas will be examined. First, the question of the illegality and/or criminality of nuclear weapons will be assessed. Second, specific forms of crime committed by the US nuclear state since 1945 will be examined. These state crimes include the actual use of atomic bombs against Japan during World War II, the repeated threats to use nuclear weapons in various conflict situations since then, and the continued possession of nuclear weapons by the USA and others in violation of the solemn legal obligation to disarm, which in turn has lead to a variety of environmental crimes and the potential for nuclear terrorism. Finally, structural and cultural explanations that have been advanced regarding these state crimes will be briefly discussed.

The Illegality of Nuclear Weapons

Although the criminologists who work in this area could argue that the use, threat to use, and continued possession of nuclear weapons are state crimes from a broader analogous injury/social harms approach, the extant criminological analysis of these acts has thus far been carried out within a strictly legalistic framework. The use, threat to use, and continued possession of nuclear weapons are considered state crimes because they involve decisions and actions by state officials, acting as representatives of the state, that violate specific *public international laws*, such as International Humanitarian Law (IHL) and the Nuclear Non-Proliferation Treaty (NPT) of 1968. As defined by the 1945 Nuremberg Charter, these illegal state actions can be designated as *crimes against humanity* and/or *war crimes*. As Agnew (2011, p. 31) points out: "The international law is especially useful for identifying harms committed by states."

Questions concerning the legality of nuclear weapons were raised early on. The first court case to address the issue was the *Shimoda* decision, handed down by the District Court of Tokyo on December 7, 1963. In May of 1955, five Japanese nationals instituted a legal action against their government to recover damages for the injuries they had suffered as a result of the atomic bombings of Hiroshima and Nagasaki. Part of their claim for compensation was based on the assertion that the dropping of the atomic bombs as an act of hostilities was illegal under the rules of positive international law. In its important ruling on the case, the Japanese court held that the atomic bomb attacks on Hiroshima and Nagasaki did indeed violate international law, although it rejected the plaintiff claims for compensation. In his classic appraisal of the *Shimoda* case, Falk (1965, p. 776) clearly summarized the principal reasons the court gave for its decision that the atomic attacks were illegal:

1. International law forbids an indiscriminate or blind attack upon an undefended city; Hiroshima and Nagasaki were undefended.
2. International law only permits, if at all, indiscriminate bombing of a defended city if it is justified by military necessity; no military necessity of sufficient magnitude could be demonstrated here,
3. International law as it has specifically developed to govern aerial bombardment might be stretched to permit zone or area bombing of an enemy city in which military objectives were concentrated; there was no concentration of military objectives in either Hiroshima or Nagasaki.
4. International law prohibits the use of weapons and belligerent means that produce unnecessary and cruel forms of suffering as illustrated by the prohibition of lethal poisons and bacteria; the atomic bomb causes suffering far more severe and extensive than the prohibited weapons.

Taken together, the international laws that the Japanese court based its ruling on constitute what is called International Humanitarian Law (IHL) or the laws of war. Since the *Shimoda* ruling, a significant number of international law scholars have concurred with its analysis of the illegality of nuclear weapons (Boyle 2002; Falk 2008b; Lawyers' Committee on Nuclear Policy 1990). The position of these legal analysts that the use or threat to use nuclear weapons violates IHL and would therefore constitute a war crime received a tremendous boost on July 8, 1996, with the delivery of an important decision by the International Court of Justice (ICJ), also known as the World Court. In an advisory opinion, *The Legality of the Threat or Use of Nuclear Weapons*, the ICJ ruled that the threat or use of nuclear weapons would generally be illegal under international law. This decision came in response to a request from the United Nations General Assembly (UNGA) for an advisory opinion on the legality of nuclear weapons. In a complicated and controversial ruling, the ICJ stated "…the threat or use of nuclear weapons would generally be contrary to the rules of international law applicable in armed conflict, and in particular, the principles and rules of humanitarian law" (International Court of Justice 1996, paragraph 105 (2) E).

It is important to stress that the ICJ advisory opinion did not create new law. Rather, the decision clarified that existing public international law, particularly the general principles and rules of international humanitarian law applicable in armed conflict (the laws of war), did apply to the use or threat to use nuclear weapons. The Court's ruling could be characterized as, to borrow a phrase from Justice Robert H. Jackson, US Chief of Counsel at the Nuremberg Tribunal, "declaratory of existent law." The opinion supports the ruling of the Japanese court in the *Shimoda* case that the United States did violate international law by dropping atomic bombs on Japan.

As the Nuremberg Tribunal made clear, the violation of the laws or customs of war are *war crimes*, and inhumane acts committed against civilian populations are *crimes against humanity*. Thus, the use or threat to use nuclear weapons is not only illegal but also *criminal*. As one legal scholar points out concerning the ICJ ruling: "Whenever the court discusses violations of the laws and customs of war; or violations of the Hague Conventions and Protocols; or violations of international humanitarian law, etc. with respect to the threat and use of nuclear weapons, the reader must understand that such violations are not just 'illegal' and 'unlawful' but are also 'war crimes' and thus 'criminal' under basic principles of international law that have been fully subscribed to by the United States government itself" (Boyle 2002, pp. 71–72).

Additionally, one of the most important aspects of the International Court of Justice's ruling on the illegality of nuclear weapons is the call, by all 14 judges, for the abolition of these weapons. The ICJ concluded its advisory opinion with an examination of the duty of states to negotiate in good faith a complete nuclear disarmament. The relevant treaty obligation the Court relied on is that found in Article VI of the 1968 Nuclear Non-Proliferation Treaty that states: "Each of the Parties to the Treaty undertakes to pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament, and on a treaty on general and complete disarmament under strict and effective international control."

At the time it was negotiated, the NPT was considered a "double bargain" (Blix 2008, p. 44). The nonnuclear weapon states agreed not to develop the weapons and accepted international inspection. On the other side, the five nuclear weapon states at the time committed themselves to negotiations that would lead to general and complete nuclear disarmament. That commitment was spelled out in Article VI, and on the basis of this provision, a unanimous World Court (International Court of Justice, paragraph 105 (2) F) found that: "…there exists an obligation to pursue in good faith and bring to a conclusion negotiations leading to nuclear disarmament in all its aspects under strict and effective international control." The ICJ interpreted the NPT provision as imposing a legal obligation to achieve a precise result-nuclear disarmament in all its aspects.

State Crimes Related to Nuclear Weapons

Using this legal framework, several criminologists have argued that a number of state actions related to nuclear weapons can and should be examined as forms of state crime. As noted above, these crimes include the actual use of atomic bombs against Japan in 1945, various threats by the USA to use nuclear weapons in conflict situations, and the continued possession of these weapons in violation of the NPT. In addition, they also assert that the continued possession of nuclear weapons leads to a variety of other criminal harms.

Kramer and Kauzlarich (2011) argue that the use of atomic bombs against Hiroshima and Nagasaki were the first crimes of the "American nuclear state." However, the political, military, moral, and legal interpretations of the atomic bombings are, to this day, bitterly contested. Many basic questions concerning the decision to drop the atomic bomb can be raised. The questions that criminologists have addressed, however, are the following: Was the use of atomic weapons against Japan illegal? Was the use of the bomb a war crime and a crime against humanity? What structural and cultural factors explain the decision to "drop the bomb?"

Some argue that it is difficult to address these criminological questions about the atomic bomb without first taking into account the more general phenomenon that developed during World War II, of the movement from sporadic, selective, and tactical attacks on military and industrial targets to the bombing of cities in an effort to terrorize and kill civilians (Kramer and Kauzlarich 2011). The aerial bombardment of civilian populations in urban areas, variously referred to as "area bombing," "strategic bombing," or "total war," has been examined by numerous scholars outside of criminology. Many of them concur with the assertion that "…deliberately mounting military attacks on civilian populations, in order to cause terror and indiscriminate death among them, is a *moral crime*" (Grayling 2006, p. 4). While the main question concerns the use of atomic weapons against Hiroshima and Nagasaki, those acts cannot be analyzed separately from the aerial bombing of civilians in cities that preceded them.

Returning to the question at hand: Was the use of atomic weapons against Hiroshima and Nagasaki unlawful and criminal? Kramer and

Kauzlarich (2011) assert that they were. They argue that the atomic bombings were objectively illegal, a war crime, because they violated the rules and principles of international humanitarian law that existed in 1945, the law that the *Shimoda* decision was based on, and the law that the ICJ would rely on in its momentous decision in 1996. These international legal rules for the conduct of warfare were codified and promulgated by the United States government itself in the War Department's Field Manual 27-10, entitled *Rules of Land Warfare*, which was issued on October 4, 1940 (and amended on November 15, 1944). As one legal scholar has demonstrated, the principles of international law specified in Field Manual 27-10 were binding on US officials throughout World War II and thus prohibited the use of atomic weapons against Japan (Boyle 2002). Thus, the *Shimoda* decision, the US government's own Army Field Manual, the ICJ ruling, and the considered opinion of many international law scholars make it clear that from an objective legal perspective at least, the atomic attacks on Japan did constitute a state crime. As one legal scholar notes: "…the unavoidable legal conclusion [is] that these attacks remain unacknowledged crimes against humanity of the greatest magnitude. The use of the atomic bomb in World War II was not merely a violation of the laws of war…but was also a criminal act of the greatest severity for which the perpetrators were given impunity" (Falk 2008a, p. 42).

But what explains this great criminal act? According to Kramer and Kauzlarich (2011), the primary goal of the United States and its allies during World War II, of course, was to win the war. The "precision bombing" of military and war-related industrial targets, with its attendant collateral damage, and then the "area bombing" of enemy civilian populations to destroy their morale were two of the means to that ultimate end. But by 1944, military victory was all but assured in both the European and Pacific theatres. At this point, secondary war goals emerged to the forefront: ending the war as quickly and decisively as possible and, by accomplishing those objectives, saving the lives of Allied military personnel. The majority of American leaders came to believe that the accomplishment of these national goals necessitated a change from a sole reliance on precision bombing to an increasing use of terror bombing of enemy civilian populations, including the utilization of newly developed atomic weapons.

Some historians argue that the atomic bombings did help to shorten the war somewhat, and thus they did save some American lives (Walker 2004). After the war however, Henry Stimson, former Secretary of War, President Truman, and others who had participated in the decision to drop the atomic bombs created an elaborate mythology that the bombings of Hiroshima and Nagasaki had been the *only way* to end the war short of a costly invasion of Japan and that the lives of up to a *million soldiers* had been saved by shortening the war and avoiding the invasion. The evidence shows neither of these assertions was true. For example, Walker (2004, p. 109) demonstrates that the bomb "…was not necessary to prevent an invasion of Japan" and that it "…saved the lives of a relatively small but far from inconsequential number of Americans." Even so, according to the principle of noncombatant immunity found in both the "just war" moral tradition and the international laws of war, it is never permissible to target innocent civilians or noncombatants to accomplish war aims or save the lives of military combatants.

The narrative created by Stimson and Truman, however, served to legitimate the atomic bombings, and by extension all forms of terror bombing during the war, in the eyes of the American people. The goals of shortening the war and saving the lives of American boys were presented as self-evidently "good" and "just." Even before this, of course, the entire conflict, in a nationalistic fervor, was defined as the "Good War." Defeating what was, to most Americans, the obvious "evil" of Hitler and the fascists, whose own state crimes during the war were massive; exacting "just retribution" for the "sneak" attack on Pearl Harbor and other Japanese atrocities during the war; and defending the American ideals of freedom and democracy at home against the criminal aggression of the Axis powers were such clear moral goals that any means necessary to accomplish them came to be viewed as acceptable and legitimate to most American leaders and the public. The social construction of the goodness and morality of the war in general, and the specific objectives of shortening the bloody conflict and saving the lives of "our boys in uniform," overwhelmed and short circuited any attempt to critically evaluate the morality and legality of the terror bombing of the civilian populations of the "evil" enemy as a means to those legitimate ends (Kramer and Kauzlarich 2011).

In addition, a number of historians have documented that the United States also shared with its adversaries certain other nationalistic and expansionist motives. The war "propelled the U.S. to a hegemonic position" that provided a unique opportunity for American leaders to pursue these imperial designs (Selden 2009, p. 91). Enhancing the economic power and geopolitical position of the American empire became central goals of US wartime policies, including the policy of terror bombing.

The United States has been an imperial project from its earliest years (Zinn 1980). The Second World War provided an opportunity for the USA to greatly expand its informal empire by confronting and defeating rival imperial powers and by creating new regional and global structures. A clash of imperial ambitions precipitated "The Day of Infamy" at Pearl Harbor. This clash necessitated the decisive defeat of Japan and the complete destruction of Japanese militarism and imperialism. According to some historians, the firebombing of Japanese cities and the use of the atomic bombs were viewed as important means to accomplish these goals and exact just retribution for wartime atrocities (Gerson 2007).

As the war progressed and it became clear that the United States would be able to exercise hegemonic power in the postwar era, American leaders began to plan for the construction of new global institutions that would greatly advance their imperial designs. As Zinn (1980, p. 414) notes: "Before the war was over, the administration was planning the outlines of the new international economic order, based on partnership between government and business." This new international economic order would enhance and expand the informal "Open Door" imperialism the United States had been practicing since the early years of the twentieth century.

Even as World War II was putting the United States into a position from which it could dominate the world, American political and military leaders recognized that the Soviet Union, their wartime ally, would be their chief rival in the postwar period. The contest for power and domination between the Soviet Union and the United States that would later be dubbed "The Cold War" was already underway before the "hot" war against fascism was over. American officials increasingly came to view Stalin and the Soviets as a threat to their postwar imperial designs both in Europe and East Asia. And the perception of this threat would be an important factor in the most momentous decision of the Second World War: the decision to drop the atomic bomb.

A number of historians have argued that the decision to use the atomic bomb was motivated more by political factors related to the perceived Soviet threat than by purely military factors. Alperovitz (1995) presents persuasive evidence that American leaders dropped atomic weapons on Hiroshima and Nagasaki in an effort to impress Stalin with the power of the bomb and to intimidate the Soviet Union in the coming postwar contest for domination. He argues that Japan was on the verge of surrender in the summer of 1945 and that Truman and his advisors were well aware that alternatives to using the bomb existed. Nevertheless, Alperovitz contends, for diplomatic considerations, US leaders decided to use this powerful new weapon on Japan. To gain political leverage over the Soviets in the postwar period, the United States carried out the terror bombing of two cities using atomic weapons.

Another political factor that played a role in the decision to drop the atomic bomb was the threat of Soviet expansionism in the Far East. Once the war in Europe was over, Stalin had pledged to enter the Pacific war by attacking Manchuria, driving the Japanese out of China, and perhaps becoming involved in a prospective invasion of the Japanese homelands. Alarmed by the prospect of Soviet territorial gains in East

Asia and a shared occupation of Japan, American leaders hoped to use the atomic bomb to end the war quickly before the Soviet Union could enter the fight and become a major player in the end game in the Pacific. Again, imperial rivalry rather than military necessity seemed to drive the decision to bomb civilian populations with a new weapon of mass destruction (Kramer and Kauzlarich 2011).

A second form of state crime related to nuclear weapons that the United States has repeatedly engaged in is the threat to use these weapons in a variety of conflict situations in order to gain geopolitical and/or military advantage. As Gerson (2007, pp. 1–2) has documented: "On at least 30 occasions since the atomic bombings of Hiroshima and Nagasaki, every US president has prepared and/or threatened to initiate nuclear war during international crises, confrontations, and war-primarily in the Third World." These threats, he argues, have been used to illegally expand, consolidate, and maintain the American empire.

On some occasions, the threats to use nuclear weapons were made in an attempt to coerce a Third World government into negotiating an end to a military conflict on terms more favorable to the USA than the current conventional warfare strategy could produce. President Eisenhower's threat to use a nuclear device during the "police action" in Korea in 1953 and President Nixon's "November ultimatum" to North Vietnam in 1969 during the Vietnam War are the two primary examples of this practice (Kauzlarich and Kramer 1998). Implicit nuclear threats, which some have called nuclear terrorism, have also been used since World War II in an attempt to impose a global American imperial order and to provide a "nuclear shield" or "umbrella of U.S. power" (Chomsky 1999) to cover the use of conventional forces and make them more meaningful instruments of military and political power. Numerous presidents have used the specter of nuclear weapons in an attempt to secure "vital interests" in the Middle East, particularly with regard to Iraq and Iran, and also in East Asia (Gerson 2007). Nuclear weapons in space and missile defense systems, viewed as offensive weapons, have also increasingly been brandished as part of the nuclear shield designed to advance US hegemony in a post-Cold War world (Chomsky 2003). Finally, the threat to use nuclear weapons to reciprocate for a first strike by the former Soviet Union (a guarantee of "mutual assured destruction") was the basis for "nuclear deterrence" policies during most of the years of the Cold War.

Some criminologists point out that all of these threats by the American nuclear state to use nuclear weapons, regardless of the circumstances, are unlawful (Kramer and Kauzlarich 2011). First of all, the ICJ explicitly ruled that in all but the most extreme circumstances, the threat to use nuclear weapons would be illegal. The legal reasoning here, as *The Lawyers' Committee on Nuclear Policy* (1990, p. 19) has pointed out, is that "If a given use of nuclear weapons is judged to be contrary to the humanitarian rules of armed conflict, then logically any threat of such use should be considered contrary to the humanitarian rules of armed conflict as well." In the view of several legal scholars, these threats, as violations of international law, constitute state crimes (Boyle 2002).

In *Crimes of the American Nuclear State*, Kauzlarich and Kramer (1998) extensively analyzed the threats to use nuclear weapons by the USA during the wars in Korea and Vietnam. In addition, Gerson (2007) and Chomsky (2003) have documented numerous other situations in which the US government has engaged in criminal acts of nuclear terrorism. In these studies, the important role of imperial motives for state crimes related to nuclear threats is stressed. And just as the bombing of civilians, with either conventional weapons or atomic bombs, became a form of normalized criminal behavior over the course of World War II (Kramer 2010), so too did the threat of using nuclear weapons become a normal and acceptable criminal act in the pursuit of empire during the Cold War and beyond.

The third form of state crime related to nuclear weapons that the United States (and all of the other nuclear states) is engaged in is the continued possession of these weapons. Since the end of World War II, the US government has maintained varying stockpiles of atomic and nuclear weapons. Today, despite the end of the Cold War and substantial negotiated reductions, there are still over 10,000 nuclear weapons in the American arsenal, out of the total of 27,000 such weapons existing among the worldwide nuclear club (Cirincione 2007).

Shortly after World War II, the United Nations General Assembly was determined to eliminate the production and possession of atomic weapons through arms control treaties. Given the Cold War and the technical problems of monitoring, inspection, and enforcement, this proved impossible to accomplish at the time. As the former UN weapons inspector Hans Blix (2008, p. 42) has admitted, “. . .we have not been able to achieve rules specifically banning the production, stockpiling and use of nuclear weapons.” Does the lack of a specific rule banning the possession of nuclear weapons mean that the stockpiling of these weapons is lawful?

Since both the use and the threat to use nuclear weapons are illegal under international law, and, as Falk argues, intrinsically criminal, would not the mere possession of weapons that cannot be legally used in any practical way also be illegal and criminal? One could certainly attempt to make that legal argument. However, there is another legal agreement that can be used to evaluate the lawfulness of the continued possession of nuclear weapons under international law. That agreement is the Nuclear Non-Proliferation Treaty (NPT) of 1968, the treaty that the ICJ used in its advisory opinion where it concluded that states have a duty to negotiate in good faith a complete nuclear disarmament.

Some criminologists have concluded that by failing to engage in good faith efforts to achieve complete disarmament and continuing to possess nuclear weapons, the USA and the other nuclear states are in violation of the NPT and engaged in a form of international lawlessness (Kramer and Kauzlarich 2011; Kramer and Bradshaw 2011). This lawlessness presents a host of nuclear problems and dangers that bear on the question of the criminality of continued possession. First, the fact that the USA maintains a stockpile of nuclear weapons provides American state officials with the opportunity to illegally threaten to use them or actually use them in a future conflict situation. Second, the manufacture and assembly of these weapons by corporations in the US Nuclear Weapons Production Complex led to the massive illegal radioactive contamination of both workers and the environment at numerous sites, a form of state-corporate crime (Kauzlarich and Kramer 1998). Third, keeping the world “awash in nuclear-weapons technology” raises “the terrifying specter of a terrorist group that acquires and uses a nuclear weapon” (Schell 2007, p. 6). Finally and perhaps most importantly, by failing to disarm and thus violating the NPT, the USA encourages the proliferation of nuclear weapons among other states, making the world a much more dangerous place (Kramer and Bradshaw 2011).

The continued possession of nuclear weapons in violation of the NPT, therefore, is not only a criminal omission and an abandonment of international law, but it also creates criminogenic environments both domestically and internationally that pose a variety of clear nuclear dangers. As Schell (2007, pp. 12–13) has pointed out, the nuclear dilemma is an “indivisible whole”; that means that “proliferation and possession cannot be considered in isolation from each other.” As the world drifts toward “nuclear anarchy,” he warns that “Not since the world’s second nuclear bomb was dropped on Nagasaki has history’s third use of a nuclear weapon seemed more likely” (p. 14).

Empire, Exceptionalism, and the Nuclear State

Kauzlarich and Kramer (1998) developed a theoretical narrative to explain state crimes related to nuclear weapons that draws on an integrated framework for the study of organizational crime. This theoretical schema, an effort at theory elaboration (Vaughn 2007), links three levels of analysis, macro, meso, and micro, with three catalysts for action: motivation (goals), opportunity (means), and formal social control (sanctions). The objective is to inventory and highlight the key factors that contribute to or restrain organizational deviance at each intersection of a catalyst for action and a level of analysis. The organization is viewed as the key unit of analysis, nested within an institutional and cultural environment, and engaged in social action through the decisions of individual actors who occupied key positions within the structure of the organization. According to this schema, organizational deviance is most likely to occur when pressures for organizational goal attainment intersect with attractive and available illegitimate organizational means in the absence or neutralization of effective formal social controls.

As noted above, Kramer and Kauzlarich (2011) drew on this framework to explain that the American addiction to nuclear weapons is generated by both structural and cultural factors. They show that as organizational goals shaped by the geopolitical and economic environment (US national security and imperialistic interests) were pursued with available illegitimate means (the threat to use nuclear weapons), certain ideological or cultural forces (American exceptionalism, interpretative denial) were drawn on or developed to support and "normalize" these pursuits and disable effective social controls.

As reviewed above, US state crimes related to nuclear weapons have generally been undertaken for reasons of empire. The United States is an empire and in the post-World War II era, its imperialism has been a strong determining structural factor in its propensity to commit a wide variety of state crimes (Kramer 2011). The "bomb" has always provided an "umbrella of U.S. power" (Chomsky 1999) that allows for the pursuit of imperial domination. As Ritter (2010, p. 377) observes: "There can be no meaningful reduction of the American nuclear arsenal so long as it is attached to a national security strategy based on global dominance."

These crimes of empire have almost always been covered by some form of "interpretive denial" (Cohen 2001) that justifies or rationalizes imperial actions that cause harm or could be labeled as criminal. US state crimes, particularly those related to nuclear weapons, have been interpretively denied by reference to a broad, historical, and cultural narrative referred to as "American exceptionalism" (Kramer and Michalowski 2011). American exceptionalism generally portrays the USA as a nation of exceptional virtue, a moral leader in the world with a unique historical mission to spread "universal" values such as freedom, democracy, equality, popular sovereignty, and increasingly global capitalism. This mythic cultural construction of exceptionalism "thoroughly informs US constructs of its identity" (Ryan 2007, p. 119). World War II, "The Good War," reinforced the mythic idealism at the heart of American exceptionalism. In the end, the fight against evil and the advancement of America's exceptional ideals justify any of the means, including violent means; it selected to accomplish national goals. In the wartime environment, conformity to these cultural mandates helped to make the bombing of civilians, even with the most horribly destructive weapon that humans had ever devised, a normal and acceptable act (Kramer and Kauzlarich 2011).

Thus, denial, rationalization, and the narrative of exceptionalism have led to the normalization of the imperial crimes of the nuclear state. And as long as these structural and cultural forces remain in place, it does not matter who occupies the White House. As long as the USA remains an empire and possesses an imperial mentality, it will continue to be addicted to the power symbolized by nuclear weapons and will continue to possess these deadly weapons in violation of the legal duty to disarm imposed by the NPT. Kramer and Bradshaw (2011) argue that there is no "hope" for "change" in US nuclear weapons policy unless nuclear abolitionists and peace movement organizations challenge empire, break through the denial and normalization related to these weapons, and empower the international community to achieve the strategic goal of a concrete and verifiable nuclear disarmament treaty. The work of the scholars reviewed here and a vigorous "public criminology of state crime" (Kramer 2010) can perhaps assist both the American people generally, and criminologists specifically, to think differently about the crimes of the nuclear state and help to enhance the nuclear disarmament movement.

Offender Change in Treatment

Caleb D. Lloyd and Ralph C. Serin
Department of Psychology, Carleton University,
Ottawa, ON, Canada

Synonyms

Motivation; Offender outcomes; Rehabilitation

Overview

This entry looks at evidence that offenders change while attending correctional treatment programs. Surprisingly few research studies can demonstrate *how* offenders successfully change within correctional treatment programs. The typical research design involves using questionnaires at the beginning of a program, then repeating the same questionnaires with the same offenders once they complete the program. Although there are hundreds of studies examining pre-post-treatment change in offenders, there are fewer than 25 studies that explicitly test whether intra-individual changes (i.e., changes within the same individual between pre- and post-program assessments on knowledge and attitudes) are related to recidivism outcome. Current research is limited when attempting to describe what makes programs effective, especially in terms of the specific constructs to be measured and what methods should be used (i.e., self-report questionnaires, behavioral ratings).

Context

This entry first reviews two areas of research that provide compelling reasons that change is possible in some offenders. Based on this evidence, it is important to attempt to understand change within an individual, and to determine what processes help individuals give up crime. Simply knowing that some offenders succeed after program completion is not enough; it is necessary to understand the factors and processes that contribute to their success.

Second, this entry describes the small body of studies that have examined what changes at the individual level when offenders are successful.

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

Specifically, these studies have examined individual offenders' changes on relevant constructs (e.g., antisocial cognitions, impulsivity, and anger) and the relationship between these changes and recidivism. These studies involve general offenders, substance misusing offenders, violent offenders, family violence offenders, and sexual offenders. When considering the many types of offenders in an area of limited research, it is challenging to make strong conclusions regarding which changes are most important within treatment programs. Still, across the studies reviewed below, changes in crime-supportive beliefs were consistently significantly related to reductions in recidivism, across a variety of types of offenders. In other words, offenders who changed their attitudes or perceptions about whether crime was a positive choice during program participation were most likely to stay crime-free after program completion. This finding suggests it is important to continue refining the knowledge regarding cognitive change that occurs during all types of correctional programming.

Finally, this entry offers some considerations about how to best move forward in developing an empirical basis for understanding offender change, including how to best conceptualize and measure the change process.

Key Issues for Offender Change in Treatment

Do offenders change? Can this change be measured as it occurs?

Paying Attention to Change has Crucial Practical Importance

There are many times in the correctional system that decisions must be made about individual offenders and indications of offender change are important for lessening of sanctions. For example, the timing of release may rest upon whether an offender made progress during incarceration, whether the offender appears ready to transition into the community, and whether the offender's release plan shows positive potential versus unfavorable complications. Daily decisions within the correctional system require staff to predict success for individuals, but current research tells us very little about individual-level change and how it may be related to improved offender outcomes.

Research on rehabilitation programs has focused on the fundamental questions, such as what programs or approaches to treatment are most effective, or which offender subgroups are most receptive to treatment. This research has typically focused on issues of program fidelity (Lowenkamp et al. 2006) and attending to risk and need principles (Smith et al. 2009). Programs with higher integrity and that target higher-risk offenders and criminogenic needs yield greater effect sizes.

Nonetheless, not all offenders benefit equally, even from "good" programs. Questions remain regarding how offenders change within programs, or how unique offender characteristics and unique program characteristics together impact outcome (e.g., see Burrowes and Needs 2009; Ward et al. 2004).

In other words, rehabilitation programs would be enhanced if greater attention was paid to the treatment journey rather than just the intended destination.

Which Offenders Change?

Two areas of research support further investigation into individual-level mechanisms of change. The first area is desistance research, which uses a variety of qualitative and quantitative methodologies and samples, but is unified in its examination of crime across the life course. Desistance research has typically examined repeat offenders who have committed acquisitive crimes. Second, evaluations of correctional treatment programs, which are more narrow and specific in scope compared to desistance studies, show that even short in-prison interventions can have lasting impact on post-release behavior. These bodies of research give reason to be confident that some offenders can change, under the right circumstances.

Crime Decreases as Offenders Age

First, criminal behavior is unstable across the life course. On average, offenders increase their criminal activity to a peak during late adolescence and early adulthood and then decrease their crime frequency (i.e., an upside-down U called the age-crime curve; Blumstein and Cohen 1987). Despite variation in age of onset and cessation, it is normative for criminal activity to drift downward throughout early adulthood. For example, in a birth cohort followed to the age of 32, self-reported antisocial behavior decreased across time, with 70 % of those involved in antisocial behavior exhibiting considerably low rates or desistance by the age of 26 (Odgers et al. 2008).

Offenders who do not desist from crime are a problematic minority responsible for a majority of crimes, with each individual committing crime at high rates. This group is known as the persisters (Moffitt et al. 2002). This means not all offenders follow the same trajectory of change. The high-rate offenders with low likelihood of desistance are characterized by early life deficits and difficulties that are not as prevalent in sporadic or short-term offenders (Moffitt et al. 2002). At the later stages of a criminal career, offenders who experience particular life events are more likely to desist from crime. These life changes typically occur concurrently with changes in the offenders' priorities, goals, commitments, and social circumstances. Some key life changes related to desistance include sustained marriage, long-term employment, and residential changes (Sampson and Laub 2005). It remains to be seen if these findings will be replicated with more contemporary samples.

Thus, research findings from a life course desistance perspective offer a macro-level understanding of the age-related changes that broadly influence the process of crime reduction within offenders. Some of this research additionally has assessed psychosocial constructs (e.g., self-control) multiple times through the life course (Kazemian et al. 2009). A less demanding and more typical approach has involved measuring life events as turning points (i.e., marital status, job attainment). When researchers have investigated the internal processes, they conclude that individual-specific features such as romantic relationship quality and engagement in employment are vital aspects of this process (Sampson and Laub 1990). A unique body of studies taking a qualitative approach provides rich descriptions or narratives of ex-offenders' perspectives on their processes of change (e.g., Maruna 2001). Together, the various approaches to life course desistance research support the conclusion that offenders entering adulthood who actively embrace major life changes begin to enact new patterns of behavior and adopt noncriminal identities.

Recidivism Rates Are Lower Among Groups of Treated Offenders

The conclusion that appropriate approaches to psychosocial treatment reduce crime is now supported by upward of 40 meta-analyses (McGuire 2004). Although treatment programs and evaluations vary in quality, research overall concludes that offenders exposed to rehabilitation programs have a lower likelihood of returning to crime, on average, compared to offenders in a no-treatment control group.

Three particular features determine whether treatment has a crime-reducing effect. Andrews and Bonta (2010) specified *who* has potential to change, *what* characteristics are required to change, and the type of environment *where* change can occur. These principles have been referred to as risk/need/responsivity model, which is a guiding principle in offender programming (Andrews and Bonta 2010). Specifically, treatment can have a positive impact on higher-risk offenders, and lower-risk offenders may actually do worse if exposed to treatment with higher-risk offenders, hence only higher-risk offenders should be targeted for rehabilitation. Targeting higher-risk offenders is the *who* aspect of effective treatment.

Second, treatment programs are effective only when they focus on changing personal characteristics (i.e., criminogenic needs) known to be associated with criminal behavior. The characteristics most related to criminal behavior include impulsive personality, negative emotion, pro-offending attitudes, association with criminal friends, poor family relationships, inconsistent employment, poor use of leisure time, and misuse of substances.

Targeting these crime-related characteristics is the *what* aspect of effective treatment.

Third, treatment programs where staff match the rehabilitation to the learning styles of the offenders (i.e., cognitive-behavioral approaches that consider offender readiness) are more effective than programs offered in an unstructured format where the learning goals are unspecified or poorly adapted to offenders. Offering well-structured, cognitive-behavioral programs is the *where* aspect of effective treatment.

Adherence to these core considerations results in the most effective treatment programs currently available (Smith et al. 2009). Beyond these arguably broad strokes, there are additional considerations that remain relatively unexamined, regarding how different offenders experience treatment and exhibit unique change processes. As a result, there is increasing interest in assessing readiness to change (Day et al. 2007) and more precise aspects of responsiveness to treatment (Ward et al. 2004) in order to augment program effectiveness.

An important limitation of this research is that it primarily examines groups (offenders in treatment vs. not in treatment) and group recidivism rates. It is still unclear from current research which particular offenders are engaging in treatment and receiving the most benefit from it. Although research indicates what characteristics should be targeted in programs, researchers rarely explicitly measure whether these characteristics have actually changed at the individual level, and confirmed these changes are related to recidivism outcome.

An Overview of Within-Individual Change

The research on crime desistance and correctional programming discussed above complement each other, each using a unique vantage point to demonstrate that offenders decrease their criminal activity. In addition, both research areas provide theoretical frameworks for understanding the broad context of *why* this change occurs (e.g., aging, new engagement in conventional living, and increased knowledge and skills development). With a few exceptions, neither area of research has employed consistent measurement of within-individual variables across time. Notably, more specific examination of the mechanisms underlying *how* change occurs has been lacking.

Serin, Lloyd, Helmus, Derkzen, and Luong (2013) recently reviewed the available academic and government corrections research to compile the constructs (e.g., changes in pro-criminal attitudes, impulsivity, hostility) that show the most promise as mechanisms of intra-individual change and markers of success. The study identified 378 studies measuring change, but only 49 tests of the relationship between change scores and recidivism outcome at the individual level. It is striking that so few studies have examined within-individual change. These reviewers found 12 cognitive programs, three substance misuse programs, and two violence reduction programs that explicitly tested the association between intrapersonal change and recidivism. Of the 49 available tests for these 17 programs, 26 effect sizes (53.1 %) were significant, ranging from small ($d = 0.06$) to large ($d = 1.48$). Across all domains, change variables significantly related to recidivism included known dynamic risk factors: antisocial attitudes, antisocial beliefs, antisocial associates, antisocial personality, social support, and substance misuse. Although these studies varied in terms of program dosage, fidelity, and follow-up times, which would influence effect sizes, it is nonetheless important to begin to examine if certain constructs, when measured pre- and post-programming, are related to post-program completion recidivism. Essentially this is the answer to which offenders change, if the change indices have demonstrated predictive validity. Other reviewers have similarly found few studies focusing on domestic violence and sex offenders.

General Offender Cognition

In these 12 programs noted above, offenders attended cognitive programs and self-reported (at least twice) regarding their beliefs about crime, whether others supported their efforts to stay crime-free, negative emotion, levels of stress, life problems, connection to criminal friends, and/or symptoms of psychological distress. Some of these measures were taken at the beginning and end of prison-based programs, whereas other programs took place after the offender was already released into the community. All of these studies are unique, however, because the researchers tested if within-person changes were related to recidivism, rather than only testing if the treatment group as a whole changed, on average. This is a more fine-tuned approach because one individual may change, whereas another individual may not change even though both attend the same program. For a full listing of the programs and measures, refer to Serin, Lloyd, Helmus, Derkzen, and Luong (2013).

Overall, within these studies, individual offenders who exhibited changes in their thinking about crime were also less likely to recidivate after release. Specifically, some of the largest effect sizes were observed for measures that assessed acceptance of responsibility for crime, rejection of criminal behavior as a suitable course of action, and disregard for the law. Individual offenders who adopted more prosocial, anticriminal ways of thinking during rehabilitation were more likely to stay crime-free.

Another set of findings highlight the importance of connection to others. In particular, offenders who reported a reduced feeling of connection to criminal friends were less likely to reoffend after release. Offenders who reported increased access to individuals who supported their decision to stay crime-free were also more likely to succeed. By contrast, offenders reporting increasing problems in their family environment were more likely to recidivate.

Finally, in one study (Brown et al. 2009), two large effects were observed for changes related to the reentry environment. Specifically, recidivism was related to increases in negative emotion (negative feeling about the world) and escalating problems with reintegration back into the community. Offenders who had increasing difficulty integrating back home after release and feeling increasingly negative emotions during their reentry process were more likely to re-offend. The opposite is also true, however, where offenders who were able to clear up practical problems post-release and feel less negative moods were more likely to succeed.

Together, these cumulative results demonstrate that those offenders who experience improving life circumstances involving connection to prosocial others are effectively on a path toward staying crime-free. Similarly, those who report perceiving less value in crime as a life choice also were more likely to desist. Notably, not all studies found similar effects of change when employing the same measures, reinforcing the view that program fidelity and other factors were not controlled. This suggests certain attitudes *sometimes* appear to drive the change process. Currently, there are too few studies to more fully understand the factors that might influence this differential effect. Since many cognitive factors are interrelated (i.e., bonds to prosocial others are likely to spark reductions in criminal attitudes Andrews and Bonta 2010), another possibility worth exploring is whether there are many paths to the same outcome. In other words, it may not be that one particular type of attitude must change for success, just that prosocial attitudes *of some sort* must develop within the offender.

Substance Misuse

Few (only three) studies explicitly examined change in variables among offenders with substance misuse problems. Each of these studies examined different change factors, and each found change was directly related to reduction in recidivism. Among these, the largest effect size demonstrated that offenders who reduced their substance use during the time period shortly after release were more likely to stay crime-free in the community (Brown et al. 2009). Small effect sizes were found in the remaining two studies, demonstrating that reductions in psychiatric symptomology (e.g., anxiety, hostility, paranoia; Sullivan et al. 2008) and increases in perceived consequences of drug use were related to reductions in recidivism (Millson et al. 1995).

Further, the first study suggests individuals who become sober are less likely to commit further crime. In the latter two studies, it is difficult to draw conclusions regarding the importance of alleviation of distress symptoms and changes in drug beliefs because individuals' substance use behaviors as they participated in treatment were not explicitly measured. It would have been a stronger approach to simultaneously measure changes in substance use, rather than only measuring change in psychological variables. Still, these studies reach a similar conclusion to the studies examining cognitive programs, namely, that reductions in negative emotion (hostility) and beliefs about crime (consequences of drug use) are mechanisms that can drive reductions in criminal activity.

Violence

Two findings emerged from two studies of change among nonsexual violent offenders (e.g., assault, armed robbery, murder). These studies found medium-to-large effect sizes for reductions in negative emotion (anger, specifically; Polaschek and Dixon 2001) and self-reported increases in personal insight about life problems (e.g., offense chain; Dowden et al. 1999). Reductions in anger were associated with a lower likelihood of nonviolent recidivism. Variables reflecting that offenders learned something about their risk factors during treatment were associated with lower likelihood of violent recidivism. However, given the limited amount of evidence available, these findings need replication.

In one attempt to replicate these findings, a recent study demonstrated that violent offenders who became actively invested in changing their problem behavior during a brief motivational intervention were less likely to commit a further offence (violent or nonviolent reconvictions; Anstiss et al. 2011). This supports the finding regarding knowledge of their offense chain, and suggests violent offenders who demonstrate more motivation to actively participate in rehabilitation are more likely to change.

From these three studies, it appears reducing anger among violent offenders can reduce recidivism, but a key mechanism of change also appears to involve increasing motivation to tackle life problems in a prosocial way. Thus, offenders who seem to connect with treatment and "get it" in terms of increased personal insight and drive to change their old patterns are less likely to reoffend. In particular, Anstiss and colleagues (2011) demonstrated that reductions in recidivism occurred as a result of a treatment focused on enhancing motivation (i.e., increasing readiness to change). In other words, simply addressing motivation without attention to other skills or variables appeared to be enough to influence violent offenders toward successful change, although again this requires replication.

Family Violence

In a review of treatment approaches, typologies, and change mechanisms in the area of family violence, Scott (2004) similarly concluded research is lacking about change processes. However, her review suggested that three variables show some evidence as potential change mechanisms and deserve further consideration: anger, psychiatric symptomology, and substance use.

Changes in psychological distress and anger were recently investigated among men court-ordered to attend treatment for violence against their partners (Alexander and Morris 2008). Results showed that some men decreased their depression and anxiety during treatment, as well as increased control over their anger, but only if they reported being ready to make behavior changes at the beginning of treatment. Only a small number of romantic partners were contacted for follow-up (15 out of 210), but among this select group, men who changed during treatment (i.e., in terms of anger, depression) were less likely to inflict injury on their partner during the 6 months following treatment, compared to men who did not change. However, outcomes were only examined in terms of pretreatment scores, ignoring post-treatment and change scores. This is unfortunate given that other studies of high quality methodology are not available in the family violence treatment domain.

Research regarding change among perpetrators of family violence is particularly limited, but it is noteworthy that the limited findings are similar to those within other offender domains. Further research should attempt to replicate these results suggesting changes in negative emotion (anger) and psychological distress are important for reductions in family violence.

Sexual Offenders

Beggs (2010) recently reviewed treatment change among sexual offenders and found that recidivism was related to within-individual changes in assertiveness, empathy, anger, beliefs specifically related to offending against children (including sexual interest in children, loneliness), and general risk factors (including criminality, substance use, and treatment responsivity). In addition, Beggs and Grace (2011) demonstrated that reductions in sexual deviance, anger, and various cognitive and psychiatric symptom variables (including loneliness, intimacy, depression, and anxiety) were related to a lower likelihood of sexual recidivism. Notably, these treatment changes predicted reduced recidivism while accounting for static risk scores. By contrast, in a large sample of sexual offenders attending community treatment (Barnett et al. 2013), change was not explicitly associated with sexual and violent recidivism, but those offenders who remained in a low functioning range at the end of treatment on particular variables (including self-esteem, loneliness, assertiveness) were more likely to recidivate.

In a large sample of sexual offenders attending prison-based treatment (Wakeling et al. 2013), post-treatment scores appeared to be more important than change scores in predicting recidivism. Those who were displaying functional (i.e., higher) scores at the end of treatment reoffended the least. It is important to note, however, that some individuals displaying functional scores following treatment may not represent offenders who changed; some offenders were in the functional range at the beginning of treatment. When change scores were explicitly examined, changes in sexual interest and impulsivity were associated with lower likelihood of sexual and violent recidivism. However, this effect was not significant after accounting for static risk scores.

Summary

It is striking that across all types of offender programming reviewed, similar variables appeared to be important mechanisms of change across the different subtypes of offenders. In particular, positive in-program changes in negative emotion (e.g., anger or hostility) and offence-related cognitions (e.g., various pro-criminal beliefs) were most consistently related to post-program reductions in recidivism. Given the limited breadth of current investigations, it is difficult to discern if these variables are definitively the key drivers of the crime reduction process. At the same time, inconsistencies were observed across studies, as change in the same measure sometimes successfully, sometimes unsuccessfully predicted recidivism at the individual level.

Nonetheless, the variables identified in this entry deserve greater attention. These include changes in negative emotion (hostility, anger, depression, and anxiety), beliefs about crime (interest in and positive evaluations of criminal activities), symptoms of distress, substance use, social support, and engagement in treatment. At this time, there is little consensus about the best questionnaires for assessing each of these variables, but research is likely to benefit from subtype-specific measurement. For example, the core beliefs that support violence are different from the beliefs that support illegal drug use or sexual offending.

Conceptual and Methodological Issues About Measuring Individual Change

Of course, paying attention to process does not come without financial and operational costs, because this involves incorporating a more holistic conceptualization of change, and more sophisticated research methodologies. Some of these considerations are highlighted below. First, from a conceptual viewpoint, a complete understanding of change requires looking more inclusively beyond the treatment environment itself. For example, it is important to consider not only whether change has occurred, but also to what degree this change occurs (i.e., mild improvement or complete "remission"?). It is also important to understand whether change is occurring in one progressive, linear stretch, or with piecemeal transitions, bursts, and starts. Second, each of these three conceptual concerns has implications for methodology. Researchers should measure offenders more than twice, measure events that occur before and after the treatment program, and explicitly test whether change is real or simply due to measurement error. Each of these conceptual and methodological considerations are described below.

Complementary Approaches to the Same Broad Process

Correctional treatment provides the most concrete framework from which to investigate intra-individual change. Yet, treatment exposure is arguably only one part of an individual's journey of change. By merging macro-(desistance) and micro-level (treatment programs) investigations of change process, it is likely that reduced risk for recidivism involves both lifestyle changes *and* specific learning moments within rehabilitation programs. These processes are complementary and each contributes a piece to a complete change process. To date, these literatures exist in isolation, with limited effort to recognize that *both* can contribute to offender change.

Thus, depending on the study, it may be difficult to find treatment effects when other processes are at play, especially given that aging offenders experience additional forces outside of treatment that decrease their likelihood of future crime. Measuring changes in crime is particularly difficult because crime is a relatively rare event in an individual's pattern of behavior and is not subject to small, incremental changes across time (unlike a behavior such as reduction in smoking cigarettes). These challenges suggest it would be productive to integrate research of broad life changes with research on treatment effects. A more holistic understanding of treatment change would attempt to link an offender's pre-post changes to his or her past and current life circumstances.

From a desistance perspective, treatment should be considered just one component of a more extensive change process that is simultaneously occurring in the offender's life (see also DiClemente 2007). Being too treatment-centric limits researchers from discovering what life circumstances outside of the treatment program may have assisted clients to change (DiClemente 2007).

Recognizing change processes occurring outside of treatment does not discount the value of rehabilitation programs. Scores of research have confirmed that correctional programming can be an important turning point in certain offenders' life courses. In addition, some of the changes reviewed throughout this entry were the result of very brief, cost-effective programs, suggesting the need to investigate change both within and without the treatment environment.

To think about change processes in a holistic, interactive way requires extending current measurement strategies beyond only pre-post-treatment measurement. Additional thought needs to be put into integrating what is known about change outside of rehabilitation into questionnaires given during treatment studies. This will require expanding the range of variables examined and the range of life experiences assessed (i.e., how did a treatment episode impact future desistance during follow-up, and how did extra-treatment experiences affect the impact of the program for that individual?).

Reliable Change and Clinical Significance

To assess reliable change and clinical significance, researchers need measurement that is both precise (good psychometric properties) and meaningful (such that scores above the threshold are associated with reduced recidivism). Conceptually, this requires building knowledge about how to best define success at the end of a program, and methodologically, this requires researching quantitative cut-off scores. (See also Nunes et al. 2011, for an application of clinical significance to a study of sexual offenders).

It is difficult to know whether pre-post-treatment change is "real" or simply the result of measurement error. Jacobson and Truax (1991) argued that research should both determine which clients have changed *and* whether the change is sizable enough to have real-world impact on the individual's life. In the context of this entry, that means predicting desistance from crime. Jacobson and Truax's (1991) reliable change index is a formula for calculating whether change during therapy is greater than what would be expected due to measurement error. In other words, if offenders typically score within a plus-or-minus five-point range on a scale across short time periods, an offender who improved by four points across treatment would not be predicted to desist, as change was not reliable. Thus, the reliable change index takes this measurement error into account, identifying only those whose scores represent "true" change.

Similarly, they recommend establishing a meaningful threshold score, or a cut-off that represents improvements strong enough to impact the individual's outcome. Some individuals may change in treatment, but is this change enough to reduce their chances of recidivism? If so, the change is meaningful, and can be considered clinically significant change.

Identifying the Precise Timing of Change

Although pre-post-treatment measurement is the most typical approach in correctional psychology, in other fields of psychological therapy, researchers measure participants at every treatment session. This allows researchers to pinpoint exactly when change occurred. Such an approach requires additional cost, time, and effort. If researchers seek to describe change by employing only two assessment periods (pre-post-treatment design), they are at a disadvantage because they can only describe linear change (i.e., do offenders improve or deteriorate; Singer and Willett 2003). At least three assessment periods, but preferably more, are required to investigate non-gradual, curving processes of change (patterns of improvement and decline within the same individual). Such nonlinear change is described in desisters' narratives (Maruna 2001) and is consistent with Stages of Change research (Prochaska et al. 1992). Adding more measurement periods allows researchers to describe the timing, patterns, maintenance, and potential causes of change.

For example, among male adolescents in a secure psychiatric treatment facility, change in traits over a 6-month period showed different patterns of development (Caldwell et al. 2012). Some traits showed little initial improvement during the first 3 months, but then substantial improvement over the latter 3 months, whereas other traits changed more steadily. The timing of change was only uncovered by including a mid-treatment assessment.

A small group of high-risk burglary offenders increased their readiness to change from the beginning to end of a brief five-session motivational interviewing treatment (Austin et al. 2011). For a smaller group of participants ($n = 12$), self-report ratings were taken a third time (3–12 months later), and results indicated that change had been maintained following the brief treatment. Without the third assessment, the timing and sustainability of change would remain unknown.

Finally, Barrett and colleagues (2003) were able to describe complex patterns of change by employing four time periods, revealing that some variables evidenced curvilinear change. Variables representing different facets of motivation and treatment engagement were coded from files for 101 male sexual offenders who underwent two treatment programs, one in the institution, one in the community. For two variables, improvements were gained early and maintained into the community, whereas for three variables, gains made in the institution were lost after release into the community (an upside-down U-shaped distribution). Evidence also suggested that only change maintained into the community was related to reduced recidivism. This research also points to the possibility that the institutional program, but not the community program, was responsible for initially sparking the change.

Additional Considerations and Final Thoughts

In conclusion, although there are financial costs and operational challenges associated with investigating change in treatment outcome studies, spending these funds is also a strategic way to ensure that knowledge will be gained even from programs that are ultimately considered a nonsuccess. Limiting understanding only to whether programs "work" or not leads to blanket conclusions about discarding or keeping programs, but attending to process uncovers *why* programs positively or negatively influenced offenders. The research on correctional program fidelity, organizational readiness, and implementation (Lowenkamp et al. 2006) must also be incorporated into such an understanding, but with effect sizes less than 0.30 for even the best correctional programs, not all offenders benefit. Hence, knowing why a program did not work and *how* it failed to influence some offenders is a valuable way to recoup some costs associated with an unsuccessful program.

Despite the singular emphasis on investigating change processes in this entry, it is important to note that fundamental considerations when researching treatment programs are still critically important, no matter how sophisticated the measurement of change within the study. Treatment change should not be studied without simultaneous attention to follow-up outcomes and control groups. A program cannot be labeled as successful without investigating if recidivism is actually reduced, and it cannot be concluded that the program was responsible for offenders' success without a control group. Also, program dropout has implications for understanding the process of treatment. In particular, when multiple assessment periods are examined across the tenure of treatment, those who drop out early will be necessarily excluded from analyses. A measurement strategy that attempts to account for and explain dropout is part of understanding treatment processes.

Although attending to change within treatment is a challenging venture, it is a fruitful one. The causes, driving mechanisms, and conditions required for sustainable change are likely to be difficult to pin down, but a better understanding of these complex treatment dynamics will lead to enhanced correctional practice. Ultimately, advancing knowledge about process will allow building an appropriately complex model of offender change.

Offender Decision Making and Behavioral Economics

Greg Pogarsky
School of Criminal Justice, University at Albany,
State University of New York, Albany, NY, USA

Overview

This entry discusses potential applications of Behavioral Economic principles in Criminology. First it highlights aspects of the deterrence and economic approaches to offender decision making. Next, it introduces concepts and seminal findings from Behavioral Economics research outside of Criminology. Finally, potential areas of interesection between Behavioral Economics and Crime decision making are addressed.

Fundamentals

In Criminology, offender decision-making typically comes within the sub-field of deterrence. This approach shares much with economic models of decision-making and behavior (Nagin, forthcoming). First and foremost, under both perspectives, crime is sometimes a voluntary choice (Becker 1968; Bushway and Reuter 2008; McCarthy 2002). Offenders are not fully impelled toward crime by external circumstances, such as poor upbringing, financial disadvantage, or psychological infirmity, though such factors can contribute (sometimes greatly) to the likelihood of offending. Incentives relating to the potential consequences from crime impact offending decisions. Someone might refrain from crime to avoid an official sanction, such as incarceration or probation. Or, he or she might commit a crime believing the likelihood of detection is acceptably low. Each of these possibilities also pertains to various potential non-legal punishments, such as social stigma or compromised employment prospects (Grasmick and Bursik 1990; Pogarsky 2002).

Both the deterrence and economic perspectives recognize the paramountcy of perceptions. Risks and/or benefits only influence offending decisions insofar as they are perceived by potential criminal actors (Andeneas 1974; Apel and Nagin 2010). Such perceptions should reflect reality (though perhaps imperfectly) in at least two ways. First, an individual's past experiences committing crime and either experiencing or avoiding punishment should influence their sanction risk perceptions in what economic theory terms a Bayesian updating process (Anwar and Loughran 2011). As a corollary, when an individual becomes aware that someone else has committed a crime and either experienced or avoided punishment, this too should affect that individual's perceptions of the potential consequences from crime (Stafford and Warr 1993). Second, the sanctioning climate for an individual, reflected for example by law enforcement presence or arrest rates, also influences sanction risk perceptions (but compare Apel, Pogarsky, and Bates, 2009; Kleck et al. 2005; Lochner 2007). Finally, under both perspectives an individual's perceptions of the potential consequences to them from crime influence the likelihood that individual will offend (Matsueda et al. 2006).

Economic models have influenced scholarship on a range of human activities, including health, finance, public policy, and even reproduction and marriage (Becker et al. 1977). And there is little doubt about the historic and continuing influence of economic perspectives on criminological thought. Beginning in the 1970s, however, scholars have documented either systematic departures from economic predictions, or behavioral regularities that could not be accounted for by economic principles. These findings, which are not routinely applied in criminology, evolved into contemporary Behavioral Economics, the topic of this entry (e.g. Kahneman and Tversky 1979).

Some early Behavioral Economic findings involve, for example, the role of risk in decision-making. Consider the "lives saved-lives lost problem" of Tversky and Kahneman (1981: 453):

Imagine that the USA is preparing for the outbreak of an unusual Asian disease, which is expected to kill 600 people. Two alternative programs to combat the disease have been proposed. Assume that the exact scientific estimates of the consequences of the programs are as follows:

- If Program A is adopted, 200 people will be saved.
- If Program B is adopted, there is a 1/3 probability that 600 people will be saved, and 2/3 probability that no people will be saved.

On average, each program is expected to save the same number of people: 1/3*600 + 2/3*0 = 200. But option B is considerably riskier, since one-third of the time, no one will be saved. In fact 72 % of individuals tend to choose option A, the less risky option that will save 200 people for sure. Next consider these reworded options:

- If Program C is adopted, 400 people will die.
- If Program D is adopted, there is one-third probability that nobody will die, and two-third probability that 600 people will die.

Notice that options C and D are functionally identical to options A and B. However, C and D are reframed in terms of how many will die (a loss) rather than how many will live (a gain). The second set of options produces a "preference reversal." That is, 78 % tend to prefer option D, the riskier option, over option C. Thus, individuals are far more comfortable taking a risk to avoid a loss than they are taking the nominally equivalent risk for gains. This finding is a profound challenge to economic theory, under which preference for risk should be invariant to the framing of choices.

Another seminal Behavioral Economic finding involves the "Endowment Effect," which was illustrated by Kahneman et al. (1990). Half of a group of students were randomly given a coffee mug from the school bookstore. Individuals with a mug were asked to report their minimum selling price, whereas the remaining participants (who could see and touch the mugs) were asked to report their maximum buying price. The mean buying price was $2.25 while the mean selling price was $4.75. In economic terms, the researchers elicited functionally equivalent information from both groups: the dollar value of a mug. Yet those who received a mug only moments earlier valued it twice as much as those who did not. As before, under economic theory, the value of the mug should not depend on the manner of valuation. But it does.

Finally consider Ellsburg's (1961) "two color" problem which explored ambiguity and choice. Respondents select one of two urns from which they will draw one ball. If the ball is red, they win a cash prize. Urn 1 contains 50 red balls and 50 black balls. Urn 2 also contains 100 red or black balls, but in unknown proportions. Although the probability of selecting a red ball and winning is identical across urns (in urn 2, the number of red balls is uniformly distributed from 0 to 100, hence, $E[x] = 50$), individuals routinely prefer Urn 1. This finding has been termed "ambiguity aversion," which cannot be accounted for under the straightforward application of economic principles.

These and other findings evolved into a body of scholarship known as judgment and decision-making research or Behavioral Economics. Among the core themes of such research is that individuals often deviate from the norms of rational choice economics *in predictable ways*. Thaler (1996: 12) has described Behavioral Economics as "economics with a higher R^2." For his pioneering scholarship on Behavioral Economics, Daniel Kahneman, a psychologist, received the 2002 Nobel Prize in Economic Science.

Just as Behavioral Economics has provided insights into other forms of human decision-making, it has great potential to elaborate crime decision-making. For example, Pogarsky and Piquero (2003) found some evidence for a "resetting effect" to explain why, contrary to deterrence and economic theory, individuals might *reduce* their estimate of the future certainty of punishment after getting caught and punished. This explanation clearly foregoes the "rational actor" assumption of deterrence and economic theory and instead relies on the Behavioral Economic principle of a gambler's fallacy in the interpretation of chance events (Gilovich 1983). Card players sometimes increase their bets after losing several consecutive hands because they feel they are due to win. Lottery participants decrease the amount wagered on a particular combination of numbers after that sequence has "hit" (Clotfelter and Cook 1993). The gambler's fallacy stems from a desire for and resultant belief in consistency. Laboring under this expectation, individuals impute an interdependence among chance events where none exists. Most offenders believe getting caught is a somewhat rare occurrence. Thus when they do get caught, under the resetting explanation, they may reduce their future estimated certainty of punishment believing they would have to be exceedingly unlucky to be caught again. If this occurs in some individuals, it is a profound challenge to both the deterrence and economic perspectives on offending decisions under which individuals should elevate their perception of the risk of punishment after getting caught.

Earlier, this entry addressed Behavioral Economic research relating to ambiguity and choice. Loughran et al. (2011) examined the interrelationship between ambiguity, sanction risks, and offending in a survey to college students with several hypothetical choice problems and data from the Pathways to Desistance study, a longitudinal investigation of serious adolescent offenders transitioning from adolescence to young adulthood. There was some evidence that individuals are "ambiguity-averse" for decisions involving losses such as criminal punishments. This means that a more ambiguous perceived certainty of punishment is a greater deterrent of some crimes than a nominally equivalent but less ambiguous one.

This finding suggests a modification of traditional deterrence and economic theory which, by omission, has presumed the irrelevance of ambiguity in perceived risk. Applying behavioral economic insights, then, generates potential policy implications not discernible from the straightforward application of deterrence and economic principles to the crime decision. In general the risk of detection for less serious crimes, such as breaking-in, stealing, theft and vandalism is quite low (e.g., Lochner 2007). Sherman (1990: 7) argued that law enforcement policies ought to exploit ambiguity aversion for these types of crimes by offering offenders "low certainty about whether the risk of punishment is high or low at any given time and place". That is, police could rotate their enforcement across both offenses and places so that the risk of punishment is far more unpredictable than it has been in the past. With the same amount of resources, an alteration of police policy by manipulating the ambiguity of the certainty of arrest – would enable them to enhance the deterrent effect they have. Thus it might be worthwhile for law enforcement to exploit any vagueness in perceptions of the risk of punishment.

This entry was intended to expose criminologists to the historical relationship between Deterrence, Economics, and Behavioral Economics. Already the few applications of Behavioral Economic principles to offender decision making have furthered our understanding of crime. These applications have helped identify policy issues not raised by the traditional approach to studying crime decisions, which is largely based on deterrence and economic principles. Further application of Behavioral Economic principles in studying crime decisions, thus, appears likely to bear even more fruit.

Offense Specialization: Key Theories and Methods

Christopher J. Schreck
Department of Criminal Justice, Rochester Institute of Technology, Rochester, NY, USA

Overview

The topic of offense specialization is one that is distinct from that of offending generally. For offending, the questions often concern how much crime that people commit and why some people do it and others do not. For specialization, the question is instead, among those who do commit crime, are there any who show a preference for a particular type of crime and, if so, then why. The question is of particular interest to policymakers, who want to be able to target their resources toward controlling, for example, the serious violent offender. Academic criminologists are interested in specialization as well, because whether it exists or not speaks to the validity of many theories of crime. The debate about the existence and value of even studying specialization has sometimes been lively.

Research on offense specialization goes back many decades and the empirical support for its patterns, and even its very existence, was long inconclusive. The development of new statistical approaches, as well as new conceptions of what specialization means, has revitalized research in this area. This more recent work has established that a small minority of offenders do specialize and even that this tendency is relatively stable over a period of time and, to some degree, predictable. Research examining how well criminological theories account for specialization, however, is in its infancy. At this point, no research has conclusively been able to locate support for any particular theory positing reasons why some offenders prefer one type of crime and other offenders another.

Introduction

In public discourse, individual offenders have commonly been described as "drug users," "sex offenders," "murderers," or "arsonists," depending on what they were arrested for, with the idea that the label characterizes the sort of crimes that they prefer and tend to commit over and over again. This, essentially, is what specialization is all about; specialists focus on a limited and specific range of offense types and thus such descriptors are appropriate. At the other end of the continuum is the idea that offenders commit a wide variety of offenses with no obvious inclination toward any one type. That is, they may take drugs but violence and property crime comprise a share of the offenses as well. Such offenders who are not specialists are described as "generalist" or "versatile." To the degree that offenders do not specialize, then attempts to classify them by the crimes they commit are pointless and targeted programs doomed to failure. The question of whether specialization even exists or not, and what causes it, is thus very important in terms of crime policy and within academic criminology.

Policymakers are particularly interested in controlling the most serious types of crime, such as violence, and so much interest in the topic of specialization reflects this. The public tends to fear violent crime, and violence produces great cost for individuals and society beyond the loss of property (if any) – injury, lost wages, death, expenses associated with attempts to improve physical security, and so on. The topic of specialization research has a long history in academic criminology as well, primarily because of its interest to policymakers as well as its relevance to many criminological theories. Theoretical concerns, however, have not generally motivated much of the research on specialization over the years; rather, scholars have invested their energies in developing innovative statistical procedures in order to address difficult methodological problems. The earliest work on specialization employed transition matrices to examine specialization and defined specialists as those who had an appropriate sequence of arrests (e.g., arrest for robbery followed by an arrest for the same crime). This type of approach, although it would dominate studies of specialization over the next two decades, only reported weak evidence of specialization and could not allow for in-depth theory testing.

Specialization has since come to include the diversity of crimes an offender commits over a period of time. Offenders who have a wide mixture of criminal activity would indicate versatility, where those who show more focus in their participation in illegal activity would indicate a specialist. Research using this conception of specialization has tended to show more consistent support for specialization. Statistical methods that define specialization in terms of the diversity of the offense repertoire have also allowed researchers to attempt to locate predictors for specialization. This research, however, is in its infancy; however, it does consistently show that groups of people do specialize in such crimes as violence.

In the following sections, a review of the major frameworks for understanding specialization will be provided as well as an examination of how researchers have attempted to not only establish the existence of specialization but also to empirically evaluate these competing theories.

Perspectives on Specialization

Notwithstanding the generally inconsistent evidence on specialization, many theories take a clear position about whether specialization exists or how it might occur. Beginning over a century ago, criminologists such as Cesare Lombroso had attempted to create typologies of offenders, classifying them based upon the sort of crimes that they tended to commit. These early schemes have largely been abandoned in favor of general theories, which are designed to encompass the processes common to all crimes.

Nevertheless, a number of perspectives have gained popularity in recent years arguing that offenders do specialize. In contrast to general theories, these approaches describe the unique process that ultimately produces a specialist offender.

The criminal career perspective. The criminal career perspective was the driving force for research on specialization between the 1980s and 1990s. This approach was not a theory, insofar as it offered no explanation for *why* individuals committed crime or specialized in some crimes over others, but rather was intended to supply a framework or language for describing the long-term development of criminal patterns. Research on specialization across the criminal career was primarily interested in the sequence of offense types committed by those who participated in crime. Those persons who switched from one type of crime to another were "versatile," whereas those who committed a series of the same offenses were defined as specialists.

The cultural deviance perspective. A more detailed account that predicts not only specialization but also explains why some offenders prefer some crime types over others can be found in the cultural deviance group of theories. The basic orientation that these theories all share is the idea that crime is something that is acquired through contact with other individuals or the prevailing culture. If an individual is embedded within a culture that values white-collar crime (and not other types of crime), for example, then those types of crime will dominate his or her offense repertoire. Specialization is not required; however, the correct combination of cultural influences can result in offenders who specialize.

A leading contemporary example of how cultural deviance theories address specialization comes from research on subcultures of violence, most notably the work of Elijah Anderson and his account of the code of the street. The code of the street is a normative system that views violence and violent retaliation as the chief means that poor African American males living in disadvantaged areas can build and assert their reputations and protect themselves. To the degree that these young males accept beliefs that acts of disrespect require a violent response, then a greater share of their crimes should be violent in nature. Similar normative systems are evident in other areas of the United States, including, for example, the Southern subculture of violence in rural Appalachia.

The control perspective. The control perspective begins with the assumption that people will naturally pursue pleasure and avoid pain; in this respect, one can understand all offenses in the same light insofar as they all bring advantage at (so far as the offender is concerned) little cost. Or, put another way, control theories typically see no distinction in the reasons offenders engage in any particular type of crime, since they all produce advantage for the offender. Gottfredson and Hirschi's self-control theory, among the most well known of control theories, explicitly rejects specialization. Self-control refers to the acquired tendency of individuals to weigh the long-term consequences of their decisions. To assume that there is specialization is to make a case that there are different causal processes that lead to the different categories of offenders. But Gottfredson and Hirschi examined the nature of crime and argued that they all share the same basic qualities. Engaging in them produces quick, easy, and certain short-term advantage and long-term negative consequences: drinking, drug use, white-collar crime, robbery, and theft. To that degree, low self-control can account for the commission of any of them and specialized theories were not necessary.

Strain theories. Strain, or anomie, theories begin with the assumption that people would like to avoid offending but are compelled by the failure to meet certain cultural expectations (e.g., the American Dream) into crime. Robert Merton's classic version of strain theory, developed in the 1930s, asserted that people adapt to strain in one of five ways: conformity, innovation, ritualism, retreatism, or rebellion. The retreatist, for example, based on their circumstances, would more likely engage in substance use. The innovator, in contrast, is an ambitious person who would break the law in order to achieve material wealth. Richard Cloward and Lloyd Ohlin's extension of Merton's theory retained the specialization argument in slightly different form, arguing that in some areas a "criminal subculture" (which would emphasize economically motivated crime) would emerge. Where opportunities for economic advancement are lacking, then a "conflict subculture" might appear; in this context, violent crime would prevail. Where offenders live in neighborhoods with diminished legitimate and illegitimate opportunities, so-called double failures, then a "retreatist subculture" is likely to emerge.

General Strain Theory, a more recent extension of Merton's theory, has begun to make arguments that indicate specialization can occur. For instance, Robert Agnew indicated that males are more likely than females to respond to strain with offending that is directed against others. Agnew's theory and research suggests that males are more expressive and retaliatory as they experience strain which increases their chances of engaging in violent crime when compared to females.

Moffitt's developmental taxonomy. Terrie Moffitt's theory is one of the leading developmental theories in contemporary criminology and it proposes that there are two distinct offender pathways, each possessing unique points of origin. The "adolescent-limited" offender is someone whose violations of the law start relatively late, in adolescence, and primarily focus on rule-breaking behaviors rather than serious crime. These offenses are perhaps best understood in terms of reactions against the rules that constrain the autonomy of adolescents, the "maturity gap," and the resultant frustration and are mainly characterized by status offending (e.g., truancy, smoking) and other minor crimes. The "life-course-persistent" offender, in contrast, begins offending fairly early in life and this offender's repertoire includes not only rule-breaking behavior but also more serious crime. This type of offender has its origins in neuropsychological deficits present at birth and extremely poor parenting. In this respect, adolescent-limited offenders tend to specialize more in minor acts of rebellion than the life-course-persistent offenders.

Methods for Studying Specialization

Although there are clearly many frameworks that allege specialization can occur, the research literature testing the validity of these is not well developed. A significant reason for this is the limitations in the availability of statistical methods with which to study specialization data, which is a problem that in recent years has begun to be better addressed. This problem suggests that the measurement of offense specialization has been a challenging issue.

In the earliest years of research on specialization, researchers have preferred to use transition matrices to explore the sequence of arrests by type. These statistical methods, used to study specialization since the 1960s, estimate the chance for an arrest of a given type at Time 2 after an arrest for a crime at Time 1. Research using this approach has often found a fairly small degree of specialization in arrests. Marvin Wolfgang and his colleagues in the early 1970s, for instance, found virtually no connection between sequential arrests, a pattern that research over the next several decades would generally replicate.

The next major innovation was the development and publication of David Farrington's "Forward Specialization Coefficient" (FSC) in the late 1980s. The FSC, which also examined specialization in the sequencing of offenses, was created in part as a response to the concern that some types of crime are quite rare, particularly those that are violent. The offenses that policymakers tended to be least concerned about – such as thefts – are in fact the likeliest crimes to occur. Not surprisingly, using a transition matrix it would be easier to detect theft specialization; however, this would not be all that meaningful given that thefts are common and could be predicted based on chance alone (evidence of specialization among rarer offense types, like violence, would be correspondingly more difficult to locate). The FSC contrasted the level of specialization that one would predict based on chance alone with that actually observed. The method produced a standardized score for the sample, with 0 indicating complete versatility (or, put another way, all evidence of specialization could be explained by chance) and 1 signifying complete specialization. The FSC in turn came to be the preferred measure for studying specialization, although not without criticism with regard to such concerns as the interpretation of the coefficient. Research seemed to indicate that adult offenders were the most apt to specialize, for example, but conclusive evidence was disappointingly elusive.

Researchers also perceived that there were disadvantages to using transition matrix approaches, including the FSC. First, many theories of crime do not appear to define specialization in terms of a sequence of events. As a result, studies examining sequences have uncertain theoretical implications because theories, such as those summarized earlier, generally do not make assertions like "a robbery arrest must be followed by another robbery arrest." Second, sequences of events create analysis problems. For instance, with the FSC and the transition matrix, a person who committed a robbery at T1 and not at T2 is not a specialist. But what if that person committed a robbery at T3? As a result of questions like this, researchers began to explore statistical methods that would capture specialization in terms of the proportion of *all* offenses that were of a given type. Third, matrix-based approaches can only report specialization in an aggregate sense. In other words, the analysis can identify the level of specialization within the entire sample, but this meant that it was extremely difficult to locate risk factors that would help academics and policymakers classify individual offenders as specialists. While the literature using transition matrixes might crudely show that adults are more prone to specialize, it was not possible to predict which individuals among these adults would be most likely to specialize without committing the ecological fallacy.

Alex Piquero and his colleagues were the first to use a "diversity index" to measure specialization. This index was originally developed by statisticians who were interested in the variety of species of animals and later applied to criminological work, and the technique offered important advantages over earlier methods insofar as it addressed the problems outlined above. Rather than considering the observed sequence of two arrests, as with transition matrixes, the index considers the entire spectrum of crimes a person has committed. Little diversity in a person's crime record would indicate a specialist offender, where a broad range of crime would mark the versatile or generalist offender. This conception of specialization offered important new advantages over the FSC. For the diversity index to show specialization, it was not necessary to find contiguous arrests because the analysis weighs the entire portfolio of offense activity over a period of time. This definition of specialization also tends to be more consistent with many of the theories designed to account for the emergence of specific types of crime.

The index also produced a score for each individual, thus allowing researchers to test the impact of theoretically relevant variables on offense diversity or specialization in a regression framework, which was a task for which transition matrixes were poorly suited. Legitimate scores would range from 0 (complete versatility) to 1 (complete specialization). Because each individual receives a diversity score, this can in turn be used as an outcome measure in a regression analysis. Tests that included both the FSC and the diversity index showed similar patterns in specialization. Tests of criminological theories using this method, often focusing on Moffitt's developmental taxonomy, has reported inconsistent results showing that adolescent-limited offenders are more apt to specialize than life-course-persistent offenders.

The diversity index, although more flexible than the FSC, also has limitations; tests of specialization often face difficult analytic problems that frequently make no single statistical method ideal. First, even if an offender committed, for example, nine offenses of the same type, if there were 10 or more crime categories then that individual will not receive the maximum diversity score. Another concern centers on the fact that the diversity index does not take into account the base rates of offending across the population. That is to say, crimes that are more common (e.g., thefts) might give the appearance of specialization when that offender's record in no way differs from that of other offenders.

Alternatively, researchers can use latent class analysis (LCA), which resembles factor analysis and is used to classify offenders rather than assess how well the component measures cluster together. Only a small number of studies have used this approach, producing some mixed findings. Some early work found that LCA could only distinguish between offenders and nonoffenders, while more recent work using offender populations and a larger number of offense categories reported the ability to classify offenders. Some scholars have noted limitations with this approach, such as the confounding between offense frequency and specialization. That is to say, offenders who commit more crimes are likely to have at least some offending of a certain type, say violence. Because of this, the determination of how much specialization there is depends upon the researcher's assessment.

A final technique that researchers have used with some frequency in recent years is the Item Response Theory (IRT)-based approach developed by Wayne Osgood and Christopher Schreck. This method employs a multilevel regression approach, with the first level assessing whether specialization exists and the second level incorporating predictors of specialization. There are additional attributes that make this approach very useful for assessing specialization. First, the approach defines specialization as the degree to which an individual deviates from the population base rates for all offenses. For instance, if we assume that 80 % of the crimes committed by everyone are nonviolent and 20 % are violent, then someone with that same distribution is not especially unique; however, a person with 70 % violent and 30 % nonviolent offenses differs quite dramatically from the population. Second, the IRT model incorporates data from all subjects, including nonoffenders and low-rate offenders; many of the approaches described in this section (e.g., the FSC, diversity index) can only employ samples of offenders, usually only those with numerous arrests. Offenders with a higher level of activity will receive greater weight in the IRT-based analyses, however. Third, the approach controls for the frequency of offending as well as for specialization. Research using this method has shown that specialization does in fact exist among a minority of offenders, that their tendencies to specialize are stable over time, and that it is possible to predict specialization in violence using theoretically relevant predictors. Jean McGloin and her colleagues, in a recently published article using this statistical method, found that subculture-of-violence measures failed to predict tendencies to specialize in violence, contrary to the theory described earlier. This body of work is in its infancy, however. The ability of the IRT method to exploit predictor variables, as with the diversity index, nevertheless leaves the field of specialization poised for significant new advances in theoretically relevant research.

As the research literature developed, however, it became clear that studying specialization introduced many challenges that make efforts to locate it more difficult. For instance, the source of data researchers use can influence whether they find specialization or not. Specialization appears more likely to emerge with self-report data, where individuals describe their own offending, than with official arrest data. This is perhaps not surprising; arrests tend to be relatively infrequent events even among those with many arrests, and many crimes that people commit go unreported to the police. Self-report data thus can provide a more comprehensive picture of what offenders are probably doing; however, there is a limit to the level of detail one can reasonably expect. For instance, with self-report data the subjects may have a difficult time, simply due to memory problems, establishing the time order of their criminal activity. Official arrest data, vetted by police and accompanied by a clear time of arrest, are more suitable for such methods as the transition matrix.

A further issue that has developed in specialization research concerns how scholars ought to measure it. That is to say, what offenses ought to get included and how ought they to be grouped together (e.g., violent vs. nonviolent, white-collar vs. street crime). The diversity index has great flexibility for incorporating multiple offense categories; however, it has a difficult time discriminating between types of offenders. For instance, two offenders with scores indicating maximum specialization might specialize in very different crimes (e.g., one in drugs, the other in rapes), with each type possibly arising from different causal processes. The IRT-based approach, in contrast, can only examine the contrast between two general categories. If theories identify three or more types of offenders, then the method cannot easily accommodate that many classifications.

Conclusion

Research on specialization is of potentially great importance in the study on crime and for policy. Those who make policy decisions have an interest in locating and targeting crime control efforts toward those who are most likely to engage in serious crime, especially violence, through practices like selective incapacitation. Academics have contentiously debated the value of research on specialization, largely because evidence (or its lack) speaks to the legitimacy of their theories. Some theories argue that violent offenders, for example, were subject to specific processes that made them violent; other processes lead to offenders who prefer other types of crime. General theories, like self-control theory, however, identify processes common to all crimes and argue that specialization cannot exist in a meaningful sense.

For decades, strong evidence of specialization (and its causes) has been elusive. In recent years, especially with the advent of research methods defining specialization in terms of diversity rather than a sequence of offenses, evidence that some offenders specialize has strengthened. Locating exactly why this is so, however, has proven difficult. This research, however, is in its early stages and can benefit from verification as well as the incorporation of additional theoretical explanations.

Overview

The concepts of officer safety, health, and wellness are both distinct and interrelated. This entry will focus on ongoing and emerging issues in police safety (e.g., increased violence toward the police, increased risks due to encounters with dangerous situations and persons, vehicular safety including officer pursuits, and protective measures that can be employed by agencies and law enforcement officers). In addition, issues of officer stress will be examined in terms of stress types, causes, and effects.

Recent research has also focused on health issues associated with shift work and the profession of policing more broadly, indicating greater risks for cardiovascular disease and cancers (compared to the general population), causes and sources of officer fatigue and its relationship to various negative outcomes, the higher rates of sleep disorders for police officers compared to the general population, and earlier morbidity from various causes including suicide.

Finally, policy and practice implications are discussed to promote a culture of safety, health, and wellness while also emphasizing personal responsibility. Individual officers vary significantly in the extent to which they make physical health a priority, focus on mental and emotional health (although many do not take responsibility for seeking out such assistance), and practice general safety procedures such as wearing seatbelts and body armor.

Introduction

The issue of officer safety, health, and wellness not only impacts the length and quality of officers' lives but also has significant implications for community safety, as well as departmental costs and liability. Although the issue of police stress has been examined by scientists and practitioners alike for many years, there has been little empirical research when it comes to long-term health, wellness, and safety. However, due to a number of recent national initiatives, there has been increased awareness of, and attention to, the issues of safety, health, and wellness among police officers. First, the National Institute of Justice (US Department of Justice) initiated a series of studies in the last decade focused on these issues. More recently, current US Attorney General Eric Holder committed $40 million for officer safety initiatives in 2010 and launched a law enforcement officer safety initiative in October of that year called VALOR – *Preventing Violence Against Law Enforcement and Ensuring Officer Resilience and Survivability* (http://www.mainjustice.com/2010/10/26/holder-launches-new-law-enforcement-safety-initiative/). Then in March 2011, the Attorney General issued a directive to all US Attorneys which was copied to the agency heads of the Federal Bureau of Investigation (FBI), Drug Enforcement Administration (DEA), US Marshals, and the Bureau of Alcohol, Tobacco, Firearms, and Explosives (ATF) calling on them for increased actions related to his Officer Safety Initiative (http://www.mainjustice.com/2011/03/22/holder-launches-officer-safety-initiative/).

As a result of these initiatives, two US Department of Justice offices have become involved in the issue. Specifically, the Office of Justice Programs' Bureau of Justice Assistance (BJA) and the Office of Community Oriented Policing Services (COPS Office) have, on behalf of the Attorney General, convened the Officer Safety and Wellness Working Group (OSWWG) made up of research scientists, practitioners, and policy makers in order to address these issues. This working group has focused on felonious killings and shootings of police officers, traffic accidents, and a variety of health and wellness issues, including officer suicides. Also, BJA has published a fact sheet entitled *Officer Safety Initiatives* (Edwards and Meader 2011) that includes links to a number of officer safety resources and web links (https://www.bja.gov/Publications/OfficerSafetyFS.pdf).

In addition, initiatives by the National Law Enforcement Officers Memorial and the International Association of Chiefs of Police (IACP) have focused on violence against officers and traffic safety. For example, in August 2011, the National Law Enforcement Officers Memorial Fund and the National Highway Traffic Safety Administration (NHTSA) initiated an innovative partnership to promote law enforcement officer safety on the roadways. Finally, the IACP has initiated and produced a number of safety initiatives and publications. One such initiative is *Safe Shield* which looks at all aspects of officer injuries and deaths through improved education, training, and policies as well as improvements to uniforms and equipment. As recently as September 2012, the IACP held a webinar on officer safety and wellness to announce the opening of its new Center for Officer Safety and Wellness with the goal of enhancing law enforcement's ability to be well equipped, well trained, and physically and mentally prepared to confront violence as well as other threats and dangers. In sum, it is increasingly apparent that researchers and police leaders have answered the call and become more involved in addressing concerns over officer safety, health, and wellness including the prevention of violence against officers and an improved ability to confront it.

Importantly political leaders have also taken an interest in officer safety issues. For example, in May 2012, US Senator Chris Coons (D-Del.) hosted a briefing for members of Congress and their staff to learn about and experience wearing bullet-resistant and stab-resistant vests. The *Bulletproof Vest Partnership* (*BVP*) *Grant Act of 2012*, which was introduced by Senator Patrick Leahy (D-Vt.) in May 2012 and cosponsored by Senator Coons, is a reauthorization of the competitive grant program from the Bureau of Justice Assistance that provides funding to state and local law enforcement agencies to assist in their purchasing of ballistic-resistant and stab-resistant body armor that complies with National Institute of Justice body armor standards. Since the BVP program's first authorization in 1999, it has reimbursed grantees approximately $247 million for their purchases of nearly one million vests.

Background on Officer Safety, Health, and Wellness

Issues of officer safety, health, and wellness are not new. However, due to advances in the field, state of the art, and a resurgence of interest in recent years, this entry will focus primarily on data from the past 10–15 years. The two major safety issues include assaults (including felonious killings) and vehicular accidents. Data on law enforcement officers killed and assaulted has been collected for decades. The number of law enforcement officers killed in the line of duty was collected by the FBI from 1937 to 1971 as part of the Uniform Crime Reports. However, in 1972 the FBI started to collect more detailed data associated with officers killed in the line of duty. Additionally, benefits are offered to victims' families via the Public Safety Officers' Benefits Program, a federal (Bureau of Justice Assistance), state, and local collaboration to provide to death and educational benefits to survivors. Most states offer pensions, worker's compensation, and burial support to spouses and children of fallen officers, and other organizations provide programs for survivors and/or law enforcement agencies. One example is the group Concerns of Police Survivors (C.O.P.S.) that provides resources to assist in the rebuilding of the lives of surviving families and affected coworkers of law enforcement officers killed in the line of duty, provides training to law enforcement agencies on survivor victimization issues, and educates the public of the need to support the law enforcement profession and its survivors.

As early as 1929, police departments began to concern themselves with traffic safety. For example, the Evanston, Illinois, Police Department established an Accident Prevention Bureau led by a young sergeant and student at Northwestern University (NWU) who developed a safety model that took ideas from engineering, enforcement, education, and research. Later, that sergeant became a lieutenant and went on in 1936 to become founding director of NWU's newly established Traffic Safety Institute, the first known of its kind nationwide. Today, many of the courses offered at NWU's Center for Public Safety are offered to the general public like defensive driving. However, the Center focuses on educating law enforcement officers in many areas such as police accident investigation, motorcycle operation and instruction, radar, and field sobriety instructor training, as well as many non-traffic safety areas.

Assaults and Felonious Killings. During the decade from 2001 to 2010, the FBI reported that assaults on police officers averaged about 58,500 (ranging from a low of 53,469 in 2010 to a high of 60,851 in 2007). While assaults on police officers appeared to be dropping at the end of the decade, data from the National Law Enforcement Officers Memorial Fund (NLEOMF) showed that during the 10-year period between 2002 and 2012, shootings of officers (570) surpassed vehicle accidents (470) as the leading cause of line of duty officer deaths. In 2011, there was a 20 % increase in fatal shootings of law enforcement officers over the prior year according to Executive Director Craig Floyd (2012) of the NLEOMF (http://www.nleomf.org/facts/officer-fatalities-data/causes.html and http://www.nleomf.org/facts/officer-fatalities-data/).

Data from 2011 showed that over 30 % of officers killed were not wearing body armor (http://www.cops.usdoj.gov/pdf/OSWG/Meeting_01-26-2012.pdf), in spite of the fact that since the introduction of modern material vests/body armor in the 1970s, the number of officers surviving shootings has gone up dramatically. Indeed as of March 2011, the IACP/DuPont Kevlar Survivors' Club® had documented more than 3,126 incidents where body armor protected officers from more serious physical injuries or death. In 1994, the FBI also found that the rate of death of officers shot is 14 times greater for those who do not wear body armor than for those who do (as reported in Miller 2001). Advanced material bullet- and stab-resistant vests can be costly. Since the 1970s, several new bullet-resistant fabrics, fibers, and construction methods have been developed besides woven Kevlar, such as DSM's Dyneema, Honeywell's Gold Flex and Spectra, Teijin Twaron's Twaron, Pinnacle Armor's Dragon Skin, and Toyobo's Zylon, to name several examples. While the manufacturers of many of these newer materials advertise these as thinner, lighter, and more resistant than Kevlar, they tend to be more costly.

Taylor and colleagues (2009) conducted a national survey of law enforcement agencies and found that the vast majority (87 %) issue body armor to their officers. Slightly fewer than 20 % (17.7 %) indicated that their officers purchase their own body armor, but 37 % of those provide full reimbursement, and the remaining 63 % provide reimbursements of at least 33 %. Furthermore, in an effort to increase protections to officers, the federal Bulletproof Vest Partnership (BVP) Program (which has a mandatory wear policy) has provided over $300 million to provide bullet- and stab-resistant vests to agencies for provision to their officers.

In light of the above statistics, it is both astounding and curious as to why officers would not wear vests especially because cost does not appear to be a major factor. One possible reason is that many agencies do not require that their officers wear body armor. Taylor et al. (2009) reported that just 59 % of law enforcement agencies surveyed had a mandatory wear policy for body armor and only 45 % had a written policy on this matter, even though most provided body armor to their officers. Anecdotal information suggests that some of the other reasons or circumstances in which officers choose not to wear body armor consistently include living in hot climates or during summer months, at times or in places where they do not feel at a high risk (even though any situation can become risky), or that they are cumbersome (although modern technology has resulted in significant reductions in weight, thickness, and heat retention). Most certainly these concerns ought to be outweighed by the lifesaving statistics.

Importantly, the VALOR program (above) provides training and technical assistance to officers and agencies in order to become more aware of and prevent violent encounters and ambush-style attacks on police. A number of other organizations are providing training in tactics, rapid response, and mitigation of risks and threats. Researchers examining aspects of deadly encounters and assaults as well as officer-involved shootings identified a number of offender characteristics in domestic assault cases that predicted assaults on police officers like alcohol consumption, living with the victim of domestic violence, and hostile demeanor toward officers. The provision of training to raise awareness of these risk factors could help prevent violent attacks on police.

Vehicle Accidents. Until very recently, traffic fatalities have been the leading cause of death of officers killed in the line of duty (at least for the years from 1997 to 2010). Yet, according to the NLEOMF, 21 % of officers killed in vehicle crashes were not wearing seat belts at the time of their fatal crashes (http://www.cops.usdoj.gov/pdf/OSWG/Meeting_01-26-2012.pdf). According to a 2011 report by the National Highway Traffic Safety Administration, 93 % of all law enforcement officers involved in fatal crashes were males, although Bureau of Justice Statistics' data indicates that by 2007, 12 % of all local law enforcement officers nationwide were women.

Among the most risky driving situations in policing are pursuits. In 2000, the IACP established a police pursuit database after years of recommending reforms via its "Vehicular Pursuit Model Policy" developed in 1996. That policy, in recognition of serious public safety risks in pursuits, establishes that officers should take into consideration the weather, population density, vehicular and pedestrian traffic, the capabilities of the pursuit car as well as the vehicle being pursued, the presence of others in the vehicle, and perhaps the most controversial aspect, the seriousness of the offense. Perhaps the reason for this controversy stems from what leading expert Professor Geoff Alpert has called the "competing values" of apprehending law breakers and ensuring public safety. Of course, it also comes from the increased liability to a law enforcement agency for injuries (or even death) of both bystanders and those involved and also for property damage. According to the IACP Pursuit Database, over 40 % of pursuits result from traffic-related infractions, and 35–40 % of pursuits end in a collision, and the FBI reports that 50 % of the collisions occur in the first 2 mins of the pursuit. As the area of pursuits continues to be more closely managed through greater restrictions and more specific policies set by police leaders, the risk factor for vehicular accidents and the associated outcomes involving the police and the public will continue to go down.

Summary. Current policies and procedures related to officer safety in public encounters and in vehicular operation and pursuits are reflective of the knowledge attained through statistics on the risk associated with various types of encounters such as traffic stops and domestic disturbances, as well as vehicle safety and police pursuit practices. Perhaps we are beginning to see signs of safety improvements and initiatives taking effect. As of September 15, 2012, firearm deaths of officers were down 38 % and traffic-related deaths 18 % over the same period in 2011.

Background on Officer Health and Wellness

Psychological Impacts of Stress. The issue of police stress has been studied for several decades. Originally thought to be one of the most stressful occupations in America, the assertion that policing is exceptionally stressful has not always been supported by scientific research. Early stress models emphasized a "life events" approach to stress; however, subsequent research has tended to focus on routine and organizational stressors. Emerging research on the personality dimension of resilience has provided some promise for new ways to prepare officers to better deal with job-related stress. Later in this entry the issue of wellness will include some discussion of programs related to building resilience and overcoming stress.

Stress Measures. Similarly, within occupational stress literature, and specifically that of policing, the measures of occupational stress have typically focused on either operational or organizational stressors. For example, Evans and Coman (1993) found that work stressors were either related to job content (the duties of the officers) or job context (derived from the police organizations). Similar research by Hart, Wearing, and Heady (1995) suggested that daily hassles associated with police work and the organizational bureaucracy produced greater levels of stress and affected quality of life more so than critical incidents. Most recently, McCreary and Thompson (2006) developed the Police Stress Questionnaire to assess two forms of stressors, those caused by the operational aspects (critical incidents) of policing and the other on the organizational stressors (administrative or imposed by the organization).

Officer-Involved Shootings. Research suggests that officers who are directly involved in shootings experience a variety of short- and long-term physical and psychological reactions such as tunnel vision, misperceptions of time, sound reductions, a sense of numbness, ruminations about the incidents, difficulty sleeping, sadness and associated crying, and nausea (see e.g., Artwohl 2002; Beehr et al. 2004). However, research over the past decade by Klinger (2006), in which he interviewed law enforcement officers involved in 113 separate shootings during the course of their careers, revealed that the act of shooting someone did not lead to lasting disruptions in the lives of officers. In more than half of the shootings, officers did not report negative psychological, emotional, or physical responses after a week following the incidents. After 3 months, that proportion increased to two-thirds. However, the primary lingering consequence appeared to be recurrent thoughts. Negative reactions appear to be mitigated by support from fellow officers following the incident and mandatory time off. However, family support and mandatory counseling did not appear to be associated with negative outcomes for police who engaged in shootings (Klinger 2006). However, it should be noted that research has previously demonstrated that officers' accounts typically differ from reality due to memory distortion. Nevertheless, recent research by Komarovskaya and colleagues (2011) indicated that killing or seriously injuring someone in the line of duty was significantly associated with PTSD symptoms and marginally associated with depression symptoms.

Police-on-Police Shootings. An additional stressor related to officer-involved shootings, is the issue of police-on-police shootings especially those resulting from mistaken identity. Unfortunately, these incidents often result from encounters between on-duty and off-duty, plainclothes officers. These encounters can escalate quickly due to misunderstandings either as a result of poor training, unclear protocols, or when officers are from differing jurisdictions. The New York State Task Force on Police-on-Police Shootings found that such shootings can easily traumatize police officers, families, and police departments, sometimes even polarizing entire police agencies. Importantly, the task force found "persuasive scientific evidence" that officers, like the rest of the population, share unconscious racial biases. This topic was of great enough concern that it became the focus of a 2010 "Research for the Real World Seminar Series" of the National Institute of Justice. In that series, an interview was conducted with the chair of the New York State Task Force Christopher Stone of Harvard University. Stone indicated that since 1981, 28 mistaken identity police-on-police shootings had occurred. The above data suggest that traumatic experiences may in fact increase officer stress and result in related physical and psychological consequences.

Posttraumatic Stress Disorder (*PTSD*). Typically associated with experiencing or witnessing severely traumatic incidents, PTSD is a constellation of symptoms of a psychiatric nature marked by clear biological changes and/or psychological symptoms. Psychiatric and psychological research over the past decade has demonstrated, consistent with other stress research, the routine work environment stressors are most strongly associated with PTSD symptoms, even when controlling for prior traumatic experiences, current negative life events, gender, ethnicity, and recent critical incident exposure (Liberman et al 2002; Maguen et al. 2009). Among the most common environmental stressors are lack of concern by management and supervisors, equipment safety, training, discrimination, shift work, role conflict, peers, and unfair public perceptions. This recent research suggests the need for greater attention to environmental stressors of a more routine nature that can build over time or be additive in nature.

Ongoing longitudinal research by Violanti and colleagues (see e.g. Violanti et al., 2006) has examined many health and safety factors for police officers in Buffalo, New York. One of the factors being examined is cortisol (otherwise known as the "stress hormone") in order to determine if stress is associated with risk factors predictive of more serious illnesses. Almost two decades ago, Violanti found that organizational stressors increased psychological distress by 6.3 times more than did inherent operational police stressors (Violanti and Aron 1994). And a decade prior to that, he found that police stress increases significantly in the first 13 years of an officer's career and then progressively decreases after 14 years (Violanti 1983).

Physical Health, Sleep, and Fatigue. Recent research by Violanti suggests that some longstanding patterns associated with police officers' careers (shift work, smoking, alcohol use, etc.) increase the likelihood of metabolic syndrome. Metabolic syndrome is a clustering of cardiovascular disease risk factors (obesity, elevated blood pressure, reduced HDL cholesterol, elevated triglycerides, and abnormal glucose levels). In one study Violanti (2012) found that officers with severe PTSD symptoms were three times more likely to have metabolic syndrome and therefore have higher risk for cardiovascular disease, further emphasizing the role of stress in ill-health and greater risks for disease including various forms of cancer (Vena et al. 1986).

Many of the ill effects of police work are attributed to shift work, which typically refers to those types of schedules that require working at nontraditional times such as evening or midnights. Violanti (2012) also found that the number of metabolic syndrome components was greater for younger officers working midnight shifts and that shorter sleep duration and increased overtime combined with midnight shifts may be a contributor to metabolic syndrome.

Shift Rotation. Various aspects of shift work and especially working night shifts have been demonstrated to be associated with poorer sleep and/or sleep disorders, metabolic syndrome, and other health risks. Another aspect of shift work that has been examined across industries is the extent to which shifts rotate. Shift rotation has traditionally been a common practice in law enforcement agencies, with officers rotating from day, to evening, to midnight shifts (forward rotation) or from midnights, to evenings, and then to days (backward rotation), although the frequency of rotation varies substantially as well. Typically, schedules that change twice a year or less frequently are not generally referred to as rotating shifts. Instead, a rotating shift is one in which officers rotate on a monthly basis or more typically on a much more frequent basis like every 2 weeks, week, or even everyday.

Given the extent of research suggesting negative impacts of rotating shifts, Amendola and colleagues (2011a) conducted a random national survey and surprisingly found that as recently as 2005, the use of rotating shifts was still a somewhat common practice (46 %), particularly in smaller agencies (52.1 %). However, they also found that the larger the agency, the less likely they were to employ rotating shifts (41.5 % for medium agencies and 30 % for larger agencies). When the survey was conducted 4 years later, the percentage of agencies using rotating shifts declined by almost half from 46 % in 2005 to 24.7 % in 2009. Similarly, there was an increase (about 40 %) in fixed shifts from 54 % to 75.3 %, a trend that seemed most apparent in small and medium-sized agencies. Again in 2009, the use of rotating shifts was somewhat more common among smaller and midsize agencies (25.2 % and 26.3 %, respectively), as compared to larger agencies (20.5 %).

These reductions may be due to an increasing awareness of research showing that rotating shifts typically disrupt circadian cycles and result in greater fatigue, insomnia, or other health problems (e.g., Colligan et al. 1979; Czeisler et al. 1982), and increases in worker errors and accidents (e.g., Gold et al. 1992). Furthermore, by 2009, we saw the advent of the use of both fixed and rotating schedules in agencies (4.3 %).

Shift Length Practices. While most law enforcement agencies have traditionally relied on a standard 40-h workweek consisting of five consecutive, 8-h shifts, followed by 2 days off, many agencies have used alternative shift schedules over the past several decades. In recent years, however, an increasing number of agencies have moved to some variant of a compressed workweek (CWW) schedule in which officers work four 10-h shifts per week or three 12-h shifts (or some variant). In the recent Amendola et al. (2011a) survey, researchers found that there had been a significant drop in agencies employing traditional 8-h shifts from 40.1 % in 2005 to 29.3 % in 2009. In the largest agencies (200 or more sworn officers), 10-h shifts are the most common with 35 % of them employing these shifts in 2005 and 33 % in 2009, followed by 8-h shifts and then 12-h shifts. However, small- and mid-sized agencies predominantly used 8-h shifts in 2005 (41–42 %); by 2009, these agencies had roughly equal numbers of 8- and 12-h shifts (32 % and 31 % for small agencies; 27 % and 26 % for medium).

While the trend toward CWWs had been increasing over the past decade, there had been few, if any, rigorous scientific studies examining the advantages and disadvantages associated with these work schedules for law enforcement officers and their agencies. As such, Amendola, Weisburd, and colleagues (2011b) conducted a comprehensive, randomized experiment in which shift lengths of 8, 10, and 12 h were randomly assigned to law enforcement officers in Arlington, Texas, and Detroit, Michigan, to assess their potential impacts on performance, health, safety, quality of life, sleep, fatigue, alertness, off-duty employment, and overtime among police. The study found some distinct advantages of 10-h shifts and identified some disadvantages associated with 12-h shifts that are concerning. Specifically, officers on 10-h shifts got significantly more sleep per 24-h period than those on 8-h shifts (approximately 30 min), had a higher quality of work life, and worked significantly less overtime hours. However, those on 12-h shifts did not obtain the sleep benefit, and indeed reported greater levels of fatigue and lowered alertness at work. It is important that agencies consider the safety and quality of life of their personnel and the public they serve, and therefore 10-h shifts may be optimal in this regard.

Causes and Impact of Officer Fatigue. According to research by Vila (2000), police officers on average get 6.5 h per sleep, less than that of the general population. Importantly, 40 % of officers screened positive for sleep disorders also a rate well above that of the general population. Indeed, officers with sleep disorders had an increased risk of falling asleep while driving, committing an error or safety violation attributable to fatigue, and experiencing uncontrolled anger toward a suspect.

Types, *Presence*, *and Causes of Sleep Disorders*. A recent survey showed that 40 % of police officers experience sleep disorders (Rajaratnam et al. 2011). The most common sleep disorders in police officers are obstructive sleep apnea (roughly 33 %), followed by insomnia (about 6.5 %), and then shift-work sleep disorder. Sleep apnea is a disorder characterized by abnormal pauses in breathing that can happen for a few times an hour or a few dozen times an hour. Obstructive sleep apnea is a form in which a blockage to air flow exists even though there is respiratory effort, as opposed to central sleep apnea in which there is a lack of respiratory effort.

Researchers at Brigham and Women's Hospital found the frequent use of extended shifts, long work hours, and extended work weeks can lead to increased risk for errors, unintended injuries, vehicle accidents, and other health risks (Rajaratnam et al. 2011). Indeed, officers with obstructive sleep apnea in that study were more apt to be diagnosed with diabetes and have cardiovascular disease, and those with apnea did consume more caffeine than those who did not have the condition. In addition, those in the sleep disorder category in this study also reported feeling burnout and falling asleep while driving, in addition to having more gastrointestinal and anxiety disorders and taking medication for insomnia, than those who did not have the disorder. And officers with obstructive sleep apnea were 1.5 times more likely to have depression than officers who did not. In terms of other causes, obstructive sleep apnea is sometimes caused by excess weight, and in this study population, 79.3 % of officers were overweight or obese by definition, and 33.5 % were obese. Another common symptom of obstructive sleep apnea is snoring. Violanti (2012) found that night-shift workers had greater levels of snoring even after controlling for a number of other factors.

Insomnia is a disorder in which there is difficulty falling asleep or staying asleep. It is often associated with impairment in functioning while awake like excessive sleepiness, fatigue, and psychomotor functioning. Finally shift work sleep disorder (SWSD) is associated with disruption in circadian rhythms, the normal internal clock influenced by light and dark. This disorder is most commonly experienced by those who work nights, very early days (starting at say 4:00 am), or rotating shifts. Those with SWSD are twice as likely to have work related accidents and have excessive sleepiness, reduced performance, and irritability.

Morbidity. Life expectancy of police officers is commonly believed to be lower than for the general population. Violanti's (2012) research with a current police population and cohort of deceased officers showed that mortality from all causes of death combined for police officers was significantly higher than that of the general US population. Police also had significantly higher death rates from cancer and circulatory system diseases as well, although they had a lower rate of death from nervous system and sense organ diseases, respiratory diseases, accidents, and motor vehicle accidents as compared to the general population. However, mortality due to cirrhosis of liver (caused primarily by overuse of alcohol) and suicide was elevated.

Suicide. Research by Violanti (2012) suggests that suicide ideation in police officers is highly associated with psychologically traumatic police work experiences, the development of posttraumatic stress (PTSD) in officers, and the "inordinate use of alcohol associated with this condition." Violanti suggested that police exposure to certain traumatic events increase the risk of high level PTSD symptoms, which subsequently increase the risk of high alcohol use and suicide ideation, noting that when combining the impact of PTSD and increased alcohol use increased suicide ideation risk by ten times.

Using data from the National Occupational Mortality Surveillance from 1984 to 1998, Violanti (2010) found that the police suicide rate was four times that of firefighters. Also when comparing police officer to firefighters, minority officers had 4.5 times the number of suicides, and female officers had 12 times the number of suicides. Finally, police suicides outnumbered homicides by more than 2.3 times. Although the suicide rate for police officers is often thought to be higher than that of others jobs, two meta-analyses have indicated that, after controlling for demographics, the suicide rate for police officers is actually lower than that of the population in general (Aamodt and Stalnaker 2001; Loo 2003).

Background on Officer Wellness Programs. Traditionally, most wellness programs have been limited to physical fitness, employee assistance programs, and critical incident stress debriefings (CISD). In the past, the typical focus on wellness has tended to emphasize the detection of problems and intervention such as in a CISD or an employee assistance program (EAP). Research and common wisdom regarding EAPs is that whether they are offered inside or outside the department, officers tend not to utilize them that frequently due to stigmas associated with the need for counseling or assistance, the fear that attending any sessions will be used adversely against an officer within the agency, or at a minimum that the agency will know who has participated.

However, in recent years, wellness programs have begun to emerge in law enforcement agencies across the USA. The concept of wellness today typically emphasizes physical, emotional, mental, and spiritual dimensions. Even at the Federal Bureau of Investigation, Former Supervisory Special Agent Samuel Feemster championed the concept of officer wellness from a broader holistic model in which spirituality was central including the most recent development of a program called “Beyond Survival Toward Officer Wellness” (BeSTOW) where emotional and spiritual intelligence take center stage and suicide prevention is no longer a taboo topic. Spirituality in this sense is not about religion per se, but a larger sense of meaning and purpose in law enforcement.

Many issues are driving the increased attention to employee wellness including health care costs during an officer’s career and in retirement, agency liability associated with the performance of their officers, absenteeism, stress-related problems, emotional problems, and more. According to Quigley (2008), fitness and wellness programs can benefit individuals and officers, as “officers stand to profit from an improved ability to perform job functions, reduced stress, and better physical and psychological preparation. Agencies stand to benefit in terms of efficiency as well as fiscally.”

According to Fiedler at the Office of Community Oriented Policing (COPS), US Department of Justice, promoting safety and supporting health and wellness, can be defined under four broad categories: (1) Leadership and Management, (2) Operational and Emergency Responses, (3) Training, and (4) Mental and Physical Health Wellness indicating the need for more comprehensive programs targeting policies, practices, tactics, strategies, academy and field training (including scenario based and simulation training), and physical and mental health programs (http://www.cops.usdoj.gov/pdf/OSWG/e091120401-OSWGReport.pdf).

Conclusions

The past several years have seen an increase in the attention paid to officer safety, health, and wellness issues by researchers, practitioners, and policy makers. This increase is due to such factors as including changing trends in the types and severity of situational risk factors for police officers, calls from political and governmental leaders, increasing costs and liabilities facing law enforcement agencies, and increased health and safety concerns of officers. Whether it be increasing gun violence, inherent dangers in domestic disturbance calls and traffic stops, or hostility and attacks and assaults on police officers, safety risks are ever present in policing. Due to these risks, improvements are necessary in officer vigilance, training geared toward preventing and combating intense threats via new and emerging tactics and strategies, improved information technology and sharing, enhanced safety equipment and vehicles, and increased self-compliance with personal safety practices (e.g., seat belts, body armor).

There are also policies and practices that management should continue to explore and improve in order to enhance and promote safety, particularly those practices derived from scientific research (i.e., evidence-based policies and practices). For example, information on shift scheduling practices and pursuits can be useful in developing agency-specific practices and policies to improve safety, health, and wellness. In addition, the continued research and testing of various information technology modalities (iPhones, Mobile Data Terminals, Global Positioning Systems and Crime Mapping, and other similar tools) should be continued so that agencies can make technological upgrades that will remove officer distractions while also providing clear, concise, and relevant information in a dynamic fashion.

While peers can play a role in helping to protect other officers and provide support and compassion to their colleagues, the role of personal responsibility of officers should not be underestimated. The fact that any less than 100 % of officers do not use seat belts 100 % of the time or that less than 100 % of officers do not wear safety equipment (i.e., vests) 100 % of the time indicates some resistance to or lack of understanding of the data and information about the safety facts. Some officers continue to use excessive amounts of alcohol and caffeine, smoke, engage in poor eating habits (or are obese and fail to lose weight), fail to get adequate exercise or sleep, or overuse or even abuse controlled substances. Despite the known health risks, these behaviors/conditions can shorten lives and increase health and safety risks many of these behaviors and conditions are within the control of individual officers. When these behaviors begin to be recognized as reducing health, wellness, safety, or shortening one's life, there are opportunities to receive assistance through peers, professional counselors (e.g., psychologists, psychiatrists, social workers), sleep experts, nutritional counselors, and fitness advisors. At the same time, law enforcement agency leadership and culture must be supportive, that is, leadership and organizational structure, policies, and practices should work toward promoting safety, health, and wellness if their agencies are to be successful in promoting public safety.

Synonyms

Adolescence-limited offending; Age-crime curve; Criminal careers; Life-course-persistent offending; Prevention; Trajectories

Overview

The age of onset of offending is the age at which the first crime is committed. Generally, this is 3–5 years earlier in self-reports than in official records. The aggregate age-crime curve conceals several trajectories and pathways. In particular, life-course-persistent offenders, who start early and persist for a long time, are distinguished from adolescence-limited offenders, who start later and have short criminal careers. An early age of onset predicts a long criminal career. The most important risk factors for early onset are similar to risk factors for offending in general and include neuropsychological problems, low intelligence, and high impulsiveness, combined with poverty and poor child rearing. However, adult onset offenders are very different, because they tend to be nervous, withdrawn and have few friends in childhood. Effective programs that can prevent or delay onset include nurse home-visiting programs, parent training, skills training, and preschool intellectual enrichment programs.

Introduction

The age of onset is defined as the age at which the first offense is committed. “Offenses” are defined as the most common types of crimes that predominate in official criminal statistics, including theft, burglary, robbery, violence, vandalism, fraud, and drug use. Ages of onset are often studied within criminal career research. A “criminal career” is defined as the longitudinal sequence of offenses committed by an individual offender (Blumstein et al. 1986). It has a beginning (onset), an end (desistance), and a length in between (duration), during which offenders commit crimes at a certain rate (frequency per year).

Criminal career research falls within developmental and life-course criminology, which is concerned with the development of offending and antisocial behavior from the womb to the tomb, as well as with risk and protective factors and life events that influence development. Crimes usually do not appear without warning; they are commonly preceded by childhood antisocial behavior (such as bullying, lying, cheating, truanting, and cruelty to animals) and followed by adult antisocial behavior (such as excessive drinking, sexual promiscuity, spouse assault, child abuse, and neglect). However, the focus in this entry is on the onset of offending.

The key questions addressed in this entry are:

1. What is known about ages of onset from official records and self-reports?
2. How does the age of onset vary with gender and race?
3. What is known about developmental sequences of onsets?
4. To what extent does the age of onset predict later criminal career features?
5. What are the most important risk factors for early onset, adolescent onset, and adult onset?
6. What are the most important theories of onset?
7. How can the onset of offending be prevented?

What Is Known About Ages of Onset from Official Records and Self-Reports?

It is well known that the aggregate (official) crime rate increases with age to a peak in the teenage years and then decreases in the twenties. It is less well known that this curve reflects variations in the prevalence of offenders rather than in the frequency of offending by offenders. A review of knowledge about the age-crime curve by Farrington (1986) concluded that the peak age of onset of offending was usually between ages 8 and 14. In the Cambridge Study in Delinquent Development (CSDD), which is a prospective longitudinal survey of over 400 London males, the peak age of the first conviction was at 14, with 5 % of the males first convicted at that age. In the CSDD, 129 males (31.9 %) were first convicted between ages 10 and 20, but only 35 (8.7 %) between ages 21 and 40, and only 6 (1.5 %) after age 40 (up to age 56; see Farrington et al. 2013).

Rather than presenting the onset rate, taking all persons in a cohort still alive as the denominator, it might be better to present a “hazard” rate. This relates the number of first offenders to the number of persons still at risk of a first offense, excluding those with a previous onset. In the CSDD, the hazard rate showed a later peak than the onset rate, at age 17, when 6 % of the males still at risk were first convicted (Farrington et al. 1990). Basically, the peak hazard rate was later and greater than the peak onset rate because of the decreasing number of males who were still at risk of a first conviction with increasing age (the denominator).

Few studies have compared self-reported and official ages of onset. In a study of 470 Montreal delinquents, Le Blanc and Fréchette (1989) found that the males had an average age of onset of 10.8 years in self-reports and 14.6 years in official records. Similarly, in the Pittsburgh Youth Study, which is a follow-up of over 1,500 Pittsburgh boys, Loeber et al. (2003) discovered that the average age of onset for self-reported serious delinquency was 11.9 years, while the first court contact for an index (more serious) offense occurred at an average age of 14.5 years. In the Dunedin study in New Zealand, Moffitt et al. (2001, p. 83) compared the ages at first arrest, first conviction, and first self-reported offense, and found that the age of onset in official records was approximately 3–5 years after the age of onset in self-reports.

Similarly, in the CSDD, Kazemian and Farrington (2005) showed that the average age of the first self-reported offense was at 11.9, while the average age of the first conviction was at 16.9. They also found that retrospective self-reports of offending (at age 32) were inadequate, compared with more contemporaneous self-reports; 41 % of prospectively admitted crimes were not admitted retrospectively, and the average retrospective age of onset was 4 years later than the average prospective age of onset. Therefore, accurate information about ages of onset cannot be obtained by retrospective questioning.

Variations by Gender and Race

In general, the official age-crime curve for African Americans is a magnified version of the curve for Caucasians, with an earlier age of onset, a higher peak prevalence of offending, and a later age of desistance. For example, Parker and Morton (2009) analyzed the criminal careers of over 800 male South Carolina delinquents and found that 32 % of African Americans, compared with 13 % of Caucasians, had an early age of onset (before age 12). Low family income and low verbal intelligence were associated with early onset and were more common among the African American delinquents.

In the Dunedin study in New Zealand, Moffitt et al. (2001) argued that gender differences in the prevalence of offending were attributable to gender differences in the number or level of risk factors such as neuropsychological problems and conduct disorder. They found little evidence for an early onset group of persistent female offenders, because females generally had fewer risk factors and because female delinquency was less persistent than male delinquency. In the Christchurch Study in New Zealand, Fergusson and Horwood (2002, p. 174) also reported that fewer females than males followed an early onset pathway, with female chronic violent offending being particularly rare. However, relative to males, proportionally more females showed early onset adolescence-limited offending (see later), and a series of explanatory factors relating to family functioning and early adjustment operated in a similar fashion for both males and females. In a multisite study in the United States, Broidy et al. (2003) showed that trajectories for male and female offending were similar in number and pattern, but the male trajectories were more highly elevated than the female trajectories, because males engaged in more delinquent behavior than females overall.

What Is Known About Developmental Sequences of Onsets?

The age of onset varies with different types of offenses. It is desirable to study sequences of onsets, to investigate to what extent the onset of one type of offense is followed by the onset of another type. In the Montreal study, Le Blanc and Fréchette (1989) discovered that shoplifting and vandalism tended to occur before adolescence (average age of onset 11), burglary and motor vehicle theft in adolescence (average onset ages 14–15), and sex offenses and drug trafficking in the later teenage years (average onset ages 17–19). In a study of over 700 adult Massachusetts sex offenders, Danielle Harris (2013) reported that their average onset ages were 15.7 for burglary, 16.0 for theft, 17.3 for robbery, 18.3 for assault, 22.4 for rape, and 25.5 for child molesting. In general, nonsex offenses occurred 6.7 years before sex offenses.

In the CSDD, Kazemian and Farrington (2005) found a typical sequence from minor to serious self-reported offenses, with shoplifting and vandalism most frequently beginning before other types of offending. In contrast, for official offenses, they found that the males were likely to be convicted for theft of vehicles and burglary before any other offense. These findings suggest that there are different onset sequences for self-reported and official offending.

How can onset sequences be explained? First, it may be that different acts are different behavioral manifestations of the same underlying construct that persists at different ages. An underlying antisocial tendency, for example, may manifest as shoplifting in early adolescence, burglary in later adolescence, and intimate partner violence and child abuse in adulthood, with no facilitating effect of an earlier act on a later one. Second, different acts may be different behavioral manifestations of the same or similar underlying constructs at different ages but also part of a developmental sequence, where one act facilitates another act, for example, cigarette smoking facilitating later marijuana use. Third, different acts may be indicators of different constructs and part of a causal sequence, where changes in an indicator of one construct cause later changes in an indicator of a different construct. For example, neuropsychological deficits may cause subsequent school failure.

The first possibility can be distinguished empirically from the second and third. When acts in a sequence are all different behavioral manifestations of the same underlying construct, preventing or changing an early act in the sequence will not necessarily affect the probability of occurrence of later acts, unless there is some change in the underlying construct. However, with developmental and causal sequences, changing an early act in a sequence will affect the probability of occurrence of later acts. In general, it is not clear whether onset sequences reflect persistent heterogeneity or state dependence (Nagin and Farrington 1992).

Rolf Loeber (1988) pioneered the study of developmental pathways and outlined five features of a developmental progression: some behaviors had an onset at earlier ages than others, there was usually escalation in the seriousness of behaviors over time, there was usually retention of earlier behaviors in the sequence when a new behavior occurred, each behavior was best predicted by the developmentally adjacent behavior, and the ordering of the behaviors in the sequence was invariant, although it was noted that many people did not progress from one particular behavior to the next one in the sequence. He proposed that there were three different developmental pathways for antisocial behavior: aggressive versatile, nonaggressive antisocial, and exclusive substance abuse.

The aggressive versatile pathway was characterized by violent, property, and drug offenses; had an onset in the preschool years; and included conduct problems, hyperactivity/impulsivity and attention deficit, educational problems, and a high rate of innovation (the occurrence of new behaviors). The nonaggressive antisocial pathway, characterized by property and drug offenses, had a later onset in late childhood or early adolescence and included only nonaggressive conduct problems, no hyperactivity/impulsivity or inattention, and a low rate of innovation. Interestingly, this latter group of children typically were involved with deviant peers. The exclusive substance abuse pathway had the latest onset (in late adolescence) and no antecedent conduct problems, but it included antecedent internalizing problems such as shyness and nervousness. Surprisingly, these categories bear a great deal of resemblance to three groups that are considered in more detail later: early onset, adolescence-limited, and adult onset offenders.

Loeber (1988) concluded that one of the factors that predicted whether there would be a transition from one behavior to the next in a pathway was the frequency of occurrence of the first behavior. This suggests that, when individuals commit trivial offenses more frequently, their behavior is likely to escalate to more serious offenses in the future. It is clear that certain types of offenses occur on average before other types and that onset sequences can be identified. There has been extensive research on Loeber's pathways, which are now termed overt, covert, and authority conflict pathways (see Farrington and Loeber 2013). The overt pathway starts with minor aggression and then progresses to physical fighting and eventually serious violence; the covert pathway starts with shoplifting and frequent lying and then progresses to vandalism and eventually serious delinquency (burglary and vehicle theft), and the authority conflict pathway starts with stubborn behavior and then progresses to defiance and eventually truancy and running away from home.

Age of Onset as a Predictor of Later Criminal Career Features

There is no doubt that an early age of onset predicts a long criminal career and many offenses. For example, in the CSDD, the boys who were first convicted at ages 10–13 had an average of 9.2 convictions and an average criminal career duration of 14.2 years, those first convicted at ages 14–16 had 6.1 convictions and a duration of 14.4 years, those first convicted at ages 17–20 had 2.7 convictions and a duration of 6.7 years, and those first convicted at ages 21–30 had 2.0 convictions and a duration of 3.8 years (up to age 56; see Farrington et al. 2013).

Less is known about whether an early onset predicts a higher rate of offending per year or whether particular types of crimes committed on the first occasion presage a long and serious criminal career. In Sweden, Robert Svensson (2002) found that theft-related offenses committed on the first occasion were most likely to be followed by long criminal careers, whereas in Australia, Mazerolle et al. (2010) concluded that a first offense of violence did not predict a distinctive criminal career (compared to a nonviolent first offense).

Terrie Moffitt (1993) distinguished between adolescence-limited (AL) and life-course-persistent (LCP) offenders. LCP offenders tend to start offending early (usually before age 13), whereas AL offenders tend to start in adolescence (at about ages 13–16). LCP offenders are relatively few in number (approximately 5–10 % of the offender population) and tend to be difficult children, often showing signs of conduct problems very early in childhood. AL offenders are highly influenced by their peers. LCP offenders have long criminal careers, whereas AL offenders often give up offending around or soon after age 20. LCP offenders are often very versatile offenders involved in both predatory and violent crime. Their offending trajectory deviates significantly from the aggregate age-crime curve, because it does not decrease dramatically after age 20. The peak in the aggregate age-crime curve in the teenage years is largely caused by AL offenders joining in with LCP offenders.

Much of the developmental research on the age-crime curve focuses on underlying trajectories of antisocial behavior and offending. There is now fairly strong empirical evidence to suggest that there are categories of offenders with trajectories that are partly concordant with Terrie Moffitt's (1993) taxonomy. Many studies have identified the two distinct offender profiles (Piquero 2008), but research has also revealed other unpredicted categories, including low-level chronics who offend at a low and stable rate across a long period of time and short-term high-rate offenders who start on a life-course-persistent path but then desist and do not show life-course-persistent characteristics by offending in adulthood (Piquero et al. 2010).

Nagin and Odgers (2010) found that four trajectories fitted the CSDD data and that there were important differences between people in each category. Other than a large nondelinquent group, these authors identified a high-rate chronic trajectory which contained the highest proportion of cases with low IQ, poor parenting, high risk taking, and parental criminality, and a low-rate chronic trajectory with fewer cases of low IQ, poor parenting, high risk taking, and parental criminality. Those in the adolescence-limited trajectory began engaging in delinquency later and ended their delinquency earlier than participants in the two chronic trajectories. A key issue is whether these trajectories differ in degree or in kind. The number of trajectories identified will be dependent on the type and size of the sample, the statistical techniques used, and the length of the follow-up period (Farrington et al. 2013).

Risk Factors for Early Onset

A number of studies have found a relationship between poor neuropsychological development and early onset life-course-persistent criminal behavior (e.g., Nagin et al. 1995; Piquero 2001). Neuropsychological deficits include delayed cognitive and motor development and poor verbal comprehension and expression. Children with neuropsychological problems are often difficult to bring up, and their parents may be those who are least able to manage a difficult child. These vulnerable children are disproportionally born into unfavorable conditions because the characteristics of parents and children, such as cognitive abilities, temperament, and personality, tend to be correlated and to some extent inherited (Moffitt 1994, p. 19). The consequences of negative interactions between the child and the parent may reinforce the problem. The impact of biological or social risk factors is likely to be affected by preexisting vulnerabilities and the timing and additive or interactional effects of other factors. Vulnerability to neuropsychological problems is probably caused by such factors as heritability, low birth weight, early brain injury, and birth complications (Piquero 2001).

Early results from the Dunedin study in New Zealand showed that young boys with both low neuropsychological test scores and adverse home environments had aggression scores more than four times greater than those of boys with only neuropsychological problems or only adverse homes. Children with poor self-control and aggressive behavior often experience rejection by adults and peers and consequently do not learn prosocial behaviors. In turn, poor socialization can cause problems at school and can result in truancy and school exclusion so that opportunities to learn basic academic and social skills are lost, and these skills become increasingly difficult to attain.

There have been very few systematic comparisons of risk factors for early versus later onset. Most research on onset compares persons who have an early onset with those who do not have an early onset (including non-offenders). Therefore, the results may reflect differences between offenders and non-offenders rather than differences between early and later onset offenders. In the CSDD, Farrington and Hawkins (1991) compared childhood risk factors for early onset (first convicted at ages 10–13) with later adolescent onset (first convicted at ages 14–20). They found that early onset was most strongly predicted by boys rarely spending leisure time with their father, high troublesomeness, authoritarian parents, and psychomotor impulsivity.

Some researchers have suggested that early onset is a behavioral manifestation of a high criminal propensity rather than a unique offender category or, in other words, that differences in onset are quantitative and continuous rather than qualitative and discontinuous. Gottfredson and Hirschi (1990) argued that the early onset of antisocial behavior was attributable to the underlying construct of low self-control that was established early in childhood because of inadequate parental management and poor socialization. They further proposed that the ordering of individuals on this trait of low self-control was stable over time and that those with the lowest levels of self-control tended to have the earliest ages of onset and high amounts of versatile criminal activity, and they desisted later than individuals with higher levels of self-control. Low self-control influences an individual's ability to delay gratification and causes criminal acts, antisocial behaviors such as promiscuous sex and alcohol and drug abuse, and substantial versatility in criminal and antisocial behavior in a range of situations and opportunities.

Risk Factors for Adolescent Onset

In contrast to those offenders who have an early onset, there is a much larger group who only offend as adolescents over a relatively short period of time. Unlike LCP offenders, these AL offenders are not handicapped by neuropsychological deficits, family problems, or socially disadvantaged backgrounds. In contrast, AL offending is often a response to changes experienced in adolescence, such as physical changes around puberty and the increasing influence of peers rather than parents. Terrie Moffitt (1993) suggested that AL offenders began offending because of a perceived "maturity gap": their inability to achieve adult goals legitimately because of their age. Delinquent acts that symbolize adult social status are common, including smoking, drinking alcohol, drug use, and promiscuous sexual behavior, demonstrating that they have left childhood behind.

Most criminal careers of AL offenders are short-lived, ending in early adulthood.

Because they have healthy neuropsychological and social development, AL offenders retain the social and academic skills to live a conventional life unless they suffer "snares," such as early disengagement from social institutions such as school and family and involvement with the criminal justice system. Breaking away from parents may occur sooner rather than later for some children, who may choose to engage with delinquent peers because of family conflict or breakdown.

Risk Factors for Adult Onset

Adult onset offenders often constitute approximately half of all adult offenders in longitudinal official data (Eggleston and Laub 2002; Zara and Farrington 2009). Terrie Moffitt (1993) denied that there were any true adult onset offenders; she thought that these offenders had previously offended but had not been caught. McGee and Farrington (2010), using data from the CSDD, found that all adult onset offenders (with a first conviction at age 21 or later) had self-reported some previous offending in childhood and adolescence, but generally for minor types of offenses with relatively low conviction rates. They concluded that about one-third of adult onset offenders were "true" self-reported delinquents who could have been convicted because of the frequency and seriousness of their offending. The adult onset offenders were disproportionally likely to commit sex offenses, theft from work, vandalism, and fraud.

It has been suggested that adult onset offending may be caused by changes in adult circumstances such as the loss of a job or a relationship or, in other words, the reduction in bonding to society (Sampson and Laub 2005). Some researchers have found that adult onset offenders are more likely than others to have mental illness (Elander et al. 2000), and findings from the CSDD suggest that these individuals are nervous, withdrawn, and had few friends in childhood (Zara and Farrington 2009). Possibly, their inhibition, nervousness, and lack of peer influence in the teenage years protected them from teenage offending but not from adult offending. Zara and Farrington (2006) systematically compared risk factors for adult onset (first convicted at age 21 or later) and earlier onset (first convicted at ages 10–20). The adult onset offenders were more nervous, less daring, and less troublesome in childhood (ages 8–10), less likely to have early sex by age 14, and less likely to truant at ages 12–14. The adult onset offenders were similar to non-offenders in their self-reported delinquency at age 14 and much less delinquent than the earlier onset offenders.

Theories of the Onset of Offending

Not surprisingly, the major theories that try to explain why people start offending, sequences of onsets, and the relation between onset and duration are the developmental and life-course theories. The important theory of Terrie Moffitt (1993) has already been discussed in some detail. Unlike Moffitt, Thornberry and Krohn (2005) did not propose that there were types of offenders, but they did suggest that different factors influenced onset at different ages. At the earliest ages (birth to 6), the most important factors were neuropsychological deficit and difficult temperament (e.g., impulsiveness, negative emotionality, fearlessness, poor emotion regulation), parenting deficits (e.g., poor monitoring, low affective ties, inconsistent discipline, physical punishment), and structural adversity (e.g., poverty, unemployment, welfare dependency, disorganized neighborhood). They also suggested that structural adversity might cause poor parenting.

According to Thornberry and Krohn, neuropsychological deficits are less important for children who start antisocial behavior at older ages. At ages 6–12, neighborhood and family factors are particularly salient, while at ages 12–18, school and peer factors predominate. Thornberry and Krohn also suggested that deviant opportunities, gangs, and deviant social networks were important for onset at ages 12–18. They proposed that late starters (ages 18–25) had cognitive deficits such as low intelligence and poor school performance but that they were protected ("cocooned") from antisocial behavior at earlier ages by a supportive family and school environment. At ages 18–25, when they became more independent, they found it hard to make a successful transition to adult roles such as employment and marriage. The theory did not postulate a single key construct underlying offending but suggested that children who started early tended to continue because of the persistence of neuropsychological and parenting deficits and structural adversity. Interestingly, Thornberry and Krohn (2005) predicted that late starters (ages 18–25) would show more continuity over time than earlier starters (ages 12–18) because the late starters had more cognitive deficits.

The key construct in Sampson and Laub's (2005) theory is age-graded informal social control, which means the strength of bonding to family, peers, schools, and later adult social institutions such as marriages and jobs. Sampson and Laub primarily aimed to explain why people did not commit offenses on the assumption that why people want to offend is unproblematic (presumably caused by hedonistic desires) and that offending is inhibited by the strength of bonding to society. The strength of bonding depended on attachments to parents, schools, delinquent friends, and delinquent siblings, and also on parental socialization processes such as discipline and supervision. Structural background variables (e.g., social class, ethnicity, large family size, criminal parents, disrupted families) and individual difference factors (e.g., low intelligence, difficult temperament, early conduct disorder) had indirect effects on offending through their effects on informal social control (attachment and socialization processes).

Sampson and Laub were concerned with the whole life course. They emphasized change over time rather than consistency and the poor ability of early childhood risk factors to predict later life outcomes. They assumed that early and later onset (and other criminal career features) depended on the strength of bonding. They focused on the importance of later life events (adult turning points), such as joining the military, getting a stable job, and getting married, in fostering desistance and "knifing off" the past from the present. Because of their emphasis on change and unpredictability, they denied the importance of types of offenders such as "life-course persisters."

The integrated cognitive antisocial potential (ICAP) theory of Farrington (2005) is mainly intended to explain offending by lower class males. No distinct types of offenders are proposed. The key construct underlying antisocial behavior is antisocial potential (AP), and there is continuity in offending and antisocial behavior over time because of consistency in the relative ordering of people on AP. Therefore, early and later onset and the relation between early onset and later criminal careers depend on levels of AP.

Long-term and short-term influences on AP are explicitly distinguished. Long-term factors encouraging offending include impulsiveness, strain, and antisocial models, while short-term (immediate situational) influences include opportunities and victims. Long-term factors inhibiting offending include attachment and socialization (based on social learning) and life events such as getting married or moving house. The theory explicitly aims to explain both the development of offending and the commission of offenses. Situational factors, motives, and cognitive (thinking and decision-making) processes are included. The theory also assumes that the consequences of offending have labeling, deterrent, or learning effects on AP.

Prevention Programs to Reduce Onset

It is particularly important to prevent the early onset of offending, since this tends to lead to LCP offending. The most effective programs are those that target key risk factors such as poor parenting, high impulsiveness, poor social skills, or school failure (Farrington and Welsh 2007). These programs include general parent education in the home, parent management training, child skills training, and preschool intellectual enrichment programs. However, evaluators have generally reported effects only on offending, not on specific features of criminal careers such as the age of onset or the duration of offending.

The best-known home-visiting program is the Nurse Family Partnership program of Olds et al. (1998). This was evaluated in a randomized trial of 400 women considered to be at high risk, such as teenage mothers, unmarried women, and those living in poverty. The results showed that the prenatal and postnatal home visits caused a significant decrease in recorded child physical abuse and neglect during the first 2 years of life, especially for those mothers who were at high risk; 4 % of visited versus 19 % of non-visited mothers at risk were guilty of child abuse or neglect. This is was an important finding, because those children who are physically abused or neglected are more likely to become violent offenders later in life. The children of visited mothers were less likely to offend later in life than the children of non-visited mothers.

A systematic review carried out by Piquero et al. (2009) concluded that early family or parent training is an effective intervention for reducing behavior problems among young children. For example, Scott et al. (2001) evaluated the "Incredible Years" program in London with 140 children aged 3–8 referred for antisocial behavior, and Gardner et al. (2006) evaluated this program in Oxfordshire with 70 children aged 2–9 referred for conduct problems. This type of research on parent training shows that it leads to improvements in child disruptive behaviors and reductions in delinquency.

In Montreal, Tremblay et al. (1995) evaluated a program that combined child skills training and parent training. Over 300 aggressive or hyperactive boys were randomly allocated at age 6 either to receive the program or not. The program reduced early offending. By age 12, the experimental boys committed less burglary and theft, were less likely to get drunk, and were less likely to be involved in fights than the controls (according to self-reports). At every age from 10 to 15, the experimental boys had lower self-reported delinquency scores than the control boys.

Preschool programs, focusing on intellectual stimulation and increasing thinking and reasoning abilities in order to increase later school achievement, have also been successful. The most famous program is the Perry project which was originally evaluated with 123 disadvantaged African American children aged 3–4. This led to reduced arrests up to age 19, and the benefits continued throughout life. A follow-up at age 40 showed that the experimental participants had significantly fewer lifetime arrests for violent crimes, property crimes, and drug crimes (Schweinhart et al. 2005). Improvements were also found in graduation from school, employment records, and annual incomes for those in the program group compared to the controls. At age 40, a benefit-cost analysis showed that the Perry project produced $17 of benefit per $1 of cost, with 76 % of this benefit being returned to the general public in the form of savings in crime, education, and welfare and increased tax revenue, and 24 % of the benefits accruing to the experimental participant.

Conclusions

The age of onset of offending is earlier in self-reports (about 10–12) than in official records (about 14–15). Because the age-crime curve is higher and wider for males and African Americans than for females and Caucasians, proportionally fewer females and Caucasians have an early onset of offending. Generally, shoplifting and vandalism have an early onset, while violence, fraud, and sex offenses have a later onset. The aggregate age-crime curve conceals different trajectories and developmental pathways. An early age of onset predicts a long criminal career, and the most famous theory (by Moffitt) that is relevant to onset distinguishes between adolescence-limited and life-course-persistent offenders. Risk factors for early onset are similar to risk factors for offending in general (and especially for serious or persistent offending), but risk factors for later adult onset are very different. There are a number of effective prevention programs, but their specific impact on ages of onset (as opposed to offending in general) is not known. Knowledge and theories about onset should be very useful in developing programs to prevent or delay onset.

Optimizing Longitudinal Studies in Offending

Magda Stouthamer-Loeber
Department of Psychiatry, Medical School,
University of Pittsburgh, Pittsburgh, PA, USA

Overview

Three aspects of potential future longitudinal studies will be discussed: (1) good practices for the execution of a study and the changes that have taken place over time; (2) opportunities to enrich the field of enquiry, thereby enabling new questions to be addressed; and (3) optimizing the use of a data set, the collection of which most likely has been very expensive.

Introduction

Longitudinal studies, with their repeated measurements spanning decades, by their nature are very expensive and should be used only for those research questions that require the study of within-individual changes over time. Thus, they should only be used when a developmental approach to offending will yield information for questions that cannot be answered by cross-sectional studies. Two topics will be discussed: the execution of longitudinal studies and increasing the yield of these studies.

Execution of Longitudinal Studies

One of the problems in executing longitudinal studies is that generally the management skills and practical experience needed to conduct such studies are rarely taught during graduate training in universities and need to be acquired by researchers by mentors or through books (Stouthamer-Loeber and van Kammen 1995). Moreover, information on how to run such studies is rarely found in articles published in scientific journals. Although we can now learn from a fair number of longitudinal studies dealing with antisocial and delinquent behavior (summarized in Loeber et al. 2008, p. 20; Killias et al. 2012), it is of great help to have a mentor who has hands-on experience and can help prevent errors.

Investigators need to be involved in all matters of data collection and management and not count on staff to run a study for them. Before researchers can withdraw behind their desks to write papers, they have to be entirely assured that the data are as good as they can possibly be. Involvement in the daily running of a study is not a distraction, but a necessity.

The optimization of the execution of a longitudinal study starts in the planning phase. Running a longitudinal study is not something one can start to think about when the grant has been awarded. The aims, budget, and plans for data collection need to be coherent. Questions that need to be answered ahead of time are the following: Can the aims be measured by the proposed data collection? Is the data collection designed to capture developmental changes? Is the sample large enough and the sample acquisition realistic? Is the timeline realistic? What efforts will be made to continue to follow up the sample? And does the budget fit all the tasks to be accomplished? Also, thought needs to be given to how the potential study results may have a social impact. Although it may be necessary to make adjustments after the project has been funded due to budget cuts, the basic framework should have been worked out in detail. This makes it also easier to discuss with a granting agency the effects of a cut and possibly argue for a lesser cut.

Longitudinal studies have changed in method of data collection and storage. In addition, issues of consent and confidentiality as well as research conditions have changed as well.

Method of Data Collection. One of the questions confronting the researcher early on is whether to contract out the sample selection and data collection or whether to keep these tasks "in-house." There are pros and cons for either decision. If the research team has no specialized knowledge of sample selection and data collection, it may be easier to use a survey organization. Also, if data collection needs to take place across the country, it may make sense to use an existing network of interviewers affiliated with a survey organization. In addition, some researchers may not have the inclination or the time to be involved in data collection and prefer to receive the data "ready-made." There are also several arguments that can be made against the use of a survey organization. First, the expense is generally larger than for in-house data collection. More important, however, is that the researchers do not have direct control over the number of contact attempts with potential participants and the quality and completeness of the data and how the participants have been treated. Survey organizations generally do their own quality control which leaves the researchers to take the quality of the final product on faith. It would be better if researchers would take some of the quality control in their own hands to ensure that the product they receive is as good as it should be. It is not wise to be just a passive recipient of a data set.

If data collection is done in-house, the greatest care should be taken in the selection and training of interviewers. Apart from finding the right persons, it is very important to be up-to-date on the current hiring and firing regulations. These regulations change from time to time and a lot of unpleasantness can be encountered by not being informed. Once the staff is on board, training needs to take place. It is advisable to have an actual written training manual which includes job responsibilities, expectations, contact with participants, and training materials for data collection. A written manual is a help for the interviewers who can consult it to refresh some information. It is also important if interviewers are trained in batches to have the same training materials. In addition, a manual can serve the purpose of evidence that rules and regulations have been laid out.

Before interviewers are allowed to do “real” interviews, they need to be thoroughly familiar with the procedures and the interview. None of the interviews done with participants should ever be used as practice or training interviews. A study is only worthwhile if the data are as close to perfect as possible. There are enough circumstances (over which a researcher has little control) that influence the quality of the data, but not enough interviewer preparation should not be one of them. Although this description generally deals with data collection by interviewing participants, similar procedures can be developed for staffs who collect and code existing data.

Once interviewers have been trained, it is helpful to have a system in place that provides the supervisor with information about quality and quantity of work done by each interviewer. This should also include information about search and contact efforts as well as address changes which can be used in the next assessment phase. If necessary, retraining can take place where procedures need to be clarified. Also errors can often be fixed if noticed early enough but not at the stage when the researcher requires the data for analyses. The information can also be used to give staff members positive feedback and even problems can be turned into learning opportunities. It is useful for interviewers to know that all aspects of their work are important enough for the researchers to be informed about on an ongoing basis. Databases should be created in which the relevant information is deposited so that reports can be created on a regular basis rather than ad hoc when one feels something is not going right.

If interviewers are working in the field, it is a good idea to have a weekly session with their supervisor. During that session, completed materials can be handed in or downloaded and problems can be discussed, including errors that still can be fixed. The supervisor can brainstorm with the interviewer about search strategies for difficult to find participants and how to deal with reluctant participants. It may be useful to convene all interviewers to share solutions to particular problems and to learn from each other’s techniques.

Various changes have taken place over the past years in the form and content of data collection. Data collection has largely moved away from unstructured interviews which required extensive training and coding afterward to interviewing with structured answer formats. The advantage of the latter method is that the questions are more likely to be asked in a uniform manner of each participant and that there is less coding to be done after the interview is completed.

Other changes have to do with the recording of the interview. Most surveys now use electronic data collection, avoiding data entry (Groves et al. 2009). An additional change has been that most studies now use multiple rather than single informants to ensure a more complete picture of the participant and his/her environment. The frequency of repeated measures has increased, and studies are continuing to cover longer periods of time, allowing a larger portion of development of offending to be studied and to move from studying persistence to also taking into account desistance. In these studies desistance from offending can be better estimated if the time window for desistance is sufficiently large to measure stable desistance. These studies also allow for the detection of cases with a late onset.

Although face-to-face interviewing will always have the advantage of ensuring a person’s identity, the ease and the reduction in cost of web-based data collection will increase over time when more people have access to online electronic devices (e.g., Celio et al. 2011; Gosling et al. 2004). Such devices do not necessarily have to be a computer but may be a phone as long as it can connect to a survey program which can provide the questions and can store the data. Various devices may also collect motion or sleep data or can alert the participant to provide some specific information (Anokwa et al. 2009). Web-based data collection makes it easier for participants to continue to participate in a study from practically all over the world. However, web-assisted interviewing still has at least three problems: getting the participant to do it, completing the survey in a confidential manner, and ascertaining the identity of the participant. Thus, face-to-face interviewing, even though it is costly, may still be the most certain way of collecting data.

Data Management. The term "audit worthiness" stands for how well data are handled, cleaned, and analyzed (Freeland and Carney 1992). Errors that may be found in an audit may not be evidence of intentional deception, but more likely the result of carelessness and/or lack of documentation. Any error reduces the usefulness of the data set, and proper data management is of the utmost importance (Stouthamer-Loeber 1993). Magnusson and Bergman (1990) lay out a set of standards on how to manage data.

With regard to data storage, we have gone from mainframe storage with backup tapes that seem to go out of date continuously to in-office servers or just desktop computers. Further changes in data storage are likely to take place. Cloud storage and computing will make it possible to use one's desktop computer just as a typing device with all the software and data stored somewhere else (Armbrust et al. 2010). Although security problems still have to be worked out, this may also be a way to make data available to certified users. Sharing data collected in large, expensive longitudinal studies is now often a requirement for obtaining funds in the first place. Cloud computing may be a way to deal with the technical, if not the confidential, end of data sharing.

Confidentiality. Robins (1976) remarked on the change that the informed consent procedures had brought to research in the United Sates. Databases that in the past could have been used to select potential participants became off bounds because prior consent was required. The more recent HIPAA law, enacted in 1996, has further restricted access to health and health-care information. Consent forms are now complicated documents. The consent and confidentiality requirements have become stricter over the years and researchers, at least in the United States, have to go to great length to explain procedures and reasons for data collection and how the data will be kept confidential. The proper execution of obtaining consent cannot be stressed strongly enough and should covered thoroughly during training. Consent forms are legal documents and no short cuts can be taken. In addition, all staff should sign a statement that assures the confidentiality of the data and identity of the participants.

Research Conditions. The increased use of answering telephone machines and the availability of the caller number has impeded the contacting of participants. Also the extensive use of cell phones makes contacting more difficult since phone numbers are not listed and cell phone numbers tend to change more rapidly than landlines. On the other hand ways of electronic searching for people have multiplied. For instance, many states have extensive databases online of incarcerated individuals. Different search and contact methods are described in Cotter et al. (2002); Haggerty et al. (2007), and Stouthamer-Loeber and van Kammen (1995).

The success of longitudinal studies depends very much on the sustained cooperation of the participants. In order for a participant to cooperate, the participant first needs to be found, contacted, and agree to another round. Although there are well-developed methods of imputation of missing data, they work best for analyzing group data (McCartney et al. 2006). However, longitudinal studies also allow the study of the developmental paths of individual participants over time, and actual data is far to be preferred over imputation. In many studies, the group of most interest (e.g., families of conduct disordered boys) requires the most attempts to find, contact, and interview (see Cotter et al. 2005; Haggerty et al. 2007). Curtailing search and contact attempts does in general yield a biased subject loss. The cost of searching for participants generally rises over time because of moves. Even though most longitudinal studies ask the participants to provide some names, addresses, and telephone numbers of people who would always know their whereabouts, this information is not always helpful because the contacts themselves may have moved or may have lost track of the participant. Therefore, it is important that the budget reflects the costs of extensive searching for participants.

Longitudinal surveys, by their nature, cannot provide extensive feedback to the participants or provide help or treatment. Thus, in general, a participant may not directly benefit from participating. The reason why people do participate in these studies is because they are curious, they are made to feel special, they are civic-minded, and/or they are paid for their time. Further factors that may influence participation are the time it takes to participate, the ease of participation, and their earlier experience in being interviewed. Since longitudinal studies are expensive and the topic of antisocial behavior and crime may be in or out of favor with funding agencies over time, it is not possible to anticipate if funds available for existing or planned longitudinal studies may fluctuate over time.

Optimizing the Content of Longitudinal Studies

Whereas the older longitudinal studies relied solely on official records, later studies also used self-reports. Considering the low proportion of crimes that are caught, the addition of self-reports is crucial. More recent studies also try to include community and socioeconomic data as well as reports of routine activities and situational information surrounding the commission of crime. Some biological information has been collected in the past such as heart rate and skin conductance; however, lately the range of biological information has increased by the collection of data on hormones, DNA, and brain activity (fMRI). The combination of individual, environmental, and biological data will make it possible to endeavor to answer complicated questions about interactions within and between these three data domains.

Content. Expansion in the array of factors included in longitudinal studies has been going on for a number of years. Measures have been developed for routine activities (Wikström 2006; Wortley and Mazzerole (2008)) and for situational circumstances surrounding the commission of antisocial behavior and crime (Wikström 2006). Also, with the enormous amount of demographic information available on the web, community information can be more fine-tuned than it was in the past, and with less effort.

Another development that will take place is that genetic databases will be formed that collect data from different studies to allow for the study of rare factors. This requires careful documentation of design and variables in the individual studies contributing to such a database and a willingness to collaborate.

The study of girls' antisocial behavior and crime is still underdeveloped. The few studies that included girls often have too small a sample to yield enough girls with problems for analyses. Very few studies have a large enough sample to focus on low base-rate behaviors (review Hipwell and Loeber, 2006). The study of girls is particularly important because they will bring up the next generation of children, often without a male in the picture. Thus, their influence on the next generation is considerable. Antisocial girls often have babies early, which may mean that they are not ready for the responsibility of motherhood. In addition, their sexual partners are likely to be antisocial themselves. This leads to the question of transmission of problem behavior across generations.

An area where progress can be made in the future is the measurement of positive outcomes. Currently in many studies the overwhelming focus is on negative outcomes and on negative factors influencing an outcome. Positive factors are often implied from the lack of negative factors. Well-measured positive factors, such as skill development and competence, and outcomes, such as jobs and stable relationships, will be of enormous help in devising treatment plans.

Most current studies have not included information on the procedures involved in moving through the justice system. So far longitudinal studies have mainly relied on official records which generally do not tell how individual cases are dealt with and how long an individual was in what kind of institution and whether treatment was applied. Such information may be very relevant to the rate of re-offending.

Longitudinal data may, in the future, be used in creative ways to look at issues that have not been extensively studied so far. With the large amount of data collected at regular intervals, modeling exercises can be undertaken to examine what the effect certain interventions could have if applied to a population. Assuming a certain level of success of an intervention, the effect on rates of later problems can be estimated. These exercises can be very useful to convince funders and politicians that certain interventions may pay off over time. Better still would be the integration of an intervention study within a survey study, something that David Farrington has advocated (2003). Such a study would have to be planned, taking into account the number of subjects that will have to be "set aside" for intervention. Such a design would make a longitudinal study even more expensive by increasing the N and instituting an intervention for a part of the sample. After the fact, not many longitudinal researchers are willing, or in a position, to reduce their N by allowing an intervention to take place with a random subsample. This would reduce the power of the survey analyses.

One puzzling question that has not yet had much attention is secular changes in the age-crime curve. Even though in general the age-crime curve has a recognizably similar shape, for different age cohorts, there is also variation is the width and/or height of the curve. Some age cohorts may start delinquency earlier and stop later or may have a higher frequency (height of curve) of offending. The variables that influence the width and the height of the curve have not been studied extensively. Information about which factors influence the age-crime curve is of great importance for public policy and for reducing future crime waves. In order to study influences on the age-crime curve, one would need several age cohorts studied over a period of time so that the ages overlap in the course of the study. If substantial differences are found in the age-crime curves of the different cohorts, then the exercise is to see if one can find variables influencing the curves. It is difficult to predict the optimal age interval between the cohorts because potential changes affecting the age-crime curve lie in the future.

Optimizing the Use of Longitudinal Studies

The expense of longitudinal studies, generally funded with tax payers' money, requires serious thought about how to optimize the use of the study.

Collaboration Within Studies. With most studies aspiring to cover many disparate areas such as genetics and environmental influences, future studies will require a team of collaborators with a lead investigator willing and able to commit a large portion of his/her professional life to keeping such a study going and attract collaborators who are experts in specific fields to work with over many years.

Since the academic system values principal investigatorship rather than co-investigatorship, a structure needs to be found that makes it worthwhile to be part of a larger team. One way to do this is to devise substudies each with their own principal investigator and funding. However, such a solution presupposes a stable line of funding for the main study.

Collaboration Across Studies or Study Sites. It is expected that in the future, there will be a better integration of biological and environmental and individual factors. This will probably be accomplished by pooling data from different studies in order to make sure the sample is large enough for small effects to show. Data pooling is often more complicated than it sounds. Presumably "comparable" data may have a slightly different format, or different collection sites may have left some questions out, leading to a cumbersome process of making a combined data set.

The funding agencies are at present the driving force for data pooling and data transfer to agencies set up to deal with data storage and data requests from researchers outside of the original group of investigators. The advantage of wider collaboration, apart from a larger sample size, is that more extensive use is made of the large investment needed for longitudinal studies. The original investigators cannot be experts on all questions that could potentially be examined with the collected data. However, the danger is that regardless of how well the data are documented, "new" researchers may misinterpret the meaning of some variables. It is, therefore, always useful to be in contact with the original investigators. Data sharing provides a challenge for the promise of confidentiality. Even if the most obvious identifiable information is removed from a file, it may still be possible to identify a participant through a combination of variables (called deductive discovery). This puts a participant at risk of being identified and information being misused. In addition, it also puts the original investigators at risk for having to pay a fine for a breach in confidentiality.

In our experience, the safest way of dealing with these confidentiality problems is to have each person wanting to use data write a small proposal that is approved by his/her university and has the appropriate IRB approval, shifting the responsibility of confidentiality to the "new" researcher who was not involved in the original data collection. Since data sharing is now more or less the norm, I expect that procedures for de-identifying data and for certifying that "new" investigators will protect the confidentiality of the data will become standard soon. De-identifying a data set, however, will reduce the number of questions that can be answered after sensitive data has been removed.

Agency Involvement. The size of future studies and the range of variables that should be included may require funding from several agencies. Collaboration between agencies and the acceptance of new thoughts in the field will require that the investigators play a very active role in preparing agencies for the scope of the planned research and for the idea of funding from different agencies. Researchers cannot just wait for a request for proposals to come out that just fits their plans or expect agencies to take the lead role in searching for collaborations with other agencies. Instead, prospective investigators need to work together with agency staff to develop a blueprint for future longitudinal studies and for finding the necessary funding.

Secondary Data Analyses. Secondary data analyses, whether it is by pooling data from different studies or analyzing data from one study for a new purpose, are a great way to increase the yield of the research investment. It is useful, however, to keep a record of secondary research projects so that researchers do not compete with each other on the same topic. That is not to say that it would not be useful to have two different views on the same research question, but researchers should be aware of other projects using the same data bordering on their areas of interest.

In summary, the complex art and science of longitudinal studies continues to be exciting and challenging. New questions can be pursued and new data collection tools spring up regularly.

"Broken windows" policing; Quality-of-life policing

Overview

Order maintenance policing is a police practice that involves managing minor offenses and neighborhood disorders in order to address community problems. Order maintenance policing is influenced by the "broken windows" hypothesis, which describes the process by which minor offenses can lead to citizen fear and the decline of neighborhoods. Order maintenance policing has been credited with crime reduction in cities across the United States, most notably in New York City during the 1990s.

Definition of Order Maintenance Policing

That officers should help to maintain order in communities has always been an expected and desired function of modern police. In the contemporary sense, order maintenance policing (also called "broken windows" policing or "quality-of-life" policing) refers to a police operational tactic that involves managing minor offenses and acts of physical and social disorder. Order maintenance is generally identified as an element of the community-policing paradigm, and as such it is closely associated with problem-oriented policing and situational crime prevention.

The merits of reducing disorder and quality-of-life offenses are self-evident (Wilson and Kelling 2006). In addition, order maintenance policing has been credited with reducing serious crime in many communities. As evidence of its effectiveness grows, more police departments and other criminal justice agencies have integrated its principles into their functions. Yet while order maintenance continues to be popular with citizens and government agencies, it is often not well understood. Order maintenance policing, for example, is often mistakenly labeled as zero-tolerance policing. The association between these terms confuses theoretical discussions and invites misinterpretation over policy and practice.

This entry begins with the origins of order maintenance policing, including a description of its theoretical underpinnings. The article then examines the approach within the context of the community-policing paradigm before turning to applications of order maintenance and evidence of its effectiveness. The entry concludes with current debates and controversies over order maintenance policing efforts.

Origins of Order Maintenance Policing

The "Broken Windows" Influence

Order maintenance policing is highly influenced by the "broken windows" hypothesis. Developed by James Q. Wilson and George Kelling in 1982, "broken windows" describes the process by which minor criminal behaviors and other types of community disorders can lead to the decline of neighborhoods. Wilson and Kelling used the term "broken windows" as a metaphor in the original hypothesis, reflecting the idea that one broken window in a building is the first sign of disorder – left unrepaired, more windows may well become broken as such behavior is overlooked or ignored.

Wilson and Kelling further argued that relatively minor offenses have the potential to generate fear among citizens, causing them to alter their own behavior to avoid confrontation with disorderly actors or conditions. As people alter their behavior to avoid disorderly places, these locations experience less informal social control and produce an atmosphere where acts of disorder appear acceptable. These places are more susceptible to serious crime because offenders will feel more at ease at locations with permissive atmospheres toward disorder and weak informal social control mechanisms.

The disorders that Wilson and Kelling refer to in the original article involve social behaviors (such as prostitution, public alcohol and drug use, public urination and defecation, aggressive panhandling, unruly gangs of youth) and physical conditions (such as vandalism, graffiti, abandoned buildings and vehicles, unkempt vacant lots, trash and litter, discarded drug paraphernalia) (see also Skogan 1990). It is important to note that disorder does not necessarily refer to illegal activities. As described by Wilson and Kelling, disorderly acts also involve behaviors that are "disreputable or obstreperous or unpredictable" (1982: 30) – although perhaps not criminal in the legal sense, these behaviors can inspire fear and apprehension in the eyes of an observer. It is also important to consider that while minor offenses and disorder can potentially impact quality of life in neighborhoods, community decline and serious crime are not inevitable. Different communities possess varying capacities to absorb disorder, and "broken windows" theorists acknowledge that numerous factors contribute to whether certain behaviors or conditions are considered problematic to citizens. For example, the time of day, the type of place (i.e., residential versus commercial versus industrial locations), the previous behaviors of disorderly persons, the condition of the observer, and the amount/accumulation of minor offenses are all factors in terms of the relative impact of disorder on a given community (Kelling and Coles 1996).

The policy implication of the "broken windows" hypothesis is clear: if police and citizens proactively maintain order by managing minor offenses, they can control a source of fear and potentially prevent more serious crime and the deterioration of quality of life in neighborhoods. Thus, “order maintenance” is a viable option for police who must address community problems involving both disorderly offenses and serious criminal activity.

Inspiration from Urban Planning, Social Psychology, and Police Practice

Three major tenets of “broken windows” (and order maintenance policing by extension) include (1) the view that citizens desire a degree of orderliness in communities, (2) the idea that minor disorder can lead to greater disorder, and (3) the belief that police are uniquely situated to support citizens in maintaining order. These three tenets were influenced by a number of works from a variety of disciplines (see Ranasinghe 2012). For example, Jane Jacobs’ *The Death and Life of Great American Cities* (1961) – a classic in the field of urban development – demonstrated the importance of order maintenance in communities by describing how citizens are strong proponents of (and can be great providers of) peace and order in public places. Experiments in social psychology – including the work of Philip Zimbardo (1970) – provided a foundation for the idea that indifference toward minor disorders can potentially lead to more serious forms of disorder. Studies in police practice, especially Egon Bittner’s (1967) seminal study of officers on skid row, demonstrated the distinction between the “law enforcement” and “peacekeeping” roles of police while revealing the police capacity for managing minor offenses in troubled communities.

Perhaps the most important empirical influences on broken windows, however, came from two sources. The first involved observations of police behavior in eight communities conducted by James Q. Wilson in the 1960s (Wilson 1968). These observations revealed three different styles of police departments – the legalistic, the watchman, and the service styles – that influence the performance and discretion of officers. The second involved the results of studies on foot patrol conducted during the 1970s. For example, researchers conducting the Newark Foot Patrol Experiment (Kelling et al. 1981) found that citizens in areas where there was foot patrol felt safer and were generally more satisfied with police services than citizens in areas where there was only motorized patrol. Drawing on these studies, Wilson and Kelling argued that foot patrol officers exercised more discretion and were more proactive in terms of regulating disorderly activities that troubled citizens. This formed the basis of the broken windows hypothesis and the idea that order maintenance performed by police can be of intrinsic value to neighborhoods.

Applications of Order Maintenance Policing

Relationship to Community Policing and Problem-Oriented Policing

Order maintenance policing and its related theory of broken windows are often associated with the origins of the community-policing paradigm. The core elements of community policing, including greater police accountability to citizens, enhanced partnerships with citizens, and proactive problem solving, began to evolve in the late 1970s in response to the failure of police strategies to adequately address urban problems and other community concerns (Kelling and Coles 1996; Kelling and Moore 1988). As foot patrol experiments informed the ideas behind broken windows, Herman Goldstein (1979) argued that the policing tactics of the mid-1900s were overly reactive in nature and focused too specifically on resolving individual incidents rather than broader community problems. To improve policing, Goldstein suggested a more proactive “problem-oriented” approach where police consider single incidents as potential symptoms of larger problems. By identifying and addressing the symptoms, officers can work to prevent future incidents and thus eliminate broader neighborhood concerns.

Since the introduction of Goldstein’s problem-oriented approach, a number of tactics have become associated with proactive activities designed to prevent crime and disorder. These include tactics that are designed to address highly problematic locations (i.e., “hot spots” policing (see Sherman and Weisburd 1995)), high-risk victims (i.e., repeat victimization strategies (see Farrell and Pease 1993)), and high-risk offenders (i.e., “pulling levers” and “ceasefire” efforts (see Kennedy 1998 and Braga et al. 2001)). Additionally, research into situational crime prevention offers police and citizens numerous options for deterring criminal activity and other community concerns (see Clarke and Eck 2005).

Order maintenance tactics can also be viewed within this problem-oriented policing framework. To the extent that community problems are associated with minor disorders and quality-of-life offenses, order maintenance offers a potential means of managing those problems. Moreover, because order maintenance tactics are generally implemented in response to public demand for enhanced police services, they represent a measure of accountability to citizens in support of the general objectives of community policing.

Specific and General Applications

Applications of order maintenance policing have ranged from microlevel initiatives to macrolevel policies. Microlevel initiatives involve programs where police seek to impact specific behaviors at targeted locations. A shopping plaza that is frequently the target of graffiti vandals, a city street that is a common stroll for prostitutes, or a public park where teenagers constantly harass and intimidate passersby could be instances where specific order maintenance interventions are appropriate. Police departments have also implemented order maintenance as a more general, problem-oriented strategy. In these cases, officers are asked to continuously analyze the impact of disorder on their beats and to be proactive in its management.

An example of a microlevel order maintenance intervention occurred in Los Angeles’ MacArthur Park in 2003 (Sousa and Kelling 2010). Over the course of decades, MacArthur Park had deteriorated from a scenic, recreational location to a hot spot for drug dealing, public drug and alcohol use, prostitution, vandalism, and various other forms of public disorder. In 2003, the Los Angeles Police Department (LAPD) began an initiative that combined elements of situational crime prevention with assertive order maintenance. By focusing resources on minor offenses, police were able to restore order to a level where citizens felt less threatened and more comfortable using the park for its intended purposes. MacArthur Park is now largely self-regulating – although LAPD continues to be mindful of the conditions in the park, the legitimate users of the park are able to maintain order on their own without substantial police intervention.

In contrast to a microlevel application, New York City provides perhaps the most well-known example of order maintenance as a macrolevel policy application. In the early 1990s, the New York City Police Department (NYPD) was facing increasing citizen demand for more effective police service as the result of high crime rates and nearly unchecked disorder in public locations and residential neighborhoods. Culturally, NYPD was a department that was generally inattentive to disorder. Officers were often discouraged from enforcing minor offenses because the department considered them to be either too unimportant or too controversial for police intervention.

Order maintenance policing in New York began in 1993 with NYPD Commissioner Ray Kelly and his much publicized efforts to have police manage aggressive “squeegeeing” – a quality-of-life offense that for many New Yorkers had become a symbol of unregulated disorderly behavior. NYPD order maintenance, however, developed further and became more closely associated with Commissioner William Bratton’s administration starting in 1994. Bratton, a strong advocate of the “broken windows” hypothesis and the principles of order maintenance, had success implementing order maintenance tactics while he was the head of the New York City Transit Police in 1990. While with the Transit Police, Bratton asked officers to more assertively manage turnstile jumping, fare evasion, and other low-level misbehavior occurring within the subway system – a tactic that was later associated with a reduction in serious crime and other forms of disorder (Kelling and Coles 1996; Bratton and Knobler 1998). When Bratton became Commissioner of the NYPD several years later, he applied the same principles on a citywide basis: NYPD officers were now encouraged to manage minor offenses and other forms of disorder that were considered problems in New York communities.

Crime in New York City declined dramatically in the 1990s following the implementation of order maintenance policing (Kelling and Coles 1996). New York's crime reduction continues to be the subject of numerous academic and journalistic commentaries. Several theories have been offered for the historic crime drop, including varying demographic patterns, shifts in economic conditions, and changes in drug-use trends – especially those associated with the crack-cocaine epidemic of the late 1980s. Other programs in the city may have played a role as well, including the influence of Business Improvement Districts (BIDs) (agreements between property owners to pool funds to provide security and maintenance for local businesses) and the establishment of the Midtown Community Court in 1993. NYPD also began additional initiatives during Bratton's administration, including the now famous Compstat system – a process that combines managerial accountability with data management and problem-oriented policing. Nevertheless, NYPD's general order maintenance policy is often considered the primary catalyst for crime reduction in New York City during the 1990s.

Order Maintenance Policing: Evidence of Effectiveness

Empirical Evidence

Researchers who study order maintenance policing will often examine the influence of the enforcement of minor offenses (a proxy for order maintenance) on instances of serious crime. One method of doing this involves the use of trend analyses that consider the impact of order maintenance tactics over time. Kelling and Sousa (2001), for example, combined data from the NYPD, the New York City Department of Education, the New York State Department of Labor, and the New York State Department of Health to conclude that order maintenance policing was the most significant factor in New York's crime reduction, suggesting that over 60,000 violent crimes were prevented during the 1990s as a result of the tactic. Corman and Mocan's (2002) time-series analysis of police and economic data also demonstrated the crime prevention benefits of order maintenance in New York, indicating that the policy produced a substantial reduction in motor vehicle theft and robbery from 1990 to 1999. Using California county-level arrest and complaint data from 1989 through 2000, Worrall (2006) found that the enforcement of minor offenses such as disorderly conduct, disturbing the peace, and public drunkenness reduced felonious assaults and burglaries.

Trend studies of order maintenance, however, have not always produced consistent results. For example, although Corman and Mocan (2002) found that order maintenance had a substantial impact on auto theft and robbery, they did not find a similar effect for other crimes such as assault and burglary. Messner et al.'s (2007) cross-sectional time-series analysis of data from New York City generally supports earlier conclusions that order maintenance policing had a significant impact on serious crime during the 1990s, but they also found that drug-use trends were important influences. Rosenfeld et al. (2007) found some crime-reduction value of order maintenance policing in New York using trend data from police, medical, and census sources, but they argue that the impact of the tactic was moderate. Similarly, Berk and MacDonald (2010) used 8 years of time-series data to evaluate the impact of an initiative that involved disorder-management activities by police in Los Angeles' Skid Row. They found that the initiative had a meaningful impact on nuisance, property, and violent crimes in the target area with some beneficial spillover effect into the surrounding areas, but they determined that the effect of the initiative was relatively modest.

Other trend/time-series analyses find few significant crime-reduction benefits of order maintenance policing. Novak et al. (1999) determined that a police initiative focusing on joyriding, loud noise, public alcohol use, and other public nuisance offenses did not reduce robbery or burglary in a community, although they admit that the project was not designed to directly impact those serious crime categories. Similarly, Katz et al. (2001) found that quality-of-life policing initiative in a section of Chandler, Arizona, did not significantly reduce calls for service for serious crime, but it did reduce calls for public morals and physical disorder offenses. Harcourt and Ludwig (2006) found no relationship between order maintenance policing and the crime decline in New York during the 1990s, although subsequent analyses failed to replicate their findings (see Messner et al. 2007).

Besides trend studies, researchers have also employed experimental designs – generally considered to be a more rigorous methodology – to study the impact of order maintenance policing. Braga et al. (1999), for example, utilized a randomized experimental design to examine the impact of a problem-oriented policing strategy at violent crime hot spots in Jersey City, New Jersey. This problem-oriented strategy, which primarily involved targeting minor offenses and forms of physical and social disorder, was successful at reducing crime at the experimental locations with little evidence of displacement. Braga and Bond (2008) used a similar experimental design to assess the effects of policing disorder at hot spots in Lowell, Massachusetts. They found significant reductions in crime in the experimental areas compared to the control areas – a result of the disorder-management strategies employed by the police.

Measuring What Matters

Studies that evaluate the impact of order maintenance policing often face several challenges in terms of measurement. One problem – particularly for trend and time-series analyses – is in the choice of the key independent variable that represents the concept of order maintenance. Researchers will often rely on a variable from agency data that measures the enforcement of minor offenses, such as officially recorded arrests for misdemeanor offenses or citations for minor legal infractions. The difficulty with indicators such as these, however, is that they do not capture the full extent of the idea of order maintenance policing. Enforcing minor offenses involves complicated interactions between officers and citizens and often includes a range of police actions that are much more complex than making arrests or issuing citations. Studies that use these measures as independent variables, therefore, are likely underestimating the extent of order maintenance policing that has been implemented. Many of the trend/time-series studies discussed above, for example, tend to rely on arrest data as a proxy for order maintenance. With only a few exceptions (see, e.g., Kelling and Sousa 2001), authors do not fully explore the limitations of such data.

A second problem with evaluations of order maintenance policing is in the choice of the dependent variable. Researchers generally choose an indicator of serious crime (i.e., felony crime) as the outcome variable because of the link between disorder and serious offenses that is hypothesized by the "broken windows" theory. This choice makes intuitive sense if the objective of the order maintenance initiative is to reduce serious crime. The difficulty, however, is that a reduction in serious crime is not always the primary goal (or even an intended goal) of an order maintenance program – sometimes the objective is to reduce disorder itself. For example, robberies may well have gone down in the New York City subway system as a result of Bratton's order maintenance program, but the initiative was originally implemented to gain control over a chaotic environment (Kelling and Coles 1996). Likewise, the order maintenance activities performed by LAPD in Los Angeles' MacArthur Park were meant to decrease disorder so that all citizens felt comfortable using the park for its intended purposes (Sousa and Kelling 2010).

Studies that fail to consider appropriate outcome variables may miss important indicators of success from order maintenance initiatives.

Thacher (2004) makes this point clear in his discussion of the value of order maintenance policing. Thacher argues that the relationship between order maintenance policing and a reduction in serious crime is *indirect* and therefore the sort of causal connection that is difficult to detect using social science methodologies. He suggests, however, that order maintenance is *directly* related to a reduction in minor offenses. As such, it is more useful for researchers to explore the importance of order maintenance policing at reducing disorder, regardless of its impact on serious offending. To the extent that disorder is itself a problem in communities, order maintenance efforts that target disorder have intrinsic value.

Recent research has indeed been more inclined to consider the impact of order maintenance policing beyond its impact on serious crime. For example, Hinkle and Weisburd (2008) use survey data from Jersey City, New Jersey, to examine the influence of an order maintenance initiative on citizens' fear of crime and perceptions of disorder. Their findings suggest that reductions in disorder can lead to reductions in fear. Interestingly, the authors also found that fear of crime may be enhanced by increased police presence, indicating that police should carefully communicate with citizens while engaging in high-visibility order maintenance activities.

Understanding Order Maintenance Policing

Controversies

Practitioners, policy-makers, and citizens commonly accept order maintenance policing as an option for improving the quality of life in neighborhoods. Within academic circles, however, order maintenance has frequently been the subject of contentious and politically charged debates. Academic criticisms of order maintenance come in various forms. Some critics question the theoretical underpinnings of order maintenance policing. Others question the appropriateness of giving officers the authority to police disorder in communities.

Critics that challenge the theoretical underpinnings of order maintenance often point to the "broken windows" hypothesis and the theorized link between disorder and serious crime. They argue that if a direct causal connection between disorder and serious crime is not strong, then efforts to manage disorder will be futile. Research is inconsistent regarding the direct link between incivilities and crime. Skogan (1990), for example, found a significant relationship between disorder and criminal activity, while analyses by Harcourt (2001) and Sampson and Raudenbush (1999) suggest that a direct link may be weak except for specific crimes like robbery. Taylor (2001) found some evidence that disorder directly leads to crime but indicates that the relationship is relatively weak and that neighborhood factors may be better predictors of criminal activity.

Two responses can be directed at the assertion that a weak direct connection between disorder and serious crime is a challenge to "broken windows" and to order maintenance policing. First, the "broken windows" hypothesis as stated by Wilson and Kelling does not propose a direct connection between disorder and serious crime – the hypothesized connection is indirect, mediated by increases in citizen fear and breakdowns in informal social control mechanisms. This explains why communities with strong informal social control can manage a level of disorder that might otherwise damage communities with weaker control mechanisms. Research that suggests a weak causal connection between disorder and serious crime, therefore, does notnecessarily disprove "broken windows" (see Gault and Silver 2008). Second, as discussed previously, there may be intrinsic value to order maintenance policing even if a strong causal connection between disorder and serious crime cannot be established (Thacher 2004). Disorder is itself a concern in communities, demonstrated by research that consistently shows a relationship between incivilities and citizen fear (see, e.g., Skogan and Maxfield 1981). A relatively weak causal connection between disorder and serious crime, therefore, does not justify the abandonment of order maintenance principles.

A second general concern voiced by critics of order maintenance policing involves the concept of "disorder" and whether it is morally appropriate for police to enforce it. Critics essentially argue that disorder is a vague concept and that one's perception of it is subjective. Police efforts to enforce disorderly behavior may therefore criminalize relatively harmless activities that some citizens consider to be acceptable (see Harcourt 2001). This is particularly a concern if police order maintenance efforts disproportionately impact people who live in poor, urban neighborhoods (see Fagan and Davies 2000). Further, critics often equate order maintenance tactics with the term "zero-tolerance" policing, suggesting that police exercise little discretion in their heavy-handed management of minor offenses (see Greene 1999).

Much of this criticism of order maintenance policing originates from academic and political sources (Sousa and Kelling 2010). These sources often differ ideologically from police administrators in terms of methods by which police should manage problems in communities. For example, although critics have warned about the misuse of order maintenance policing, few have provided empirical evidence of its misuse. Those that claim that order maintenance criminalizes harmless behavior, for instance, usually do not consider the fear-inducing qualities of disorder. Critics who argue that order maintenance practices disproportionately impact citizens living in poor, urban communities often do not consider the demand from those communities for police to deal with incivilities and minor offenses (see Skogan 1990). Finally, those that claim that order maintenance is "zero tolerance" have rarely viewed order maintenance in practice, relying instead on dramatized media accounts and agency data that are limited and often flawed.

Order Maintenance in Practice

Critics of order maintenance appropriately call attention to the moral complexities of policing disorder – and the proper deployment of order maintenance is indeed a concern. In fact, the authors of the original "broken windows" essay warned against the misuse of policies derived from the theory. Wilson and Kelling (1982) indicated, for example, that caution is necessary to ensure the fair balance between individual rights and community interests when managing disorder. Also, proper care must be taken to make certain that police use discretion appropriately when enforcing neighborhood rules and the criminal law. Like many police tools, order maintenance is a tactic that can be abused. (The history of interrogation practices demonstrates how a powerful police technique requires continuous oversight and vigilance.) Yet, like interrogation practices, order maintenance can provide a valuable option to police if properly managed.

Due to the moral complexities of policing disorder, Thacher (2004) suggests that the merits of order maintenance should be examined based on how it is deployed in communities. Some recent research has proceeded along these lines by evaluating citizens' views of order maintenance and by examining the activities of officers who practice it. Weisburd et al. (2011), for example, administered telephone surveys to citizens living in neighborhoods that had received aggressive order maintenance policing. They found that residents were not negatively impacted by police actions at those locations, suggesting that police legitimacy is not harmed by order maintenance activities. Sousa (2010) conducted observations of officers practicing order maintenance policing in New York City. Contrary to critics' claims that order maintenance is the equivalent of zero tolerance, he concluded that officers were aware of the complexities of policing disorder and often used their discretion to informally resolve situations that involved minor offenses. Importantly, the observations revealed that "maintaining order" involved making arrests and writing citations only rarely – officers were much more inclined to warn or verbally reprimand citizens for committing disorderly acts. Order maintenance activities were better categorized as officers "paying attention" to minor offenses (rather than ignoring them) – but where official action (arrest or citation) was only one of several options.

Despite the controversies, the available evidence suggests that order maintenance policing can be implemented fairly and appropriately. As with any police-involved initiative, order maintenance practices are most promising when the community accepts the intended police tactics. Therefore, to lessen controversy, supervision over officers and communication between police and the public concerning quality-of-life policing are an important part of an order maintenance program.

Overview

Institutional theory holds that service organizations within a given field operate according to established, value-based myths. Adherence to the myths legitimizes an organization, while departure from them may spark a legitimation crisis. Police institutional legitimacy depends, in part, upon every organization's continued observance of the symbols and ceremonies that characterize the policing mythology. Importantly, these myths have been substantially decoupled from task performance, such that effectiveness and efficiency of operations are less important than is paying homage to the rituals. This entry presents suggestions for programs, policies, selection and training, and media and public relations. These suggestions are framed using the discourse of police institutional legitimacy. They are contended to be methods by which organizations can enhance task-based legitimacy without blatantly flouting myths and threatening to spark legitimation crises. It is argued that even in a value-laden institutional environment, task performance can be consonant with, if still inferior to, myth and ceremony.

The Institutional Theory of Police Organizations

Institutional theory posits that individual organizations are situated within large networks comprising other, similar organizations, interorganizational relationships, and the social and political landscapes that delineate reigning normative frameworks governing agencies' administrations and operations. The institutional climate is shaped by the socially constructed "solutions" to the (sometimes artificial) problematization of particular societal phenomena. Every organization is subsumed by and must conform to these existing social facts, or it will lose legitimacy and, possibly, perish entirely.

Under institutional theory, organizations must arrange their structures, policies, and personnel strategies to meet one or both of two ultimate ends: survival and performance (Zucker 1987).

The two goals operate in tandem in the best-case scenario, but are not always closely linked in practice (Meyer and Rowan 1977). In the private or business sector, where the free market theoretically rewards high-quality products and efficient resource management (and punishes the opposite), performance determines survival, and only those organizations that are effective and efficient endure long term. In the public sector, however, survival is often an institutional given because the organization boasts state-sanctioned legitimacy and has become a staple feature of the modern US municipal, county, or state jurisdiction (see Crank 2003 for a general discussion). State-sanctioned organizations – unlike their product-oriented business counterparts – provide services rather than readily identifiable goods (Crank 2003). State-sanctioned organizations thus cannot derive institutional legitimacy from the competitive marketplace and must, instead, actively and consistently prove their credibility, worthiness, and necessity.

Police agencies, as state-sanctioned organizations, exist in an institutional environment (see Zucker 1987). Their survival is guaranteed – police have become a fixture in modern American government, and they have no credible competitors – but their performance and legitimacy are not. Legitimacy, in turn, does not flow automatically from task performance. In policing, as in other organizations that navigate institutional environments (Meyer and Rowan 1977), effective and efficient execution of tasks is a matter quite separate from value-laden judgments about the ideal structure, function, and mission of the organization. Police organizations' legitimacy is based not on actual task performance, but on values and on institutional myths.

As explicated by Crank and Langworthy (1992), myths are socially constructed, norm-derived mandates of policing that when present, legitimize the police and, when absent, delegitimize them. Institutional myths include the image of police as crime fighters, the assumption that civil service is preferable to other hiring and evaluation schemes, and that procedural due process ensures fair and impartial outcomes. These value systems all pertain to the "ought" of policing, to the near-total exclusion of the "is"; that is to say, values are decoupled from task performance. The myths are so deeply embedded in society and in the institutional environment that they have taken on "an intrinsic quality of 'truth' or 'rightness'" (1992: 347). They are self-evident and beyond question.

Myths are observed and reinforced through the use of ceremonial rituals. The militaristic uniforms and insignia-bearing patrol cars are important symbols (Manning 1988) conveying to the public that this police agency "*looks like* or *acts like*" (Crank and Langworthy 1992: 347, emphasis in original) the archetypal police organization. The archetype is the product of a diffusion of innovation that produced isomorphism as, over time, police agencies observed the legitimacy enjoyed by successful agencies and consequently adopted their structural and operational arrangements in a process of mimicry. Isomorphism, though, can be coercive – once a standard or modal arrangement exists, nonconforming organizations may acquire a deviant status and be viewed as less competent, irrespective of the actual effectiveness and efficiency of their own model or of that to which they are being unfavorably compared (DiMaggio and Powell 1983). To establish their institutional legitimacy, then, police organizations, executives, and officers must engage in a dramaturgical (Manning 1996) display of visible activities and appearances that reaffirm their status as a "real" police organization.

That the institutional legitimacy of a police organization is predicated less on its performance than on its conformity with expectations imposed by nonexpert constituents poses obstacles for both effectiveness and legitimacy. The archetypal police organization is built upon articles of faith articulated by police leaders, union representatives, politicians, and community leaders who have opined and argued about what, precisely, police should be and do (see Wilson 1968). The result is an institutional mythology that puts police, scholars, and society alike "in the unenviable position of taking the word of those who are presumed to be knowledgeable" (Langworthy 1986: 126).

The decoupling of values from tasks and the superiority of the former over the latter create opportunities for legitimation crises. These crises occur when constituencies with competing value sets clash, and it suddenly becomes unclear just who it is the police are here to serve. Events such as corruption scandals and high-profile instances of excessive force against racial minorities can trigger these crises. The traditional methods for quelling legitimation crises at the organizational level involve the public degradation of the department and the ousting of the existing chief (Crank and Langworthy 1992). A special commission may be convened to issue observations and recommendations that will probably be ignored. The public eventually forgives (or simply forgets) the indiscretion, and the new chief – because he is isomorphic with the disgraced one due to the homogenizing influence of police hiring and promotional practices (see also DiMaggio and Powell 1983) – substantially maintains the status quo. The process of scandal and reform is complete, and time passes until the next scandal erupts.

The purpose of this entry is to propose strategies for enhancing the institutional legitimacy of police using methods that are consistent with both the legitimacy-granting myths of policing and, to the extent possible, with actual task performance. Myths, despite their flaws, must be treated with due deference. Some modern reformers have argued for radical reformation of the administration and operations of police organizations, such as delayerizing, decentralizing, and civilianizing (Maguire 1997). The institutional environment of policing, however, balks at such bold moves. Any department that attempts to alter itself in ways discrepant from institutionalized myths will likely meet the same end as the well-intentioned but ill-fated department described by Crank and Langworthy (1992). The department attempted a wholesale overhaul of its uniforms, rank structure, and even its name. As a consequence, the agency was ostracized and alienated until it finally succumbed to the pressure and reverted to looking and acting like a "real" department. The power of the institutional monolith likely helps explain why even those police organizations that pay homage to community policing have not structurally or functionally reorganized in a manner consistent with the philosophy (Maguire 1997; Mastrofski and Ritti 2000).

It is, therefore, important that the infusion of task-based performance into the extant myth-based environment be a subtle process of shift and subversion rather than a precipitous, highly visible event. The following discussion describes strategies that may be used to enhance the institutional legitimacy of the police in a manner that incorporates a discussion of task performance. "Task" is used broadly here and ranges from crime reduction to public image management; this loose definition recognizes the spectrum of ends that organizations can seek to meet in their efforts to be successful. The section subheadings contain the goal that the proposed strategy is meant to serve. The list of proposals is not by any means exhaustive, but it draws attention to some of the most prominent options for organizational and institutional legitimacy enhancement.

Programs

The existing structure, operations, and policies common across police organizations are not inevitable. They are not tied to or required by larger environmental characteristics (such as the size of the jurisdictional population) or by agency size (Langworthy 1986). Police executives have a choice in the problems they wish to target and in the programs they adopt to meet those goals. That being said, the programs discussed below are deliberately framed as being moderate in scale so as to harmonize with reigning myths and thereby avert legitimation crises. Each proposed program, and the specific problem it is suggested to address, is described below.

Community Policing to Enhance Quality of Life

Community policing arose as a backlash against the detached, forceful, strictly centralized nature of the traditional model. The community model was intended to make policing more democratic by conceptualizing local residents as stakeholders and giving them a voice in police operations. This program is thought to enhance police legitimacy by showing the public that the police are responsive to them. This entry's treatment of the subject balances two perspectives. The first involves the premise that community policing is nothing more than an elaboration of questionable assumptions about the nature of "community," about the relationship between policing and informal social control (Manning 1984), and about the extent to which police can exert actual (as opposed to apparent) control over social behavior (Manning 1988). The second is more pragmatic, if less philosophically coherent, than the first: Community policing is already institutionalized, and its absence is itself a threat to an organization's legitimacy. That being the case, the following discussion focuses on potential strategies and tactics that might lend this program an element of task effectiveness.

Community policing targets those who abide by the law rather than those who break it. One of the program's stated goals is to make police accessible and responsive to the public and to thereby reduce people's fear of crime and enhance their quality of life. The implications of community policing for (task-based) institutional legitimacy emanate from the research showing that community policing can have positive outcomes on people's emotional states, their assessments of their neighborhoods, and their satisfaction with police. Reisig and Parks (2004), for example, found that people who thought that the police worked with their neighborhoods to solve problems and that viewed their neighbors as being willing to work with the police perceived fewer incivilities and felt safer in their areas of residence. Furthermore, perceptions of community policing and coproduction nullified the deleterious impacts of neighborhood disadvantage on perceived incivilities and personal safety. It is worth noting that there was no consideration of the effectiveness of community policing at reducing crime; it was the mere act of visible police involvement that influenced citizens' quality of life. Other studies of community policing have employed various methods and variables and have arrived at mixed conclusions (see Rosenbaum 1994, for a review), likely due, in part, to a lack of uniformity in programs and methodologies.
