Preface

Introduction

When we began our effort to outline and organize the *Encyclopedia of Criminology and Criminal Justice* with our distinguished Associate Editors, we set before ourselves a major task that would be different from that of most other encyclopedias that are produced today in various fields. We looked back in history to find our task. We sought to define the parameters of the discipline of criminology and criminal justice, in the spirit of the encyclopedias first developed in the 18th century. This Encyclopedia would not be a dictionary of the field, but a cutting edge statement of knowledge in the field at this time.

Crime and criminal justice are major dynamic issues in contemporary societies. Every society is confronted with variations in crime rates and has to deal with large groups of crime places, offenders, and victims. Crimes appear in changing images in everyday life and criminal justice agencies have to find solutions for these societal phenomena. This means that the science of criminology is important not just for scientists and scholars who want to develop basic knowledge and understand the causes of crime, but also to policy makers and practitioners. Criminology as a discipline spans both basic and applied research questions, and criminology has been enriched by its ability to both provide scientific knowledge to practice and to raise critical questions about the basic principles and effects of policy and practice. There is an international community of active producers of criminological knowledge in every continent at universities, research institutes, and governmental offices. The globalization of criminological knowledge has increased the dissemination of criminological research and theory to all parts of the world. This Encyclopedia seeks to summarize that broad array of knowledge.

Undergraduate and graduate students in criminology and criminal justice are taught using general text books with brief sections on relevant topics. Further information is explored on the Internet, using Wikipedia texts for additional knowledge or for writing papers. These texts have not been reviewed by scholars in the field. The print and online versions of this Encyclopedia give students, researchers, policy makers, and practitioners direct access to a reliable body of knowledge on topics that have been written by experts in the discipline. Indeed, in this Encyclopedia it is often the originators of theories, practices, or methods that are writing the entries. These entries will give students and scholars efficient and solid insights into the knowledge they need for their courses.

Goals

This *Encyclopedia of Criminology and Criminal Justice* presents the current state of knowledge of this discipline. Like science in general, criminology expanded during the last two centuries, starting with the first geographic studies on the distribution of crime rates until new neurological knowledge of offenders and innovative forensic techniques to detect perpetrators, and to evidence-based treatment programs for serious or frequent offenders or local governmental to private interventions in crime situations. We needed ten volumes with 579 entries to display today's criminology and criminal justice knowledge base. It represents our efforts to provide the reader with current state-of-the-art knowledge in criminology and criminal justice.

The aim of the *Encyclopedia of Criminology and Criminal Justice* is to supply a comprehensive reference tool for the field of criminology and criminal justice that is both cutting edge and of very high scientific quality. This ten volume work provides a complete and systematic coverage of this growing field that is unprecedented, as it is truly international and includes fields related to criminology, such as police science, forensics, and certain areas of psychology. Each entry offers an extended description of the topic, relevant literature, current base of knowledge, and ideas about what needs to be studied in the future. The on-line version will be updated continuously after the first publication serving millions of students, researchers, policy makers, and practitioners of all continents.

Defining the Discipline

The goal of this Encyclopedia is to provide a comprehensive reference work for the field of criminology and criminal justice. We worked hard, meeting multiple times with our Associate Editors, to identify what the critical areas were, and what research existed that we could include in the Encyclopedia. The Encyclopedia in this sense "defines the field" through its choice of organization and entries. We aimed at identifying emerging ideas and trends, so that the work will be timely at publication and afterwards. This Encyclopedia covers the field broadly, and internationally, and attempts to be up to date as to recent developments in research and practice in the field. This Encyclopedia is not a dictionary, nor a kind of Wikipedia without any quality assessment, and aims at comprehensive and cutting edge knowledge that defines the contours of the field of criminology and criminal justice. That is why we included the fast developing new fields of forensics, psychology of law, and investigative psychology. The ten volumes cover the following broad fields of criminology and criminal justice (listed with the Associate Editors responsible):

Corrections and Criminal Justice Supervision in the Community (Doris MacKenzie)
Courts, Sentencing, and the Judicial System (Leslie Sebba)
Police and Law Enforcement (Stephen Mastrofski)
Crimes, Criminals, and Victims (Alex Piquero)

Crime Places and Situations (Cynthia Lum)
Explanations for Criminal Behavior (Sally Simpson)
History of Criminology (all Associate Editors and Editors-in-Chief)
Data, Methods, and Statistics (Arjan Blokland and Dan Nagin)
Social Interventions and Prevention (Gwladys Gilliéron & Martin Killias)
Forensics and Forensic Science Investigative Psychology (Peter Neyroud)
Psychology of Law (Karen Amendola)

Every section defines a number of areas of research (a total of 111), and consequently a number of relevant topics or articles that are included as entries (579). The entries are arranged in alphabetical order. Each entry provides an overview of what is covered, followed by a short list of suggested readings and references. All entries have been reviewed, first by the Area Editors, then by the Associate Editors, and finally by the Editors-in-Chief. Not all of the articles submitted could be accepted into the Encyclopedia, as is the case with other academic work that is reviewed. We very much appreciate the efforts of all of our authors, who have truly produced an important work in criminology and criminal justice.

Acknowledgements

As the reader can imagine, this ten volume *Encyclopedia of Criminology and Criminal Justice* is a work that involves the collaborative efforts of many people. In the 18th century, Dennis Diderot and Jean le Rond d'Alembert published between 1751 and 1772 the first encyclopedia on science with the assistance of hundreds of scholars. It consisted of 28 volumes with 60,000 articles on all imaginable topics of the natural sciences. The editors themselves contributed 6,000 articles. This Encyclopedia is also a joint effort of many people.

When David Weisburd was approached by Springer, he invited Gerben Bruinsma to join him as Editor-in-Chief. We contributed equally to the Encyclopedia, explaining the alphabetical order of our names. We had the magnificent support of a group of 12 Associate Editors, all renowned experts in their fields. They organized their section by defining the areas of research and used their extended professional network to contact the 111 Area Editors. We owe them very much for their efforts: Karen Amendola (Police Foundation), Arjan Blokland (NSCR), Gwladys Gilliéron (Distance Learning University Switzerland, Brig, Switzerland), Martin Killias (KRC Killias Research & Consulting SA), Cynthia Lum (George Mason University), Doris MacKenzie (Penn State University), Stephen Mastrofski (George Mason University), Daniel Nagin (Carnegie Mellon University), Peter Neyroud (Cambridge University), Alex Piquero (The University of Texas at Dallas), Leslie Sebba (The Hebrew University), and Sally Simpson (University of Maryland). We also would like to thank the 111 Area Editors who selected the authors and reviewed the papers in their areas. Their names are listed separately in this Encyclopedia. Lastly, we are grateful to all our authors who contributed with scholarly entries to the Encyclopedia. It is their collective effort and expertise that has made the publication of Springer's *Encyclopedia of Criminology and Criminal Justice* a successful enterprise.

A special word of gratitude is for the staff of the publisher, Springer. Many people have contributed to the Encyclopedia from its inception through its production. We thank them all for their wonderful work. But some Springer staff deserve special mention. Welmoed Spahr, Executive Editor, Social and Behavioral Sciences, and Katie Chabalko, Criminology Editor, supported us from the beginning to the end of the project often going much beyond their obligations to ensure the academic quality of the work. Without Saskia Ellis, the project manager, this project would never have been finished, or at least would not have come out in a timely manner. She was a power house in moving the Encyclopedia along, and worked closely with us in bringing this major project to completion. To the literally hundreds of people who worked on this project we thank you all, and hope that you are very pleased with the scope and quality of Springer's *Encyclopedia of Criminology and Criminal Justice*.

Gerben Bruinsma Netherlands Institute for the Study of Crime and Law Enforcement (NSCR), Amsterdam, The Netherlands

VU University Amsterdam, Amsterdam, The Netherlands

Professor Dr. Gerben Bruinsma is, since 1999, director of the Netherlands Institute for the Study of Crime and Law Enforcement (NSCR) in Amsterdam, a national research institute of the National Organization for Scientific Research (NWO). He is also, since 2009, professor of environmental criminology at VU University Amsterdam. In the past he has held positions as professor of criminology at Twente University and Leiden University. He studied sociology and criminology at Utrecht University and finished his doctoral dissertation *Crime as a Social Process: A Test of the Differential Association Theory in the Version of K-D- Opp* at the Radboud University Nijmegen. In the 1990s he co-founded the International Police Institute at Twente University. He was president of the Dutch Society of Criminology and one of the founding fathers of the European Society of Criminology, editor or editorial board member of various journals, and has held a great number of advisory and board positions in the field of police and criminal justice. In 2009, he received the Freda Adler Distinguished International Scholar Award of the Division of International Criminology of the American Society of Criminology (ASC). He has researched and published on juvenile delinquency, organised crime, spatial distributions of crime, police theory, and methodological issues. He has published more than 100 articles, 30 books, and 60 book chapters. His current interests are geographical, theoretical, and historical criminology.

David Weisburd Department of Criminology, Law and Society, George Mason University, Fairfax, VA, USA

Faculty of Law, The Hebrew University, Mt. Scopus, Jerusalem, Israel

David Weisburd is Distinguished Professor of Criminology, Law and Society at George Mason University (and Director of its Center for Evidence Based Crime Policy) and Walter E. Meyer Professor of Law and Criminal Justice at The Hebrew University, Faculty of Law in Jerusalem. He also serves as Senior Fellow at the Police Foundation in Washington, DC and is Chair of its Research Advisory Committee. Professor Weisburd is an elected Fellow of the American Society of Criminology and of the Academy of Experimental Criminology. He is a member of the Science Advisory Board of the Office of Justice Programs (USA), the Steering Committee of the Campbell Crime and Justice Group, the Harvard Executive Session in Policing, and the Committee on Law and Justice of the National Research Council (National Academy of Sciences, USA). Professor Weisburd is one of the leading international researchers in crime and justice. He is author or editor of more than 20 books and more than 100 scientific articles that cover a wide range of criminal justice research topics, including crime at place, violent crime, white collar crime, policing, illicit markets, criminal justice statistics, and social deviance. Professor Weisburd is editor of the *Journal of Experimental Criminology* and sits on many journal editorial boards, including *Evaluation Review*, the *Journal of Research in Crime and Delinquency*, and the *Journal of Quantitative Criminology*. He is the 2008 recipient of the Joan McCord Award from the Academy of Experimental Criminology, the 2010 recipient of the Stockholm Prize in Criminology, and the 2011 recipient of the Klachky Prize for the Advancement of the Frontiers of Science. In 2011, he was chosen by a committee of the Israeli Academy of the Sciences and Humanities as a recipient of the Minister's Prize for Outstanding Immigrant Scientists.

Principles of effective correctional intervention; Principles of effective intervention; RNR; RNR model; Treatment matching

Overview

The Risk-Need-Responsivity (RNR) model for correctional programming has served as a framework for promoting the use of evidence-based correctional strategies. The RNR framework has three core principles: (1) identify and target the static risk level of the individual, (2) identify the dynamic risk factors (needs) that are associated with offending behavior and that affect psychosocial functioning, and (3) identify appropriate correctional interventions that are suitable to address the risk-need interaction. Adherence to all three of these principles promises a greater impact on recidivism and other individual offender outcomes. This essay provides a brief overview of (1) risk assessment, (2) dynamic offender needs, and (3) responsivity.

The Risk-Need-Responsivity Model

The core components of the RNR Model are:

- **Risk**: Match the intensity of service to the offender's static risk level. Target moderate and higher-risk cases for more intensive treatments and controls. Generally, avoid creating interactions of low-risk cases with higher-risk cases.
- **Need**: Target criminogenic needs (needs that are directly related to recidivism) predominately. Define offender needs both in terms of deficits but also in terms of strengths to improve overall psychosocial functioning.

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

- **General Responsivity**: Employ evidence-based behavioral, social learning, and cognitive-behavioral treatment strategies.
- **Specific Responsivity**: Adapt the style and model of service according to the setting of the service and to relevant characteristics of individual offenders, such as their strengths, motivations, preferences, personality, age, gender, ethnicity, cultural identifications, and other factors.

The RNR framework essentially focuses on reducing recidivism through providing effective interventions that are targeted to the risk and needs of people involved in the justice system. According to the model, the focus of interventions should be on individual-level factors (needs) that directly contribute to criminal behavior. The model also stresses that certain types of interventions are more likely to have recidivism-reducing effects than others. Application of the Risk-Need-Responsivity framework requires that criminal justice agencies (1) use a validated risk assessment instrument to identify static risk and prioritize justice-involved individuals for more intensive services and controls, (2) identify dynamic offender needs (e.g., antisocial cognitions, antisocial peers, and substance abuse) and target rehabilitative interventions to specific offender needs that are related to recidivism, and (3) utilize evidence-based treatment practices grounded in behavioral and cognitive-behavioral models. The model stresses the importance of taking a human services approach to correctional rehabilitation. It is grounded in an extensive empirical literature base that indicates that adherence to the three core principles of the model is related to improved offender outcomes (see Andrews and Bonta 2010 for a review).

Criminal Justice Risk and Risk Assessment

The first ingredient in the Risk-Need-Responsivity model is static risk level. Risk in this context refers specifically to an offender's likelihood of reoffending and is operationalized by indicators of prior criminal involvement. Since the 1920s, there has been a growing awareness of the factors that predict the likelihood of reoffending and the usefulness of these factors in identifying of risk for recidivism. Risk assessment tools are designed to measure the degree to which the individual is likely to have negative outcomes (e.g., more recidivism) during or after experience with the justice system. There are a number of standard risk assessment tools such as the Wisconsin Risk and Need Instrument, the Level of Service Inventory-Revised (LSI-R), the Correctional Offender Management Profiling for Alternative Sanctions (COMPAS), the Ohio Risk Assessment System (ORAS), and a myriad of other tools, some in the public domain and others proprietary. Each of these tools has some standard reference to historical involvement with the justice system (i.e., takes into account criminal history). The use of standardized risk assessment tools is an evidence-based best practice in the field of corrections and is a central component of the Risk-Need-Responsivity framework.

Risk assessment is not a new concept in the field of corrections. The use of interviews and assessments that collect data on individuals and predict how they will do during or after involvement with the justice system has been commonplace within the criminal justice system for nearly 100 years. When reviewing what is known about risk prediction in the justice system, it is typical to trace the development of risk assessments through four generations. The four generations of risk assessment are briefly reviewed here:

- **First Generation**: **Clinical Assessment**. First-generation risk assessments rely solely on professional judgment. Depending on the skill of the interviewer, the nature of the decision being made, and the degree to which the offender is forthcoming in the interview, the clinical interview can generate valid information about an individual's risk to reoffend. But, the interview process has been critiqued due to the potential for bias related to subjective factors (e.g., age, race, gender, and other demographics of the offender) that may affect the decision of the interviewer and/or system. This criticism has led to concerns about introducing systematic bias into the risk assessment process. First-generation clinical assessments are based on criminal justice history (generally referred to arrest history or rap sheet) along with unspecified characteristics of interest of interviewers. The risk of bias in these professional judgments limits their utility for risk prediction. Accordingly, actuarial measures of risk are now preferred over professional judgments and have become fairly standard within justice settings.

- **Second Generation**: **Actuarial Risk Assessments**. The second stage in the development of risk assessment techniques involves an actuarial (or statistical) risk calculation. Beginning with parole hearing officers in the 1920s, there was a growing realization that prior involvement with the justice system can be a strong predictor of future involvement with the justice system (recidivism). Key criminal history risk factors such as number of prior arrests, number of incarcerations, attempts to escape, behavior in the institution, prior probation violations, and age of first arrest have been found over the past 90 years to be consistent predictors of continued involvement in the justice system. Interviewer or system biases regarding the demographic characteristics of the offender are minimized by the actuarial approach to risk assessment. Since the statistical assessment is generally demographically blind – it does not include gender, age, or race factors – it minimizes the potential that justice workers will allow bias regarding these factors to impact decisions. Actuarial risk assessments can also be used to improve resource allocation. Consistent with the risk principle of the RNR model, risk assessment tools can be used to identify an offender's risk level, and higher-risk offenders can be placed in more intensive and more control-oriented correctional programs. This resource allocation model represents a practical use of the risk assessment tool and makes up a central component of the RNR model. Risk assessment can have an impact on recidivism through the use of assessment tools to assign higher-risk offenders to more intensive programming.
- **Third Generation**: **Actuarial Risk and Dynamic Risk** (**Needs**). The third generation of risk assessment tools added in dynamic risk factors to improve the alignment between correctional programming and offender needs. Dynamic risk factors are offender characteristics that are amenable to change. In the Risk-Need-Responsivity model, when dynamic risk factors are directly related to recidivism, they are labeled "criminogenic needs." Beginning with the Wisconsin Risk and Needs Assessment Tool, this third generation of risk assessment instruments added needs or psychosocial factors into the equation of risk assessment. Dynamic risk factors may include antisocial attitudes and orientation, employment, substance abuse, living arrangements, mental health status, leisure time activities, associations with criminal peers, and other areas that have a hypothesized correlation with offending. Third-generation risk assessment instruments have two means by which to assess outcomes: historical risk factors (static risk) and dynamic offender needs (dynamic risk). By including dynamic factors in the risk assessment equation, third-generation tools are better equipped to identify targets (treatment needs) for correctional programming. Identifying dynamic needs is an essential component of both the need and responsivity principles of the RNR model.
- **Fourth Generation**: **Case Management Through Risk and Need Assessment**. Fourth-generation risk and need assessment tools are an extension of third-generation tools with a focus on treatment matching/ case management. In these instruments, risk and need factors are used to identify appropriate services (treatments and controls) to reduce the risk of recidivism. These tools focus on addressing offender needs by creating service matching algorithms based on the risk and need profile of the offender. Fourth-generation tools are designed to improve the quality of assessments and to make them more applicable to offender case management and resource allocation by identifying individual-specific behavioral targets for intervention. Fourth-generation tools identify specific offender needs and making treatment placement recommendations.

The use of a validated risk-need assessment is an essential piece of the Risk-Need-Responsivity framework. Identifying static risk is the first step in applying the framework and should occur as early as possible after an offender comes in contact with the justice system. Static risk is generally the strongest predictor of recidivism; however, this construct is limited from a case management perspective because it does not identify factors that are amenable to change. While second-generation risk assessment instruments are sufficient for identifying static risk and subsequently predicting recidivism, they fail to consider dynamic offender needs that can be addressed through programming. Accordingly, the use of a third- or fourth-generation risk and need assessment is recommended by the RNR model.

Dynamic Risk and Criminogenic Needs

In the Risk-Need-Responsivity framework, there is recognition that an individual's current situation – dynamic factors – also influences his or her involvement in criminal behavior. For the most part, these factors, such as substance abuse, mental health, employment retention, pro-social values, friends and families, and criminal thinking, are amenable to change. Because these dynamic factors are amenable to change, they are identified by the model as the targets for rehabilitative correctional interventions. The questions are: which of these needs are criminogenic (needs that are directly related to offending behavior and recidivism), and which are more related to psychosocial functioning as opposed to future offending? Criminogenic needs have a direct link to recidivism, whereas other types of psychosocial functioning needs have an indirect link. The need principle of the RNR model stresses the importance of triaging dynamic offender needs to focus correctional rehabilitation on those needs that are most directly related to recidivism. This process in intended to save resources by focusing interventions on the treatable characteristics of the offender that have an impact on recidivism and can be changed through programming.

The Risk-Need-Responsivity model identifies eight key dynamic needs: history of antisocial behavior, antisocial personality pattern, antisocial attitudes/thinking, antisocial associates, family/marital problems, low levels of education or financial achievement, lack of pro-social leisure activities, and substance abuse. These factors are labeled as the "Central Eight" dynamic risk factors for continued involvement in offending behaviors. The first four needs – history of antisocial behavior, antisocial attitudes, antisocial peers, and criminal personality – are considered to be more predictive of recidivism outcomes than the remaining factors. These four "criminogenic" needs have been labeled as the "Big Four" by the creators of the RNR model. According to the model, these are the dynamic factors that should be the primary target of correctional treatments and interventions. The need principle of the RNR model stresses the importance of using screening and assessment instruments to identify dynamic offender needs to prioritize targets for correctional treatment and interventions.

The following discussion briefly describes each dynamic need included in the RNR model as well as a discussion of a few other key dynamic risk factors that were omitted from the model in its original statement. The goal is to distinguish between criminogenic and non-criminogenic needs, both important facets in a human service-driven model of recidivism reduction. This discussion extends the RNR model beyond its original conceptualization and takes into account empirical evidence regarding the link between dynamic risk factors and recidivism outcomes.

Substance Abuse. The RNR framework identifies substance abuse as a dynamic, but not "Big Four," criminogenic need. The framework generally neglects the fact that there are different types of drug users, and the linkage to criminal conduct varies considerably by substance use disorder problem severity and by drug of choice. Some substance abuse behaviors drive criminal behavior while other use behaviors have negligible or no impact on offending behavior. Most criminal justice risk assessments include substance abuse related questions but fail to distinguish between substance abuse and dependency.

For example, in the Wisconsin Risk-Need Instrument and the Level of Service Inventory-Revised (LSI-R) (among others), the substance abuse questions generally ask whether the individual has ever had a problem with substance abuse. In the Ohio Risk Assessment System (ORAS), substance use is measured with items that reflect lifetime use, longest period of abstinence, and employment-related problems stemming from drug use. All of these assessments are limited in their capacity to identify current substance use disorders and current substance use treatment needs.

Validated substance use screening and assessment tools, such as the Addiction Severity Index, the TCU Drug Screen, and others, tend to garner a better understanding of the offender's pattern of drug use and misuse. These instruments include more detailed information about lifetime use of drugs, drug of choice, mode of delivery (e.g., smoking, injection), longest periods of abstinence, and whether drug use affects employment or is related to legal problems. In general, the risk-need screening instruments used in the justice system tend to cast a large net to describe an array of substance use behaviors, some of which are pertinent to recent use and predicting recidivism, some of which are not.

The drug use and crime relationship (the drug-crime nexus) is complicated. In general, empirical research suggests that there is a link between drug use and offending. The strength of this relationship is conditioned by both the type of drugs being used and the severity of the substance use disorder. Because of this varying relationship between drug use and offending, it is important to consider both drug of choice and clinical diagnosis/level of treatment need when factoring substance use into the Risk-Need-Responsivity framework.

The drug-crime nexus theory suggests that involvement in criminal behavior will be disrupted by providing substance abuse treatment in the justice system especially for those users for whom drug use directly affects criminal behavior. The RNR framework does not differentiate on severity of substance use or on drug of choice. A revisited model of RNR would prioritize substance use treatment needs based on substance use disorder (SUD) severity and drug of choice since there are evidence-based interventions available to address this dynamic need. There is a clear link between dependency on hard drugs (e.g., cocaine, opiates, and amphetamines) and offending which makes hard drug dependence a criminogenic need that should be prioritized for treatment in the justice system.

Based on the extant empirical research, the following refinements to the consideration of substance use in a RNR framework are suggested:

1. Some types of drug use do not impact criminal behavior. The literature illustrates that opiates and cocaine use are more likely to influence criminal conduct through the need to acquire money, to participate in the drug trade to support one's own habit, and the decisions made by an individual in the inebriated state. There is increasing evidence that amphetamine use falls into this category as well.
2. Marijuana use does not appear to follow the same trend as other "hard drugs" (i.e., cocaine, opiates, amphetamines), and therefore marijuana abuse should not be considered a criminogenic need. Marijuana users with criminal thinking patterns should be prioritized for interventions that can address their antisocial thinking needs rather than their substance use issues.
3. The offense should not drive a determination of a substance abuse treatment need since many offenders are arrested on charges that are not related to substance abuse, and many times substance abuse is a secondary driver of criminal behavior. Additionally, many offenders arrested for drug-related offenses do not have clinical SUDs that necessitate intensive treatments and therefore are unlikely to benefit from substance abuse treatment programs.
4. Offenders should be divided into four categories regarding substance abuse: (a) nonusers, (b) used drugs in the past with current use of soft drugs, (c) used hard drugs within a month of the arrest, and (d) used hard drugs prior to the arrest. This classification is suggested

because most studies and assessment tools examine these issues, but they do not include factors that are used in clinical assessments (such as the DSM-IV). This pattern is also more similar to proposed changes in the DSM-V which focuses on dependence disorders and tolerance to substances.

Antisocial Cognitions/Criminal Thinking. Antisocial cognitions are the means by which people can rationalize their deviant behavior to neutralize or reduce the negative consequences resulting from offending. Typical thinking errors include dominance, entitlement, self-justification, displacing blame, optimistic perceptions of realities, and "victim stance" (e.g., blaming society because they are considered outcasts). Offenders tend to exhibit more of these thinking errors than members of the general population. Criminal thinking or antisocial cognitions are included in many criminological theories including subcultural, anomie, differential association, control, labeling, and self-control theory. More importantly, antisocial cognitions contribute to continued involvement in criminal behavior and are identified as a "Big Four" criminogenic need by the RNR model. These distorted thinking patterns are a primary target of the behavioral and cognitive-behavioral treatment approaches that are recommended under the general responsivity principle of the RNR framework. As a criminogenic need, criminal thinking/antisocial cognitions should be prioritized for treatment during correctional supervision. Over the last two decades, a number of instruments have been developed to measure criminal thinking. These instruments may include the Psychological Inventory of Criminal Thinking Styles (PICTS), the Criminal Sentiments Scale, the Measure of Offender Thinking Styles, the Criminogenic Thinking Profile, and the Criminal Cognitions Scale.

Antisocial Personality Pattern. The RNR framework also identifies an antisocial personality pattern as one of the "Big Four" criminogenic needs. This criminogenic need factor is generally characterized by proneness for adventurous pleasure-seeking behavior, low self-control, and/or aggressiveness. The DSM-IV criteria for an antisocial personality disorder (ASPD) is characterized by a callous disregard for the feelings of others; gross or persistent attitude of irresponsibility; disregard for social norms, rules, or obligations; incapacity to maintain enduring relationships; low tolerance; frustration and use of aggression or violence; incapacity to experience guilt or to profit from experience; or marked proneness to blame others for the behavior that the person exhibits. DSM-IV criteria for ASPD offer one possible operationalization of this antisocial personality criminogenic need factor. As with any personality trait, it is important to recognize that all human beings exhibit some aspect of this but the criminal offender tends to have sustained characteristics. Measures of ASPD are as close to a diagnostic criterion for criminal personality as exists. This conceptualization recognizes that such behaviors are common and that the issue is whether the individual consistently displays the traits.

Another possible indicator of an antisocial personality pattern that has been operationalized is the construct of low self-control. Impulsive and risk taking behavior is a dynamic characteristic often noted among offenders. The general premise is that low self-control does not define criminal behavior; instead it provides a context for criminal acts depending on opportunities and other motivating factors. Low self-control is exhibited by the offender being easily persuaded by situational and environmental factors, and without attachments, there is little to constrain the individual. The Risk-Need-Responsivity framework holds that an antisocial personality pattern is in fact amenable to change and can be addressed through cognitive restructuring interventions (e.g., cognitive-behavioral therapy (CBT)).

Antisocial Associates and Social Supports. Consistent with its grounding in social learning theory, the RNR framework stresses antisocial associates (family and peers) as a criminogenic need. At the same time, the model identifies pro-social family and peers as potential protective factors against continued involvement in offending. Pro-social family relations are important for reducing offending behaviors. Family ties can provide emotional support and facilitate the offender change process. But, histories of family involvement in crime and prior incarcerations are often precursors to learned behaviors regarding criminal behavior and drug use. The role of family in the RNR framework is complex. Having an antisocial family is criminogenic while having a pro-social family is identified as key facilitators of desistence from offending.

Relations with others, including antisocial peers and families, can affect three aspects of future offending involvement. As noted by Huebner and Berg (2011), three mechanisms of family and peer associations (referred to as social ties) may foster desistance are (1) ties with pro-social individuals control offender behavior, (2) ties can provide emotional support, and (3) ties can help offenders facilitate a transformation in identifying from offender to citizen, or reinforce an offender identity. While adult pro-social bonds to family and spouse can serve as a catalyst for desistance, a strong empirical link has been established between associations with antisocial peers and offending. Accordingly, the RNR framework stresses identifying family and friends as either supportive of or detrimental to a crime-free lifestyle and prioritizing antisocial associates as a criminogenic need that needs to be addressed in order to improve the likelihood of desistence from crime and/or drug use.

Employment and Educational Attainment. Offenders tend to have lower educational attainment than the general population including a higher percentage of offenders that do not graduate from high school or receive a General Educational Development (GED) degree. But, not completing high school is not criminogenic in that it does not "cause" a person to commit crimes. Not graduating high school however may affect verbal intelligence or literacy levels, which may affect the ability to obtain employment. Prior research has found that individuals who do not graduate high school are more likely to recidivate than those who do graduate high school. Much of the impact of education on recidivism outcomes may operate through its impact on employment which has generally received more empirical support as a correlate of recidivism outcomes. Because it is not directly related to recidivism, education is considered a non-criminogenic dynamic need that requires less treatment attention than criminogenic needs.

Offenders tend to have lower steady employment than non-justice-involved individuals. Again, employment-related issues are not criminogenic given that there is no causal linkage between employment and recidivism. But, employment has an indirect relationship with recidivism and therefore may be targeted through correctional programming when other more direct needs are not present. Employment after release from prison is shown to foster better outcomes, but the overall pattern is unclear regarding the relationship between employment and recidivism. Further research is needed to (1) clarify the mechanisms through which employment and education affect recidivism outcomes and (2) clarify the recidivism reduction potential of educational and employment-related treatment programs.

Mental Health Status. Mental health functioning is a complex need given the prevalence and diversity of mental health conditions in the justice system and their varying impact on offender functioning. Despite the high prevalence of mental health and co-occurring disorders (CODs) in the justice system, few empirical studies have found that the presence of a mental health condition is a direct predictor of criminal conduct. While it does not appear that mental health status is directly related to recidivism, mental health conditions may negatively impact the performance of offenders in programming and can increase risk for technical violations related to failure to complete mandated treatment. While there is no direct link between mental health issues and recidivism, failure to provide mental health services to those with mental illness can negatively impact the outcomes of offenders and lead to increased recidivism rates.

Housing. Housing is another dynamic offender need that warrants consideration in the RNR framework. Although housing status does not directly predict recidivism outcomes, instability in housing indirectly affects outcomes because it impacts the overall stability of the offender in the community. While the relationship between housing stability and recidivism remains empirically unclear, addressing housing issues can provide stability in an offender's life and potentially have an indirect impact on recidivism outcomes. Addressing housing needs may also improve offender performance on community supervision and within community-based treatment. Like other non-criminogenic needs, housing is treated as a tertiary dynamic risk factor within the RNR framework.

Risk of Recidivism and Location. A number of recent research studies have emphasized the importance of examining the influence of both individual and community risk factors. There is much more research available about individual risk factors than about community-level risk factors that can be directly linked to recidivism. This paucity of empirical research on the community context of recidivism is a major impediment to efforts to improve correctional performance. Offender's risk of recidivism is influenced by both individual- and community-level risk factors. The location where the offender resides makes a difference in the likelihood of recidivism.

The notion that offenders with similar individual risk profiles (based on such factors as prior offense history, prior incarceration, history of substance abuse, and employment/education deficits) are more likely to fail if they are released to a small number of identifiable high-risk communities is a factor that has emerged in the recidivism literature in recent years. To the extent that high-risk communities are also resource-poor communities, it seems logical to suggest that as a general principle, you cannot change offenders unless you also change the communities in which offenders reside. Accordingly, when implementing the Risk-Need-Responsivity framework in practice, it is essential to consider the community context in which it is being applied. The RNR framework is unlikely to be successful in improving offender outcomes if programming is not available to address dynamic offender needs. The availability of programming is a central component of the third and final RNR principle: responsivity.

Identifying Targets for Programming

Many individuals have more than one of the "Big Four" or "Central Eight" needs. By examining the number and type of criminogenic needs an offender presents, it is possible to identify offenders who are more ingrained in a criminal lifestyle and therefore should be targeted for more intensive services designed to affect criminal thinking and potentially reduce recidivism. Additionally, screening and assessment of needs provides guidance regarding which needs are present and which needs should be prioritized in interventions.

Within the Risk-Need-Responsivity framework, the goal is to identify dynamic factors – amendable to change – that contribute either directly or indirectly to criminal behavior. Identifying dynamic needs that affect both the opportunity to participate in and the desire to commit criminal acts is important. Similarly, it is important to give attention to factors that either can serve to protect the individual from criminal involvement (stabilizers) or those that may contribute to the opportunity or desire to commit crimes (destabilizers). Included in this framework are factors that tend to have an indirect relationship with recidivism including mental health status, educational attainment, employment history and options, housing, location of residence, and other factors frequently discussed in the realm of dynamic offender needs. The inclusion of these clinically relevant factors is grounded in the notion that these non-criminogenic factors impact the decisions and choices made by offenders and therefore need to be included in decisions regarding treatment matching and amenability to change. And, to some degree, these factors may also indicate severity of problem behavior warranting attention.

The following conceptualization of need severity can be used to augment the original Andrews and Bonta Risk-Need-Responsivity framework and foster more efficient correctional resource allocation:

1. Primary criminogenic needs should fall into three categories: substance dependence (on a criminogenic drug), criminal lifestyle (made up of criminal thinking and other Big Four criminogenic needs), and specific offender type (e.g., sex offender, domestic violence offender, or drunk driver). This priority is based on magnitude of relationship to recidivism and knowledge of effective interventions and the

availability of programming to target these specific criminogenic factors.

2. Offenders who have three or more criminogenic needs should be prioritized for treatment. Offenders with substance dependence on opioid, cocaine/crack, methamphetamines or chronic drunk drivers with alcohol disorders should prioritized for treatment. Research has shown that the number of needs affects recidivism (see Andrews and Bonta 2006), and therefore offenders who present with higher scores on criminal attitudes and values, antisocial peers, family criminal networks, and history of antisocial behaviors need to be prioritized for more intensive and structured programming.
3. Core demographics are important in guiding assignments to programming. Gender, age, and location of residence warrant consideration in the treatment matching process.
4. Substance abuse and mental illness, although not directly related to recidivism, should be prioritized among non-criminogenic needs as intervention targets because they are clinically relevant and treatment programs are available that target these specific offender needs.
5. Given their generally weaker correlations with recidivism, the remaining dynamic need factors should be considered as either stabilizers (protective factors) or destabilizers (negative indicators). This distinction provides for a greater opportunity to consider factors that should be used to adjust programming given the number and type of stabilizers and destabilizers in a person's life.

Responsivity: An Overview

The responsivity principle of the RNR framework has two components: general responsivity and specific responsivity. The general responsivity principle suggests that correctional interventions will have the greatest impact on recidivism when they are evidence-based and employ treatment techniques that have been empirically linked to improved offender outcomes. The principle identifies behavioral and cognitive-behavioral approaches as those that are most likely to result in reduced recidivism. Adherence to the general responsivity principle requires that all offender treatment programs be theory-based and employ either behavioral or cognitive-behavioral offender change approaches.

The RNR framework conceptualizes specific responsivity in terms of the personal characteristics of the offender that can affect their engagement in treatment or prevent them from being successful in programming. These personal characteristics generally included things like mental and emotional problems, cognitive functioning, and the individual's level of motivation and readiness to change. The specific responsivity principle has expanded and also includes personal characteristics such as age, gender, cultural background, personality, and past treatment experiences among other factors. Under the specific responsivity principle, these client characteristics are considered when identifying the type and level of correctional intervention that will be most "responsive" to the treatment needs of the individual offender and therefore most likely to result in improved outcomes.

The term responsivity has evolved into more of a general principle for matching the appropriate type of programming based on the risk and need factors of offenders – recognizing that these risk/need factors should drive the level and type of programming. This conceptualization mirrors some other efforts to develop treatment placement criteria (e.g., American Society of Addiction Medicine (ASAM)) but recognizes that the setting and the type of intervention are important in affecting outcomes. Embedded in this conceptualization of responsivity are a number of program- or intervention-level factors that affect the quality and potential impact of the programming that should also be considered when determining the most appropriate level of correctional intervention for a justice-involved individual. These additional program features include the dosage, the content, the fidelity or adherence to the program model, and the quality of the program resources. It is beyond this essay to review all of these components. But, consistent with the evidence-based practices literature, we are aware that:

- Dosage or the number of hours that a person is involved in the correctional program should vary by risk level and that higher-risk offenders should be involved in larger quantities of programming.
- Content or the theoretical orientation of the intervention should include cognitive-behavioral therapy, therapeutic communities, or integrated service models like drug treatment courts. The nature of the treatment programming has an impact on results.
- Fidelity, adherence to core correctional practices, or the degree to which the program is implemented as planned is directly related to program effectiveness. This construct includes the dosage, content, type of staff, curriculum, and other key functional components of the program and is essential for bringing about offender change.
- Program resources include facilities, resources, and staffing available to the program. These should be aligned with the intended goals of the intervention. Program resources are important to ensure the clinical or responsivity components are adequately resourced to be effective.

While the original Risk-Need-Responsivity framework stands, an expanded empirical literature base has assisted in reconfiguring some of the decision criteria for responsivity to include:

1. Static risk level should drive dosage and type of programming. Since static risk accounts for the majority of the variance in explaining recidivism, it appears that placing moderate to high-risk offenders, with various criminogenic needs, into more intensive programming should be the priority.
2. The concept of problem severity should be integrated into the RNR framework. While the original RNR model separated by priority (Big Four) and lesser priority (non-criminogenic) needs, it appears that this distinction does not separate out those that have more severe behavioral issues from those with less severe issues. The responsivity model should consider all dynamic offender needs, including the host of clinically relevant, non-criminogenic factors in identifying problem severity.
3. Substance use dependence and criminal lifestyle (a composite measure of the "big eight") should be prioritized for more structured, intensive programming. These severe behavioral issues generally require more intensive services, particularly for moderate to high-risk offenders.
4. Age and gender are important responsivity factors that should adjust the content of the program/services.
5. Programming content should be categorized into four levels: cognitive and behavioral, interpersonal and social skills, lifestyle skills, and punishment (no programming). Cognitive and behavioral programming should be the primary intervention type for individuals who are moderate to high risk with criminogenic needs.

This expanded responsivity conceptualization can be used to match justice-involved individuals to levels of care in adherence with the Risk-Need-Responsivity framework. The steps of responsivity are conceptually clear: (1) identify static risk and prioritize high and moderate risk offenders for more intensive treatments and interventions; (2) identify criminogenic needs and target specific criminogenic needs during treatment; (3) use cognitive-behavioral, behavioral, and other evidence-based interventions to address criminogenic needs; (4) take into consideration non-criminogenic needs, stabilizers, and destabilizers in determining the appropriate level of care for a justice-involved individual; and (5) focus on client strengths to refine and improve the treatment match.

Conclusion

The original RNR framework has had a positive impact on the growth of evidence-based programming and treatments in the field of corrections. The model has identified the importance of individual-level factors in making determinations about the appropriate level of programming that is needed. However, a review of the literature on recidivism found that the original positioning of various criminogenic needs in the RNR framework may need to be altered. This is especially true when examining how these individual factors affect the results from participation in different type of programming or the type of programming that is likely to reduce recidivism for specific profiles of offenders. The quagmire of recidivism reduction is that (1) there is great variability across studies regarding the size and (sometimes) the direction of the effect between an individual-level factor and recidivism; (2) oftentimes an individual-level factor is indirectly related to recidivism, usually when other individual-level variables are present; and (3) program-level effects may vary from merely examining the impact of various individual factors on offender outcomes. That being said, these inconsistencies in the literature do not challenge the RNR framework but merely suggest a slightly different ordering of importance of different factors, and the inclusion of clinically relevant factors such as mental health, housing stability, and substance abuse. And, it means that there should be certain drivers of who needs more intensive programming – namely, individuals with moderate to higher risk or individuals with more severe constellations of criminogenic needs.

Adhering to the principles of the Risk-Need-Responsivity framework at a system level can lead to reduced recidivism rates and improved cost-effectiveness of the US correctional system. The RNR model combines several evidence-based correctional practices into one, versatile framework. A particularly valuable component of the RNR framework is its potential to guide resource allocation and improve the fit between correctional interventions and individual offender needs. The framework stresses the importance of building a human services culture within the correctional system; a goal that empirical evidence has shown is more effective at reducing recidivism than incarceration or sanctioning alone. In a time when correctional resources are sparse, the Risk-Need-Responsivity framework offers a model to efficiently and cost-effectively respond to the needs of the offender population. The framework offers not only improved cost-effectiveness but also improved public safety returns.

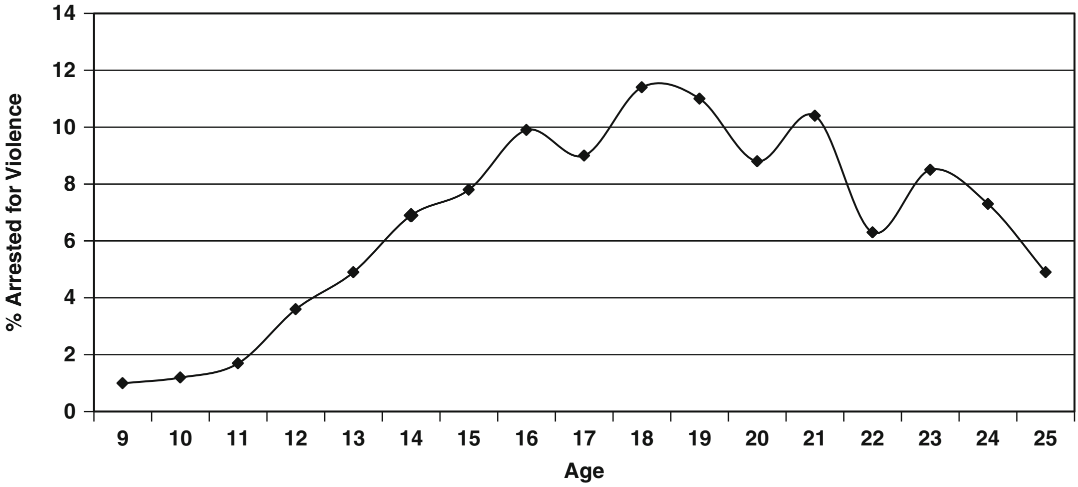
Overview

One of the most consistent findings across studies on offending in different countries is the age-crime curve (Farrington 1986; Tremblay and Nagin 2005). The relationship between age and crime is of an asymmetrical bell shape, showing that the *prevalence* of offending (the percentage of offenders in a population) tends to increase from late childhood, peaks in the teenage years (around ages 15–19), and then declines from the early 20s, often with a long tail (Fig. 1). The sharp increase during adolescence in the curve reflects an increase in new delinquency recruits during that period, and the rate of recruitment tends to slow down subsequently (Smith et al. 2002). The age-crime differs from developmental trajectories (qv) of offending in that the age-crime curve indicates the prevalence of offending by age of populations of individuals, whereas developmental trajectories make distinctions between subgroups of offenders, such as life-course persistent offenders and adolescent-limited offenders.

Key Issues

Although universal, the age-crime curve is not invariant but differs depending on characteristics of offenses and offenders (Farrington 1986). For example, the age-crime curve for violence tends to peak later than that for property crime (Piquero et al. in press). Studies also show that the age-crime curve for girls peaks earlier than for boys (Farrington 1986; Elliott et al. 2004). The curve is also higher and wider for young males (especially those of a minority status) growing up in the most disadvantaged compared to advantaged neighborhoods (Fabio et al. in press). There are similarities between the age-crime curve and the age-co-offending curve (Piquero et al. in press) and between the age-crime curve and the victim age curve (Stolzenberg and D’Alessio 2008). Since most of the violence is directed at same-age victims, it is not surprising that the age period 16–24 is also a high-risk period for violent victimization (e.g., Kershaw et al. 2008).

In addition, the criminal propensity of successive age cohorts is not necessarily the same, with more individuals in some age cohorts being



Age-Crime Curve, Fig. 1 Age-crime curve, based on longitudinal data from the Pittsburgh Youth Study (oldest cohort) and using self-reported delinquency and official records of offending

delinquent and over a larger number of years (i.e., with a higher duration) than individuals in other age cohorts (e.g., Farrington 1986; Cook and Laub 2002). The majority of the published age-crime curves are based on cross-sectional data, which usually means that they are based on multiple age cohorts and for that reason are usually different from curves based on longitudinal data. For these data, it is often hard to disentangle cohort, age, and period effects (i.e., changes in historic time). Therefore, preferred are age-crime curves based on self-reports and official records that are usually based on a single cohort (e.g., Loeber et al. 2008) as preferred, because they avoid the confounding influence of multiple cohorts.

Most of the studies on the age-crime curve have been based on official records, which often underestimate the number of delinquent individuals and, hence, the height and probably also the shape of the age-crime curve. Therefore, it is important to examine the age-crime curve based on more comprehensive information, such as that based on self-reports of offending and complemented by reports by parents and teachers (Loeber et al. 2008). There are several other caveats about the age-crime curve that may influence conclusions drawn from it. For example, self-reported delinquency shows an earlier peak than official records (Piquero et al. in press). This may reflect the fact that juvenile offending at a young age (as evident from self-reports) goes unrecorded by the police or there may be a delay in arrest, and as a consequence these offenses remain undetected in official records until a later age.

Researchers have not been in agreement about whether the prevalence of offending is correlated over age with the frequency in offending (e.g., Blumstein et al. 1986) and whether as the prevalence increases so does the frequency (i.e., in the upswing of the age-crime curve). Conversely, when the prevalence of offending decreases, does the frequency of offending also decrease (in the downslope of the age-crime curve)? Yet, research on the frequency of offending at different ages has been scarce (e.g., Barnett et al. 1987; Loeber and Snyder 1990; Piquero et al. in press).

It is not well known that, although an early age of onset, compared to a later age of onset, is associated with a longer criminal career, the highest concentration of desistance takes place during late adolescence and early adulthood *irrespective* of age of onset. This corresponds with the downslope of the age-crime curve. In fact the decrease in prevalence in the downslope of the age-crime curve is very substantial.

In some data sets, it goes down from about 50 % to about 10 % of all persons (e.g., Loeber et al. 2008). Important for our understanding of the transition between adolescence and adulthood is the right-hand tail of the age-crime curve. The higher and longer that tail, the more this indicates that there is a population of youth who may not have outgrown delinquency or who may have started offending during adulthood (see below). In summary, the downslope of the age-crime curve varies between different populations of young people, but often extends from adolescence into adulthood. It is important to realize that the majority of serious forms of crime – including violence – take place in the period of downslope of the age-crime curve.

Individual Differences, Offending Careers, and the Age-Crime Curve

Some criminologists have assumed that individual differences in the propensity of offending are stable over time, including the age-crime curve (e.g., Gottfredson and Hirschi 1990). However, a recent reformulation that corresponds more with the age-crime curve is that the magnitude of the individual differences in offending is modest in the early part of the age-crime curve, increases toward the peak of the curve, and then decreases in the downslope of the curve (Loeber et al. 2012). It still can be argued that what remains stable is the rank-ordering of individuals' propensity of committing delinquent acts.

Factors Influencing the Height and Width of the Age-Crime Curve

Loeber and Farrington (2012) postulated ten processes that might explain the downslope of the age-crime:

1. Individual differences in self-control
2. Brain maturation
3. Cognitive changes (e.g., decision making to change behavior)
4. Behavioral risk factors (disruptive behavior and delinquency) and behavioral protective factors (nervousness and social isolation)
5. Social risk and protective factors (family, peers, school)
6. Mental illnesses and substance use/abuse
7. Life circumstances (e.g., getting married, becoming employed)
8. The situational context of specific criminal events, including crime places and routine activities
9. Neighborhood (e.g., living in a disadvantaged neighborhood and the concentration of impulsive and delinquent individuals in disadvantaged neighborhoods)
10. The justice response (e.g., transfer to adult court, longer sentences)

Of the above processes, several are thought to also explain the upslope of the age-crime curve (Nos. 1, 4, 5, and 9). For example, parents' influence over their children's behavior tends to decrease, and the influence of peers tends to increase during the upslope of the age-crime curve.

The critical question is: *Does each process explain the onset, persistence, and desistance in offending from childhood into early adulthood?* The explanatory processes reviewed by Loeber and Farrington (2012) tend to take place at different age periods from childhood to early adulthood and, consequently, may influence different but interrelated outcomes. For example, early individual differences become manifest after birth and evolve subsequently; exposure to new risk factors increases from childhood through adolescence, while changes in desirable life circumstances – such as marriage and employment – typically accelerate from late adolescence into early adulthood. Thus, the explanatory processes tend to operate at different ages, some early and some later in offending careers.

We will highlight only a few of the ten processes and concentrate on individual differences and brain maturation. Many scholars focused on different underlying constructs thought to be central to individual differences. However, there is little agreement on whether poor self-control, reckless behavior, impulsivity, poor executive functioning, or sensation seeking is the important construct (see also Jolliffe and Farrington 2009), and there is even less agreement on how best to quantify them independent of disruptive child behavior and delinquency. Also, the assumed stability of the underlying constructs across the life-course is often untested and is rarely based on a follow-up of the same individuals over time (but see Piquero et al. 2009). Another possible flaw is the fact that individual differences, in for example, self-control, do not easily map on the age-crime curve, especially on the upslope of the curve representing the increase of offending from childhood (ages 7–12) to middle adolescence (ages 13–16) *and* the downslope of the age-crime curve representing the decrease of criminal activities from late adolescence (ages 17–19) into early adulthood (ages 20–25). Further, the individual differences approach usually does not focus on brain maturation from childhood to early adulthood (but see Moffitt 1993).

Loeber et al. (2008), who examined a large array of protective factors, concluded that in the Pittsburgh Youth Study, desistance in the downslope of the age-crime curve was more difficult to predict than desistance at earlier ages. Specifically, *none* of the protective factors measured either in early adolescence (ages 13–16) or late adolescence (ages 17–19) predicted desistance in early adulthood (ages 20–25), but not all research is in agreement on this point (Stouthamer-Loeber et al. 2008).

Some researchers have proposed that changes in life circumstances, such as marriage and employment, also impact the timing of the decrease in the age-crime curve (e.g., Theobald and Farrington 2009). It should be noted that these changes in life circumstances often occur late into the downslope of the age-crime curve, where they could still cause a decrease in offending.

A critical issue is whether mental maturation and the associated emergence of internal controls are related to brain maturation and whether both influence the downslope of the age-crime curve. In brief, an improved understanding of individual differences would suggest something like the following. Young people differ in the speed of brain maturation, and this brain maturation, accompanied by social learning, causes improved internal controls. These improved controls become evident through a decrease in risk-taking behaviors, reckless behavior, and sensation seeking and improvements in problem solving, future orientation, and decision making. Improved controls are thought to reduce deviant behavior, including the commission of delinquent acts, and increase prosocial behaviors.

There are several pieces of research that fit these propositions. There is increasing evidence that the brain continues to develop during childhood into early adolescence, including ongoing myelination (e.g., Giedd et al. 1996; Sowell et al. 2001), and into adulthood when white matter increases and synapses are pruned. Research also shows that “the dorsal lateral prefrontal cortex, important for controlling impulses, is among the latest brain regions to mature without reaching adult dimensions until the early 20s” (Giedd 2004, p. 77). The importance of white matter is underscored by the finding that decreased white matter is significantly more common among boys with psychopathic tendencies compared to controls (De Brito et al. 2009). Biological changes in the prefrontal cortex during adolescence and the early twenties lead to improvements in executive functioning, including reasoning, abstract thinking, planning, anticipating consequences, and impulse control (Sowell et al. 2001).

The data on brain development, although mostly cross-sectional, is much in line with behavioral evidence that reckless behavior tends to decrease as late as early adulthood, as is evident from data on the incidence of car accidents, even when controlling for the number of miles traveled (Foss 2002). This is widely recognized by insurance companies whose premiums for car insurance for young drivers up to about age 25 are dramatically higher than for older drivers. The idea of improved behavioral controls that emerge between late adolescence and early adulthood is also evident from psychological research. For example, Steinberg et al. (2009) investigated time perspective, planning ahead, and anticipation of consequences among individuals between ages of 10 and 30. Although this was a cross-sectional study, the results suggest that the ability to plan ahead improves dramatically between early adolescence and the early 20s along with the anticipation of consequences, while time perspective improves slightly less in that same period. In addition, a recent meta-analysis concluded that children's and adolescents' coping repertoires increase with age, including planful problem solving, more diverse distraction techniques, positive self-talk, and intentional self-regulation of emotions (Zimmer-Gembeck and Skinner 2011).

A key piece of evidence, however, derives from longitudinal research in which the same individuals are followed up over time. In general longitudinal research shows that childhood impulsivity measured by ratings made by adults (as early as age 5) is significantly predictive of violence (Jolliffe and Farrington 2009). Corresponding to the thesis that young individuals differ not just in their stable traits over time but also in their developmental maturation, research based on the Pittsburgh Youth Study (Loeber et al. 2011) shows that individual differences in cognitive impulsivity, as measured by young males' performance on several psychometric tasks at age 13, map onto individual differences in the age-crime curve. Individuals scoring lowest on cognitive impulsivity at age 13 on average had the highest prevalence of arrest for delinquent acts throughout adolescence into early adulthood (ages 12–26), but from age 27 to 28 onward, their prevalence of arrest became very similar to those with lower cognitive impulsivity. Second, *all* groups that differed in their level of cognitive impulsivity (from highest to lowest) showed the age-crime curve, meaning that *each* group showed a decline in the 20s in the prevalence of convictions for delinquent acts. This is contrary to the notion that highly impulsive individuals or individuals with little self-control on average remain highly delinquent over time (e.g., Gottfredson and Hirschi 1990). Instead, the results show that on average, even highly impulsive individuals decrease their level of delinquency with age, although they took longer to outgrow delinquency than less impulsive individuals.

Yet another piece of evidence contradicts the assumed stability of underlying traits. Piquero et al. (2009) reviewed the evidence that several intervention programs improved self-control and reduced delinquency in young people. The programs reviewed targeted those up to age 10 and showed that juveniles' self-control can be changed as a result of systematic interventions. Less well documented is how well interventions promoting self-control influence older populations.

In summary, the central issue is not whether there are stable individual differences between individuals in their cognitive control and their delinquent acts. Instead, the key question is: To what extent *individual differences increase over time and then decrease?* Thus, the age-crime curve with its increase, peak, and then decrease in prevalence *and*, possibly, severity over time should be related to within-individual differences in brain and cognitive development. However, brain and cognitive development has not been related to adult-onset offending.

Lowering the Age-Crime Curve

One of the limitations of current evaluation studies is the absence of yearly long follow-ups of treated and nontreated individuals during adolescence and early adulthood. For that reason, published evaluation studies have not been able to show the degree to which interventions could have lowered the age-crime curve. To resolve this, longitudinal data from the Pittsburgh Youth Study was used to simulate the impact of an intervention on offending by at-risk youths (Loeber and Stallings 2011). Simulation can be compared with asking the question "What if…" we changed one aspect of the data set, what impact would that have on future offending? To address this, the authors modeled first the efficacy to screen for high-risk individuals and then to apply a treatment that "knocked out" youth who otherwise would have been at risk of committing serious delinquency. To identify high-risk boys, a screening risk score was computed from data collected at the first assessment for each of the three cohorts at ages 7, 10, and 13, for the youngest, middle, and oldest cohorts, respectively (Loeber et al. 1998). This screening score included conduct problems and delinquency as reported by the boys and their parents and teachers. The intervention modeled was inspired by the best intervention programs available (Lipsey and Wilson 1998) evaluated by the comparison of an experimental sample receiving the intervention with a control sample not receiving the program (or receiving an alternative program). Loeber and Stallings (2011) took as a conservative criterion a success rate for the intervention of 30 %.

The intervention was associated with a substantial reduction in serious delinquents by one fifth to one quarter (21.5 % and 27.6 % for the youngest and oldest cohort, respectively), especially from ages 11 to 21. Other results indicate that the intervention also was associated with a decrease of 20 % in the prevalence of arrest by the police, a 35 % lower prevalence of homicide offenders and homicide victims, and a 29 % reduction in the weeks of incarceration. Thus, the modeled intervention had a substantial benefit of lowering the age-crime curve by reducing the prevalence of self-reported serious offenders, officially recorded homicide offenders and homicide victims during adolescence and early adulthood, and had benefits for the justice system by greatly reducing arrests and convictions.

In conclusion, there are many intervention programs available outside of the justice system that reduce recidivism and prevent persistence of offending from adolescence into early adulthood. Preliminary results indicate that such interventions may lower the age-crime curve for a population of youth.

Policy Implications

All available age-crime curves show that the legal age of adulthood at 18 (or for that matter ages 16 or 17 in some states) is not characterized by a sharp change (or decrease) in offending at exactly that age and has no significant relevance to the downslope of the age-crime curve. Serious offenses (such as rape, robbery, homicide, and fraud) tend to emerge after the emergence of less serious offenses of the late adolescence-early adulthood window. Even for serious offenses, however, there is no clear dividing line at age 18. Steinberg et al. (2009) concluded that "The notion that a single line can be drawn between adolescence and adulthood for different purposes under the law is at odds with developmental science" (p. 583). Piquero et al. (in press) emphasized that knowledge about the age-crime curve during the transition from adolescence to adulthood potentially offers valuable insights for incapacitation and reentry policies. Finally, lengthier sanctions administered in the adult court aimed at young offenders, based on our understanding of normative outgrowing of delinquency in young populations, will have no bearing on lowering the age-crime curve. In summary, if lowering of the age of adulthood is advocated, legislators need to take into consideration the age-crime curve, costs and benefits, and the need to screen vulnerable populations who take longer than others in their brain maturation and their outgrowing of the age-crime curve. The litmus test is whether concerted preventive and remedial interventions inside and outside of the justice system can lower and shrink the age-crime curve for future generations of young people.

Overview

This entry discusses the application of computational agent-based models (ABM) in exploring the ramifications of crime event mechanisms proposed by criminological theory. In particular, it describes how simulation experiments can be used to systematically assess the plausibility of crime event theories in explaining commonly observed patterns of crime and how the use and development of ABM may offer a viable method of theoretical prototyping free from traditional empirical constraints which in turn encourages theorists to explicitly specify the mechanisms by which they propose observed crime phenomena come about.

Introduction

A wide range of criminological theories provide individual-level depictions of the crime event. Such theories outline hypothesized mechanisms of cognition and action for both potential victims and offenders and, in turn, the influences that the local environment place upon them in situating victimization. Criminologists hypothesize that these mechanisms are operating, interacting, combining, exciting, inhibiting, and subsuming one another in complex and dynamic ways which influence the spatiotemporal distribution of criminal opportunities and in turn crime. Unfortunately, key problems associated with observation and experimentation endemic throughout the social sciences dictate that we often struggle to directly observe how, and in what ways, such interactions take place and instead are left to observe only their output – the patterning of crime. As a result, a divide exists between observed aggregate crime patterns and proposed individual-level crime theory. This divide dictates that many theoretical propositions relating to the proximal causes of crime can be difficult to empirically verify to the degree that would be desirable.

The past decade has seen a number of criminology scholars begin to explore potential applications of computational models in a hope of better characterizing and understanding these complex interactions of the crime event (Birks et al. 2008, 2012; Bosse et al. 2010; Brantingham and Brantingham 2004; Brantingham et al. 2008; Brantingham and Tita 2008; Eck and Liu 2008; Groff 2007; Johnson 2008; Liu et al. 2005; Malleson et al. 2009; Van Baal 2004; Wang et al. 2008). Such approaches aim to provide support to existing theoretical and empirical efforts by allowing researchers to generate artificial worlds free from logistical, monetary, and ethical constraints in which the likely downstream impacts of theoretical propositions can be systematically estimated through simulation experimentation.

Drawing heavily on Epstein’s (1999) generative approach, this entry provides an overview of one particular type of computational model: the agent-based model, advocating its use in exploring the generative sufficiency of individual-level criminological theory, that is, the capacity of proposed individual-level mechanisms in explaining commonly observed aggregate patterns of victimization. The entry begins with an introduction to the agent-based modelling methodology, highlighting a number of its characteristics that are of considerable use in exploring complex social systems. Subsequently, Epstein’s (1999) notion of the generative explanation as afforded by ABM is set out, and a discussion relating to its application in the study of criminological theory provided. In concluding several strengths, weaknesses, and requirements for a generative approach to the study of criminological theory are discussed.

Computational Agent-Based Modelling in the Social Sciences

By definition, the social sciences deal with the functions and interactions of society; thus, complexity is inherent in almost all phenomena they aim to study. In relation to this issue, Herbert Simon called for the so-called "soft" social sciences to be relabelled the hard sciences due to a range of issues that encumbered investigation. Simon asserted that the laboratory conditions used by those who deal with the natural sciences permit a much clearer observation of cause and effect than is ever possible within the social sciences. Similarly, Epstein and Axtell (1996, p. 1) discuss a number of methodological difficulties that have to date limited the productivity of traditional equation-based models commonly applied within the social sciences for the purposes of theory testing. A summary of these observations follows:

- Social systems are rarely characterized by discrete, easily decomposable subprocesses; instead most social phenomena encompass numerous mechanisms which all act in unison – spatial, cultural, economic, demographic, and so on.
- Controlled experiments that aim to test hypotheses within the social sciences are often very difficult to perform due to a number of ethical and logistical constraints.
- Traditional social science models often assume that entities are perfect rational actors who have access to perfect information.
- In order to manage computational requirements, typical social science models suppress unit heterogeneity through the use of "representative agent" methods.
- Such heterogeneity is inherent in social systems; however, within the social sciences "there has been no natural methodology for systematically studying highly heterogeneous populations" (p. 2).
- Models within the social sciences often assume social systems can be characterized as static equilibria and as such ignore the importance of temporal dynamics.

In the attempt to overcome some of these problems, research within the social sciences over the last two decades has begun to embrace the application of computational modelling techniques drawn from a number of disciplines in exploring complex social systems. Agent-based models (ABMs) are one particular technique that offer considerable promise to those who aim to build explanatory models of complex social systems. ABM is a well-established method of computer simulation with many real and promising applications across a range of disciplines. Although technically straightforward, its concept is considered profound (Bonabeau 2002).

Rudimentarily, agent-based computational models simulate the interactions that occur between multiple autonomous entities with the aim of analyzing how the decentralized behavior of individuals impacts on the behavior of the system as a whole. ABMs have been applied in a vast range of applications that include investigating the dynamics of pedestrian flow in emergency situations, exploring youth subcultures, the study of financial markets, and understanding consumer purchasing behavior.

ABM allows social science researchers to create virtual societies and inhabit them with simulated populations of heterogeneous autonomous actors. Using these models, the societal level impacts of differing individual-level behaviors can be examined (Epstein and Axtell 1996). In this way, ABM provides a platform to explore how the decisions people make on a day-to-day basis translate into observable phenomena. Advocates of the approach suggest that it is this ability to capture the links between micro-action and macro-outcome that place ABM as a "natural" methodology for the study of human systems (Axelrod 1997; Bonabeau 2002; Epstein 1999; Hedström 2005). The observed behavior of complex societal systems often arises from the interactions of relatively simple microlevel behaviors (Schelling 1978), and it is in exploring this micro-macro divide among complex social systems that ABM offers considerable promise. By manipulating the initial conditions of the ABM and scrutinizing data collected about virtual populations, researchers gain insight into the likely dynamics of certain societal configurations. Fundamentally, ABMs are made up of two key components: a population of agents and a simulated environment in which they are situated.

Simulation Agents

In an ABM each member of the virtual population is represented by an autonomous decision-making entity, commonly referred to as an agent. Just like the members of a real population, agents can exhibit individual characteristics, preferences, and behaviors; for example, each agent might have an age, home location and preferred social group, etc. Within an ABM agents execute a variety of behaviors that govern how they perceive, reason, and act in particular circumstances. These behaviors define how agents interact with one another, how they observe and analyze their surroundings, and how they might alter that environment or their internal state by performing certain actions. Such agent behavior is commonly defined by a series of condition-action rules (this is a gross, but necessary, oversimplification – for a review of agent behavior architectures, readers are directed to Gilbert and Troitzsch (2005)). In the case of explanatory ABM this decision calculus is often inspired by the formalization of theory, such that algorithms and heuristics are developed to reflect the mechanisms theory suggests are operating at the individual level. By exploring the macro-level ramifications of particular individual-level theoretical constructs and comparing them to known aggregate characteristics of the real-world system, social scientists can use ABM to interrogate the validity of social science theories.

Simulation Environment

Agents within ABM are situated within an environment. This environment may take on a wide variety of forms depending upon the purpose of the model being built. For instance, a model environment may represent some form of abstract physical or social space, where proximity relates to the spatial convergence of entities or, alternatively, their ideals, opinions, and connectivity. Conversely, model environments may also be developed to closely mirror real environments, be they individual floor plans, neighborhoods, or cities. The significant notion here is that agents are situated in an explicit space, abstract, or otherwise, thus allowing the concept of localized interaction to be appropriately modelled. The level of realism suitable for particular simulation environments, and moreover ABM in general, is subject to much debate (Elffers and Van Baal 2008).

The statement that simulation agents should be situated in an environment that is as close to reality as can be managed may sound like a truism. For example, if one aims to study patterns of burglary by examining simulated burglar agents who roam some environment, applying some hypothesized choice mechanism, it may sound desirable to situate these agents within an environment that closely mirrors a map of say Amsterdam, representing all Amsterdam homes as targets and in turn their associated characteristics – i.e., value, visibility, and population density. However, on second thought, such environmental realism may not be such a good idea after all. If, for instance, this simulation does show the emergence of burglary patterns congruent with empirical study, how does one recognize whether such results emerge as a result of the specified choice mechanism of interest or, alternatively, the peculiarities of the Amsterdam housing constellation? If, as is usually the case in simulation research, and as argued here, one tries to establish whether the specification of the agents' choice mechanism is sufficient to generate the pattern of interest, this environmental setup only serves to obfuscate this assessment. As such, the application of simulation seeks to establish the sufficiency of the mechanism irrespective of the specific environment in which it operates. Thus, regularities should occur not only in Amsterdam but also in Brisbane, Cancun, Durban, etc. One, rather cumbersome, solution to this problem may be to devise simulations in all of the above realistic environments. An alternative is to attempt to reduce the environment to its bare essence and have the simulation work in an abstract environment, specifying the minimally necessary characteristics of the geography in which the agents operate (Elffers and Van Baal 2008).

In considering model complexity in general, Gilbert (2004, p. 9) succinctly states that " the art of modelling is to simplify as much as possible, but not to oversimplify to the point where the interesting characteristics of the phenomenon are lost." It may of course be the case that the actual spatial configuration is indeed part of the essence of a simulation study. In studying whether the Amsterdam canal configuration hampers burglars in their movements, one may well classify the Amsterdam geography to be an essential part of the agents' decision rules. In such cases, a realistic background (with respect to those characteristics, that is) is indeed necessary, as leaving them out would be a case of Gilbertian oversimplification in which essential characteristics are lost.

Agent-Based Interactions

Given these two key components, a number of interactions may be modelled through ABM. *Agent-agent* interactions are those where agents receive information or resources from one another, develop social links with other agents, or compete for some entity within the simulation, be it territory, resources, or status. *Agent-environment* interactions are those where agents draw information or resources from the world in which they are situated. *Environment-agent* interactions characterize those situations where the environment influences an agent, perhaps by constraining movement or defining the locations in which certain activities can and cannot take place. *Environment-environment* interactions may also occur, for instance, a resource within some environment may spread over time from its initial location to those adjacent. In reality, the types and ways in which elements of ABMs may interact are almost limitless, and it is this level expressiveness that allows ABMs to be used to represent an unprecedented number of systems, processes, and mechanisms.

The Temporal Dynamics of ABM

Another important feature of the ABM is its inherent ability to capture the temporal dynamics of a system. ABMs simulate the progression of time via discrete increments, often referred to as cycles. During each cycle agents within the environment perceive, reason, and act based upon their specified behaviors that in turn draw on an agent's local circumstances and individual characteristics. Many thousands of these cycles may occur as a simulation progresses. Thus, ABM is performed in an iterative fashion, permitting the longitudinal examination of time-dependent phenomena and the formation, interaction, and separation of system elements over time. Such temporal dynamics are especially important for the modelling of phenomena such as tipping points, where the accumulation of individual action over time can lead to rapid and significant diversions in system behavior.

Common Characteristics of ABM

Considering the utility of ABM within the social sciences, Epstein and Axtell (1996) and Epstein (1999) succinctly highlight a number of key characteristics that, while not requisite, are often exhibited by ABM. These characteristics, they suggest, make ABM ideal tools for the study of complex social systems and provide a number of strengths that overcome some of the weaknesses associated with more traditional attempts to understand complex dynamic social systems. A summary of these characteristics follows:

- *Autonomy*: ABMs are devoid of overarching top-down control mechanisms. Rather, each agent within the simulation perceives, reasons, and acts individually. While exchanges of information between agents may occur directly or indirectly through the environment, no centralized controller regulates behavior.
- *Heterogeneity*: ABMs often simulate large numbers of entities as agents, which differ both within and between groups. For example, agents may operate using different decision-making strategies: for instance, probabilistic vs. deterministic reasoning. Agents may also differ by characteristics, with all agents utilizing the same decision calculus but drawing on

different internal characteristics. This ability to capture unit heterogeneity is of great importance, especially when attempting to investigate real-world phenomena where unit homogeneity is rare.

- *Explicit Space*: ABMs represent entities embodied in some abstract or realistic space, allowing the concept of local interaction to be well formed.
- *Local Interactions*: Equation-based models often assume system entities possess complete knowledge of both the world they inhabit and the other entities within it. This is often an unrealistic assumption. ABMs, on the other hand, predominantly deal with localized interactions occurring between entities that are spatially or socially proximate within the simulation environment.
- *Bounded Rationality*: While agents are often bestowed with rational decision-making behaviors, these behaviors can be developed to draw only from localized, limited information. Thus, rationality is limited by the information available at the time a decision is made. In addition, agent behaviors can be designed to utilize limited processing power – *bounded computation* – and therefore do not exhaustively search all possible actions in order to determine an optimal solution. Such representations of rationality are much closer to those employed by human actors in the real world.

In addition to these inherent strengths in modelling social systems, the agent-based methodology also confers a number of distinct epistemological benefits:

- *Accessibility*: Agent-based approaches are often very effective at demonstrating complex concepts to both researchers and a wider audience. ABM elements are most commonly specified at the individual level – that is, as the decision-making strategies of individuals. Specifying model concepts at this level means that model assumptions and propositions can be much more easily understood than models which require complex mathematical abstractions (Bonabeau 2002). This dictates that the ABM audience need not be highly skilled in the field of ABM in order to both inform and interpret ABM. As a result, ABM can often be interrogated by domain experts who may well ask more pertinent questions of models than those whose interests lie predominantly in their development (Gilbert and Troitzsch 2005).
- *Aiding Scientific Discourse*: ABM's intuitive depiction of complex phenomena also dictates that they can often better scientific debate concerning the target system they examine. The process of theory formalization whereby theoretical constructs are formalized for inclusion within an ABM forces researchers to be explicit about the mechanisms their theories propose. This process can often highlight logical inconsistencies which are not readily apparent when theories are represented by traditional verbal or written models. Furthermore, the results of ABM can lead to the development of new questions and the generation of novel hypotheses, some of which may have seemed counterintuitive prior to the observation of ABM.
- *Simulation Experimentation*: ABMs allow for experiments to be performed that would otherwise be impossible due to monetary, ethical, or logistical constraints (Gilbert and Troitzsch 2005). Furthermore, simulation experiments can be performed en masse easily and quickly. Once a model is built, minor adjustments are simple to perform (Gilbert and Troitzsch 2005). In essence, the number of experiments that can be performed is only limited by the computing power and the time available to researchers.
- *Absolute Control*: ABM offers a novel analogue to controlled experiments for examining social phenomena. Researchers can manipulate any number of influencing factors otherwise outside their control in traditional experimentation, thus allowing the exploration of dose-response relationships in endless configurations.
- *Absolute Observation*: ABMs provide synthesis of real-world systems in which perfect observation and measurement can occur. Many social science problems deal with

phenomena for which real-world data cannot be obtained. By contrast, in simulation data sets can be collected to describe every action undertaken by members of a virtual population and furthermore the internal calculus employed by each member in undertaking such actions.

- In Situ *and In Silico Experimentation*: ABM may also identify potential new lines of empirical enquiry. In turn, this external experimentation may lead to the development of better ABM through parameterization and/or validation. This iterative interaction of in situ and in silico experimentation can offer substantial advances in the way phenomena are investigated.

Agent-Based Modelling of Social Systems and the Generative Explanation

Drawing heavily on the inspiring work of Thomas Schelling, recent advances in the application of ABM within the social sciences have seen authors propose that ABM permits a new "third way of doing science" alternate to traditional forms of inductive and deductive reasoning (Axelrod 2005). This approach sees the agent-based computational model or artificial society, as it has become known (Epstein and Axtell 1996), as a new scientific instrument that permits a unique experimental method through which social macrostructures of interest can be "computed" (Epstein 1999, 2006; Hedström 2005). As a branch of analytical sociology, this approach focuses on mechanisms as explanations, and in doing so its advocates suggest that artificial societies allow researchers to systematically establish which microlevel mechanisms *can* and *cannot* be viable explanations for observed macroscopic phenomena: "Agent-based models provide computational demonstrations that a given micro specification is in fact sufficient to generate a macrostructure of interest" (Epstein 1999, p. 42).

This approach views society itself as a form of distributed computational device through which macrostructures are computed from micro-action. The generativist proposes that complex social science phenomena can be understood through the synthesis of their emergence from lower-order action and interaction. The central premise of generative social science is as follows: "If you didn't grow it, you didn't explain its emergence" (Epstein 2006, p. 6). Consequently, the generativist approaches observed macro-phenomena by attempting to identify what combination of micro-conditions is capable of generating them. Or more specifically, "How could the decentralised local interactions of heterogeneous autonomous agents generate the given regularity?" (Epstein 2006, p. 5).

In attempting to answer this question, the ABM is employed. In addressing the above question, the following course of action is proposed: "Situate an initial population of autonomous heterogeneous agents in a relevant spatial environment; allow them to interact according to simple rules and thereby generate – or "grow" – the macroscopic regularity from the bottom up" (Epstein 1999, p. 42). Following this approach it is suggested that theory describing observed social science phenomena can be tested by building ABMs of the proposed microlevel mechanisms of a system and testing if these mechanism are sufficient to produce observed macroscopic regularities of the target. Such macroscopic regularities describe those salient macro-level patterns that are consistently observed in the empirical study of the target system. Examples of such regularities might include right skewed wealth distributions, price equilibria, segregation patterns, or in the case of criminology the spatial clustering of crime.

Whereas traditional statistical or equation-based explanations operate in a *top-down* manner, with the identification of associations between aggregate observations used to make inferences about underlying mechanisms, generative social science operates from the *bottom-up*, identifying *generative explanations* as those hypothesized microlevel mechanisms that produce macro-level output patterns consistent with observed regularities of the target (Epstein 1999). Applying ABM as its principal scientific instrument, generative social science assesses the generative sufficiency of theory. Generatively sufficient mechanisms are those that when employed by an agent population are sufficient to generate macro-level patterns congruent with the target. The more regularities a mechanism is capable of generating, the greater the confidence one can have in its validity. Importantly, if a mechanism cannot produce such regularities, confidence in its validity is reduced, and it may be eliminated as a potential explanation of the target phenomena. Thus, the use of ABM provides a method through which theory can be falsified, a principal requirement of any scientific proposition.

An important observation regarding this form of investigation is that while generative sufficiency is a prerequisite of causal explanation, the converse is not necessarily the case. While mechanisms may be deemed sufficient to bring about the observed effect, they are not necessarily necessary. Thus, while ABMs may identify hypotheses that are generatively sufficient, they cannot be used to infer causal explanation (Epstein 1999; Hedström 2005). This is obviously the case. It is highly probable that a number of different microlevel mechanisms may produce output phenomena consistent with that observed of the target. This however is no different from the scientific discipline as a whole – there is no finite limit of the number of potential explanations one can conjure up for a given phenomena. Generative social science aims to use ABM to identify which of those potential explanations are viable candidates. It is only through further empirical experimentation that the most tenable sufficient mechanisms can be identified (Epstein 1999; Hedström 2005).

The initial task of the generativist, then, is to eliminate those theories that are generatively insufficient, leaving only generatively sufficient candidate explanations. This ability to identify insufficient hypothetical constructs is where the strength of the generative approach lies. Having identified a number of candidate explanations, each should be examined in further detail, considering its plausibility and identifying other potential metrics that may be used to test for the presence of the mechanisms purported using empirical experimentation. As such, the development of generative models guides further empirical observation of the target phenomena, which in turn may identify further potential explanations that can subsequently be assessed for generative sufficiency (Epstein 1999). While this process is unlikely to produce a single viable explanation of a phenomenon, it has eliminated those that are insufficient and implausible or have been falsified through empirical observation, in effect prioritizing theory in terms of its plausibility.

In application, generative social science has demonstrated its utility in exploring a number of social science phenomena. Epstein (2006) provides a review of a number of these endeavors, which include exploring the dynamics of civil violence, potential strategies for controlling epidemics, and the impacts of cultural change within indigenous communities. Note that the choice to treat generative simulation is indeed a choice. Other uses of simulation methodology are available, but are not discussed here.

Linking Microcrime Theory and Macrocrime Patterns: Generative Agent-Based Models of the Crime Event

Having outlined the ABM approach and its potential application in exploring generative explanations of observed phenomena, the following sections now discuss how the ABM can be used to explore propositions derived from criminological theory. As previously discussed this is certainly not the first time the ABM methodology has been suggested or undertaken within criminology. Here, however, this entry draws heavily on Epstein's principle of generative social science advocating the application of ABM in systematically exploring the robustness of criminological theory.

To undertake the generative approach in examining the interactions of crime, two distinct constructs are required: (1) micro-specifications of the crime event and (2) empirically derived macroscopic regularities of crime against which the explanatory sufficiency of such micro-specifications can be assessed. Luckily within criminology both abound.

Micro-specifications of the Crime Event

For a theory to be explored in the ways proposed here, there is a sole requirement. Theories must provide individual-level mechanisms describing how they propose observed outcomes come about. As such, researchers are forced to specify mechanisms not correlates. A number of criminological theories provide such individual-level depictions of the crime event. This section does not attempt to sketch these well-known theories in detail, but instead aims to highlight a few that might be explored through simulation, hinting which agents and rules would be pertinent in such research:

1. Routine activity approach and pattern theories of crime outline how the characteristics and interactions of individual-level activities dictate the spatial and temporal distribution of offending and victimization. Agents may be the potential offenders, potential victims, and potential guardians, moving around in a geographical space. Decision rules specify how the various agents react on each other's presence.
2. The rational choice perspective offers a tangible offender decision calculus that relies on boundedly rational assessments of the perceived risks, rewards, and efforts encountered in potential pre-crime situations. Agents are individual would-be offenders, reacting on various opportunities that may have rewards and efforts needed to victimize targets and associated risks, partly in terms of social (dis)approval) by other agents that form a social network, having certain relations among each other.
3. Social learning theory provides hypotheses concerning mechanisms of offender reinforcement. Here, agents may be potential offenders who repeatedly get the opportunity to misbehave, and their decision calculus is taking stock of previous decisions to offend and their success or failure.
4. Network theory of peer association. Agents may be individuals, having certain peer relations among each other. Decision rules to engage in crime as well as decisions to (dis)continue being a member of a peer network are specified in terms of number of peer agents that commit simulated crimes themselves.
5. Social disorganization theory proposes communications of risk and crime control among peer (neighborhood) groups. Agents will be individuals in a social environments, modelled by social connection and disconnection between various agents. Agents may engage in crime and may exercise crime control against other agents; decision rules will be in terms of risk communication between agents and the likelihood that agents will engage in crime control against others.

All of these examples provide theoretical depictions of autonomous, heterogeneous actors whose interactions are well suited for formalization in computational agent-based models. While deriving formalized mechanisms will likely be more difficult for some theories than others, undertaking such formalization is of obvious utility. That is to say, formalized depictions of theoretical constructs are desirable irrespective of modelling, computational, or otherwise.

Assuming then that agents and their associated behaviors can be specified to reflect these theories, the plausibility of proposed mechanisms can then be evaluated by assessing their ability to generate known macro-patterns of crime – several of which are now discussed.

Macrostructures of Crime

Empirical research in the field of criminology has highlighted a number of macroscopic regularities of crime consistently observed across a wide range of crime types, contexts, localities, and measurement instruments (Birks et al. 2012). These regularities are the emerged trace effects of whatever mechanisms are indeed operating at the microlevel and thus are those that many individual-level theories of crime attempt to explain. To illustrate, five regularities are briefly summarized. While by no means exhaustive, this list alone demonstrates well that individual crime variability can give rise to macro-level crime pattern predictability. Again, this section refrains from paying detailed and due attention to the literature, instead just hinting at what is out there:

1. *Spatial and Temporal Clustering* – Research consistently shows that the spatial patterning of crime conforms to a Pareto law of concentration,

with the majority of crime concentrating in a minority of geographic areas often referred to as crime hot spots or hot places. Similarly, crime is not uniformly distributed over time. Very few locations experience constant levels of victimization. Instead, crime hot-times where the level of victimization is disproportionate relative to other times are often observed, be they by hour of the day, day of the week, or month of the year.

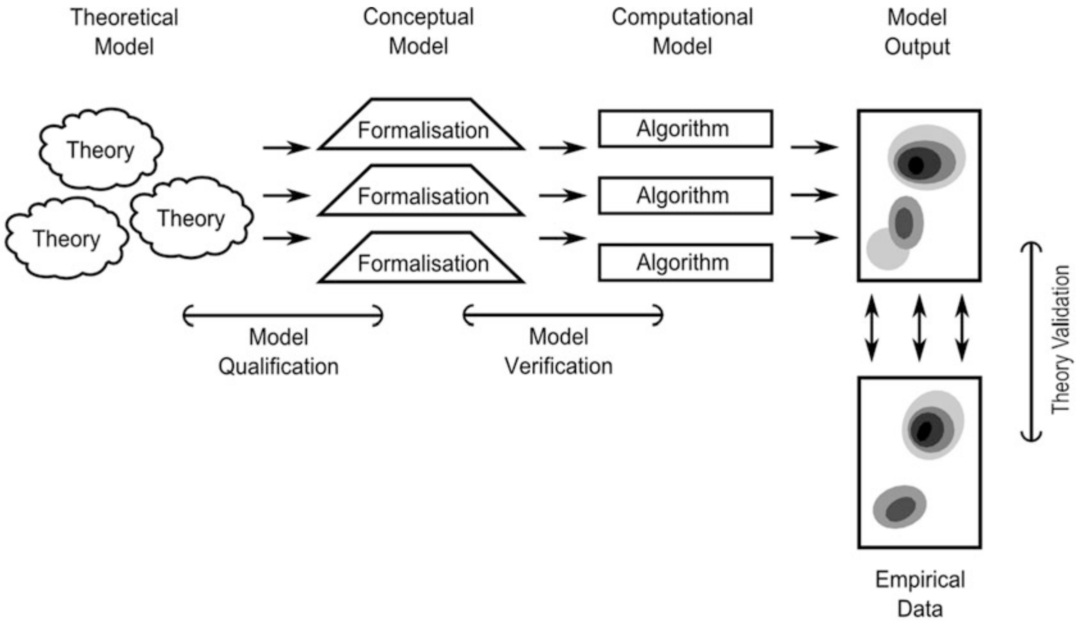
2. *Repeat and Near-Repeat Victimization* – Crime not only concentrates spatially and temporally but also with respect to a small number of persons/places/targets. These individuals commonly referred to as "repeat victims" experience disproportionate levels of victimization. Recent research has also consistently demonstrated spatiotemporally clustered near-repeat victimization, i.e., victimization of other targets close by earlier victimized targets.
3. *Repeat Offending* – While research has demonstrated that victimization concentrates in specific locations, at specific times, and against specific targets, research also consistently shows that the incidence of offending is also disproportionally distributed among offenders. As such, a small proportion of offenders are commonly responsible for a large proportion of offending.
4. *Journeys to Crime* – Numerous studies examining the spatial characteristics of crime trips have demonstrated the presence of a distance decay function where the majority of crime trips lie within a short distance of offenders' homes. Such observations have been made across a range of different crime types including residential burglary, robbery, and rape.
5. *The Age-Crime Curve* – Research consistently shows that younger offenders are more likely to commit crime than their older counterparts. The oft-cited age-crime curve follows a steady decay after initially ramping up through adolescence and peaking in the late teens/early twenties.

Computational Experiments

Given proposed theories of the crime event and the observed macro-regularities of crime, the generative ABM is ideally placed to explore if the former is indeed, as theorists would suggest, capable of generating the latter. If propositions provided by theory do reflect proximal mechanisms that are significant in the commission of crime, one would expect a virtual population of offenders operating according to them to generate patterns of crime which exhibit similar characteristics to those observed in empirical research.

In testing these hypotheses simulation experiments are performed whereby the mechanisms under which virtual populations operate are systematically manipulated. Subsequently, simulated crime patterns produced by virtual offenders are compared to suitable macroscopic regularities of crime. From this analysis conclusions are drawn about the generative sufficiency of the mechanisms formalized and moreover the validity of the theories from which they are derived.

Adapting from Schlesinger (1980), Fig. 1 depicts conceptually how such efforts can be undertaken. First, a theoretical model is selected for study and formalized as a conceptual model, through which key propositions of theory are defined. Model qualification then assesses through observation if this conceptual model is an adequate representation of the original, and often "fuzzy," theoretical model, posing the question: *do these conceptual formalizations and the proposed interactions amongst them adequately capture the theoretical propositions they aim to explore*? Where discrepancy or ambiguity exist, conceptual formalizations are refined to reflect more accurately the theoretical constructs of interest. Once qualified, a computational model representing the conceptual model is created, such computational models commonly define agents within the model, their characteristics, behaviors, and the environment in which they are situated. Model verification then assesses whether these computational constructs sufficiently represent the conceptual model from which they are derived. Verification often takes place by examining the output of specific algorithms in relation to particular scenarios. While the emergent properties of simulation are often beyond the scope of model verification (as they are often unexpected), model verification allows



Agent-Based Assessments of Criminological Theory, Fig. 1 Generative ABM development, validation, and experimentation

computational constructs to be examined individually with respect to the results expected by theory. Given a sufficient number of test cases where model outputs are consistent with the results expected by both theoretical and conceptual models, the computational model may be considered appropriately verified. After both conceptual and computational models have been assessed, model outcome validation assesses the sufficiency of theoretically defied computational constructs in capturing the output behavior of the target system as a whole. This is done by comparing characteristics of both simulated data and empirical data. In undertaking such endeavors, systematic controlled simulation experimentation is not just sufficient, but necessary. The following section outlines several characteristics critical in the design of implementation of such simulation experiments:

- *Address Theoretical Research Question* – Just like traditional experimentation, simulation experiments must be designed to address a specific theoretical research question. While simulation can be a useful tool, it can also be unwieldy when no clear goals of experimentation are specified. While perhaps obvious, this requirement is of considerable importance.
- *Systematic Control of Experimental Conditions* – Further mirroring traditional experimentation, in silico experiments should follow strict design principles. Appropriate counterfactual simulation states can and should be developed through which the impact of particular model manipulations can be systematically assessed. To illustrate, when exploring the impact of proposed offender behaviors, equivalent agent behaviors should be developed to reflect both the absence (a behavioral control condition) and presence (a behavioral experimental condition) of a proposed mechanism (see Birks et al. 2012). Subsequently simulations should be run with agents operating under both experimental and control conditions, and resulting outputs analyzed.
- *Simulation Replication* – While the results of a single simulation may be interesting, the stochastic nature of ABM dictates that experiments must be reproducible in order for

them to be deemed valid (Axelrod 1997; Townsley and Birks 2008; Townsley and Johnson 2008). Simulation replication, just like its empirical counterpart, aims to highlight implementation-specific factors which may influence observed results. Indeed, simulation models may be more susceptible to these factors due to their relative complexity and the skill set required in examining them (Axelrod 2005). As a result, without systematic and rigorous methods for scrutinizing simulation, factors unbeknownst to onlookers, or even the investigator, may influence simulation outcomes and, hence, the inferences being drawn from them. *Within-model* replication commonly averages the results of specific simulation configurations over numerous "runs." Such replications provide an important method through which the range and consistency of possible simulation outputs can be explored, assessing simulation statistical conclusion validity (Townsley and Johnson 2008). Thankfully, the nature of development environments used in simulation development dictates that within-model replication is relatively easy to perform, requiring little investment other than time and computing power. The main effort, however, is making sense of the multiplicity of generated results.

- *Robustness Testing* – Researchers commonly select model parameters that dictate the initial conditions of a given simulation. Such parameters might describe the size of the simulation environment, agent populations, or specific thresholds at which agents undertake certain actions. Such parameters may be derived from empirical research or, where appropriate, common sense estimations. Importantly, this mapping between input parameters and output behavior should be scrutinized (Axelrod 1997; Gilbert and Troitzsch 2005). Model robustness tests seek to examine the influence that changes in model parameters have on outcome patterns, thus ensuring that observed results are not unique to specific parameters. Akin to sensitivity analysis performed in a number of statistical models, simulation robustness tests involve systematically manipulating model parameters (ideally reflecting both model initial conditions and behavioral parameters (Fung and Vemuri 2003)), rerunning simulations, and examining changes in model outcomes. While it is unlikely that model outputs from such robustness tests will not differ somewhat, when variations in outcomes are observed, the evaluation of robustness testing assesses distributional equivalence. That is, *do the same types of macro-patterns remain given changes in initial parameters*?. Such tests ensure that model plausibility does not break down when seemingly innocuous changes in model parameters are performed (Fung and Vemuri 2003). When this does occur, underlying model structures should be scrutinized (returning to the processes of qualification and verification), ensuring that observed results are indeed indicative of unforeseen but plausible interactions, rather than an indication of underlying errors in the model formalization. While it is often impractical to sweep an entire range of possible input parameters, it is reasonable to explore a number of key model parameters within the computational constraints of a proposed study. In addition, models that incorporate stochastic elements should also be subjected to robustness testing with respect to selected random number seeds (Axelrod 1997).
- *Levels of* In Situ/In Silico *Equivalence* – In comparing empirical and simulated data, it is obvious that various levels of equivalence can be observed. Axtell and Epstein (1994) propose multiple cumulative levels of in situ and in silico system equivalence, beginning at qualitative macro equivalence (that is, where simulated outcomes offer a macro-level caricature of the system of interest) to both micro and macro quantitative equivalence – where both individual- and aggregate-level regularities can be shown to be statistically similar to empirically observed regularities. With respect to the study of crime, it is suggested that any model providing some level of in situ/in silico equivalence should warrant interest from scholars. Importantly, in this regard such demands for quantitative replication of

"real world results" are dependent on the often not warranted hypothesis that there is a clear and concise picture of the totality of real-world data. For example, while "distance decay" is a generally recognized characteristic in the journey-to-crime literature, there is not even a beginning of a commonly supported body of knowledge about the exact, let alone parameterized, form of the distance decay curve's functional form. Thus, while abstract models may well not provide quantitative equivalence, they do permit estimations of generative sufficiency and in doing so offer insight into the likely underlying dynamics of those processes which are difficult to characterize.

- *Multiple Output Measures* – A basic premise of the scientific enterprise is to identify parsimonious depictions of a system which are compatible with the widest variety of observable phenomena. Thus, when assessing in situ/in silico equivalence, the use of multiple distinct outcome measures is desirable. In this sense, while a proposed mechanism may generate highly plausible patterns of one macroscopic regularity, it is important to examine other related regularities. For instance, if a model of target selection produces spatially concentrated crime similar to that observed in empirical research but analysis of repeat offending highlights that only a single offender is responsible for all victimization throughout a virtual society, confidence in the validity of such a mechanism should be reduced. Here, it is reasonable to assume that some proposed mechanisms may only have explanatory capacity with respect to one regularity. However, the most tenable (and most useful) are likely those which are sufficient to explain multiple regularities of the target system.

Conclusion

This entry has discussed how computational agent-based models can be used to gain insight into the potential ramifications of individual-level crime event mechanisms proposed by theory and, in particular, assess their plausibility in explaining patterns of crime that are commonly observed in empirical studies. Given the numerous constraints placed upon observation and experimentation which face those who aim to study the crime event, the computational agent-based modelling approach provides criminology scholars with a unique and significant method that is complimentary to existing theoretical and empirical efforts. Contrasting itself against the commonly applied statistical explanation where associations are commonly observed, quantified, and mechanisms through which they might come about inferred, ABM provides a bottom-up approach to understanding crime patterns where the ability of hypothesized mechanisms to generate known associations is assessed through simulation experimentation.

This approach allows researchers to explore complex, dynamic, spatially situated interactions between boundedly rational, heterogeneous actors without the need to suppress important complexity and, in doing so, provides an analogue to the petri dish for criminology scholars. By undertaking controlled simulation experimentation using ABM, the underlying dynamics of proposed mechanisms can be examined and the viability of theories from which they are derived better explored, in ways that are often beyond the scope of traditional empirical activity alone. The purpose of the generative agent-based model is not to mimic reality, but instead to provide a tool through which the content, extent, and ramifications of criminological theories can be systematically explored. Not predicting, but understanding, complex behavior is the ultimate goal of generative simulation research.

Yet, while there are many advantages to a generative study of crime events, there are also clearly many considerations that must be undertaken in order that the utility of simulation be capitalized upon. In summary, simulation experiments must be systematic, rigorous, have clear goals, and be subject to replication and robustness testing.

While one cannot overstate the importance of theoretical and empirical efforts, the computational agent-based model and the generative approach it affords may well provide a complimentary method through which the consistency and plausibility of theory can be assessed without need for significant ethical, logistical, and monetary investment. Identifying those mechanisms that offer viable generative explanations for observed crime patterns both increases our ability to select those theories whose propositions are most likely to reflect real-world mechanisms and diminishes the likelihood of pursuing mechanisms that lack explanatory capacity.

Furthermore, the principle requirement of the generative approach – an adequate micro-specification of the crime event from which to derive computational constructs – is of considerable use in highlighting those theories that lack adequate specification of the mechanisms through which they propose observed outcomes come about. Without revision, such theories are likely of little use in developing either simulation or, more importantly, crime prevention intervention. Looking forward, it is hoped that an adaptation of the crime script methodology (Cornish 1994) will bear fruit in this regard, given the obvious parallels between both approaches.

While assessing the generative sufficiency of theory is but one potential application of simulation, it is one that we believe (1) is of considerable utility and (2) can be realized.

Individual-based simulation modeling

Overview

Many questions in criminology focus on dynamic processes and individual decision-making. For example, crime events represent the end result of a multitude of decisions made by a variety of different people in the context of specific situations. Potential offenders, potential victims, police, and other informal guardians of places make choices that bring them together at the same place and time. However, data describing any of those individual decisions prior to, during, and after the crime event are only rarely available and never complete. Once at a place, potential victims may take actions that make them a more suitable target. Potential offenders observe these actions and reevaluate the likelihood of getting away with a crime. At the same time, likely offenders also notice the actions of potential guardians and make adjustments. Even if data were collected to document the actions of individuals, the dynamic and nonlinear nature of human interaction and decision-making makes them difficult to study using traditional statistical techniques.

Agent-based modeling is a type of computer simulation modeling that allows the study of dynamic processes and the outcomes that emerge from individual decisions. An artificial world, akin to a scientific version of a video game, is created. This model is a simplified version of "real life" that contains only the most important aspects of the behavior being simulated. The computer program is initiated and the agents (i.e., representations of individuals) in the model interact. The patterns of outcomes produced by those interactions, for example, a distribution of crime events, is then compared with the pattern theory would predict or empirical data indicates. Since, we would expect that crime would concentrate across space, so geographic patterns of crime from a model should evidence this characteristic. Agent-based models (ABMs) allow group-level outcomes to emerge from individual decision-making. They enable researchers to conduct "what if" experiments because the outcome under alternative scenarios is known (i.e., both the control condition and the treatment condition can be simulated). The bottom-up approach, rather than the top-down of traditional statistical models, combined with the ability to systematically change the rules governing individual decision-making, creates a powerful modeling environment for exploring and strengthening theory as well as uncovering new insights.

Fundamentals of Agent-Based Modeling

Some Background and Basic Definitions

Computer simulation is a broad area of study. Flight simulators are a familiar example of a computer simulation that allows the user to practice flying an airplane. Agent-based modeling is one type of simulation modeling within the general category of computer simulation modeling "that enables a researcher to create, analyze, and experiment with models composed of agents that interact within an environment" (Abdou et al. 2012, p. 141). *Models* are simplified versions of the real world and have long been used to understand both structure and process. *Simulation models* are simply models that are programmed to run inside a computer and as such they share many characteristics with computer games but their purpose is scientific rather than recreational. An *agent-based model* (ABM), then, is a simplified representation of a real-world process that is implemented in the form of a computer program. ABMs employ a bottom-up approach in which agents are imbued with unique characteristics and general behavioral rules (Epstein and Axtell 1996; Gilbert and Troitzsch 2005). The *agents* in an ABM are typically individuals but can also represent collective entities such as neighborhoods or schools as well as companies or organizations. The fact that the agents are autonomous and make decisions based on the changing circumstances that occur during the running of the model is what makes ABMs unique. Because the decisions of individual agents are at the heart of ABMs, they are said to take a bottom-up approach to modeling processes. The individual decisions made by agents are what generate the outcome. This characteristic is what makes ABMs so valuable for modeling social processes as outcomes of individual decisions. It is also what has led some to call it a *generative social science* (Epstein and Axtell 1996). A core characteristic of agent-based models (shared by cellular automata) is the capacity to produce unexpected results. The term *emergence* is used to describe outcomes from a model that were not anticipated.

Simulation models, in general, have a variety of uses (Gilbert and Troitzsch 2005). They can be used to improve our *understanding* of processes that are hard to measure directly. Offender decision-making is an example of one potentially fruitful area of inquiry because we can look inside the criminal decision-making process and examine the relative importance of each piece of information considered. Another use of ABMs is for *prediction*. If a model is built that can faithfully reproduce a dynamic process, then it can be used to predict an outcome based on different inputs or different behavioral rules. One example of prediction using ABMs are the models used to predict changes in demographic structure based on decisions related to decisions regarding age of first childbirth, family size, and other related factors. Not all ABMs are suitable for prediction; specifically in the case of micro-level ABMs that test nonlinear theories, prediction is not an appropriate standard because they are inherently unpredictable (Gilbert and Troitzsch 2005). ABMs are of particular interest to scientists because of their utility for *discovery* and *formalization*. A simple model can be created that embodies a theory about how a process works. The simulation can be run in the computer and the outcomes tested to discover whether the predicted outcomes occur. In order to create such a model, the scientist must formalize critical aspects of the theory in order to program it. The process of formalization is important because it forces scientists to increase their precision as compared to verbal or statistical realizations of a theory. In this tradition, simulation allows for the exploration and elaboration of theory (Dowling 1999). Some have proposed that ABM can be used to investigate theoretical mechanisms and provide a way to eliminate potential explanations that cannot be grown from individual behavior (Eck and Liu 2008a; Epstein and Axtell 1996).

Components of an ABM

An ABM has two main components, the agents and the environment in which the agents interact. While there is no standard definition, an agent can be thought of as an "autonomous goal-directed software entity" (O'Sullivan and Haklay 2000, p. 1410). Agents have characteristics and behaviors which are modeled after their real counterparts. The environment in which they interact also can have characteristics and rules.

Agents and Their Characteristics

Agents can represent people such as potential offenders or police officers. Even groups of people with a collective identity such as neighborhoods, gangs, businesses, or city departments can be agents.

Agents share several general characteristics, only a few of which are highlighted here (Crooks and Heppenstall 2012). First, they are autonomous; they make decisions for themselves. Second, agents are heterogeneous. They have a set of characteristics that are unique to them. For example, an agent representing a police officer can have a race, a gender, an age, a number of years on the job, and any other characteristic pertinent to the goal of the model. More importantly, each police officer agent can have their own values for each of those characteristics. This means the modeler can have an agent's characteristics factor into her own decisions as well as the decisions made by other agents.

Third, agents are proactive and have goals that guide their actions. They are interacting and changing over time. They can interact with other agents and perceive and react to their environment. In the case of individuals, the actions they undertake often require movement. For example, a police officer agent may begin patrolling using a random pattern within her assigned beat. She is constantly scanning her immediate environment with the goal of identifying crime events and stopping them. A potential offender may proceed through a number of routine activities. During the course of those activities he may notice the quality of opportunities to commit a crime he encounters. Whether or not he takes advantage of those opportunities may depend on whether it will make him late for his legitimate job, whether a police officer is at the same place and his perceived chance of success as compared to potential reward. But organizations, such as businesses, can also be dynamic and take purposive action. For example, they can choose to reinvest in the community in reaction to public pressure or continue to prioritize maximizing profits.

Each type of agent in a model is given a set of rules that guide their behavior and interactions with other agents and their environment (Crooks and Heppenstall 2012). For example, an offender agent would have a different rule set than a police officer.

Agents are typically created within an object-oriented programming environment (Abdou et al. 2012). Such programs contain collections of *classes* and *objects*. Classes describe groups of agents that share the types of actions they can undertake. For example, citizens would be in a different class from police officers since only police officers can make arrests. Each class has a set of shared *attributes* and *methods*. *Attributes* are the characteristics of the agents. For example, attributes of age, offending propensity, and income are possible if the agents represent people. Characteristics are unique to each agent. *Methods* are the actions members of a class can undertake (e.g., movement, making an arrest, committing a crime). During the model run, classes are *instantiated* in the form of objects representing individual agents with unique characteristics. For example, the first agent might be 24 years old, have an offending propensity of .49, and an income of $129 per week. The next agent might be 62 years old, have an offending propensity of .05, and income of $1,129 per week. Both agents have the ability to move and to commit crime because these methods belong to each agent in that class.

Environments in ABM

All agents exist in an environment and this is what allows them to interact with each other and with their surroundings (Crooks and Heppenstall 2012; Gilbert and Troitzsch 2005). However, there are several types of environments that can be used, and the type of environment chosen is dependent on the phenomena being modeled (Gilbert and Troitzsch 2005). In some models, there is no need for movement. For example, deterrence theory has been tested by modeling an agent's likelihood of engaging in income tax fraud based on their own and their neighbor's experience with being audited and the perceived rewards of cheating (van Baal 2004). Environments can also provide a spatial context for agents to interact.

Spatial context can be derived from the position in geometric space or geographic space. Geometric spaces can be represented as grids (similar to the squares on a checkerboard) or networks. Each agent is located within the geometric space. Some models have agents on a grid that can move from one adjacent grid cell to another. Other models have agents connected to one another via a social network (with the agents as nodes and the connections as lines). Networks in models can represent connections that are physical (e.g., a transportation network) or relational (e.g., friendships or trading relationships).

Models that use geographic space are enhanced by situating agents in "real" environments. These "real" environments can be raster surfaces describing land use or the street network from a city. Such simulations use data created by a geographic information system as the environment in the simulation model but do not actively use the topological properties of the data during the model run.

There are also software packages that integrate GIS and ABM to provide a platform for the dynamic modeling of individuals across space and time. One example is Agent Analyst, which follows the middleware approach in which the temporal relationships are handled by the ABM software and the topological relationships are managed by the GIS (Brown et al. 2005). Agent Analyst combines two of the most popular packages for ABM and GIS, the Recursive Porous Agent Simulation Toolkit (Repast) and ArcGIS. To make the software easier to use, Agent Analyst is built using the rapid development version of Repast called Repast for Python Scripting (RepastPy) which has a graphical user interface that automates much of the programming to create the framework of a model (see Johnston, 2012 for an introduction to Agent Analyst). Agent Analyst is designed to be added into ArcGIS as a toolbox. Once the toolbox is added in ArcGIS, models can access shapefiles allowing (1) individual agents to become spatially aware and (2) the visualization of agent movement and decision outcomes (e.g., patterns of crime events).

The integration of ABM and GIS leverages the temporal capabilities of ABMs and the spatial capabilities of GIS. ABMs permit the researcher to (1) collect data about the characteristics of each individual present during an interaction, (2) randomly assign characteristics to agents greatly reducing the possibility of systematic bias, (3) have agents make independent decisions within behavioral guidelines, and (4) systematically vary one attribute while holding all others constant to undertake controlled, repeatable experiments (Epstein and Axtell 1996). GIS makes it possible to take into account how the characteristics of the real environment (e.g., transportation networks and land use) impact the activities of spatially aware agents.

ABM as Methodology

ABM is a research methodology in its own right (Axelrod 2007). Some have suggested it is a third type of scientific inquiry (Axelrod 2007) in addition to deduction and induction. Like deduction, the beginning point is a set of theoretically based assumptions, but instead of proving theorems, ABM produces data which is analyzed inductively. But these data have not been measured empirically (in the real world); they have been generated from agent interactions in a virtual world. It lends itself to conducting thought experiments, but in a virtual world.

Other scholars have labeled ABM a third symbol system in addition to natural language and mathematics (Ostrom 1988). ABM is capable of incorporating both natural language descriptions of behavior and relationships as mathematical ones but is not limited to one or the other. ABM allows the researcher to examine "bottom-up" processes that involve the interactions of heterogeneous individuals with each other and with their environment. Thus, ABM can be used to systematically examine complex and dynamic relationships at the individual level.

The guiding principle of ABM is "simpler is better." Modelers want to build a model that is as simple as possible while maintaining the most important aspects of the target phenomena. This is primarily because complex virtual behavior often develops from relatively simple rule sets. In order to recognize when surprising (i.e., emergent) phenomena occur and to be able to explain what is happening in the model, the modeler must be clear about every aspect of the model (Axelrod 2007). It is easier to be clear when the model is simple.

This section focuses on ABM as a methodology and details the process of conducting such investigations. In other words, it provides the series of steps that are followed to construct an ABM. Although presented in a sequence here, these steps are often iterative with the results of one step causing a reevaluation of an earlier step.

Building an ABM

The initial task is to identify a problem that needs solved, a theory that needs tested, or a question that needs answered (Abdou et al. 2012; Gilbert and Troitzsch 2005). For example, a researcher might want to test a theory of how gangs form. ABMs are also frequently constructed to investigate regularities in patterns of behavior observed at societal or macro levels (Abdou et al. 2012; Gilbert and Troitzsch 2005). One example involves the clustering evident in the spatial distributions of crime events. Several authors have used the ability of their models to replicate clustering as a by-product of the individual decisions of agents (Birks et al. 2012; Groff 2008).

The next task is to examine existing theories which are important to explaining the phenomena of interest. When building an ABM, it is necessary to systematically examine the specific components of theory that may be relevant and to attempt to define them as explicitly as possible based on existing research (Birks et al. 2008, 2012; Groff 2008). While models vary in how faithfully they represent reality, they typically operate on the principle that “simpler is better”; thus a primary goal of modelers is to try to assemble the most parsimonious model to answer a question. The degree to which the theory is represented in the model represents the structural validity of the model (An et al. 2005). Simulation models, in particular, start with simple models and then systematically add complexity to ensure that the dynamics are well understood before continuing (Gilbert and Troitzsch 2005). These two tasks provide the basis for the more programming-oriented ABM building steps.

At this point, the modeler is ready to create a conceptual model. This is usually a visual diagram that captures both the essential constructs and how they are related to one another. The types of agents to be included in the model are specified, as well as the environment. A model exploring routine activity theory would, at a minimum, need to have potential offender agents, target agents, and guardian agents (Groff 2007). One examining crime pattern theory would need to include activity spaces of offenders (Brantingham and Brantingham 2004).

Once a model has been specified, it is programmed. The constructs of the theory are formalized at this point so they can be coded in the computer program. In some cases, the constructs are formalized as clearly stated verbal guidelines that underlie the behavior of agents, their interactions with other agents, and their interaction with the environment. For example, a potential offender will not commit a crime if a police officer agent is present. In other cases, the definition of these constructs takes the form of mathematical equations for evaluation of specific situations an agent encounters during the course of a simulation. Where theory is not detailed enough for implementation or does not address an issue, empirical research is used to enhance the representation of behavior within the model. The programming to implement the model is typically done via a software package.

Random numbers are an important component of ABMs. They are used to represent uncertainty in the model. Random number generators (RNGs) are used to provide numbers that fit a statistical distribution (e.g., normal, Poisson, or uniform). The modeler chooses the distribution that reflects the assumption of the model. The seed, or beginning number for the RNG, produces a set of random numbers. Each time the same seed number is used, the RNG produces the same set of numbers. This critical property of RNGs is what enables experiments to be run in ABMs. If an assumption of the model is changed but the same seed or series of seeds is used in the experiment, everything else is held constant from one experiment to the next. Thus, the researcher knows any changes in outcome are due to the change in the model assumptions. Seeds can be systematically varied across a set of runs and the results from those runs averaged before being presented as model results. This ensures the outcomes are not dependent upon the numerical value of the seed.

RNGs are also used to compensate for the fuzzier areas of what is known about how a phenomena "works." Returning to the example of exploring guardianship, we know bystanders in a situation act as informal guardians but we do know exactly how the presence of those individuals translates into potential risk as perceived by an offender, and we are not likely to be able to collect data on that aspect of offender decision-making. If we assume it is equally likely that each agent present in a situation represents one additional unit of guardianship, as it is that they represent five units of guardianship, we can use a uniform random number generator that ranges from 1 to 5. Since the distribution chosen is uniform, each time the RNG generates a new number it has an equal probability of being a 1, 2, 3, 4, or 5.

Verification, Validation, and Sensitivity Analysis

Three types of model testing are important to understanding the quality of the model results, verification, validation, and sensitivity analysis. "*Model Verification* is substantiating that the model is transformed from one form into another, as intended, with sufficient accuracy. Model verification deals with building the model *right*." (Balci 1994, p. 121). This usually takes the form of debugging and logic-testing both during the programming of the model and during its testing to ensure the interactions produced by the code are as the theory intended. When ABMs include random numbers, without specifying the seed, no two model runs are alike and the only point of comparison is the distribution of results that the theory would suggest (Gilbert and Troitzsch 2005).

In contrast, "*Model Validation* is substantiating that the model, within its domain of applicability, behaves with satisfactory accuracy consistent with the study objectives. Model validation deals with building the *right* model." (Balci 1994, p. 123). This aspect of model testing answers the question of how well the model represents the "target." Model validation is analogous to the criteria of external validity used in traditional modeling (Gilbert and Troitzsch 2005). Validity in an ABM context is not an all or nothing proposition (Law and Kelton 1991). Rather, a model can have varying levels of validity relating to different properties of the target. There are several challenges in evaluating model validity of ABMs (Gilbert and Troitzsch 2005). First, both the target and the model have random components. Thus, the outcomes will vary across model runs. The critical question concerns how much the model varies from the expected statistical distribution of the outcomes. Second, many models are sensitive to the starting values of parameters (e.g., the ratio of motivated offenders to suitable targets in the model). Third, there may be problems with the "real" data rather than with the model results. This is an important issue especially when data sources are nonexistent (e.g., threshold of risk versus reward when deciding to commit a crime) or when they are unreliable (e.g., reported crime data only contains events reported by the public and those deemed to be crimes by the police officer taking the report) (Eck and Liu 2008a; Groff and Birks 2008).

Some researchers have compared the results of their simulations to widely recognized regularities in crime patterns, also known as "stylized facts" (Birks et al. 2012; Groff 2008). For example, crime patterns should exhibit (1) a high degree of clustering, (2) concentration of crime in relatively few places, (3) relatively few offenders responsible for most of the crime, (4) rather few victims accounting for most of the victimization, and (5) non-static patterns of crime over time. When results from a model share characteristics with empirical ones, their credibility increases (Eck and Liu 2004).

Sensitivity analysis addresses whether the parameter values chosen to represent the assumptions of the model affect the outcome of the model. For example, in a model of guardianship, if the number of people necessary to establish guardianship in a potential offender's view is set to one person, will the model results change significantly if the parameter is changed to require two people, or three or four? Sensitivity issues can be tested by varying the parameter values and looking whether the overall results change. Given the large number of parameter values that are typically used in a model, only the parameters which are most likely to affect the results are usually investigated (Gilbert and Troitzsch 2005). Sensitivity to initial parameter settings and agent interaction rules are widely recognized limitations of ABMs that can only be partially mitigated through sensitivity testing (Couclelis 2002).

In sum, the strength of a model increases when rigorous verification is implemented throughout the programming process. It is improved further when validation tests reveal the model-produced findings share stylized characteristics with empirical findings. For example, since crime is clustered, crime events produced by a model should also be clustered. However, matching distributions is not a sufficient criterion for validation since a different model could also produce comparable patterns investigated (Gilbert and Troitzsch 2005). Establishing model credibility is an incremental process that involves multiple comparisons and is not an exact science.

Communication for Replication and Evaluation

One of the most challenging yet important stages of ABM is sharing the model with other researchers. This requires in-depth and complete description of the model which is difficult to accomplish in the space available in the typical journal. A template called the Overview, Design concepts, and Details (ODD) protocol has been developed for communicating models to facilitate replication and evaluation (Grimm and Railsback 2012). The first section of the ODD describes the focus of the model. The next section describes how the model implements ten core design elements including emergence, adaptation, objectives, learning, prediction, sensing, interaction, stochasticity, collectives, and observation. The final section contains all the information necessary to replicate the model. This protocol is becoming more widely used which should facilitate replication and evaluation of ABMs (Grimm and Railsback 2012).

When to Use an ABM

There are several circumstances in which ABMs are an appropriate method to use. When existing theories describe the mechanisms involved in criminal behavior (Eck and Liu 2008a), ABMs can be used to test the mechanisms in silica. For example, rational choice perspective (Clarke and Cornish 1985) describes how offenders make decisions whether to commit a crime based on situational characteristics. Agents can be created that use the logic of rational choice perspective to evaluate a situation. The modeler can examine what combination of situational characteristics translates into a decision to commit a crime.

When there are no data available to test a theory or describe the phenomena of interest (Eck and Liu 2008a), an ABM may be the only methodology available. For example, convergence is a core mechanism for crime events in routine activity theory (Cohen and Felson 1979). Data describing the movements of individuals prior to their involvement in a crime event are rarely available now and that is not likely to change (O’Sullivan 2004). The space-time movements of agents can be collected within an ABM and used to explore explanations for how offenders and victims converge in space-time.

In the same vein, ABMs can be used to explore the decision-making process related to crime. Crime events are the end result of decisions made by both offenders and victims that bring them together at the same place and time. However, data describing individual decisions prior to, during, and after the crime event are not available. Even if the data were collected, the dynamic, nonlinear quality of crime events makes them difficult to study using traditional statistical techniques. Agent-based modeling can accommodate individual agents with unique characteristics and decision-making capability.

When opportunities to conduct field experiments are challenging or even impossible, ABMs can be used as exploratory devices (Groff and Mazzerole 2008), for example, when ethical concerns preclude random assignment of people to treatment and control conditions or when it is not practical to vary the attribute of interest, such as changing the configuration of streets, which would be prohibitively expensive to do in a field trial but is easily done in an ABM. Although ABMs are not inherently experimental, they can be designed to systematically manipulate or randomly allocate a condition. The counterfactual or "null model" is simply the model without the "treatment" or behavior of interest turned on. The outcome from the null model can be compared to systematic manipulations of some aspect of agent behavior or the environment while literally holding all other aspects of the model constant. This provides a level of control nearly impossible to attain in field experiments. "While there is no substitute for field experimentation, simulation may be able to play a significant role in vetting and/or strengthening programs prior to their empirical testing." (Groff and Mazzerole 2008, p. 189).

Along those lines, ABMs can be used to vet potentially expensive or invasive crime-prevention strategies prior to implementation (Groff and Mazzerole 2008). The combination of heterogeneous agents and complete control allows testing of a variety of crime-prevention programs and evaluation of outcomes for minimal cost as compared to field experiments. This makes them an excellent alternative when field experimentation would be prohibitively expensive or ethically difficult to mount (Eck and Liu 2008a). ABMs generally represent a complimentary research method to existing empirical ones.

Modeling the Process and Structure of Crime

ABMs have been used to study a variety of crime types including residential burglary, commercial robbery, street robbery, fraud, heroin use, drug markets, and crime in general (see both Eck and Liu 2008b; Groff and Birks 2008 for an overview). Most persuasively, these examples have illustrated how ABMs are able to model both the process and structure of events. In the case of crime events, ABMs can take into account the process that brings together the actors involved in crime. They can also represent the interactions that occur among those actors plus the decision-making process as the situation unfolds. ABMs can include structure in the sociological sense in terms of social influences on agent behavior. This is analogous to modeling the effects of unemployment, poverty, and education on crime. They can also incorporate the physical structure within which agents interact in terms of, for example, transportation and land use.

Future Directions and Challenges

ABM offers a promising alternative method for exploring how individual/micro-level actions over time produce group/macro-level phenomena. Although ABM has been around for over 30 years (40 years if theoretical/pen-and-paper models are included), significant challenges to using the methodology remain. Firstly, and most practically, the use of ABM as a methodology continues to be hampered by the steep learning curve required. Skills involved in the development of conceptual models for the most part follow standard model-building practice. Of course, modelers do have to learn to think using a bottom-up rather than a top-down paradigm, which can be difficult. But the greater challenge remains the need for programming skills to implement models in current software. Given the lack of experience of most social scientists with computer programming, this represents a significant hurdle to using ABM.

Secondly, validation of ABMs generally is challenging. Many of these challenges are widely recognized such as the need for standardized techniques for model building and for analyzing models and routine replication of models (Gilbert and Troitzsch 2005), as well as the fact that ABMs using different mechanisms can produce similar results.

In addition to these intrinsic challenges, the use of ABMs to examine crime has to depend on outcome data (i.e., crime statistics) with widely recognized shortcomings. Since crime data only reflect a subset of the crime that is committed, comparing the crime patterns produced by an ABM to empirical crime data is, in effect, comparing them to the subset of crime that is both reported to the police and for which the police take a report. Thus, it is difficult to tell whether the ABM's crime pattern is incorrect or whether it actually reflects the "real" distribution (i.e., the full set) of crime committed (Eck and Liu 2008a; Groff and Birks 2008).

Despite these challenges, ABM's use to investigate the potential crime prevention value of situational crime prevention techniques has great potential. The necessary foundation for agent-based modeling to contribute in evaluating crime-prevention strategies is the development of models that can produce realistic crime patterns. ABMs have traditionally emphasized offender behavior but there are other actors who have important roles in whether a crime occurs when the necessary elements converge in space and time (Eck and Liu 2008a). Decision-making by non-offenders such as potential victims, intimate handlers, and place managers are critical to understanding why crime occurs in one situation and not another (see Groff and Birks 2008 for additional suggestions). Given sufficiently robust models of why a particular crime occurs where it does, the possibilities for testing crime-prevention strategies in a relatively low-cost environment like an ABM would be limited only by the imagination of the researchers.

Agent-Based Models to Predict Crime at Places

Nick Malleson and Andrew Evans
School of Geography, University of Leeds,
Leeds, UK

Overview

Crime occurrences are driven by a complicated mix of distinct influences, including those of the environment, the surrounding social context, and personal behavior/psychology of the people who could influence a crime event. Agent-based modelling is a methodology used in computer simulation that concentrates on individual-level behaviors and is ideally suited to modelling crime. This is particularly true of crimes such as burglary or street crime, which are heavily influenced by environmental factors and by the behavior of individual people. In an agent-based crime model, virtual "agents" are placed in an environment that allows them to travel through space and time, behaving as they would do in the real world. This entry will discuss why the crime system is such an ideal candidate for agent-based models and will review a number of crime models that have recently arisen.

Introduction

Individual crime occurrences are caused by a complicated mix of factors, including – but not limited to – the surrounding physical environment, the local social context, the presence or absence of crime reduction programs, and the behavior, psychology, and interactions between those people who might be able to influence a crime event (including victims, offenders, and guardians). Traditional mathematical models of crime can face difficulties with modelling systems which are inherently nonlinear (Eck and Liu 2008), and therefore, methods which are better suited to capturing the dynamics of complex, nonlinear systems are becoming popular.

Agent-based modelling (ABM) is a methodology used in computer simulation that concentrates on individual-level behaviors and is ideally suited to modelling crime. This is particularly true of crimes, such as burglary or street crime, which are heavily influenced by environmental factors and by the behavior of individual people. In an agent-based crime model, virtual "agents" are placed in an environment that allows them to travel through space and time, behaving as they would do in the real world. The environment can be as simple or detailed as the researcher chooses so the methodology can thus be used both to explore criminology theory in the absence of confounding factors or to make realistic predictions in a real-world virtual environment.

This entry will review the technique of agent-based modelling and discuss what advantages it offers to the field of environmental criminology. It begins an overview of the "crime system" and discusses what makes it such an ideal candidate for agent-based modelling, followed in Section 3 by a discussion of the technique itself. Section 4 continues by reviewing a small number of the most recent and advanced agent-based crime models. Finally Sections 5 and 6 review some of the controversies in the literature and propose open questions for future research.

Background: Crime Is a Complex System

Social systems, including that of crime, belong to a class of system known as "complex systems." These are systems that consist of large numbers of diverse components, varied and complex interactions between components, and emergent properties – in this case city – or neighborhood-wide crime rates that cannot be attributed to any individual part of the system. Coupled with this inherent system complexity are "human" factors, such as a complex psychology, that further compound the rules that drive the individuals (Bonabeau 2002). In addition, the crime system is made even more complicated because as crime at places (Eck and Weisburd 1995) and situational crime prevention (Clarke 1995) research have demonstrated, the geography of the system itself introduces additional complexity. However, understanding the processes and drivers that characterize the crime system is the key to crime prevention and policy development.

Acquisitive crimes, such as burglary and street robbery, are important exemplars of the manner in which environmental, social, and individual drivers combine to create a set of complex processes. Because occurrences are dependent on a number of interacting factors (motivation, opportunity, recidivism, etc.), it is difficult to predict crime hotspots in advance, and therefore, many reduction schemes react to a crime hotspot once it has formed. Ultimately, acquisitive crimes are committed by individuals in a local environment and a particular time. Modern criminology highlights the importance of "micro-places" that act as the environment for a specific crime (Eck and Weisburd 1995), and research at scales larger than houses and streets hides key crime dynamics. The same scale issues apply to the individuals involved in a crime event (be they perpetrators, victims, or bystanders) whereby aggregate treatment of individual people is likely to miss the key dynamics associated with individuals and their daily lives. As Brantingham and Brantingham (1993) predicted:

> Potentially, the most productive model in environmental criminology is one that places both the actual criminal events at a specific site, situation and time and the individual committing the crime while in a specific motivational state on (or in) an environmental backcloth, that may itself be mostly stable, regular and predictable or may instead be irregular, rapidly changing and unpredictable.

With this in mind, agent-based modelling is a technique that is being shown to hold considerable promise as it represents a shift away from aggregate models towards those that work at the level of the individual. An agent-based computer model is comprised of autonomous entities called "agents," who have the ability to make decisions and interact with each other and their environment. As the model iterates, each agent has the ability to assess its circumstances and, based on a set of probabilistic rules or more advanced decision-making algorithm, make an informed/educated decision about its future course of action. Through this mechanism, it is possible to incorporate realistic human behavior into computational models. With respect to modelling crime, an agent-based model can be built to directly simulate the behavior of offenders/victims/guardians as they travel around their environment on typical routine activities and predict, as a result of these individual behavior patterns, when a crime occurrence is likely to occur. Building a model in this manner – *from the bottom up* – is a much more natural way of describing a complex system than by formulating rules to drive the system from an aggregate level

(Bonabeau 2002). Section 3 will now discuss the technique of agent-based modelling in more detail.

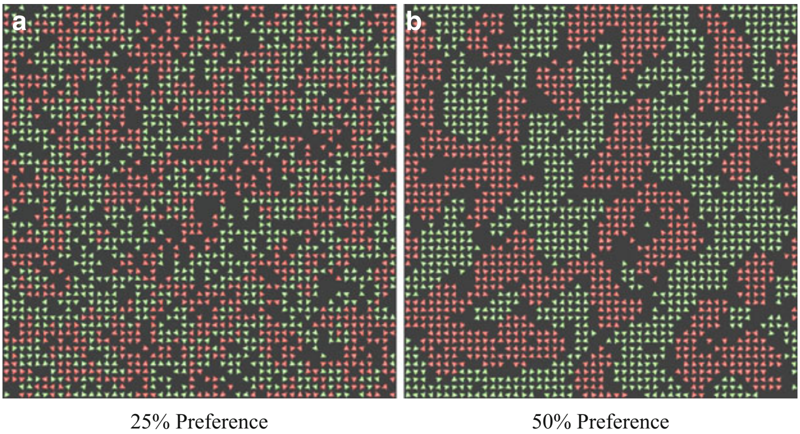
A Description of Agent-Based Modelling

The range of general agent-based theory is extensive, and so this entry will not attempt to provide a full account of all concepts, practices, and applications. For this, the reader is directed to Wooldridge (2009). Instead, it will provide a brief introduction to the methodology and focus on its application to crime. Described as a “breakthrough in computational modelling in the social sciences” (Gilbert and Terna 2000, p. 60) and “one of the most exciting practical developments in modelling since the invention of the relational database” (Macal and North 2005, p. 2), ABM is a reasonably new method of modelling systems. An agent-based model is comprised of virtual “agents” who are able to behave autonomously (i.e., without a central controller). They exist in a virtual environment which is often spatial, they can navigate around their environment, and they are able to make decisions about what they would like to do in a given situation. This approach is particularly relevant to criminology because using ABM, it becomes possible to use models to carry out experiments that would be impossible or unethical to perform otherwise.

There are many definitions of the term “agent” but, from a crime modelling perspective, the following are consistently applied:

- Autonomy: an agent should be free to control its own state, interact with other agents and its environment, and make decisions without direct control from some central source. This seems to be an ideal mechanism for modelling people, including offenders, victims, or other necessary individuals (guardians, managers, passersby, etc.).
- Heterogeneity: agents need not be identical. Offender agents can thus be created to reflect the variety of different offending behaviors that have been exhibited, allowing for the incorporation of qualitatively obtained data and theories.
- Reactivity: agents should be able to respond to changes in their environment, and the response should be proactive, indicating goal-directed behavior (Wooldridge 2009). This is particularly useful for a crime model because the environment will change as a result of crime which will in turn influence the future behavior of the agents.
- Bounded rationality: particularly with modelling in the social sciences, it is important that agents do not always act perfectly rationally. Agents can be programmed with “bounded” rationality by limiting their knowledge of the world so that choices are not always perfectly optimal (Castle and Crooks 2006).

Perhaps the most significant advantage of ABM is the “natural description” of a system which it provides. Complex systems, whose behavior is characterized by the behavior/interactions of its individual components, cannot usually be described by mathematical equations. Although mathematics provides a good basis for describing unexplained phenomena in the natural sciences, this experience is not echoed in the social sciences (Moss and Edmonds 2005). Often simplified assumptions are required if mathematical models become too complicated and these assumptions are often implausible or reduce the realism of nonlinear systems (Evans 2011). To understand geographical human systems, it is necessary to understand the reasoning behind individual decisions and modelling individuals directly is more natural than trying to build aggregate equations to control them (Bonabeau 2002). For example, with acquisitive types of crime, an individual’s cognitive understanding of a local area can be as important as the physical characteristics of the area, as offenders commonly commit crimes within their routine activity spaces. These cognitive representations would be very difficult to incorporate into models which do not characterize individuals directly, whereas in an agent-based model they can be built directly up as the virtual agents navigate around their environment. The same can be said of environment: it has been shown that spatial aggregation hides important patterns in crime (Andresen and Malleson 2011) and ABM is



Agent-Based Models to Predict Crime at Places, Fig. 1 An example of an agent-based model of segregation, based on Schelling (1969). Figures show the percentage of similar racial type that each household unit wants to live next to

ideally suited to modelling at resolutions of the individual street or household.

Arguably the first published agent-based model in the social sciences was Schelling's hand-developed model of residential stability (Schelling 1969). Although extremely simple, the model goes a long way to illustrate how useful ABM can be for modelling social systems. The model consists of a one-dimensional environment (a line of spaces, some empty) populated by households that belong to one of two types of racial group. A global parameter dictates the percentage of the same group that each household wants to live next to. Households are able to move to an empty cell if they are unsatisfied (i.e., they live near to too many of the opposite racial type). The novel research finding was that, even with a relatively low preference for the same racial type, the environment can become highly segregated. It is relatively simple to develop a two-dimensional version of this now, and such a model, which is included as a demonstrator in the agent-based modelling software "NetLogo," is illustrated in Fig. 1. Here a preference to live next to only 50 % of the same racial group leads to clear segregation. Methodologically the Schelling results are interesting because they would not have been predicted by examining the rules of the individual in isolation, and from a practical position, it provides an insight into the dynamics of human residential segregation, suggesting that extreme segregation can emerge from individuals who actually have low preferences for segregation.

The finding that segregation arises even though no individual wants to live in a completely homogeneous area relates to the concept of *emergence*, exploring which is a key advantage of ABM. An emergent phenomenon is one that comes about as a natural (and often unintended) consequence of the behaviors and interactions of a system's constituent components. A city-wide crime rate is an example of an emergent phenomena and one which cannot be attributed to any part of the system itself – there is no single person who is responsible for, or even attempts to generate, the observed crime patterns. Rather than attempting to find global rules that determine aggregate crime rates, the agent-based crime modeller describes the individual components of the system and then tries to "grow" the observed crime patterns from the "bottom up." This also has the advantage of being a much more naturalistic way of describing a system. Social networks, human psychology, and detailed physical environments are essential parts of the crime system, and these are relatively simple to incorporate by using ABM. A related advantage, which is particularly relevant in environmental criminology, is that with ABM it is possible to treat offenders in a similar manner to non-offenders and explore the effects that noncriminal activities will have on crime. In this manner, the "natural variety" of cities becomes part of the model, rather than being smoothed out by aggregate methods (Brantingham and Brantingham 2004).

There are, of course, certain drawbacks to ABM which must be addressed. The advantage of being able to describe the behavior of individual people directly is tempered by the difficulty in modelling the “soft factors” exhibited by humans – such as seemingly irrational behaviors and complex psychology (Bonabeau 2002) – which can be very difficult to actually implement in a computer model. These factors must be defined explicitly in models which work at the microlevel, leading to a strong commitment to minimal behavioral complexity (O’Sullivan and Haklay 2000). This is compounded in crime modelling research by problems with the availability and accuracy of crime data to build up an accurate picture of offending behavior. Although there is considerable qualitative information available, quantitative data is sparse, and even when data are available, it is unclear whether or not they are an accurate reflection of true offending patterns because of potential reporting biases. For more information the interested reader could refer to Chainey and Ratcliffe (2005) for a comprehensive assessment of the issues surrounding the use of crime data.

There are also major difficulties that relate to the implementation of the model. Firstly, although there are numerous ABM tools that can assist with the development of models (NetLogo is a good starting point for those new to the technique), it is likely that a researcher will need a relatively high level of computer programming experience. Agent-based models are also extremely processor and storage heavy, not least because most are run multiple times with varying parameters to give probabilistic results. This means that the most advanced models often need to be distributed across large collections of computers to obtain the required processing and storage power. Such models present considerable debugging issues, not least because small pieces of computer code can form integral parts of hundreds of agents, with small errors in the logic of the code having huge effects on the outcome of the model.

Nevertheless, ABM is becoming an increasingly popular tool to aid crime analysis. The following section summarizes some of the more recent and advanced approaches.

State of the Art

The last decade has seen a gradual rise in agent-based crime simulation work. The earliest models are generally abstract and take place either in geographical social spaces or on abstract plains (much like the segregation model outlined in section “A Description of Agent-Based Modelling”), whereas more recent models include realistic representations of the physical environment and comprehensive agent decision-making. Most models consider some subset of the core elements of the crime system, such as the physical environment, the social context, victims, offender motives, and offender behaviors. However, the system is clearly extremely complicated, and it should come as no surprise to find out that most models concentrate on one particular aspect of the system. To provide an overview of the current research, this entry will briefly summarize a small number of applications which have very different foci. For a much more comprehensive review, the reader is directed to the book entitled *Artificial Crime Analysis Systems* (Liu and Eck 2008), a special issue of the *Journal of Experimental Criminology* entitled “Simulated experiments in criminology and criminal justice” (Groff and Mazerolle 2008) or the review paper by Malleson et al. (2011).

Offender Behavior

One of the obstacles with agent-based crime modelling is that it becomes necessary to explicitly define how agents in the model will behave. However, modelling human behavior is an extremely challenging endeavor. Fortunately there are numerous cognitive architectures that have been designed to model human behavior, and these can be used in crime models. Malleson et al. (2010) provide an example of such a model applied to residential burglary. The authors use the PECS (physical conditions, emotional states, cognitive capabilities, and social status) model of human behavior which controls agents by comparing the sizes of different *motives*. At any given time, the motive which is the strongest determines what the agent’s current behavior will be such that the agent tries to satisfy that motive. Some motives can be very simple to satisfy (such as travelling home to sleep), but others might require considerable planning and reevaluation before they can be accomplished (such as making money through the commission of burglary). By varying the ways that different motives affect the agents' behavior, it is possible to create different types of offender agents to reflect current criminological thinking (e.g., the difference between a "professional" burglar and an "opportunist"). By placing the virtual offenders in an environment that closely reflects that of the real world, the authors are able to explore the potential real-world crime patterns that might emerge under different scenario conditions.

Street Networks

An example of research which takes advantage of ABM's ability to incorporate a highly detailed physical environment is that of Groff (2007). Due to the lack of dynamic, individual-level interactions, the authors note that previous studies had failed to effectively test routine activity theory. The model by Groff addresses this through the incorporation of accurate street-level data in order to test the applicability of routine activity theory to street robbery. The model contains two types of agent: citizens (offenders, victims, and guardians) and police. The citizen agents are randomly assigned a particular home location, and in the model's most advanced form, they spend time away from home by visiting randomly assigned work and activity nodes following predefined routes. The offenders' decision to offend is stochastic and based on levels of guardianship and the wealth of the potential target at their current location. The model found that the number of street robberies increased with the amount of time spent away from home because citizens had the chance to meet more potential offenders. Interestingly, some street intersections exhibited significant clusters of events even though the travel patterns of the agents were random. This provides an insight into how the urban configuration of streets can influence locations of street crime with direct reference to the roads in a real city.

Social Networks and Cohesion

Plainly the social structure of areas and criminals will play a big part in developing larger patterns of offending. Hayslett-McCall et al. (2008) include a number of social-cohesion and guardianship indicators in their household burglary model. Homes are given attractiveness values based on variables including the socioeconomic status of the area and the degree of guardianship, as well as the ethnicity and income levels of the inhabitants – with agents preferring areas that are similar to their own. In terms of social interaction, Dray et al. (2008) include the relationships between local actors, including law enforcement agencies, social services, and drug users and dealers in an ABM of the Melbourne drug market. The model also includes larger-scale variables such as the strength of the national drug supply chains. Using this model, they showed that small-scale interventions were generally more successful at disrupting drug markets than national initiatives.

Abstract Theory

The models introduced thus far both utilize realistic virtual environments in order to place crime in an accurate environmental context. However, accurately predicting spatiotemporal crime patterns does not need to be the aim of the research – indeed, as the following section will discuss, a realistic virtual environment is seen by some as a drawback. An advantage of ABM is that the model can act as a "virtual laboratory," allowing researchers to explore the individual-level dynamics that emerge as a result of different crime theories in an environment that is free from the usual complexity of the real world. Brantingham and Brantingham (2004) have developed a model of crime in which they utilize an abstract state machine to provide a precise logical/mathematical foundation to an agent-based model. In the model, agents can move through time and space, interacting with each other and the environment. They are also able to learn, and they have "preferences" which translate to forms of behavior. Along with experimenting with criminology theory, the resulting simulation can be used as an interdisciplinary tool to assist criminologists in investigating the dynamics of urban crime.

Controversies in the Literature

In general, agent-based models tend to either be pessimistically abstract or optimistically realistic. The Schelling segregation model and the model by Brantingham and Brantingham (2004) both fall at the more abstract end of the scale. With these types of models, the difficulty of capturing the total behavior of such large, open, and nonlinear systems is accepted, and modellers concentrate on building simple models based on limited subsets of the rules and environmental conditions that may be operating. These models are then treated as thought experiments and can be manipulated to see what effect varying our broad ideas about the systems has on the patterns it generates. In the field of crime modelling, Elffers and van Baal (2008) advocate the notion that such simple models can be a powerful explanatory force, particularly when the aim of the research is to explore theory rather than make accurate predictions. One always has to be aware, however, that patterns may match models even though explanations differ (the identifiability problem), and it is often difficult to verify that human systems would respond as these simple models do.

The second point of view holds that it is possible to accurately model the world with a finite ruleset and list of environmental variables, but that the more realism the model encompasses, the more constrained to the real world the model will be. In some cases, such as the models by Groff (2007) and Malleson et al. (2010), geographical realism is added by combining the model with a geographical information system (GIS). The hope with more realistic models is that the multiple patterns and data streams used to constrain the model will resolve the identifiability problem and make comparisons with reality more reliable. However, it is usual to calibrate such models using real data, and the large numbers of variables involved may mean that the models are over-flexible, essentially fitting any data – again raising the issue of identifiability. Rigorous retesting with new data is often difficult for models that study crime; even though more accurate data is being made available to researchers all the time, it is still at a premium and it is usually unclear how well the data reflects real-world crime patterns in the first place. In general, models are best built up gradually, verifying that simple behaviors with simple elements of the system work as expected to start with and then, if needed, build up the complexity to something that more closely matches reality in order to make more reality-aiming predictions. However, as Edmonds and Moss (2005) note, a phrase such as “for the sake of simplicity” is not well founded, and simplicity should only be a target if this is justified by the underlying system. The crime system is not, usually, simple.

Open Questions

Two significant and related directions seem of immediate future significance in the ABM of crime (Malleson et al. 2011). The first is the more detailed simulation of social networks, particularly within criminal organizations. There has been some work in this area; however the potential for spatially enabled social network modelling is increasing as law enforcement agencies gain access to mobile phone and internet records. The second direction is more contentious – the modelling of specific individuals within ABM. To our knowledge there are not, as yet, individual-level models that predict the actions of real individuals. However, there is an increasing use of real crime data to seed models of abstract individuals, and increasing amounts of personal information about all citizens, potential victims, and potential offenders are stored electronically on a daily basis. It seems likely, therefore, that the modelling community will need to consider the ethical issues of the Minority Report option within the very near future: is it appropriate to model real individuals in a predictive sense, and what use should such predictions be put to once made?

Aging Correctional Populations

Brie Williams, Cyrus Ahalt and Louise Aronson
Division of Geriatrics, University of California
San Francisco, San Francisco, CA, USA

Overview

The American prison population is rapidly aging. Yet relatively little is known about the unique challenges facing older adults in the criminal justice system. This knowledge gap has significant implications for the understanding of the health and health-care needs of a growing, medically vulnerable population. This entry describes the demographics of aging in corrections, focusing on the dramatic growth in the geriatric prison population that has taken place since the early 1990s; introduces the comprehensive, integrative framework of geriatric medicine, the medical specialty focused on the care of older adults; and reviews what is known about the health of older prisoners through the lens of geriatric medicine, examining biomedical, psychosocial, and environmental contributors to health and physical function. Age-related risk factors that may result in obstacles to successful reentry for older adults following incarceration are also discussed throughout. This entry concludes with a proposed agenda for future policy and research based on the geriatrics framework.

Demographics: The Aging of the Criminal Justice System

Over the past several decades, a dramatic increase in the overall population of US prisoners has included staggering growth in the number of incarcerated older adults. At its zenith in 2008, the criminal justice system incarcerated 1 in every 100 US adults, and 1 in 31 was a ward of the criminal justice system in some way, via jail, prison, parole, or probation (Pew Center on the States 2009). In the two decades from 1990 to 2010, there was a 100 % increase in total state and federal prisoners. During the same period, the number of prisoners 55 years of age or older grew by over 300 % to nearly one in ten of all prisoners. Although the total prison population decreased 0.5 % from 2009 to 2010, the number of prisoners aged 55 or older increased by 57.3 % (Human Rights Watch 2012). Absent significant policy change this exponential growth in the number of older prisoners is likely to continue as more than 450,000 prisoners, nearly one in three, are between the ages of 40 and 54 (Bureau of Justice Statistic [BJS], 2011).

There are many reasons for the disproportionate growth in older adult incarcerations: increased arrests and sentencing of older adults, increased use of life sentences, the discontinuation of discretionary parole, tougher drug laws, and mandatory sentencing practices (Aday 2003; Williams and Abraldes 2007; Human Rights Watch 2012). As a result, older prisoners represent a range of criminal justice dispositions. According to a 2012 report from Human Rights Watch, approximately 45 % of older state prisoners (in this case, prisoners aged 51 or older) are serving sentences of less than 10 years, 35 % are serving sentences of more than 10 years but not a life sentence, and 20 % are serving a sentence of life or greater. While 65 % of older prisoners in 2009 were serving sentences for violent crimes, 35 % were in prison for property, drug, or other nonviolent crimes. In 26 states, so-called "Three Strikes" laws, which confer extended sentences for some repeat offenders, likely contribute to the increasing number of older prisoners serving long sentences for nonviolent crimes. In California, for example, 43,500 prisoners were serving enhanced sentences under Three Strikes Laws in 2010, prompting the state auditor to release a report pointing to $19.2 billion in additional anticipated costs associated with these prisoners as a significant source of strain on the state budget (California State Auditor 2010).

Indeed, the aging correctional population is increasingly cited as one of the main contributors to the rising cost of incarceration nationwide, primarily due to the greater health-care usage of older prisoners. In 1976, the Supreme Court's ruling in *Estelle v. Gamble* guaranteed prisoners' rights to "community standard" health care. Failure to provide such care, the court ruled, would be considered a violation the 8th Amendment's prohibition on cruel and unusual punishment. Since the *Estelle v. Gamble* ruling, however, a host of litigation targeting inadequate prison health care suggests that many prison systems are struggling to meet the appropriate standard of care (Wool 2007). The majority of states are also experiencing significant budget constraints alongside widespread prison overcrowding; as of 2005, 239 prisons (13 %) across 32 states were under court order to improve conditions (Pew Center on the States 2009; Damberg et al. 2011). It is in this challenging context that the number of older prisoners, many who would be considered medically vulnerable even outside the prison setting, continues to grow at a faster rate than any other demographic groups.

The Field of Geriatrics

Geriatrics is the field of medicine specializing in the care of older adults, defined in the community as people aged 65 years and older. The goal of geriatric medicine is to increase the health, independence, and quality of life of older adults by providing high-quality, patient-centered, interdisciplinary care. At the same time, the field recognizes that life circumstances may create a mismatch between physiologic and chronologic age. Thus, while the age of 65 was an appropriate demarcation between middle and older age at the inception of Medicare and Social Security in the 1950s, subsequent increases in lifespan and decreases in years of disability for certain populations (e.g., whites and upper income groups) have meant that some Americans remain physiologically middle aged well into their 70s. Conversely, a condition known as *accelerated aging* is often evident in vulnerable aging adults and may apply to groups like the homeless, refugees, the very poor, prisoners, and individuals with profound, lifelong, or chronic mental or physical illness (Aday 2003; Wahidin 2006). Because many incarcerated adults fall into several of categories of increased vulnerability, most criminal justice systems consider prisoners to be "older," or geriatric, by age 50 or 55 (Aday 2003; Baillargeon et al. 2000).

Most medical specialties in the USA approach health and illness using the biomedical model as their core theoretical paradigm, focusing on anatomy, physiology, disease, and organ systems. Geriatrics, by contrast, is based on the integrative biopsychosocial model. The biopsychosocial model recognizes many aspects of a person's well-being – biological, psychological-behavioral, and sociocultural – as integral to their health. Geriatric medicine takes this approach one step further by placing the biopsychosocial paradigm within a person's larger environmental context – in this case, prison – and by making explicit associations between functional status, goals of care, and health in the context of one's environment. This integrative conceptual framework accounts for the many interrelated influences that affect the health and functional status of older adults. In turn, the health and functional status of older prisoners is best understood by considering the relevant biomedical, psychological, social, and environmental factors that underlie health outcomes for the aging correctional population.

Biomedical Factors

Older adults in America have higher rates than younger adults of nearly all chronic medical conditions including hypertension, arthritis, heart disease, chronic obstructive pulmonary disease (COPD), and cancer. Indeed, a strong association between age and disease burden in general is well established, though some notable exceptions, like HIV and hepatitis B and C, are more common in younger adults. Additionally, for most medical conditions, and many disabilities, prisoners have higher rates than non-prisoners (Aday 2003; Baillargeon et al. 2000; Williams et al. 2006). Studies further suggest that older prisoners have a higher burden of medical conditions than their younger counterparts (Binswanger et al. 2009; Baillargeon et al. 2004).

Despite robust evidence of increased disease burden, many questions regarding the health of aging prisoners remain unanswered. Most relevant studies are small and limited to one geographic area. It should also be noted that the health of older prisoners serving long sentences may differ from the health of prisoners who were first arrested or incarcerated as older adults as the concept of incarceration as a potential accelerator of poor health is itself controversial. For example, some authors note that older prisoners often experience poor health and inadequate care throughout their lives. As a result, they suggest, incarceration may lead to improvements in health due to access to meals, shelter, and health care, even though prison-based care is diminished in quality relative to the standard of care generally available outside of prison (Aday 2003).

This section considers the biomedical aspects of health for older prisoners by examining, in turn, the current base of knowledge on chronic medical illnesses, geriatric syndromes, infectious diseases, death, and health services and utilization patterns.

Chronic Medical Illness

In the prison setting, as on the outside, the prevalence of chronic medical conditions increases dramatically with age. Data from the Texas Department of Criminal Justice (TDCJ) shows that 85 % of prisoners aged 50 or older have one or more chronic medical condition and 61 % have two or more. By comparison, 37 % of prisoners age 30–49, and just 16 % of prisoners under age 30, have more than one such condition (Baillargeon et al. 2000). Moreover, three of the most common chronic medical conditions found in the US population overall – hypertension, arthritis, and diabetes – appeared twice as frequently in the TDCJ prisoner population aged 50 or older. This trend of increasing illness burden continues as older prisoners are divided into subgroups by age. A study in Iowa compared prisoners in their 50s to prisoners over age 60 and found increases in not just hypertension, arthritis, and diabetes but also in ulcers, prostate disease, myocardial infarction, emphysema, and stroke (Colsher et al. 1992). Among female prisoners, another growing demographic, a study of 120 women aged 55 and older in California prisons found similarly high rates of chronic medical conditions: hypertension (64 %), diabetes (16 %), COPD/asthma (43 %), arthritis (73 %), stroke (13 %), depression (36 %), cancer (12 %), and heart disease or heart attack (31 %). In this study, 33 % of self-reporting respondents said they had three or more of these conditions (Williams et al. 2006). Though few nationally representative studies of older prisoner health have been conducted, one such study using BJS data from 2004 found that adults aged 50 or older in prisons and jails are far more likely than their age-matched counterparts in the community to suffer from chronic illnesses including hypertension, diabetes, asthma, arthritis, and liver disease (Binswanger et al. 2009).

Geriatric Syndromes

Geriatric syndromes are defined as conditions that have multifactorial etiologies, significant morbidity, adverse effects on quality of life, and are more common in older adults (Inouye et al. 2007). The term is often used for clinical conditions such as frailty, falls, dementia, incontinence, and sensory impairment that do not fit easily in traditional disease categories. A person may develop such a syndrome in myriad ways, and treatment often requires a multifocal intervention to minimize the impact of the syndrome on the person's health, functional status, and well-being.

In the community, geriatric syndromes have been shown to be more important than medical conditions in predicting older adults' quality of life, morbidity, mortality, ability to remain independent, and health-care utilization (Landefeld et al. 2004). For this reason, geriatricians and other health-care providers who specialize in the care of older adults focus as much on assessing and addressing geriatric syndromes as on the diagnosis and management of medical conditions like heart disease or diabetes. In prison, geriatric syndromes are similarly important, afflicting many older prisoners and increasing their risk for adverse events (Aday 2003; Hill et al. 2006; Williams et al. 2006).

Functional Status

Often, geriatric syndromes have an impact on functional status, which is defined as a person's ability to be independent in Activities of Daily Living (ADLs) which include bathing, dressing, eating, transferring, and toileting. Dependence in these and higher-level or *instrumental* ADLs ("IADLs," e.g., managing medications and finances, transportation, or shopping) increases with advancing age and is associated with higher health-care costs, further decline, and morbidity (Covinsky et al. 1997). One study of prisoners found that 20 % of men over age 50 were dependent in instrumental activities and 11 % required assistance in some ADLs (Colsher et al. 1992). Such figures, however, may underestimate the true effect of limited functional status on health and well-being for older adults living in the unique prison environment. In a cross-sectional study of women prisoners in California, for example, 16 % needed help with one or more ADL, but 69 % reported great difficulty in performing at least one Prison Activity of Daily Living (ADL-P) (Williams et al. 2006). In this case, ADL-P included dropping to the floor for alarms, standing for head count, getting to the dining hall for meals, hearing orders from staff, and climbing onto and off of the top bunk. Not surprisingly, prisoners with worse functional status reported more chronic medical conditions, lower self-rated health, and higher rates of falls and depression (Williams et al. 2006). Using the ADL-P to measure functional independence in the prison environment, the study's authors showed that many older prisoners who would not be disabled in the community are disabled in prison because of the unique physical demands of the prison environment (Williams et al. 2006).

Falls

In the USA, approximately one third of adults aged 65 or older fall each year, and falls are a leading cause of injury and injury-related deaths in older adults. Many older people who fall develop a fear of falling that may limit their activities, sometimes resulting in social isolation, depression, increased fall risk, and a further decline in functional status (Landefeld et al. 2004). In the California study, 55 % of prisoners over age 55 reported a fall in the previous year (Williams et al. 2006). In addition to accelerated aging and increased morbidity, prisoners must also negotiate prison settings often marked by poor lighting, a lack of handrails, crowds of younger prisoners, and strenuous work assignments (Hill et al. 2006).

Dementia

Dementia is defined as the impairment of memory and at least one other cognitive area interfering with daily function. Dementia prevalence doubles every 5 years from age 60 to 80 and, overall, dementia afflicts one third to one half of people over age 80 (Landefeld et al. 2004). Dementia risk is increased for populations that are also at risk for incarceration, including those with less education and racial minorities such as African Americans and Latinos (Alzheimer's Association [AA] 2010). Court liaison referrals show rates of dementia in older adults of 19–30 %, and in prison, correctional officers identify cognitively impaired prisoners at nearly five times the rate of prison health-care officials (Aday 2003; Williams et al. 2009). Adding to the sizable personal costs associated with cognitive and behavioral symptoms, dementia presents a huge cost to society. One 2010 report cited $172 billion as the annual cost of care in the USA related to dementia (Alzheimer's Association [AA] 2010). The implications of these findings for older prisoners, and for the correctional system itself, are significant. Undiagnosed older prisoners with dementia may be at risk for poor self-care, abuse or manipulation by other prisoners, citation for behaviors beyond their control, and failure to meet parole requirements leading to reincarceration for reasons having to do with an undiagnosed or inappropriately managed medical condition rather than a criminal offense. These prisoners are also likely to increase financial burdens on an already strained correctional system at a point in their lives when they may be less and less capable of committing crimes or posing a threat to society.

Incontinence

Incontinence also increases with age (Landefeld et al. 2004). Still, community-based studies consistently find that incontinence is underdiagnosed and that older patients are unlikely to raise the issue unless specifically asked by their provider. Very little data describing incontinence in prisoners exists; however, one study of prisoners with data collected in 1989 found incontinence in 13.9 % of inmates in their 50s and in nearly 40 % of those aged 60 and older (Colsher et al. 1992). In another study of female prisoners aged 55 and older, 22 % of participants reported incontinence (Williams et al. 2006). Although incontinence can be reversible, and a majority of cases will improve with treatment, a study of California prisons found no evidence of nursing or medical staff investigating the causes of incontinence (Hill et al. 2006). The same study found that in many prisons incontinence supplies were either unavailable or required a co-pay. The observed lack of either provider training or readily available supplies in many prisons could result in social isolation, depression, decreased functional status, and potential ridicule or violence (Williams et al. 2006).

Sensory Impairment

Of similar concern, sensory impairment increases markedly with age and affects a majority of older adults (Landefeld et al. 2004). In the community and in prison, hearing and vision impairment are common with age and are associated with increased rates of balance impairment, social isolation, and disability (Hill et al. 2006; Williams et al. 2006). The risks associated with sensory impairment while in prison are significant as older prisoners may have trouble negotiating unseen obstacles and can be unable to hear orders or accused of disrespecting other inmates whose comments they have not heard (Williams and Abraldes 2007).

Infectious Diseases

Prisoners of all ages tend to have higher rates of hepatitis B and C, HIV/AIDS, and sexually transmitted diseases (STDs) than do non-incarcerated persons. Among older prisoners, both acute and chronic infectious diseases account for many hospitalizations (Glaser et al. 1990). Several studies from the Texas Department of Criminal Justice found that prevalence rates of tuberculosis, hepatitis B and C, methicillin-resistant Staphylococcus aureus (MRSA), syphilis, and pneumonia were all substantially higher in prisoners 50 years of age or older than in young or middle-aged prisoners. It should also be noted that while HIV/AIDS prevalence was highest among prisoners aged 30–49 in these studies, 10 % of all new AIDS diagnoses in the USA outside of prison were in older adults aged 65 or older (Baillargeon et al. 2000, 2004). High rates of infectious disease among older prisoners may increase their risk of adverse outcomes following release while presenting an added public health challenge.

Death

Both inside and outside prison, death rates increase with advancing age. The death rate for prisoners over age 55 is three times that for prisoners aged 45–54, and two thirds of all state prison deaths occur in people aged 45 or older (Bureau of Justice Statistics 2007). While prisoners 65 and older make up just 1 % of the prison population, they account for 15 % of deaths. For the 55–64 age group, prison death rates are 56 % higher than for community populations of the same age (Bureau of Justice Statistics 2007). During incarceration, the three leading causes of death are heart disease, cancer, and liver disease (Bureau of Justice Statistics 2007). For female prisoners, breast, ovarian, cervical, and uterine cancers together accounted for 24 % of all cancer deaths in prison (Bureau of Justice Statistics 2007). In addition, during the first 2 weeks following release from prison, older former prisoners face a relative risk for death that is three times the community norm (Binswanger et al. 2007).

Older prisoners with compromised health or functional status worry about dying while incarcerated (Aday 2003). Such worries appear well founded given current sentencing practices and the lack of control prisoners often feel over their lives and health-care options (Linder et al. 2002). Prisoners' limited understanding of the terminology related to end-of-life care, and their desire to be dependent on family or friends for care rather than on institutional staff, may contribute to such feelings. Further, services for chronic medical conditions, age-related functional disabilities, palliative care, and death are far from optimal in prisons (Kerbs and Jolley 2009). There is, however, some evidence of increased attention to end-of-life services in prison, including an increase in the number of prisons providing hospice care (Linder et al. 2002).

Psychosocial Factors

The approach of geriatric medicine is to understand how psychosocial factors in an older adult's life interact with biologic attributes and the environment to accelerate or decelerate health problems and functional ability over time. While many individual psychological and sociocultural factors exist for older prisoners, this section highlights several that are particularly salient in understanding the health and function of older adults in the criminal justice context. Specifically, this section discusses five interrelated "psychosocial" factors that are of particular importance in understanding and contextualizing the health of older prisoners: sociodemographics and identity, educational attainment and health literacy, mental health problems, substance abuse, and social support and isolation.

Sociodemographics and Identity

The racial and ethnic composition of America's older population is changing, trends that are mirrored in US prisons. According to the US Census Bureau, the percentage of Americans aged 55 or older who are nonwhite increased from 12.1 % in 1990 to 14.7 % in 2010. Estimates from the American Geriatric Society suggest that the proportion of nonwhites in America's older population will increase in coming decades. In prisons, while people from racial or ethnic minorities make up a disproportionately large percentage of the overall population, this is less so in the older prisoner age groups. Black men, for example, comprise 39.0 % of the total state and federal male prison population, yet they account for only 24.8 % of male prisoners aged 50 years or older (BJS 2011). Yet, as many prisoners in the 40–55-year-old age group have long, indeterminate, or life sentences, a significant demographic shift towards a higher percentage of older, nonwhite prisoners is anticipated.

As a result, health conditions that disproportionately affect nonwhite prisoners are likely to become more common in prison, as may racial and ethnic variations in disease presentation and response to medications. Unfortunately, the precise ways in which the health of older prisoners differs according to race/ethnicity is understudied and can only be extrapolated from what is known about racial/ethnic differences in health among older Americans in general. For example, black Americans have a higher mortality and morbidity than white Americans, and numerous racial/ethnic health disparities exist in areas like cognitive impairment, functional impairment, chronic medical conditions, and nursing home placement (Gornick et al. 1996). More research is needed, however, to understand how these health-related epidemiologic differences may play out in the criminal justice population as demographic shifts occur.

Educational Attainment

Low educational attainment and poor health literacy are strongly associated with increased morbidity and mortality. The 1992 National Adult Literacy Survey revealed that 60 % of all prisoners performed at the lowest literacy levels, placing prisoners among the least literate populations in the country (Kirsch et al. 1993). Moreover, approximately half of those over age 60 in the USA read at the lowest reading level (Sudore et al. 2006), suggesting that older prisoners may have even lower literacy rates than the overall correctional population. Educational attainment can also affect adjustment to prison life, whereby older prisoners who are able to read and can participate in prison activities requiring some educational skills are found to be more likely to make a positive adjustment to prison life (Kratcoski and Babb 1990). In the period following release from prison, attaining a job and secure housing may also be more difficult for older adults with limited literacy.

Mental Health

Diagnoses of mental health disorders have reached epidemic proportions in US prisons. Many experts ascribe the high rates of mental health problems to the "deinstitutionalization movement" of the 1970s which sought to treat persons with serious mental illness in community mental health facilities rather than in psychiatric hospitals (Baillargeon et al. 2009). Unfortunately, the policy change was not accompanied by a corresponding increase in the number of mental health facilities, leaving a significant gap between communities' needs and their capacity to meet them. As a result, prisons and jail have increasingly assumed the burden of care for psychiatric patients. The Bureau of Justice Statistics now reports that half of prisoners have at least one mental health condition (James and Glaze 2006).

The precise prevalence of mental health diagnoses in older prisoners is not known. One study by the Department of Justice found that 39.6 % of state prisoners aged 55 or older had mental illness (Haugebrook et al. 2010). Other studies have reported rates of "serious mental illness" among older adults in prison similar to rates in non-incarcerated older adults. Such mental health conditions generally include depressive disorders, bipolar disorders, and schizophrenia or related psychotic disorders, and it is important to note that some mental health problems, such as posttraumatic stress disorder (PTSD), are often not captured in the definition of "serious mental illness." Reported rates vary from state to state, from Texas (11.0 %) and Utah (13.6 %) to Tennessee (16.0 %). In comparison, the prevalence of serious mental illness in non-incarcerated older adults is approximately 15–20 % (Caverley 2006).

Prison mental health systems have been criticized for focusing on the management of mental illness-related crises at the expense of facilitating recovery and promoting coping skills. A BJS report found that although more than 50 % of inmates exhibited symptoms of mental illness, only 22 % of state prisoners and 7 % of jail inmates received treatment (James and Glaze 2006). Indeed, a review of the existing health-related research on older prisoners found that psychiatric conditions are the most commonly untreated health problem (Loeb and AbuDagga 2006). Even in the absence of a diagnosis of serious mental illness, the psychological stress and acutely depressed moods often associated with incarceration may have an additional negative impact on older prisoners' overall health status (Aday 2003).

Substance Abuse

Substance use and abuse in prisoners is both common and often related to their incarceration. Over 80 % of state prisoners in 2004 reported past drug use, and over 30 % said they were using drugs at the time of their offense (Mumola and Karberg 2006). Over half of all state prisoners (53 %) met the *DSM-IV* criteria for drug dependence or abuse (Mumola and Karberg 2006). In addition, a study using similar data found that 20 % of state prisoners had a history of injection-drug use (James and Glaze 2006), a practice associated with increased risk for a number of infectious diseases. Unfortunately, there are limited substance abuse treatment programs in the US criminal justice system. Despite the high rate of prior substance use among prisoners, only 40 % reported participating in any type of drug or alcohol treatment or related program during their incarceration (Mumola and Karberg 2006). Little is known about the prevalence of substance abuse in older prisoners or effective methods of treatment in this population.

Social Support and Social Isolation

The social science literature suggests that, with increasing age, adults constrict their web of social interactions. The same effect appears to occur as a result of imprisonment, where Bond et al. (2005) showed a general decrease in the size of social networks for older and younger prisoners alike. This study also noted that social visits from outside prison were less common for older prisoners (Bond et al. 2005). Similarly, Kratcoski and Babb (1990) found that nearly one in three older prisoners never had visitors. Those who did, the study reported, had them less frequently than younger prisoners. This was explained in part by prisoners' preexisting social networks and in part by factors within the correctional system. Over 50 % of older prisoners, for example, were separated, divorced, or single at the time of their incarceration. Older prisoners were also less likely to interact with their fellow prisoners, with less than half of study participants reporting involvement in educational programming and fewer than a quarter involved in self-help groups (Kratcoski and Babb 1990). Such isolation may lead to depression and other mental health problems, a fact underscored by Bond et al.'s (2005) finding that older prisoners tend to place greater emotional value on their diminishing social networks than do younger prisoners.

Problems with social support and social isolation may also lead to restricted prisoner participation in programming with the potential to improve physical health and functioning, such as recreational activities. Declining physical health in older prisoners can itself limit the range and number of activities in which they participate, thus contributing to their social isolation and completing a cycle of worsening overall health outcomes (Kratcoski and Babb 1990). For this reason, and also because some older adults report being fearful of younger prisoners, prison experts have debated the benefits of age-segregated housing for older prisoners

(Kerbs and Jolley 2009; Williams and Abraldes 2007). In this debate, the potential to decrease victimization and improve the physical environment for older adults (e.g., more lower bunks, ramps, and wheelchair accessibility) is balanced against the potential pitfalls of segregation, which may include decreased access to programming and informal caregiver support from younger inmates as well as increased social isolation and boredom (Kerbs and Jolley 2009; Williams and Abraldes 2007).

Environmental Factors

Both functional ability and one's environment have an impact on older prisoners' health because of the interrelation of health and function in older persons and also because the unique environment often mediates the impact of medical, psychological, or social factors on an older person's health and functional status.

Most jails and prisons were built and intended for younger persons. An older prisoner with poor vision and arthritis who is placed with a cell-mate willing to help with his personal care might be able to function adequately despite his limitations. Still, facilities that are generally geared to younger, healthier prisoners are likely to adversely affect an older prisoner's health due to environmental factors that disregard older prisoners' needs such as inappropriately high calorie meals or psychological services which fail to assess cognition. Prisons are also frequently located in remote rural areas. This basic geographic characteristic can decrease prisoners' access to ADA-type resources (Kerbs and Jolley 2009) and/or decrease their access to outside health-care services, such as physical therapy, occupational therapy, and speech therapy. In addition, remote prison locations may lead to prohibitive expenses associated with family visitation or duress on the part of similarly aged spouses or siblings, contributing to the social isolation that is a common feature of incarceration.

Geriatric medicine distinguishes between *disability*, defined as the physical inability to perform a task, and *handicap*, a functional deficit in a social role or context that may result from a disability. Given skilled medical assessment and adequate environmental accommodations, disabilities do not necessarily need to lead to handicaps. Assistive devices, social supports, and environmental modifications can each prove essential in effectively managing disabilities. As such, older prisoners often require modified routines and environments to meet common health and functional challenges (Aday 2003; Wahidin 2006). This is of particular import as correctional facilities, when compared to the community, typically require a higher level of physical functioning for older adults. Common daily activities that might be difficult for older prisoners to perform include, for example, climbing onto a top bunk and dropping to the floor for alarms (Williams et al. 2006). In some instances, specialized housing units have been developed within prisons to provide specialized services for older prisoners with functional limitations (Aday 2003). In other jurisdictions, younger prisoners are identified to assist older prisoners with the daily tasks of prison life (Hill et al. 2006). At a minimum, provision of adequate heating and cooling, signage, lighting, and accessible bathrooms and sleeping spaces are necessary to decrease the functional threats to safety that can be present for older, often frail prisoners (Hill et al. 2006).

In many prisons, accessing medical care can paradoxically pose disproportionate challenges for ill and functionally challenged prisoners. The report (Hill et al. 2006) on California prisons described four "unnecessary bureaucratic and financial obstacles" associated with some prisoners' access to health-care services. First, prisoners were required to make a written case for their need before they could schedule nonemergency appointments. As described above, older prisoners are more likely than their younger counterparts to have low literacy levels and poor writing skills. Second, to receive same-day care, prisoners had to sign in and wait outside, regardless of weather and often in a standing position. Older and ill prisoners are both less likely to be able to stand for hours at a time and are often more vulnerable to the effects of extremes in temperature. Third, prisoners in need of emergent care were required to convince untrained guards of the legitimacy of their needs.

Here, language barriers, guards' inflated perceptions of malingering, and illness itself can interfere with older prisoner's abilities to effectively plead their case. Finally, the report noted that most medical services required a co-pay of between 2 and 10 dollars. Prisoners could accrue money for co-payments from family or through work during incarceration. Yet, older prisoners are more likely to lack social support from outside prison and may be unable to work due to functional or health-related limitations, possibly leading to delayed care. Further, in such instances where co-payments work as a disincentive to seeking preventive or routine care, overall health-care expenditure may go up as older prisoners are only treated at the acute stages of illness. While some of these issues may be unique to the California prison system, most are paradigmatic of barriers found in prisons nationwide.

An Agenda for Future Policy and Research on Older Prisoners

Given the many potential biopsychosocial challenges that exist for older prisoners, a research agenda focused on identifying, assessing, and improving the myriad threats to optimal health is needed. Ideally, such an agenda would reflect existing opportunities for policy change. For example, increased attention is being paid to periods of transition: from one prison to another and from incarceration to the community. Here, improved policies to minimize the adverse health events that occur at the time of release (such as homelessness, lack of access to medications or care, recidivism, and emergency services utilization) could begin to address the elevated death rate for older prisoners during community reentry.

In addition, compassionate (or "medical") release, which allows eligible prisoners with serious medical illness to die outside of prison before sentence completion, is being increasingly examined by policymakers. These programs are being assessed for their potential to optimize the care of prisoners with life-limiting illnesses while unburdening prison health-care systems and lowering state correctional expenditures. Increased leadership and research from the medical and public health communities is needed to develop compassionate release programs with transparent, evidence-based medical eligibility criteria. These criteria should move beyond the common criteria of having a prognosis of 6–12 months and instead reflect the many ways that people experience serious medical illness and death. For example, progressive frailty and dementia may lead to profound impairment lasting far beyond 12 months – such scenarios are not addressed in many compassionate release policies. The application process for compassionate release should also be designed so that it can be navigated by seriously ill prisoners and their advocates (Williams et al. 2011). These policy challenges, and others related to the rapid growth of older prisoners, require a more substantial research base than currently exists to describe this growing population.

The integrative biopsychosocial geriatrics model presented in this entry presents a framework through which to fashion a research and policy agenda. In many states, however, health-related data collection carried out by state correctional systems is not differentiated by age groups. Moreover, the age-related statistics that are collected are not always divided into those subgroups with the greatest clinical utility. Unfortunately, the existing knowledge gap only widens when considering how to optimize care for older prisoners with complex medical conditions such as dementia and functional impairment (Williams et al. 2012a). Future policy-oriented research should specifically focus on caregiver and prison-worker education and on the development and provision of strategies to screen older prisoners for cognitive dysfunction, fall risk, sensory deficits, and functional impairment. In addition, because many older adults will develop a serious medical illness and die in prison but will not qualify for early release, enhancement of prison palliative care services is greatly needed. In the psychosocial arena, it is important to systematically and scientifically explore the utility and acceptability of prison-based volunteer programs designed to address the needs of older adults. Also important is the need to develop and test treatment programs that can address the complex impacts of substance abuse and mental health disorders on optimal health status in older prisoners. From an environmental standpoint, the academic debate about clustering or age segregation of prisoners is sure to continue, with future cost-effectiveness and quality research likely playing a central role (Williams et al. 2012b). Other potential strategies, however, such as designated "older prisoner" yard time, which might serve as an effective compromise between total segregation and total immersion, should also be explored.

As the population of older and frail prisoners increases, it is critical that health and social science researchers work together with clinicians, criminal justice health-care and policy experts, and legislators. This would enable, for example, more analysis of current and future unintended public health consequences of criminal justice policies and sentencing laws. Enhanced collaboration between the health sciences, law, bioethics, and criminology will help to ensure socially acceptable, legally appropriate, and medically justifiable medical programs that pose minimum risk to public safety and span from the time of arrest through successful reentry into the community (Williams et al. 2011). Overall, the "aging crisis" in corrections requires medical, legal, social policy and political input to identify humane and cost-effective ways of promoting safety and optimizing health and function for older adults in the criminal justice system. Analyzing the aging crisis through a multidisciplinary geriatrics lens is a good first step.

Acknowledgements Funding Support: Brie Williams received funding from the National Institute of Aging (K23AG033102) and the John A. Hartford Foundation's Center of Excellence in Geriatric Medicine and Training. Dr. Williams is an employee of the Department of Veterans Affairs. The opinions expressed in this entry may not represent those of the VA. Potential Conflicts of Interest: Dr. Williams has been a consultant in legal cases about prison conditions of confinement.

Aging Prison Population: Factors to Consider

Jeanne Subjack[1], Gracie Aguilar[2] and Victoria B. Titterington[1]
[1]College of Criminal Justice, Sam Houston State University, Huntsville, TX, USA

Overview

Elderly inmates are considered the fastest-growing segment of the incarcerated population. In turn, they pose unique challenges for corrections management, particularly as it relates to their health. This review includes a description of the historic growth of an older prison population, the current health-care demands being placed upon prison services and budgets, and the attendant controversies about how to best address these demands. This entry concludes with the open questions that must necessarily be answered in moving forward with the effective care and management of an ever-growing group of older, and often infirm, inmates.

Introduction

There is unprecedented growth in the incarcerated elderly population. These prisoners are now the fastest-growing group of inmates, increasing at a rate three times that of the general prison population. Thousands of inmates are baby boomers, and as they age, prisons find themselves having to plan to care for an aging population (Gater 2010). Among reasons for this growth are changes in sentencing and parole practices, recidivism rates, and increasing incarceration rates in several major offense categories (Reimer 2008). For example, in the past decade, the war on drugs and tough mandatory sentencing laws have doubled the number of incarcerated persons. Inmates sentenced to life, or practical life, represents the future of the already growing population of older inmates. This population has an increased potential for medical problems and emergencies, and these circumstances often develop sooner in prison populations.

Understanding and addressing prisoner health care is a relatively recent phenomenon, primarily in the past 30 years. Prior to the 1970s, little was known about how inmates were cared for in prison. What really put the health-care issue on the forefront for change were lawsuits filed by inmates against prisons. As a result, the US Supreme Court became more interested in changing health-care practices. Professional standards of care were implemented, beginning with the American Public Health Association and followed by the American Medical Association, American Correctional Association, and the National Commission on Correctional Health Care.

Older Prison Inmates Today

Defining the Elder Inmate

It is difficult to determine how states classify their elderly inmates and what differences exist among prisons. In a statement made in a report written about California, regarding the differing ages, “it is virtually impossible to determine how many elderly are incarcerated nationwide because scholars and correction officials differ as to what age is an appropriate cut off to label someone as elderly” (Gubler and Petersilia 2006, p. 10). Using the National Institute of Corrections as the benchmark, the elderly incarcerated are defined as any inmates above the age of 50 years, because, morphologically, the average prisoner has a reduced health status approximating the health condition of a non-incarcerated person who is 10–15 years older. In turn, research indicates that since 1995, the total population of older prisoners has grown by about 10,000 per year (Aday 2003). Prison administrators have found that the “graying” of America is evident in the prison population as well.

Due to high-risk lifestyles and the lack of regular health care before their incarceration, many inmates age faster than their contemporaries on the outside. So, for example, a 50-year-old inmate may be considered a “senior citizen” and would need to take advantage of services and facilities for the aging (Gater 2010). The inherent stress of prison life, along with the declining health of many inmates, also contributes to them being elderly before their time. As a result, they have become the major consumers of corrections services (Aday 2003). Collectively, Beckett et al. (2003) found that incarceration results in aging in place, challenges to self-care abilities, and greater likelihood of parolees that leave prison with serious health problems.

Reasons for Their Imprisonment

Tougher sentencing accounts for much of the increase in the proportion of correctional populations who are considered old. In the 1980s, many states abolished parole and passed "three strikes and you're out" laws. The intention of three strikes laws has been to ensure longer prison sentences and greater punishment for those who commit a felony and have been previously convicted of serious and/or violent felony offenses (California Penal Code, Section 667.5). Though the average age of persons nationally who fall under three strikes legislation is 31 (Reimer 2008), individuals convicted of second or third strikes may not be granted probation and must serve their sentences in state prisons. Unintended consequences of this legislation include an overcrowding crisis and an aging prison population.

Using California as a major example, at the end of 2004, there were almost 43,000 inmates serving time in prison under the three strikes law, making up about 26 % of the total prison population. Of the striker population, more than 35,000 were second strikers, and about 7,500 were third strikers. The most common offenses for which strikers were currently serving time in prison were robbery, burglary, assault, and possession of drugs (California Legislative Analyst's Office 2005, pp. 15–16). But critics of these laws seriously question their cost-effectiveness.For example, Greenwood (1994) and colleagues constructed a mathematical model that predicted the benefits and costs of the three strikes law in California and found a possible increase to the costs of that state's criminal justice system of an average of $5.5 billion annually.

At the federal level, Congress imposed mandatory sentencing guidelines, such as determinate terms, requiring the application of maximum sentences for crimes of violence and the doubling of maximum penalties for all felony classes (Reimer 2008). Truth-in-sentencing laws (requiring the convicted criminal to serve 85 % of the time imposed before qualifying for release) will push these numbers even higher. More inmates will remain in prison for longer periods of time. And more inmates will grow old in prison.

Recidivism is another factor accounting for an ever-older inmate population nationally. Reimer (2008) defines recidivism as a new criminal activity or technical violation of parole, probation, or nondepartmental community placement within 3 years of release. Colorado is used as an example to show the high frequency of recidivism. The average recidivism for males is 53.15 % and for females is 51.1 % (Bureau of Justice Statistics 2006). This amounts to one person for every two that are released from prison returning to prison within 36 months (Reimer 2008).

Factors Negatively Impacting Elder Inmates and Their Health

The increasing numbers of older offenders behind bars have resulted in greater numbers of persons needing specialized medical treatment, meaning they will consume a disproportionately large share of health-care resources. This reality of a larger portion of health care being consumed by a smaller subgroup of prisoners parallels the phenomenon in the general US population: approximately one-fifth of all persons consume about 80 % of all medical resources. Offenders are more likely to require hospitalization than younger offenders and account for a large proportion of hospital and specialty services costs to prisons. Much like the free world populations, the aging offender population has a high incidence of hypertension, diabetes, atherosclerotic heart disease, and other medical conditions that require long-term and oftentimes expensive treatment. Issues concerning diet also arise, especially if inmates require liquid diets or restricted diets due to an illness or other condition (Caverley 2006).

Stress is yet another factor contributing to the acceleration of the aging process in prison.

For example, there is an increasing concern about the growing number of older prisoners and their safety (Aday 2003), including a fear of victimization by younger, stronger inmates.

Similar to older males, older female inmates housed in the general prison population often express a need for greater privacy, and studies report that many older inmates prefer to live with people of their own age (Walsh 1992). Research indicates that these older females are much more likely to see other inmates as aggressive and violent than do older male inmates (Krabill and Aday 2005). In one study, a significant number (30 %) of the older female inmates stated that they were either occasionally, frequently, or always afraid (Kratcoski and Babb 1990). Additionally, older women are significantly less likely to be involved in various forms of sporting and recreational activities (Krabill and Aday 2005), thereby contributing to the possibility of victimization due to their relatively poorer health.

Along with an increase in medical issues that may typically accompany the aging process is the effect that poor health-care services and prison conditions may have on inmates' health. It is believed that the reality of being imprisoned as well as the conditions therein may adversely impact older inmate's health (Aday 2003; Haugebrook et al. 2010). Other issues exist as well, such as confrontations among older and younger inmates. Assaults are common among prisoners, especially among those inmates other prisoners view as weak. This may further contribute to the weakened state of elderly inmates and therefore increase their need for medical attention (Oklahoma Department of Corrections 2008). Many older inmates have to address the fact that they may die while incarcerated, and the social support to deal with such issues is lessened for them while in prison (Haugebrook et al. 2010).

Prisoners' Rights to Health Care

Although prisoners have diminished rights compared to those in the free world, health care is one right to which they are entitled. They are given a basic right to health care, because they are unable to care for themselves and once they are imprisoned, they are the responsibility of the state. The landmark case that addressed prisoners' right to health care was *Estelle v. Gamble*, in which the US Supreme Court ruled that deliberate indifference to a prisoner's medical needs is considered cruel and unusual punishment under the Eighth Amendment (*Estelle v. Gamble, 429 U.S. 97* 1976). This established the minimum standards for prisoner health care, which instructed prison officials that a basic level of health care was required for prisoners and intentionally overlooking their needs would be unacceptable. Although the case did not create specific guidelines for prison officials to follow when implementing health-care policies, it still indicated that prison officials can be held accountable for the mistreatment of their prisoners' medical needs and rights. *Estelle*, however, was not the only case to address prisoner health care.

West v. Atkins declared that the state has an obligation under the Eighth Amendment to provide proper medical care to an incarcerated inmate (*West v. Atkins, 487 U.S. 42* 1988). This case was significant because it stated that even state prisons that contracted physicians to care for inmates could still be held accountable for the care provided to its inmates. Therefore, the physician has a duty to provide the necessary medical procedures to ensure the well-being of the inmate. Under the decision of *Fernandez v. United States* in Florida, it was decided that prisons must provide "services at a level reasonably commensurate with modern medical science and of a quality acceptable within prudent professional standards" (*Fernandez v. United States and 500 U.S. 948, at 10* 1991, p. 10). Finally, *Tillery v. Owens* stated that all prisoners are to receive a "level of health services reasonably designed to meet routine and emergency medical, dental and psychological or psychiatric care" (Tillery v. Owens, 907 F23d 418 1989, p. 1301). This decision was decided in Pennsylvania and upheld by the State Supreme Court as well, making it a requirement for all prisons in the state. Combining the declarations of the landmark cases on the issue, all inmates have three basic rights to health care. They are the right of access to care, the right to the care that is ordered by officials, and the right to a medical judgment by a professional in the field (Oklahoma Department of Corrections 2008). Prisoners are the only persons in the USA who have a constitutionally protected right to health care, and the courts show no sign of extinguishing that right.

Considering that elderly prisoners may face more serious illnesses, and more frequent illnesses, what level of care is considered appropriate and satisfactory? Things to consider for elderly prisoners include kidney dialysis, routine exams such as colonoscopies, glasses, canes, walkers, and other tools to help them function, as well as cancer treatment.

Current Controversies

Service Needs

It has long been believed that aged inmates should receive special attention reflecting the physiological, psychological, and sociological effects of aging. Yet in a prison system assessment conducted by the Criminal Justice Institute (2001), only 15 of the 49 state prison systems had housing areas designated for elderly inmates. Of these 15, seven were only available for elderly inmates who may have had special medical needs or were eligible for hospice care. Thus, an overarching theme to the current challenges of providing for health-care and related needs of older prisoners is that current services and programs are inadequate. For example, elderly inmates need additional preventive care, orderly conditions, safety, and emotional support. Geriatricians also recommend the immediate step of increasing preventive care and educating older prisoners in strategies for maintaining and monitoring their own health (Aday 2003).

The mental health needs of inmates, including dementia among older persons, currently represent another major challenge to correctional programs. Sufficient community-based treatment resources are presently inadequate to support and stabilize mentally ill persons in their communities, with the result that prisons and jails have become the principal institutions for housing mentally ill persons. Also, according to Reimer (2008), conditions of poverty, isolation, and abandonment may contribute to anger and depression in the aging incarcerated population. Those who are depressed and suicidal must be taught what symptoms may be part of a condition that is treatable (Goldney et al. 2002). Even though older prisoners still encompass a relatively small percentage of the inmate population, they represent significant managerial challenges in relation to adapting prison programs to meet their developmentally specific needs for counseling, health care, education, recreation, and vocational training (Aday 2003).

Staffing Challenges

Typically, recruiting prison physicians trained in specialties has been difficult. A common solution is to hire specialists on a consulting basis to conduct periodic “clinics” at the prisons. Some prisons, however, have determined that it is cost-effective to buy equipment and to build suites for certain frequently used technologies, such as x-rays. Further, some prisons have implemented medical copayments as well as educational programs as means of controlling the use of medical services and their attendant costs.

Another barrier in responding fully to the special needs of the aging inmate is a deficit of the necessary staff aptitudes or essential skills to manage elderly people. This lack of gerontological training for correctional officers suggests that they may fail to properly supervise and safeguard an aging prison population (Aday 2003). Experts believe that corrections staff who work with the elderly should receive specialized training to effectively provide care for the physical and mental health of these inmates (Reimer 2008). In addition, there is much debate about inmates receiving advanced medical care that is not equally available to poorer, uninsured people in the free world.

Prison- and Community-Based Options

In 1992, Flynn recommended that corrections officials pursue a number of strategies to address the health care of elderly inmates, including modify existing work and education programs to include health-care education, preventive medicine, and counseling of the elderly. Staff should also be encouraged to seek inmates who have no close ties to the free world and encourage them to become involved in organized educational, recreational, and vocational activities (Krabill et al. 2005). Corrections professionals must find a way to balance public safety concerns and public demands for a government that operates with economy and efficiency, while responding appropriately to legitimate correctional interests.

Health Care and Other Costs of Older Inmates

Increasing costs are arguably the major issue associated with this rapid increase in older inmates. Studies indicate that inmates 55 and older suffer from an average of three chronic illnesses at a time, and they may experience these illnesses at earlier ages than the general population due to conditions of imprisonment and difficult lives prior to incarceration (Aday 2003). Part of the recent increased cost of elderly inmates includes the mental health services they require, as elderly inmates are more likely to suffer from mental illnesses than other inmates (Caverley 2006). As a result, it is estimated that average annual costs nationally for inmates over age 50 is $70,000, three times the cost of younger inmates (Davidson 2009; Rikard 2007). It is expected that these costs will continue to increase rapidly, especially if the cost of health care in the free world increases.

Current Examples of Meeting the Challenges

A recent edition of the *Correctional Health Care Report* (National Institute of Corrections 2004) highlights some examples of how the program, housing, and treatment considerations of elder inmates are being accommodated. For example, in Fishkill, New York, there is a 30-bed center for inmates who are cognitively impaired. This facility provides for the treatment of inmates with dementia-related conditions, which is something that typically worsens with age. Within the unit, the staff is specially trained to handle inmates with dementia and other related conditions. Although the inmates may commit acts while imprisoned that would typically result in punishment, they often times may not understand the implications of their actions because they lack the cognitive ability (New York Department of Corrections 2008).

Some other examples of special facilities prisons have implemented include Texas, which has a Type I Geriatric Facility that is specifically designed for geriatric offenders and eight Type II Geriatric Facilities to house portions of geriatric offenders. In Michigan, there is a men's geriatric unit and a long-term care unit, while Rhode Island has special housing for wheelchair-bound male inmates. Nevada has one geriatric prison in the entire state, while Alabama also has one facility for elderly and medically disabled inmates. In Florida, there are two facilities for elderly inmates and dorms at two other facilities for elderly inmates within those facilities (Price 2006).

The State of Washington (2010) has an extensive health-care plan that is listed on their Department of Corrections website. Inmates are eligible for infirmary and hospital care, medical and surgical services, maternity services, chemical dependency treatment, mental health services, dental care, emergency care, skilled nursing care and hospice, preventive care, access to pharmacies, durable medical equipment, optical care, and hearing care. While this represents the treatments and options available for all prisoners, there are certainly many treatments that are applicable to elderly inmates, such as hearing, optical, nursing care, and hospice. Although all of the treatments are restricted by necessity, approval, and other means of regulation, the State of Washington clearly has an expansive array of services that it provides to its inmates.

Oklahoma also has health assessments for all prisoners. According to the state's procedure on assessments, "periodic health assessments are to be done every 3 years for offender's age 18–39; every 1–3 years for offenders age 40–64; and annually for offenders 65 and older" (Oklahoma Department of Corrections, p. 7). The increased frequency for elderly prisoners over the age of 65 indicates the importance of monitoring inmates more frequently as they age in order to better assess their needs and conditions as time progresses.

North Carolina conducted an extensive survey of elderly inmates and their health conditions while in prison. The state experienced a 61 % increase in its elderly inmates in a 5-year span, while the overall inmate population only increased by 16 % (Price 2006). Concerning the health status of elderly inmates, 20 % of the surveyed inmates were on a special diet due to various health issues. Furthermore, 28 % of those surveyed required some type of walking assistance, whether it was a cane, brace, or wheelchair. Finally, the cost of housing inmates 50 and older was almost four times the cost of housing younger inmates (Price 2006). Taking all of the costs into consideration, it is understandable why officials are concerned with the growth in the elderly prison population.

As indicated by the above examples, some state prisons provide thorough care of elderly inmates. This increased concern and care, however, is not without its problems. Victims and their families are upset over the care given to the offenders who have negatively impacted their lives so significantly. For example, a proposal in Illinois which would have provided for a path to parole for inmates over 50 years of age who had served more than 25 years in prison has been voted down three times (Davidson 2009). Families of victims advocated against the bill because they believed the prisoners should serve their full sentences.

A major concern when discussing the early release of older prisoners is research indicates that many elderly inmates are in prison due to violent or sexual offenses (Abner 2006). The facility in New York that was described above, however, took the risk offenders may present into consideration when designing the facility. As a result, the facility is analogous to a maximum security prison and has the ability to house all levels of offenders. Facilities with this security level may be more satisfactory to those concerned with the risk presented by violent offenders, regardless of their age.

Compassionate Release

The cost of treating sick, elderly inmates as compared to early release is another issue that brings about several concerns among policy makers and the general population alike. A specific issue that has been considered for elderly prisoners is compassionate release and whether it should be an option for some low-status offenders. Compassionate release programs are those which "call for the early release of prisoners with terminal illnesses that are expected to die within 6 months and whose release poses no risk to society" (del Carmen et al. 2008, p. 15). However, this too continues to be a controversial means of addressing the ever-growing proportion of elder inmates.

Budgetary concerns will continue to increase as the population increases, thus perpetuating the argument for alternative options. Related to early release for low-status elderly prisoners is the idea of transferring some low-risk inmates to nursing homes. However, there are still several issues that exist with this alternative, including the fact that the burden of paying for their care shifts from prisons to other government agencies. Furthermore, statutes that require nursing homes to make public the criminal records of their residents may cause serious public backlash. Although the inmates who were transferred may be too unhealthy or physically unable to present any harm to the other residents, the public may still resent the idea of having convicted offenders residing with other elderly people who have no criminal record.

End-of-Life Issues

Yet another unprecedented challenge for corrections management of older prisoners is the provision of end-of-life services. Action needs to be taken to ensure that elderly inmates are adequately provided for while incarcerated, including those inmates who will pass away during the span of their sentence. Presently, the California Department of Corrections and Rehabilitation (CDCR) operates a licensed hospice for terminally ill inmates. In New York, terminally ill inmates are not dealt with according to age per se, but rather their ability to take care of themselves. Some 70-year-old inmates are in very good shape while some in their 50s are not (Gater 2010). In Virginia, end-of-life or palliative care approaches are provided in-house, and inmates are directly involved in delivery of hospice services to fellow inmates in Angola, Louisiana. Family involvement, including liberal visitation, is also a vital feature to this process. The balance is between addressing public safety concerns while providing for the unique end-of-life care requirements of the elderly (Gater 2010).

Elderly prisoners will continue to serve prison sentences within facilities, whether it is offenders who age while incarcerated or those who are imprisoned at an older age. As a result, it will be interesting to see if, or when, the Supreme Court rules on a case dealing with the compassionate release of an elderly, low-status offender who is in fragile health. This is something to consider for the future, knowing that the elderly prison population continues to increase. Related to this is the question of what is considered deliberate indifference, and if these standards will also evolve over time or if detaining inmates with chronic illnesses who are almost to the point of death will ever be viewed as cruel and unusual punishment. The important question to ask concerning all of these possibilities is if the country will ever be at a place to allow such a release. As it stands now, the general population may view compassionate release as a policy that is too lenient for prisoners, regardless of the crime they committed and their current age and health condition.

Conclusions and Future Research

States are struggling with the best models of both facilities and programs to deal with an aging inmate population (Aday 2003). Also, the diversity of the growing number of older offenders should be recognized and incorporated into rehabilitative programs. In some cases, instead of preparing the inmate for reentry as a productive member of society, wellness programs which aim to keep the individual alert and active are needed. It is also the case that, in order to transfer elderly offenders back to the community, housing and financial assistance must usually be secured for inmates who have been imprisoned for long terms and who have lost all contacts in the community.

There are several ways this current research could be expanded upon in order to increase our understanding of the health care of elderly inmates. One interesting approach would be to study the different needs that exist among male and female elderly inmates, since men and women suffer from different illnesses and chronic diseases throughout the life course. Furthermore, some states have specialized facilities for male elderly inmates, but few have such facilities for female elderly inmates.

Another area for more in-depth research will be to further investigate different chronic illnesses and ailments from which elderly inmates suffer. Instead of looking at the health care of elderly inmates in general, focusing on specific diseases such as cancer and examining how prisons respond to these inmates would be beneficial. Related to this, some research indicates that those inmates who have aged in prison may be healthier than individuals who were older at the time of their incarceration (Caverley 2006). Among other things, this may give us a better assessment of the health services provided in prison.

At this practical level, Aday (2003) points out that corrections administrators and policy makers still want empirical answers to some fundamental questions. These include what may be categorized as the relative costs (savings) to relative benefits of long-term incarceration versus early parole or extended medical furlough for infirm prisoners. Administrators and policy makers also need more information on aging lifers without parole and the effects of long-term institutionalization, as well as the impact of sentencing law changes on the size of the long-term inmate populations. At both programmatic and policy levels, there remain many open questions and much work to be done as it relates to the graying of the US prison population.

Alternatives to Pre-trial Detention

Christine Morgenstern

Greifswald, Germany

Overview

All over the world, unconvicted prisoners form a large part of the prison population; in some countries they even outnumber sentenced prisoners. This is contrary to the fact that, from the fundamental right to liberty and the presumption of innocence, deprivation of liberty must only be applied when less severe mechanisms are insufficient to control the suspect and to guarantee his or her presence at trial. Generally, the principle of necessity or subsidiarity must be applied in a way that the suspect or accused may await the procedure in unrestricted liberty or, in justified cases, under specified conditions. The authorities may only detain a suspect if no noncustodial options are adequate to meet the established aims. The available alternatives to pretrial detention (conditional bail) and their use vary considerably throughout the world. They may take less invasive forms, such as release on recognizance with some obligations attached or reporting regularly to the authorities. But they also may take the form of curfew, electronically monitored curfew, or drug treatment. A problem that arises from the use of alternatives to pretrial detention are the potential for net-widening. Additionally, there may be a hidden agenda of punitive or coercive, and sometimes also rehabilitative or therapeutic, aims of alternative measures that go beyond the legitimate goals of ensuring that the suspect stands trial and does not continue offending. Further problems are the exclusion of foreigners or the poor from such alternatives. Other questions relate to the consequences of breach of conditions and how periods spent or efforts made under bail conditions may be credited in the sentencing decision.

Fundamentals on Pretrial Detention and Its Alternatives

Statistical Background

According to the World Pre-trial/Remand Imprisonment List (Walmsley 2008), two and a quarter million people were known to be held in pretrial detention and other forms of remand imprisonment throughout the world in 2008, and a further estimated 250,000 were held in countries on which such information was not available. At midyear 2010, about 460,000 persons were in pretrial detention in the USA (U.S. Bureau of Justice Statistics 2011b). In the 47 Member States of the Council of Europe, the number of remand detainees amounted to 370,000; 136,000 of them in the 27 Member States of the European Union (Council of Europe Annual Penal Statistics 2011, data for the year 2009). Globally, one out of every three detainees has not been found guilty of a crime (Open Society Justice Initiative 2011, on the Basis of the World Prison Population List, Walmsley 2007). In Europe, between 11 % (Poland, Germany) and almost 60 % (Turkey) of all prisoners are remand detainees (Morgenstern 2013). In the USA, the percentage was 28 % in 2010 (U.S. Bureau of Justice Statistics 2011a and 2011b), in Canada it was 37 % (Statistics Canada 2011, for 2009/2010). It is important to note that in countries heavily burdened with high prison population rates, remand imprisonment does not always contribute greatly to this burden. On the other hand, some countries seem to manage to contain their overall prison population but have a high number of remand detainees, so that their share is considerable. This is a problem not only for those affected but also for the prison authorities, who must deal with these “preliminary prisoners.” Some of the obvious differences are explained by different scopes and notions of remand detention (see below), but the data nevertheless show that, in many countries, the remand population impacts significantly on the overall prison population.

Statistical data on the use of alternatives to pretrial detention are often hard to obtain and even harder to compare. What can be seen, however, is that the use of precautionary measures during pretrial procedures varies greatly. In England and Wales, 9 % of all persons charged with an offense were remanded in custody in the year 2009. While it is not exactly known how many of the other 91 % were subject to bail conditions ("alternatives to pretrial detention" in the sense used here), research studies suggest that this was the case for over half of them (Hucklesby 2011; Hucklesby et al. 2007). In Ireland, bail is granted in about 25 % of all murder cases and 80 % or more in cases involving less serious offenses (Mellett 2012). In New Zealand, 13 % of all persons charged with an offense were remanded in custody and 87 % were remanded at large or on bail with or without conditions, most typically the latter (Young 2012, for the year 2008). In the USA, a study showed that, in the year 2004, more than 40 % of defendants who had state felony charges were detained in custody. Released defendants were most likely to be released on commercial surety or their own recognizance (Viano 2012). In Germany, in a sample of 1,000 recent convicts, 30–40 had been remanded in custody before. No statistics on alternatives exist, but studies suggest that, additionally, between four and ten of those 1,000 convicts had been under pretrial supervision in the community (depending, for example, on their age; Morgenstern 2009, with further references). In other states, remand detention still clearly outnumbers unconditional or conditional release. In China, for example, almost 80 % of all suspects were detained on remand, more than 16 % were released under supervision, and only 4 % were released without conditions (Zhang 2012).

Scope and Definition of Pretrial Detention

"Pretrial" and "remand" detention are used synonymously here. It must be recognized, however, that depending on the criminal justice system, different scopes and definitions of remand detention and consequently of its alternatives exist. Remand detention may include pretrial detention in a strict sense (police custody and remand custody ordered by a judicial authority), trial pre-conviction detention, and trial post-conviction detention. The latter may include the period between conviction and sentence and detention during an appeal or cassation procedure (Morgenstern 2013). In all these stages, alternatives may apply.

As indicated above, remand detention primarily serves procedural purposes, that is, to prevent a suspect from absconding or from tampering with evidence. The justice system needs him or her to be present and at its disposal – the etymology of the word *remand* (from the Latin *re*- and *mandare*, literally "order back") points to this original meaning. For this period of custody, the term "pretrial" detention is also often used, but it is obvious that remand detention may last longer as it may extend beyond the beginning of the trial. The legal status of remand prisoners is shaped by two factors: the first has to do with criminal procedure (i.e., the need for certain precautionary measures), while the second relates to the presumption of innocence, which implies that an unconvicted person must be treated as such and may not be restricted in his or her rights and liberties any further than absolutely necessary. Additionally, it implies that a remand prisoner must be treated differently from a sentenced prisoner. This latter principle plays a central role in the theoretical underpinning of remand detention as well as of the criminal justice system as a whole. The role and scope of the presumption are not entirely clear, not within certain jurisdictions and even less in a comparative perspective. They vary from a mere rule for the burden of proof to an overarching principle to guarantee procedural rights of the suspect or accused (Ashworth and Redmayne 2010; Stuckenberg 1998, with further references). One difference relates to the period during which the presumption has an effect on those detained during a criminal process. In most European countries, persons are presumed innocent until there is the last and final sentence and, therefore, are (or should be) kept in institutions other than ordinary prisons. In others, however, namely in England and Wales (Morgan 1994), this is not (necessarily) the case. Here, the presumption of innocence expires with the conviction of first instance. From a European perspective, both concepts seem acceptable as the European Court of Human Rights (ECtHR) explicitly acknowledged that the English practice meets the criteria of Article 6 (2) and Article 5 (1) of the European Convention of Human Rights (ECHR; Monell and Morris v United Kingdom, application no. 9562/81 and 9818/82, judgment of 2 March 1987 and Wemhoff v. Germany, application no. 2122/64, judgment of June 27, 1968, Series A No. 7). These conceptual differences explain some of the above-mentioned disparities in the size and proportion of the remand prison population and also have implications for the understanding of alternatives.

Avoiding Pretrial Detention: Concepts and Forms of Alternatives

The concepts and forms of avoiding remand detention are diverse and relate to different systems of imposing detention. Generally, however, judges all over the world find themselves in similar situations when they have to choose between three options for the suspect: The first option is unrestricted liberty (release on recognizance) and the sincere hope that the suspect will show up once the trial starts. The second is conditional bail or a similar concept with some safeguards put in place by imposing certain obligations on the suspect. The third option is remand custody. To avoid remand custody, two models may be distinguished. For example, the English (or other Common Law) along with the Polish and French practices can be described as choosing from a continuum – from no restrictions (unconditional bail) to more restrictions (conditional bail) to a full restriction of freedom (custody) (van Kalmthout et al. 2009a). The German model is different: the legal hurdle to order remand custody has to be taken (implying certain thresholds, excluding minor offences and a certain degree of risk of absconding or collusion). Only if this can be done may the judge choose less restrictions; that is, release the suspect or accused under certain conditions (conditional suspension of the arrest warrant). Here, noncustodial measures are meant solely as substitutes for detention and should be able to avoid net-widening effects. More often than not, however, they are merely used to shorten the term of remand custody and not as a substitute from the outset (Morgenstern 2009). Other examples for this substitution model are found in the Netherlands (van Kalmthout 2009) and Denmark (Rentzmann 2012).

Alternatives to pretrial detention may take various forms, usually with obligations imposed on the offender such as reporting to the police; depositing of passports or other identity papers; observing of orders relating to residence, work, spare time, association with certain persons; making oneself available for inquiries and reports; submitting to supervision (involving adherence to the instructions of the probation service); residing in a special hostel or other institution; undergoing psychiatric or addiction treatment; participating in a day training program; monetary bail; and curfew/house arrest with or without electronic monitoring (this is by no means an exhaustive list; examples are taken from country reports in van Kalmthout et al. (2009b) and van Kempen 2012). In these reports as well as in this essay, the concept of "bail" is frequently mentioned: it should be clarified that this term does not only cover property or money deposited or pledged to a court on the understanding that the suspect will return for trial or forfeit the bail. This sometimes is misunderstood when the word "bail" is translated (e.g., into the German word *Kaution*, *caution* in French or *fianza* in Spanish, which all exclusively refer to a financial surety). It rather must be understood in a much wider sense as a status in which the suspect is obliged to turn up before court or before the police (often with conditions attached to secure this aim). The measures listed above stand alone or are conditions of bail or of the suspension of detention that can be combined. An accumulation of several bail conditions may ultimately lead to severe restrictions of personal liberties with a serious risk of breach.

Further practical and ethical grounds exist for why unrestricted bail or alternative measures should be applied instead of remand custody. Usually, remand prisons are in far worse condition than ordinary prisons (Hucklesby 2002, for England/Wales; van Kalmthout and Knapen 2012, with reference to the work of the European

Committee for the Prevention of Torture, CPT and examples from all over Europe; Maruna et al. 2012, with examples from the USA). They are often subject, far more than regular prisons, to overcrowding (France and other countries, van Kalmthout et al. 2009b) and they often are not able to provide any meaningful activities for the inmates, leaving them "languishing for weeks, possibly months, locked up in their cells" (European Committee for the Prevention of Torture and Inhuman or Degrading Treatment or Punishment 2010).

The Use of (Conditional) Bail and Other Alternatives to Pretrial Detention

Grounds and Limitations

The legitimate aim of remand regulations, custodial or noncustodial, is securing the attendance of the defendant at the trial. Reasonable suspicion of the committal of an offense is an undisputed requirement. The traditional grounds to order pretrial detention that are applied all over the world are flight or risk of absconding, tampering with evidence, interfering with witnesses, or otherwise obstructing the course of justice (van Kalmthout et al. 2009a). Increasingly, however, preventive purposes play a role and are accepted as legitimate aims as well (Ashworth and Redmayne 2010, for England and Wales; Morgenstern 2009, for Germany; Maruna et al. 2012, for the USA). The latter is acknowledged also in the European Convention on Human Rights (ECHR) as long as the danger of re-offending is a concrete and palpable one. Art. 5 ECHR generally secures the right to liberty of everyone by restricting the grounds for detention: "[. . .]No one shall be deprived of his liberty save in the following cases and in accordance with a procedure prescribed by law." The normative justification of pretrial detention follows more specifically from Art. 5 (1) lit c ECHR, which allows "the lawful arrest or detention of a person effected for the purpose of bringing him before the competent legal authority on reasonable suspicion of having committed an offence or when it is reasonably considered necessary to prevent his committing an offence or fleeing after having done so."

This must be read in conjunction with Article 5 (3) of the Convention, which incorporates a number of essential guarantees in order to make deprivation of liberty an exception to the rule of liberty and to ensure that judicial supervision is in place. The European Court of Human Rights has, on several occasions, stated that pretrial detention shall be used only as a measure of last resort. This, on the one hand refers, to the shortest possible time spent in pretrial detention (e.g., Wemhoff v. Germany, application no. 2122/64, judgment of June 27, 1968, Series A No. 7) and, on the other hand, to the use of alternatives from the outset (e.g., Neumeister v. Austria, judgment of 27 June 1968, Series A No. 8; Jabłoński v. Poland, application no. 33492/96, judgment of 12 December 2000; see also van Kalmthout et al. 2009b, with further references). Art. 9 of the International Covenant on Civil and Political Rights (ICCPR) equally protects the liberty of every person against arbitrary detention without, however, specifying legitimate grounds for pretrial detention. Art. 9 (3) ICCPR states, somewhat more weakly than the ECHR, that "[i]t shall not be general the rule that persons awaiting trial shall be detained in custody, but release may be subject to guarantees to appear for trial, at any other stage of the judicial proceedings, and, should the occasion arise for execution of the judgment." In addition to that guarantee of personal liberty, and as mentioned already above, it has to be taken into account that "[e]veryone charged with a criminal offence shall have the right to be presumed innocent until proved guilty according to law.' (Art. 14 (2) ICCPR; Art. 6 (2) ECHR)."

Three consequences follow from these provisions with regard to alternatives to pretrial detention. Firstly, there is a presumption in favor of liberty, which must be interpreted as a right to bail, or more precisely a right to have bail considered in every individual case (see, for example, ECtHR, Caballero v. the United Kingdom, application no. 32819/96, judgment of 8 February 2000: The applicant was arrested for attempted rape and there had been a violation of Article 5

(3) ECHR because the court refused the applicant bail pursuant to a law that precluded – without exception – all persons charged with, or earlier convicted of, murder, manslaughter and rape from being granted bail. This prevented the courts from considering the particular circumstances of the case). This means, secondly, that pretrial supervision measures generally are restricted to the same aims and objectives as pretrial detention. Thirdly, the same human rights guarantees – safeguarding the right to liberty, the presumption of innocence, and the principle of minimum intervention – must be applied to supervision measures that, albeit less severely, restrict personal liberties and freedoms within the community. Equally, due process safeguards must be provided for, in particular the right to judicial review and a proportionate approach to breach of condition.

Further restrictions to impose pretrial detention and a larger scale of alternatives are provided in the area of juvenile justice (see Dünkel et al. 2011; in particular, the chapter of Dünkel, Dorenburg and Grzywa, 1747 ff), however, the practice does not always consider them sufficiently, partly because of a lack of resources in the juvenile welfare agencies at the community level.

Problems

Problems relating to the imposition and execution of pretrial detention are widely acknowledged. This is far less the case for its alternatives because they operate below what can be called a custody threshold and are, therefore (seemingly) less troublesome. First of all, practical problems relate to the availability of suitable and proportionate alternatives to supervise suspects in the community; either because of the lack of the necessary infrastructure and human resources (in particular, probation or other services able to supervise efficiently) or because legislation does not foresee enough noncustodial options (see country reports in van Kempen 2012, and the case studies in the volume compiled by the Open Society Justice Initiative 2008). Particular problems arise for suspects who are not citizens or residents of the state they are charged in. The risk to abscond is easily assumed and noncustodial options to supervise them are either not deemed sufficient or are not be applied for practical reasons such as language difficulties, imminent deportation, or the like (van Kalmthout et al. 2009a, with further references from the country reports in that volume).

Where a range of alternatives exist, it is often the neglect of human rights of a suspect, mentioned above, that may lead to serious problems. There are, for example, indications that bail conditions – unintended or intentionally – often serve coercive, therapeutic, or punitive purposes (Hucklesby 2011). The latter can be seen, for example, when judges, particularly for juveniles, want to start a meaningful program run by the probation service without losing time during the trial (Morgenstern 2009) or try to compensate for far-reaching possibilities to suspend prison sentences (Tange 2011). Whenever pretrial measures serve purposes other than securing the due course of justice, because they are designed as rehabilitative measures or therapy, it is important to note that they depend on the consent of the offender at that stage. Criminal Justice authorities may also intend a smooth move from unconvicted to convicted status for offenders supervised in the community that, even if well-meant, equally neglects that the person affected is still presumed innocent. Even if programs are intended to address social needs, negative impact can be seen when they do not have "a consistent exit strategy" (Hucklesby 2011, in an evaluation of the "Effective Bail Scheme" in England/Wales). First, these programs may ignore the fact that a significant number of those suspects involved are acquitted; here, social support instead of contact with the criminal justice system would be the only adequate way of assisting people. Second, even when they are not acquitted but receive another noncustodial sentence, they often may fall out of the scheme immediately, which then makes the support during the bail period meaningless.

Another issue connected to the use of alternatives to pretrial detention is their potential for net-widening. Although difficult to prove, some indications can be found for this matter. It is noteworthy that, in several of the countries that have very high rates of pretrial prisoners, for example, the USA and South Africa (van Kempen 2012; see also Morgenstern 2013, on different rates in Europe), alternatives – particularly conditional bail – are applied on a large scale, while they are hardly ever applied in other countries with moderate or low rates (e.g., Germany or Norway). In an illustrative country case study for Belgium, it is shown that the introduction of alternatives was not able to reduce the use of pretrial detention, albeit crime rates only increased to a very small degree. Instead, the number of conditionally suspended warrants now is almost as high as the number of arrest warrants (Jonckheere and Maes 2011). On the other hand, we find examples of countries that have a low rate of remand detainees making use of bail to a high degree (Ireland; see Mellett 2012), which shows that alternatives may be of great value when they are carefully monitored. This refers both to individual cases where it is particularly necessary to adapt the measure to the suspect and also to react adequately to breach of condition, and to the legal and practical provisions of a criminal justice system more generally.

Both aspects are equally important with regard to electronically monitored curfew as bail condition. Electronic monitoring in various forms of pretrial supervision is used in an increasing number of jurisdictions (e.g., Australia, the USA, New Zealand, England/Wales, Scotland, and Belgium) and tested in various others (e.g., Germany, France, and Portugal). It is generally acknowledged that it reduces the risk to public safety from offenders living in the community as it reduces the likelihood of individuals committing new offenses and acts as deterrence in relation to absconding from a curfew. On the other hand, electronic monitoring often is experienced as particularly intrusive and also impacts on other persons living in the same household and, therefore, may be regarded as disproportionate in many cases (Nellis et al. 2012; see also the entry on electronic monitoring in this encyclopedia).

A further unresolved question is how periods under conditional bail can be credited, particularly when electronic monitoring and other pretrial supervision measures are involved that significantly restrict the rights and liberties of the suspect. While at least in most European states periods spent in pretrial detention must be deducted from the prison sentence, usually a day for a day (van Kalmthout et al. 2009b), normally, no legal provisions exist for these periods under conditional bail. It is then left to the discretion of sentencing judges whether and how they are credited. This problem is aggravated by the fact that cases where suspects are supervised in the community procedures may take longer than in cases of pretrial detention because the courts feel less committed to ensure a speedy trial (Morgenstern 2009).

The risk of discriminating against foreigners has been mentioned above. Serious disadvantages for another major group of suspects can be seen where bail is mainly understood as providing financial surety (bail bonds). In the USA, where most states use a system of commercial bail bonding, many suspects cannot afford to post bail. This has been heavily criticized for several reasons, among them the far-reaching and insufficiently controlled power of the commercial bail bonding entities and their extended arms, the bounty hunters. Most prominently, however, it has been seen as clearly discriminating against the poor (see Maruna et al. 2012, for a recent account).

Future Developments

With relatively little attention paid by scholars, conditional bail and other pretrial supervision measures in some parts of the world have developed in a way that fits well with policy trends toward a harsh response to (alleged) criminals, a punitive turn and the “new penology” framework. Indicators are the accumulation of intrusive bail conditions, certain net-widening effects, privatization, and commercialization, often along with the neglect of the presumption of innocence and due process requirements (such as a review of the measure imposed, the monitoring of those implementing it, etc.). In other countries, however, both unconditional bail and pretrial supervision measures in the community obviously are widely used, having a beneficial impact on the remand practice and remand prison population.

In recent years, not only pretrial detention but also the aforementioned problems and the merits of its alternatives have increasingly aroused scholarly interest from a comparative perspective. Several volumes compiling case studies, thematic essays, and country reports (Open Justice Initiative 2008 and 2011; van Kalmthout et al. 2009b; van Kempen 2012) provide insight in current developments throughout the world. Nevertheless, sound criminological (empirical) research is still needed in many countries, for example, with regard to net-widening issues and more generally the decision-making process of the competent authorities, and also with regard to discriminatory effects and implementation practices.

In Europe, pretrial supervision more recently became a matter of discussion for pan-European criminal policy as the European Union adopted a Framework Decision in this regard. It seeks to avoid pretrial detention for EU citizens who are not resident in the state where they are charged with an offense (Council framework decision 2009/829/JHA of 23 October 2009 on the application, between Member States of the European Union, of the principle of mutual recognition to decisions on supervision measures as an alternative to provisional detention, OJ L294/20). By applying the principle of mutual recognition of judicial decisions – the decision in this case being the order to supervise the suspect – they shall be able to return to their home under certain conditions instead of being detained in the state where they are prosecuted. Several issues are discussed regarding this Framework Decision, namely whether there is a real need for it and whether it will have net-widening effects. Doubts are particularly expressed as to whether it can really function in the face of diverse legal and practical provisions as well as different legal traditions and cultures in the EU Member States. Also, the Council of Europe (2006) adopted a recommendation that contains safeguards for the rights of pretrial detainees and also seeks to encourage the use of alternatives to pretrial detention (Morgenstern 2013). Follow-up is needed for both initiatives; whereas the recommendation by the Council of Europe is soft law, the Framework Decision must be implemented by the Member States of the EU. Pretrial supervision, therefore, will stay (at least for now) on the European agenda.

Anomie theory (strain theory)

Overview

For over a century, anomie theory has had a profound impact on the direction of sociological criminology. Originally emerging in classical social thought as an analytical tool to study how broadly defined social conditions influence normative regulation and rates of deviant behavior, anomie theory has been applied and extended in different directions, guiding macrolevel research on societal crime rates as well as microlevel research on individual differences in crime. This entry reviews the theoretical and empirical work on anomie and crime, starting with the classic theoretical propositions and then moving on to contemporary extensions and applications.

Classic Anomie Theory

Anomie is introduced as an analytical tool for studying the social causes of deviance in the writings of the French sociologist Émile Durkheim. Focusing on the structural bases for social organization, Durkheim ([1893] 1984) first uses the anomie concept in his classic work *The Division of Labor in Society* to refer to situations when society fails to provide the appropriate cultural regulatory codes – normative values and beliefs – that are necessary to regulate the cooperation of individuals in complex societies. "Equilibrium" between different parts of the social system, Durkheim (p. 301) writes, requires "predetermined rules of conduct" entailing "rights and duties" that are "obligatory" and applicable in "most common circumstances." In a state of anomie, that is, when normative values are weak, irrelevant, or absent, cooperation becomes unstable and rife with conflict.

In *Suicide*, Durkheim ([1897] 1951) extends anomie theory to study the consequences of social disruption for well-being and deviant behavior. Emphasizing that human aspirations lack biological limits, Durkheim argues that normative values are necessary to define and restrain the desires of individuals so that they can become achievable by the means available to them. "A regulative force must play the same role for moral needs which the organism plays for physical needs" (p. 248). Thus, Durkheim assumes that under "normal" conditions, social values are in place that convince most individuals that they are getting what they should and that they are not justified in wanting more. These include, for example, commonly accepted standards that members of different social classes can legitimately aspire to as well as rules specifying how they can legitimately attain their social positions (pp. 250–251). In a state of anomie, society fails to produce normative values to restrain the aspirations of many individuals who may experience limitless and unattainable aspirations, resulting in disappointment and frustration that increases suicide and deviant behavior (p. 293).

Durkheim goes on to discuss the social conditions causing anomie in modern society, all of which he regards as temporary by-products of modernization. First, the weakening of traditional institutions such as religion and marriage constitutes a fertile ground for anomie, since the main function of such institutions is to provide moral regulation of goals and behavior. Thus, for example, the institution of marriage regulates desire for love and sex, but a high divorce rate weakens this regulatory power, as it makes married individuals aware of other possibilities (Durkheim [1897] 1951, p. 271). Linked to the weakening of traditional institutions is the increasing dominance of the market economy in the society, which Durkheim sees as a major source of anomie. Increasingly unregulated by religion and other traditional institutions, the sphere of "trade and industry" promotes a cultural orientation of materialism that not only encourages overweening ambition but represents it "as a mark of moral distinction" (p. 257). For Durkheim, the disposition of excessive materialism and unlimited want emerging in the economic sphere extends to other parts of society, further undermining the moral authority of traditional institutions.

Second, Durkheim ([1893] 1984, pp. 310–322; [1897] 1951, pp. 250–251) provides a link between anomie and distributive justice, arguing that since unequal opportunity contradicts the cultural ideals justifying inequality in modern society, it may cause anomie. Again, cultural restraint on ambition is efficient insofar that it makes individuals believe that they are not justified in asking for more. Since equal opportunity is widely accepted as the just rule for the allocation of social status in modern society, social practices contradicting this principle – privilege, inheritance, and the like, which Durkheim views as remnants of traditional society – undermine people's sense of distributive justice. Thus, when inequality is rooted in unequal opportunity, many individuals see their social positions as unjustly "forced" on them, and they thus think that they deserve something better – another case of society's failure to place moral restraint on ambition.

Finally, Durkheim argues that abrupt changes may create a temporary state of anomie. Normative values change only slowly because they emerge only in repeated social interaction. Thus, slowly changing normative values will fail to limit aspirations if they do not correspond with a rapidly changing social reality. For example, in modern society, economic fluctuations routinely disrupt the connection between social reality and normative values. Thus, a sudden depression casts many individuals into worse conditions than they have internalized as just, while sudden growth raises prosperity so rapidly that existing standards can become irrelevant but "a new scale cannot be immediately improvised" ([1897] 1951, p. 253). In both cases, normative regulation of aspirations is temporarily weakened due to rapid change, resulting in widespread disappointment and frustration.

Merton's Anomie Theory

Durkheim's discussion of anomie has influenced criminological research, particularly through the extension of Robert K. Merton (1938). While Durkheim sees anomie as the consequence of social change, Merton uses the anomie concept to explain how stable features of contemporary societies influence criminal behavior. Merton focuses on a malintegration *within* and *between* two fundamental components of society: *cultural structure* and *social structure*. Cultural structure comprises two distinct sets of commonly held normative values governing the behavior of individuals: values regulating goals, and values regulating the means of achieving goals. Social structure by contrast refers to ongoing patterns of social relationships and positions. Merton assumes that in a well-integrated society, the cultural structure strikes a rough balance between its emphasis on goals and means, that is, various social mechanisms are in place that sanction individuals roughly equally for striving for normative goals and for using normative means to do so. Moreover, a well-integrated society comprises a social structure providing avenues for most individuals to achieve valued goals via normative means.

However, disjunctions can emerge among these elements: On the cultural level, a disjunction may emerge between the relative emphasis placed on goals versus means. Moreover, the social structure may not offer opportunities for many individuals to achieve normative goals using normative means. Merton focuses on the United States as a prime example of a society characterized by such disjunctions. On the one hand, its cultural structure overemphasizes goal achievement, placing a pressure on all individuals to strive for economic success but placing comparatively little pressure on individuals to use legitimate means to achieve such success. Thus, there are more social rewards for achieving economic success than for playing by the rules, creating an imbalance that often encourages individuals to bypass the legitimate means and “innovate,” that is, to use the most efficient means to achieve economic goals, including crime. Thus, support for the normative means is weak and only personal interest and fear of punishment are left to control behavior, which therefore increases crime and deviance.

For Merton, this cultural imbalance is manifested in the American Dream ideal that places an exaggerated value on the single goal of monetary success as a common goal for all citizens to strive for, regardless of their social background or position. The social rewards for economic success are high almost regardless of how it is attained, which leads to attenuation of the normative values regulating means, that is, to a situation of anomie, or normlessness.

On the other hand, Merton points out that the social structure of American society is characterized by economic and social inequality, and hence, the cultural mandate to strive for economic success creates strain for a large part of the population that in fact has limited access to legitimate means to achieve economic success. The reality of inequality thus creates a lack of legitimate avenues for many individuals to strive for the valued goals, creating a strain toward normlessness and crime. Individuals in the lower social strata have the most limited access to the legitimate means, and hence feel this strain most acutely. The commonly valued goal of economic success is most likely to undermine commitment to normative means among disadvantaged groups and individuals. But, in an open society, affluent members of the society provide an influential reference point for economic success, and thus, strain toward anomie and crime is also felt in the middle and even the upper middle classes where individuals may feel deprived relative to those who are more affluent than they are.

Contemporary Applications and Extensions

The statements of Durkheim and Merton have been applied and extended in several directions in crime causation research, both in macrolevel and microlevel research. First, theorists have elaborated and extended the propositions of Durkheim and Merton regarding the macrosocial conditions conducive to anomie, focusing in particular on inequality, materialism, and social change. Second, scholars have applied and revised anomie theory on the microlevel, focusing on the interrelations among socioeconomic status, goal-means disjunction, frustration, normlessness, and delinquency.

Macrolevel Applications

Inequality

Based on anomie theory, particularly the extension of Blau and Blau (1982), macrolevel research has examined the association between inequality and crime, particularly violent crime. This work has interpreted anomie theory to imply that extensive economic and social inequality may increase crime in democratic societies. Again Merton emphasizes that economic inequality blocks access to legitimate opportunities for a large part of the population, producing strain as well as feelings of injustice. Moreover, extending Durkheim’s idea that unequal opportunity may lead to anomie, Blau and Blau (1982) argue that excessive inequality in democratic societies may produce widespread normlessness, resentment, and frustration, especially if it is rooted in unequal opportunity.

Thus, anomie theory implies that the effect of economic inequality on crime should be more pronounced in cultures emphasizing economic goals and equal opportunity. In such contexts, excessive inequality is most likely to create normlessness and resentment, due to widespread upward social comparison and relative deprivation (Stack 1984). Few studies have tested this proposition, with the exception of Krahn et al. (1986) who finds support for a more pronounced effect of inequality on homicide rates in more democratic nations, and Stack (1984) who does not find support for such a pattern in his cross-national study of property crime. More research is needed to examine how democratization contextualizes the impact of inequality on crime rates.

Research has examined whether inequality rooted in unequal opportunity increases violent crime. Again, as Durkheim implies, social practices inconsistent with equal opportunity may create a sense of distributive injustice, hence undermining normative regulation and creating widespread resentment, frustration, and conflict in the society (Blau and Blau 1982; see Messner 1989). Blau and Blau (1982, p. 119) examined metropolitan areas in the United States and separated the statistical effects of economic inequality and black-white inequality on violent crime rates. Blau and Blau argued that while economic inequality should generally increase normlessness and frustration, racially based inequality should do so in particular, as socioeconomic inequalities associated with ascribed positions are condemned as illegitimate in democratic societies. In support, the study found that economic inequality and black-white inequality both influence violent crime rates. Messner (1989) has provided cross-national evidence on this point, showing that nations with a high level of economic discrimination against social groups (e.g., ethnic minorities) have higher homicide rates, net of economic inequality. Finally, Chamlin and Cochran (2006) studied homicide rates among 33 nations and found that a measure of citizens' perception of the illegitimacy of social stratification has a positive effect on the homicide rate, but the effect held only for highly modernized societies.

Materialism and Social Institutions

Messner and Rosenfeld's (2007) institutional anomie theory elaborates and extends the classic idea that excessive materialism breeds anomie. Institutional anomie theory situates anomie in the context of the broad institutional framework of society, seeing it resulting from (as well as exacerbating) an imbalance among the major social institutions: economy, polity, education, and family. These major social institutions entail different orientations and sometimes competing claims. The key argument is that when the institutional balance of power is tilted toward the economy, that is, when the values of the economy are given higher priority than noneconomic values, crime rates increase (American society is discussed as a case in point).

The reason is that the dominance of economic values undermines normative regulation (that is, increases anomie) as well as informal social control. First, the cultural dominance of the value-orientations of the market economy, namely, pursuit of self-interest, attraction to monetary rewards, and competition, breeds the type of cultural disjuncture that Merton sees in the American Dream, namely, the cultural overemphasis on economic goals coupled with relatively weak emphasis on normative means. Second, the dominance of the economy weakens the moral authority of noneconomic institutions. For example, individuals receive more social rewards, such as prestige, for performing economic roles than noneconomic roles, and they frequently feel a pressure to give priority to economic roles (e.g., to skip family dinner so that they can work overtime). The regulatory functions of noneconomic institutions are thus weakened, reducing their crucial function in providing informal social control through socialization and social sanctions.

In recent years, institutional anomie theory has inspired macrolevel research on whether crime rates are influenced by the relative strength of economic and noneconomic institutions. The theory has been tested in cross-national research by treating low welfare state spending as an indicator of economic dominance in the society. Consistent with the theory, such research finds that welfare state spending is associated with less violent crime (Messner and Rosenfeld 1997), and it reduces the positive effect of economic inequality on violent crime (Savolainen 2000).

Most tests of institutional anomie theory have examined crime rates across states and counties within a single society, mostly within the United States. Measuring the strength of noneconomic institutions with data on divorce, voter turnout, civic engagement, educational and welfare expenditure, and the like, this research generally finds lower crime rates in places characterized by stronger noneconomic institutions (Maume and Lee 2003). Moreover, strong noneconomic institutions appear to decrease the crime-enhancing effects of poverty (Chamlin and Cochran 1995).

Social Change

Durkheim's idea that social change can cause anomie has prompted cross-national research to examine the association between modernization, social change, and crime. For example, researchers have recently used the opportunity to test anomie theory by focusing on the crime-enhancing effect of the social transition from communism to capitalism in Russia (Pridemore et al. 2007), Eastern Europe (Zhao and Cao 2010), and China (Liu 2005).

For example, Pridemore et al. (2007) examined changes in crime rates in transitional Russia, noting that Russia in the 1990s and 2000s provides a unique large-scale natural experiment to test Durkheim's thesis. Following the dissolution of the Soviet Union in the beginning of the 1990s, the society was suddenly converted from communism into a market society, celebrating ideals of open competition and individual achievement. The sudden political and economic changes were not accompanied by comparable institutional changes, thus the "legal, political, regulatory, and social institutions necessary for a properly functioning market economy were and continue to be underdeveloped in the country" (p. 275). As Durkheim's theory would predict, Pridemore et al. find huge increases in rates of crime, suicide, and alcohol-related deaths in Russia during this period.

The Missing Element of Social Values

An important limitation associated with macrolevel research on anomie theory is the common failure to include direct measures of normative values. None of the aforementioned studies directly show that the effects of structural factors (inequality, economic dominance, social change) on crime are actually mediated by normative deregulation. One way to overcome this problem is to combine the use of survey data and official statistics, but such research has been rare. Baumer and Gustafson (2007) examined county-level crime rates in the United States, using aggregated survey responses to examine normative values in combination with social structural factors. Supporting anomie theory, the study found higher crime rates in counties characterized by the particular cultural disjuncture discussed by Merton, namely, strong average commitment to economic success *and* weak average commitment to legitimate means. Moreover, consistent with Messner and Rosenfeld, the tendency for goals-means disjuncture to increase crime was less pronounced in counties characterized by more family socializing and more welfare assistance. Finally, consistent with Merton, commitment to economic goals had a more pronounced effect on crime in counties where legitimate means are more limited and unequal (indicated by low levels of educational and economic attainment and high levels of inequality).

Multilevel Approaches

Baumer (2007) has argued that since anomie theory implies links among sociocultural elements, individual attitudes and experiences, and criminal behavior, a comprehensive test of it requires a multilevel research strategy connecting group-level and individual-level data. Multilevel tests of anomie theory have been rare, however, with the exception of a few recent studies. Zhao and Cao (2010) combined survey data and official data and examined the effect of national residence on the experience of normlessness. Normlessness was measured with survey items asking respondents what they felt about the legitimacy of several instrumental crime-related scenarios. The study found citizens of Eastern European countries, which at the time were undergoing rapid democratic transition, to exhibit more normlessness than citizens of other countries (also, see Bjarnason 2009). Finally, a multilevel study by Cao et al. (2009) found more normlessness in countries with the most rapid population growth in recent decades, again supporting the idea that swift social change is conducive to anomie.

Microlevel Applications

Although classic anomie theory defines anomie as a societal-level condition and emphasizes the effects of macrosocial conditions on crime rates, it has implications for microlevel research on individual engagement in crime. Merton's discussion of how a cultural emphasis on economic goals creates strain for individuals has been applied, extended, and revised as microlevel strain theory. Also, anomie theory has guided research on the role of value commitments (and lack thereof) in crime and delinquency.

Classic Strain and Subculture Formation

Early extensions of classic strain theory attempted to integrate it with subculture theories. Cohen (1955) argued that the emergence of delinquent subcultures among low class youths can be seen as a collective response, a type of subcultural adaptation, to structural strain. That is, strained youths collectively adapt to the perception of blocked opportunities for conventional success by developing an alternative status system revolving around the subversion of conventional norms. Cohen's idea of subcultural adaptation to strain is not easily studied with quantitative data, but the notion that youths adapt to blocked opportunities by collectively creating a status system that defies common norms is consistent with qualitative studies on troubled working class kids (Willis 1977).

Cloward (1959) provides a different link between anomie and subculture theory by emphasizing that access to illegitimate opportunities is unevenly distributed in the society just like access to legitimate opportunities. Criminal behavior often requires and is greatly enhanced by illegitimate opportunities, that is, exposure to criminal networks and groups that entail social learning mechanisms (techniques, attitudes, etc.) as well as access to social networks that allow individuals to profit from crime. Association with criminal groups may thus explain why some individuals adapt to structural strain by engaging in crime. In subsequent work, Cloward and Ohlin (1964) argued that low class youths are differently exposed to criminal opportunity structures in their neighborhoods, and hence adapt differently to strain. Some low class youths are raised in neighborhoods characterized by a well-developed illegitimate opportunity structure, a tradition of criminal behavior that integrates criminal activity and conventional business activity. These youths are exposed to opportunities to learn and use illegal means for their advantage, and hence are more likely to adapt to strain with utilitarian criminal behavior. Conversely, low class youths in neighborhoods with no legitimate or illegitimate opportunities tend to adapt to strain by forming subcultures of violence and vandalism.

Limited research has examined how illegitimate opportunities may specify the effect of strain on crime. Hoffman and Ireland (2004) examined whether the influence of strain on adolescent delinquency was contingent on school-level opportunity structure (as indicated by the school-levels of delinquency, delinquent values, school problems, and school quality). The study found that classic strain (measured as the disjunction between personal economic goals and perceived educational opportunities) was positively associated with delinquency, but it did not support Cloward and Ohlin as the effect of strain was not contingent on school-level opportunity structure.

Classic Strain and Individual Criminal Behavior

Most research on strain theory has focused more narrowly on the individual-level effect of strain on criminal behavior, usually examining juvenile delinquency. The research literature is characterized by different methods of operationalizing classic strain. A common strategy has been to assume that individuals are differently committed to the goal of economic success, and will therefore respond differently to blocked opportunities for success. Thus, having high success aspirations and low expectations for success should increase engagement in crime and delinquency more than, say, having low aspirations and low expectations. But, support for this hypothesis is weak and appears to depend on the way in which aspirations and expectations are operationalized. Thus, studies have found little support for the hypothesis that juveniles with high educational aspirations but low educational expectations are more delinquent than others (Liska 1971). But, as Farnworth and Leiber (1989) argue, examining the dysjunction between *economic aspirations* and *educational expectations* may be more consistent with Merton's emphasis on the strain stemming from the cultural emphasis on economic success. Their study and others (Hoffman and Ireland 2004) find that having both high economic goals and low educational expectations is associated with increased adolescent delinquency.

Other studies have operationalized classic strain by focusing on expectations of success, assuming that most individuals value the goal of economic success. This work generally finds a positive effect of low expectations on delinquency (Menard 1995), but the association may be spurious due to missing variables from social control and social learning theories (Burton et al. 1994).

Agnew et al. (1996) propose a different approach to test classic strain theory. Instead of focusing only on aspirations and expectations, Agnew et al. argue that classic strain may be directly operationalized by measuring the individual's subjective dissatisfaction with his or her monetary status. Agnew et al. found that low socioeconomic status is in fact positively associated with dissatisfaction with monetary status. Furthermore, net of socioeconomic status, both high economic goals and low expectations about future economic success, was positively associated with monetary dissatisfaction, net of socioeconomic status. In turn, dissatisfaction with monetary status was associated with income-generating crime and drug use. Finally, the effect of dissatisfaction on crime was stronger among those having criminal friends and those having beliefs conducive to crime, lending support for the role of illegitimate opportunity in enhancing the effect of classic strain on delinquency.

Menard (1995) has tested classic strain theory by including a measure of normlessness, or "anomia," which is measured with questions about the individual's expectancy that socially unapproved behaviors are necessary to achieve one's goals. Among other findings, Menard found low socioeconomic status to positively influence adolescent anomia, in part through the negative effects of socioeconomic status on educational performance and expectations of success. In turn, anomia was associated with delinquency. Menard's findings support classic strain theory, indicating that limited access to legitimate means is conducive to anomia and involvement in crime.

Finally, researchers have operationalized classic strain by focusing on relative deprivation as a key social-psychological mechanism through which the cultural-structural discrepancies, described by Merton, produce anger, normlessness, and crime. As Passas (1997) has argued, in societies characterized by egalitarianism and economic materialism, reference group comparisons tend to be focused upward, with many individuals in the lower and middle classes experiencing anger and injustice due to unfavorable comparisons to more affluent members of the society. Guided by this view, researchers have found that measures of subjective relative deprivation, that is, the individual's frustration about other people being more economically successful than they are, positively influences delinquency, regardless of socioeconomic position (Agnew et al. 1996; Baron 2004; Stiles et al. 2000). In a multilevel study of adolescents, Bernburg et al. (2009) argued that economic deprivation should have a more pronounced positive effect on adolescent anger, normlessness, delinquency, and violent behavior in affluent neighborhoods (where comparisons of poor youths to other residents are highly unfavorable) than in impoverished affluent neighborhoods (where comparisons of poor youths to other residents are more favorable). The study found evidence of such a pattern, thus supporting the criminogenic role of relative deprivation.

General Strain Theory

In recent years, the revisionary work of Robert Agnew has led research on the strain-crime link to move away from anomie/classic strain theory to focusing more generally on the criminogenic effects of all categories of social strain. Agnew's (1992) general strain theory broadens the focus of strain theory at the social-psychological level and attempts to incorporate all major types of potentially criminogenic social strains. Specifically, the theory focuses on three major categories of social strain. First, building on classic strain theory, it emphasizes that strain may stem from actual or anticipated failure to achieve positively valued goals. This type of strain includes the failure to achieve culturally valued economic goals (classic strain), but it also includes strain stemming from a failure to achieve various other valued goals, such as being popular or getting good grades. Second, actual or anticipated removal of positively valued stimuli may cause strain, for example, loss of a parent or a friend. The third type of strain is the presence of noxious stimuli, such as being the victim of violence or sexual abuse.

Each of these strains may trigger negative emotions, including disappointment, fear, and anger. The theory focuses on anger in particular. Anger presumably increases the individual's level of felt injury, creates a desire for retaliation, energizes the individual for action, and lowers inhibitions, and hence increases the likelihood of delinquent behavior. In short, the theory argues that the three major types of social strains increase the likelihood of delinquency because strain often triggers anger and frustration. Finally, the theory argues that various social and personal factors are likely to determine whether strain leads individuals to engage in delinquency, for example, value commitments, social bonding, and involvement in delinquent associations or networks.

Due to the social-psychological focus of general strain theory, research on it rarely attempts to link strain with macrosociological issues, but its broader view of social strain has added to our understanding of the role of social strain in delinquency. Studies show that various types of social strain increase juvenile delinquency, including negative life events, conflict with parents, parental fighting, and that such effects are conditioned by factors such as association with delinquent peers and having values that are conducive to delinquency (Baron 2004; Brezina 1996).

Microanomie

While classic anomie theory implies that strain and frustration plays a role in crime and delinquency, it also implicates personal commitment (or lack of commitment) to social values as an important factor in deviance (see Bernard 1987). Again anomie refers to situations where social values do not provide sufficient control of the thoughts and behaviors of individuals. Nevertheless, microlevel applications and extensions of anomie theory have not focused much on commitment to social values (Bernard 1987).

But there are noteworthy exceptions. Hagan et al. (1998) argue that the core values of the market economy, namely, the emphasis on competition and individual achievement, can promote an excessive emphasis on individual self-interest that in turn is conducive to anomic amorality (lack of personal commitment to normative means) and delinquency. Building on this idea, Konty (2005) has termed the concept of "microanomie." Konty argues that individuals may be imbalanced in terms of their commitment to values that promote social-interest (self-transcendent values) and values that promote self-interest (self-enhancing values). When individuals are more strongly committed to self-enhancing values than to self-transcending values, they are in a state of microanomie. Microanomie is criminogenic in that it encourages individuals to pursue self-interested goals by using any means necessary. Konty implies that microanomie should be more prevalent in societies characterized by the dominance of the economy in the institutional balance of power, as Messner and Rosenfeld's institutional anomie theory suggests. Although providing no evidence for this macro–micro link, Konty's study confirms a positive association between microanomie and delinquency.

It may be noted that research based on social control theories has also attempted to measure individual normlessness. But in contrast to anomie/strain theory that sees normlessness resulting from blocked goals, social control theory argues that weak social bonds undermine commitment to normative values because they constitute channels for communicating and reinforcing normative values as well as entailing social sanctions for norm violations (Bernburg and Thorlindsson 2007). Research has underscored the role of weak social bonds and neighborhood networks in adolescent normlessness and delinquency (Bernburg and Thorlindsson 2007). Also, neighborhood research has relied on the normlessness concept arguing that the concentration of disadvantage in the neighborhood can lead to the "attenuation" of normative values. As Warner (2003, p. 76) has argued, disadvantaged residents are less likely to "live out and thereby reinforce within their communities many of society's common values," rendering cultural values less present in their everyday lives. Attenuation of culture decreases residents' willingness to exert informal control of places and property, due to mistrust stemming from the perception of low normative commitment of others.

White-Collar and Business Crime

Criminologists have yet to make full use of anomie theory in studying white-collar and business crime, but this perspective appears to be well suited for studying these topics. Building on Durkheim's idea that modern economic life promotes an exaggerated materialism leading to limitless monetary aspirations that breed anomie, anomie scholars have emphasized that strain toward anomie and crime exists in all social strata (Passas 1990, 1997). Passas (1990) has argued that in capitalist societies, egalitarian values and materialism jointly promote upward social comparisons and feelings of relative deprivation in all social classes: "the meaning and content of success goals vary from one part of the social structure to another, similar difficulties in attaining diversely defined goals may be faced by people in the upper social reaches too; they are, therefore, far from immune to pressures toward deviance" (p. 159). Indeed, the cultural emphasis on economic success is particularly salient in the corporate world. Scholars have suggested that the overemphasis on economic goals may have important effects on the ethical climate within business organizations, for example, by promoting organizational cultures that rationalize and neutralize crime and unethical conduct.

There is limited research that has directly applied anomie theory to white-collar, corporate, and business crime, but noteworthy exceptions (e.g., Vaughan 1997) indicate the usefulness of this approach. Criminological research needs to move beyond its usual focus on delinquency and street crime in order to examine the full range of the explanatory power of anomie theory. Perhaps events such as the global financial crisis of 2008 will prompt criminologists to devote more attention to developing research strategies to study these issues.

Conclusion

Anomie theory brings attention to the ways in which macrosocial forces influence the power of social values and norms in constraining the behavior of individuals, thus highlighting macrolevel as well as microlevel mechanisms in criminal behavior. Consistent with anomie theory, macrolevel research finds support for the role of social and economic inequality, economic dominance, and abrupt social change in societal crime rates. However, this research is limited in that it has usually failed to examine the role of social values (or lack of values) in mediating the effects of these features on crime rates. Recent attempts to use survey data to measure social values are promising, and will hopefully prompt future macrolevel research on anomie and crime to incorporate measures of social values.

Anomie theory has inspired different methodological and theoretical strategies to capture the individual-level manifestation of anomie. Scholars have focused on the role of opportunities and subculture in specifying how individuals adapt to blocked opportunities, and they have argued that anomie results in individual strain that can be measured by focusing on goals-means dysjunction, perception of limited life chances, relative deprivation, and subjective dissatisfaction with monetary status. Finally, researchers have examined how lacking normative restraint – anomia, normlessness, microanomie – influences criminal behavior. The variety of approaches at the individual-level bears witness to the fact that the broad social forces emphasized by anomie theory can be thought to impact crime through different social and psychological mechanisms. As each of these methods provides at least some support for the validity of these mechanisms, strain and anomie theories will continue to guide research on individual differences in crime. More research is needed on how broad social forces influence these microlevel mechanisms. Multilevel research linking the macro- and microlevels is likely to be especially valuable in providing full tests of anomie theory.

Overview

Geographical offender profiling (GP) is the practical application of various geographical, criminological, and psychological principles to typically estimate the most likely area of an offender's home base (e.g., the offender's residence) or anchor point (e.g., place of work or frequent activity) based on the location of their criminal activity (e.g., crime sites) (Rossmo 2000). The output of a GP analysis can inform ongoing investigative strategy in several ways (Rossmo 2000): suspect prioritization, patrol saturation, neighborhood canvasses, police information systems, and DNA searches, to name but a few (for further strategies used, see Knabe-Nicol and Alison 2011). This entry aims to introduce the reader to the environmental criminological and psychological basis of geographical profiling, discuss state-of-the-art journey to crime (JTC) research, and advocate the further integration of routine activity theory into a geographical offender profiling framework.

Although GP is not firmly grounded in empirically tested theories (Levine 2005), it does utilize several theoretical approaches from the broader framework of environmental criminology: namely *Crime Pattern Theory* (Brantingham and Brantingham 1984), the *Routine Activity Approach* (Cohen and Felson 1979), and the *Rational Choice Perspective* (Cornish and Clarke 1986). A number of researchers have (partially) borrowed from these three theories to develop mathematical and computerized models to (typically) predict the location of an offender's home (see Canter and Youngs 2008a, for review). However, to date, very few studies (see section " Journey to Crime (JTC)" for a review) have tested theories and/or provided empirical explanations integrating the routine activity of offenders or the socio-geographical features of the areas surrounding crime locations (e.g., topography, transportation routes, social nodes, etc.).

It is perhaps an obvious fact that to commit an offense, an offender must, in all but the rarest of cases, be at least for some time period in the area of the crime location. Even so, an offender may still live far away from that area and/or they may only be in that area for a short period of time. Nevertheless, the offender *must* be in that area at some point and thus the area *must* form part of geographic area they (now) know of – their *activity* space. Further, several researchers (e.g., Canter and Larkin 1993) have suggested that offenders, just like any other individual, will *routinely* visit the same areas (e.g., activity space) and are less likely to venture into unknown areas of equal opportunities. This suggests that offenders not only have areas of *activity* but also areas of *routine activity* – places or area they routinely travel to or through. According to routine activity theory (discussed in detail in section " Routine Activity Approach" below), crimes (and their associated geographical locations) occur during this routine, normal activity of everyday life. As such, offense locations may give insight into that particular offender's *routine activity* – which may give rise to their identification (Canter and Gregory 1994).

Thus, it is vitally important to know who is routinely using the area in which a crime is committed and for what reason because the offender will theoretically be among this, albeit potentially large, list of individuals. In spite of this, the majority of GP approaches and computerized systems do not prioritize lists of people known to use the area around a crime location but instead typically prioritize areas to investigate, which in turn, may generate a list of actual suspects. However, even in cases where a GP prediction of an area is so precise that it pinpoints a single dwelling (e.g., a GPS coordinate or prioritized area), the *identity* of the offender is still not predicted, only that dwelling is the area most "associated" with the crime locations (e.g., may indicate a psychological anchor point or place of importance to the offender, such as their home). Arguably, this can still be vitally important to an investigation if accurate, but ultimately, incorporating information on who (e.g., individual identities) routinely uses that space (among other types of information) may elicit a more comprehensive view of the crime location area, potentially identifying the actual perpetrator.

In the latter half of this entry, the current authors call for a greater integration of routine activity theory in GP research and theory, highlighting the current practices of geo-profilers and future directions of geographical profiling. However, first, the underlying theoretical aspects of GP, the state-of-the-art research in JTC analyses, and the prominent debates within the literature will be highlighted. Our aim is to state the importance of moving away from a largely mathematical and computational approach focused on predicting an offender's home base (or anchor points) using *only* x/y coordinates to a more substantive and comprehensive psychological sociological and criminological GP model.

Describing Offender Movements: Environmental Criminological Theory

There has been a long history of describing the geographical or spatial movements of offenders (see Canter and Youngs 2008b for review). Research has developed largely from a criminological perspective, describing the movement in relation to differences in offender characteristics, victim types, and cultures and most commonly in relation to sex offending (e.g., Rossmo 2009, for review). The basis of the environmental criminological perspective will now be discussed.

Crime Pattern Theory and Awareness Space

In their seminal *Crime pattern theory*, Brantingham and Brantingham (1984) consider how offenders move about in time and space. Building on the work of urban planners, they suggest that the spatial occurrence of crimes is not random, but directly related to the immediate physical and environmental circumstances. Brantingham and Brantingham (1984) propose that offending has a rational basis as offenders move predominantly within familiar spaces in which they identify potential targets. Therefore, each person's own *activity* space is confined by their *awareness* space, which is reflected in each individual's own "*mental map*." The latter is a unique cognitive representation that explains and defines each individual's *awareness* space, where the *activity* space represents the *habitual* area that the offender uses for the majority of his non-criminal activity. However, the nonuniform distribution of targets (e.g., victims) causes criminals to offend in a subset of their *awareness* space, termed the *opportunity* space. *Activity* space and *opportunity* space will most likely overlap completely (Brantingham and Brantingham 1984). Hence, the *opportunity* space (e.g., criminal area) of an offender can also reveal the non-criminal *activity* space (e.g., routine activity space) of the same individual.

Routine Activity Approach

Routine activities approach posits that offender and victims (or targets) usually meet during daily, non-criminal activities or routines (Cohen and Felson 1979). In other words, crime originates in the context of the normal everyday routines as three spatiotemporal factors converge: a *motivated offender*, a victim or *potential target*, and the *absence of a capable guardian* (Cohen and Felson 1979). This is important for practical purposes since it suggests that offenses committed in a rather spontaneous fashion are likely to be in an area familiar or habitual to the offender. Thus, it may be hypothesized that a rapist that attacked his victim in an impulsive or opportunistic way was in the area for non-criminal reasons (e.g., on his way home from his local bar). In other words, the area is likely a part of the offender's routine activity space and, as will be discussed in later sections of this entry, there is possible information (e.g., eyewitness, archival records, parking tickets, etc.) relating this particular offender to that particular activity space, potentially leading to his identification.

Rational Choice Perspective

The *rational choice perspective* suggests that crime is committed in terms of a multi-level, goal-oriented, purposeful, and crime-specific decision-making process, especially concerned with the analysis of costs versus benefits within a constrained situation (Cornish and Clarke 1986). However, determining the proportion of offenders using an implicitly unconscious cognitive or consciously reasoned cost-benefit analysis to commit crime is difficult. On the other hand, the concept of "satisficing" could account for a rather intuitive approach of offender decision making (Canter and Shalev 2000). *Satisficing*, derived from "satisfy" and "suffice," refers to the acquirement of just enough information to make an acceptable but non-optimal decision. This is also supported by recent research investigating the heuristics burglars use to determine whether or not a house is occupied (Snook et al. 2010). Regardless of the underlying decision process, Cohen and Felson (1979) propose that the rational choice perspective better accounts for the *content* of the decisions, while routine activities approach better accounts for *why* decisions are made.

Theory Summation

These three general environmental criminological theories converge in the following way: Offenders are relatively more compelled to commit an offense (than not) if the situation is attractive (*routine activity approach*), if it occurs in a familiar environment (*crime pattern theory*) and yields a desired reward (*rational choice perspective*). Such an environmental criminology perspective emphasizes the complex interplay of the offender motivation, situational factors, geographical location, and the victim or target in the genesis of a criminal event.

Geographical Offender Profiling (GP) Theory

In order to understand, and ultimately predict, the geographical mobility of offenders, one must take certain psychological principles into consideration, hence the emergence of the application of psychological principles to geo- and environmental criminology, namely, *geographical offender profiling*.

The Circle Hypothesis: Commuters and Marauders

It has been postulated that an offender's home is a psychological anchor point that influences their geo-spatial movements and criminal activity (Canter et al. 2000; Gabor and Gottheil 1984; Rossmo 2000). In fact, over 80 % of the homes of serial rapists (Canter and Larkin 1993) and arsonists (Kocsis and Irwin 1997) were located in the center of a circle whose diameter was defined by the two most distant crime locations in their series.

This phenomenon, now known as the "circle hypothesis" (Canter and Larkin 1993), led to the bifurcation of offenders into *marauders* and *commuters*. The former live somewhere within the area circumscribed by their offenses, with their home base as the nexus of their criminal activity (e.g., they offend outwardly from the center of the circle). Conversely, commuters live outside the circle, which may be due to more optimal offending opportunities elsewhere from the area around their home. However, the ratio of marauders to commuters found initially, roughly 80–20 % respectively, has not been consistently observed. For instance, looking at international studies, the percentage of serial raping marauders varies from 60 % to 71 % in Germany (Janke and Henningsen, 1995 in Mokros and Schinke 2006 and Snook et al. 2005a, respectively), 71–93 % in Australia (Kocsis and Irwin 1997 and Meaney 2004, respectively), while research into serial property offenders has found an approximately 50/50 split between commuters and marauders (Van der Kemp et al. 2005).

Even considering a liberal proportion of commuters (20 %), one in five offenders typically live outside the area circumscribed by their offenses, making any GP predictions of where the offender lives based on the circle hypothesis alone inherently flawed. Therefore, before embarking on GP analysis, Rossmo (2000) suggests that it is imperative that the geo-profiler establishes whether the offender is a commuter or marauder (or "*poacher*" or "*local hunter*" in Rossmo terms, respectively). Although Rossmo does not elucidate on how this distinction is to be accomplished (Van der Kemp et al. 2005), some researchers have suggested a framework to predict whether an offender is a commuter or marauder (Meaney 2004), albeit with limited success (Paulsen 2007).

Thus, it seems that although utilizing the circle-hypothesis principle to predict the home location of an offender is unlikely to be *enough* to produce accurate results in all cases, it is not without its theoretical wisdom. Conceptually, the circumscribed area is identical to that of Brantingham and Brantingham's (1984) criminal space, a subset of the offender's overall routine activity space. Therefore, the circle hypothesis may be a useful "rule-of-thumb" to begin conceptualizing the routine activity space of the unknown offender – the area the offender may commonly frequent in their everyday normal life as well. Accordingly, one can begin to investigate what features that space has, how that space was used in the criminal activity, and importantly, why the offender chose that particular space in relation to their criminal activity. A careful examination of the nature of the space and its relationship to the routine activity space of the individuals within it may help to develop a richer geo-profile of the crime or crime series. In a routine activities approach to GP, what topographic features, transport routes, sociogeographical aspects, etc., of that area are likely influencing the offender and how does that inform predictions or prioritization of the offender?

Geo-spatial Decision Making: Distance-Decay Theory

The *least-effort principle* (Zipf 1965) offers a very plausible explanation of an offender's decision-making process in selecting criminal activity targets by postulating that an individual faced with alternatives will most likely choose the easiest course of action. This appears to be supported by a wealth of research on *distance-decay theory* (e.g., Snook et al. 2004) which states that the probability of offending decreases with increasing distance from the offender's home. The generalizability of distance-decay as a function of various types of crimes and individual offenders has been both supported (Rengert et al. 1999) and contested (Townsley and Sidebottom 2010; Van Koppen and De Keijser 1997). For example, first Van Koppen and De Keijser (1997) and later Townsley and Sidebottom (2010) demonstrated that the phenomenon of distance-decay may be due to the *aggregation* of the individual variations in distances traveled by offenders, not by the individual distances themselves. However, a recent study by Bichler, Christie-Merrall, and Sechrest (2011) supports the robust findings of distance-decay advocated by Rengert et al. (1999), suggesting that the *ecological fallacy* argument in distance-decay research is perhaps unwarranted.

Nevertheless, on an individual level, the least-effort principle, routine activity approach, and rational choice perspective offer explanations of offender movements and geographically related offending decisions. Pragmatically, it takes time, resources, and effort to overcome distance. Thus, close targets and locations – especially those involved in daily routines – are preferable to those further away if the subjective benefit remains the same. Additionally, it is more challenging to function effectively in an environment one knows little about which makes familiar areas more attractive (Bernasco 2007). The inherent nonuniformity in target (or area) attractiveness and familiarity in offenders' routine activity spaces offers rational choices to be made – *if (or when) I offend where should I do it* and *how close is too close to home*?

Accordingly, distance-decay is thought to be modified by two additional rational choice perspectives: *specialist selectivity* and *buffer zones*. Pettiway (1982) found that specialist selectivity is best reflected in the amount of effort that an offender puts into planning and selecting a crime. Criminals that were more specialized and selective in their choice of targets did not follow normal distance-decay patterns, but offended further away from home. This appears to apply interrelatedly across crime types as well, with the more impulsive crime of rape occurring closer to home than carefully planned armed robberies (Pyle 1974). Furthermore, the risk to the offender of being identified may result in *less* criminal activity around the offender's home.

This area, of relatively higher risk to the offender of identification, the so-called *buffer zone* (Brantingham and Brantingham 1984), exists as a sort of bulwark between the offender's *activity* space (e.g., home) and their criminal *opportunity* space. Research findings are mixed with regard to the existence of a buffer zone, some studies show confirming evidence (e.g., Canter and Larkin 1993; Dern et al. 2005; Rossmo et al. 2004) while other studies refute it (e.g., Levine 2005). However, it seems plausible that a buffer zone may exist and that it may be closely related to population density such that offenders operating within areas of high population concentration (e.g., urban areas) are less likely to have "buffer zones" as these areas offer greater anonymity than less densely populated areas. Additionally, Goodwill and Alison (2005) argue that, particularly for violent and sexual crime series, the buffer zone may expand from one offense to the next as the offender's perception of risk and consequence of detection increases. At the least, it is conceivable that an offender's perception, his psychological understanding, of the area that he offends influences whether he feels there is an increased or decreased risk of identification due to the familiarity or anonymity the areas provides. Applying this to geo-OP would require the reverse logic, potentially making an inference about how much risk the offender perceived to predict how familiar they might be to that area.

Journey to Crime (JTC)

As discussed in section " The Circle Hypothesis: Commuters and Marauders," the "psychological center" of most individuals lives is their home (Gabor and Gottheil 1984), this is also literally the case in strictly geographical terms (Canter and Larkin 1993). Research has consistently found that most offenders, across many types of crimes, commit their offenses in areas that form a routine part of their lives (e.g., Cornish and Clarke 1986; Rengert et al. 1999) and thus the central point of their offending is hypothesized to be their home (Canter and Gregory 1994; Canter and Larkin 1993; Snook et al. 2005b). Further, it has been theorized that offenders travel outward from their homes to commit offenses based on various psychological, geographical, and situational aspects (Goodwill and Alison 2005). Researchers have utilized this theoretical approach by considering that the *distance* an offender travels to their crimes from their home (journey to crime, or JTC) may be related to various aspects of their character or situation.

Distances and Offense Characteristics

Overall, the JTC distance an offender travels has been found to vary between crime types (Goodwill and Alison 2005; van Koppen and Jansen 1998) and across individuals (e.g., van der Kemp and van Koppen 2007). Goodwill and Alison (2005) illustrated that serial murderers traveled in a far more distributed pattern than serial burglars and rapists, based on sequential angulation scores and pattern-analysis techniques. However, the displacement *within* a sexual offense (e.g., contact location compared to the offense location compared to the release/disposal location) has evidenced no clear patterns (Dern et al. 2005; Rossmo et al. 2004). Across individuals, research (see Wiles and Costello 2000) has indicated that the more person-targeted, expressive offenses (e.g., rape, murder) tend to occur much closer to the offender's anchor point or home base (e.g., shorter JTC distances) than object-targeted, instrumental offenses (e.g., burglary, armed-robbery, etc.). For example, Van Koppen and Jansen (1998) found that bank robbers will travel farther, typically over 10 km, for greater rewards, whereas rapists appear to travel on average just 2.5 km (Rossmo 2009). Dern et al. (2005) illustrated that planning rapists had significantly larger JTC distances than those that acted spontaneously. Further, Santtila et al. (2007) and Rossmo et al. (2004) found sexual offenders that used vehicles and exhibited planning in their offenses traveled farther than sexual offenders who did not. Clearly the access to a vehicle enables an offender to cover greater distances and has thus been found to be positively correlated to distance traveled in German sexual murderer body disposal sites (Snook et al. 2005a) and Dutch robbery crime locations (van Koppen and Jansen 1998).

Temporal aspects of an offense are also posited to relate to JTC distance (Ratcliffe 2006), in which "weekend" rapists in the UK traveled longer distances than "work-week" offenders (Canter and Gregory 1994), as did day-time as opposed to night-time rapists (Santtila et al. 2007). Mokros and Schinke (2006) offer a hypothetical explanation of disparate JTC distances based on temporal aspects by suggesting that offenders who work during the week may be more socially integrated into their surroundings and thus may feel the need to move either farther away from their home (typically on weekends) or to attack at night to avoid being identified by potential witnesses. Similarly, Rossmo (2000) suggests that the opportunity for night-time offenses is spatially biased toward certain activity areas: A rapist is much more likely to find a suitable victim in an urban night-time entertainment area or arterial routes of a city than in a rural area in general. In fact, utilizing the temporal aspects of a crime series to predict the home base of an offender was introduced by Kind (1987) in the "Yorkshire Ripper" investigation in the UK. Kind (1987) combined the time when murders were committed with assumptions about the offender's routine activities, concluding crimes later in the day would be closer to the offender's home base.

Distances and Offender Characteristics

Research has consistently shown that many offender characteristics are related to JTC distances and the overall spatial behavior of offenders. For example, JTC distance varies with gender (Wiles and Costello 2000), race (Canter and Gregory 1994) intelligence (Pettiway 1982), and arguably age. Some research has found age and JTC distance in rape offenses to be positively correlated (Dern et al. 2005) while other studies have found no significant age-related trends (Rossmo et al. 2004; Wiles and Costello 2000). However, age-related studies may be confounded by the fact that younger offenders may commit crimes closer to home due to lack of vehicle access (Dern et al. 2005).

Other relationships between offender characteristics and crime distances have also received mixed support (Mokros and Schinke 2006). For example, across several disparate crime types, offenders with previous convictions appeared to travel longer distances (Gabor and Gottheil 1984; Rossmo et al. 2004), whereas others have failed to find such a relationship (Dern et al. 2005).

The inconsistency of findings relating JTC distances to offender characteristics is perhaps not surprising; offenders, particularly across crime types, will make risk versus reward and cost versus effort judgments disparately (Goodwill and Alison 2005). This has an effect on comparative distance-decay readings which will inevitably reveal that different types of offenders may form subgroups where interrelated JTC distances are significantly different than intra-subgroup or aggregated group-level distances. This has led researchers (see, e.g., Santtila et al. 2003) to suggest that JTC research, based on distance-decay modeling to predict offender movements, is limited in use if not calibrated on the subgroup (e.g., offense type) and area (e.g., city or neighborhood) under scrutiny. Moreover, as JTC studies are not typically focused on *why* the particular pattern or distance-decay model exists for a given group of offenders, there is little prospect of applying these findings in real-world investigations.

Distance-Decay Models and Computerized Geographical Profiling (CGP) Systems

GP has seen rapid growth both in academic interest and practical use. As crime analysis in general has increased, policing agencies around the world have begun to increasingly focus on the operational use of geographic profiling in case investigations (Van Schaaik and van der Kemp 2009). Although in recent years, the breadth of operational issues and support a geographical profiler may be involved in has increased (see section "Beyond the Pins: Revealing How UK Geo-profilers Operate" for discussion), the primary role of geographic profilers is still often to predict offender anchor points (e.g., their home, place of work, etc.) through the computerized analysis of crime locations (e.g., approach, abduction, offense, release sites, etc.). There are several computerized geographical profiling (CGP) systems used by police investigators and geographical profilers and these mainly differ in how they apply various forms of the distance-decay function to produce probabilistic predictions of offender anchor points.

Dragnet (Canter et al. 2000), *Rigel* (Rossmo 2000) and *CrimeStat III* (Levine 2010) are the most common CGP systems. *Dragnet* utilizes a negative exponential function for the computation of distance-decay so that as an offender moves away from their home base, the probability of offending decreases exponentially. *Rigel* utilizes a distance-decay function with two parts, the first being a positive linear exponential function and the second a negative exponential function. Rossmo has not stated explicitly in his published work on Rigel, but it can be hypothesized that the first positive linear function reflects the assumption of a "buffer zone." *CrimeStat* III can utilize a number of JTC distance-decay functions, including a Bayesian JTC module, or calibrated functions based on an analysts' or researchers' own data. Similar to Dragnet and Rigel, it creates a probability grid in which each observation falling into an area (or "bin") is replaced by a density function (or "kernel"). The sums of those probabilities across the search area indicate the most likely areas that an offender may live Santtila et al. 2007). Density functions are used to enable a "continuous distribution" without probability "borders" giving a more realistic interpretation of the probability distribution for offending (Santtila et al. 2007, p. 5).

Although these approaches are useful tools for mathematically predicting likely areas of the offenders' anchor points (e.g., home, work, etc.), they are limited by the fact that they all assume a uniform distribution of targets across the search area by default (Kent and Leitner 2009). However, the latest version of CrimeStat (ver. 3.3) can utilize a Bayesian origin-destination function that can model previous crime activity and offender home-base backcloths (Levine 2010). A study by Van Koppen, Elffers, and Ruiter (2011) sought to develop an *ex ante* test based on the distribution of targets to determine if geo-OP was possible for a particular series. Although the results proved accurate in determining if a crime series followed a specific distance-decay pattern, it is still unclear what influence that may have on the ability to provide useful geo-OP advice. Nevertheless, if target backcloth is ignored, much of the information needed to make an accurate probabilistic estimation of the offender's anchor points cannot be made (Bernasco 2007). Next to the distribution of targets, the offenders' activity space is also influenced by environmental factors such as lakes, rivers, highways (Kent and Leitner 2009), and also by social boundaries, such as neighborhoods (de Poot et al. 2005), which are again, not considered. The saturation of targets is itself related to the environmental characteristics of an area; high-rise buildings might give less opportunity to commit burglaries, for instance. The creators of Dragnet, Rigel, and CrimeStat all purport that these factors should be taken into consideration when "applying their tools" by "trained geo-profilers"; however, how this is to be done has not been explicitly stated or published (Snook et al. 2004; Van der Kemp and Van Koppen 2007).

Finally, most CGP systems, and the vast majority of the GP and JTC research, rely on using straight-line (e.g., Euclidian) distance to compute JTC and home-base predictions (Kent et al. 2006). As Kent et al. (2006) point out this means that current profiling models assume an isotropic surface, where impedance is uniform in every direction. As a result, contemporary GP techniques do not accommodate the inherent variations of an area, such as the influence of a particular transportation network, landscape features, land-use policies, physical and psychological boundaries, etc. However, on a different note, Kent et al. (2006) suggest that a more realistic way to model the geographic space offenders are utilizing is to use a street-grid system (e.g., Manhattan distance) that better captures the potential travel patterns of offenders. Although Manhattan distance may be a more appropriate measure for North American cities, that typically have a grid-style pattern of roads and transportation networks, many cities in Europe have circular-style grid pattern in which a Euclidian approach may be more effective (Canter and Youngs 2008a). In this regard, a novel method proposed by Trotta, Bidaine, and Donnay (2011) does take account of the road networks surrounding crime locations investigating the effect of driving time and speed. Clearly, such an approach has a greater potential benefit for real-world investigative applications than elaborating on distance-decay functions that ignore important environmental aspects.

Computerized Geographical Profiling Systems in Practice

In terms of geographical profiling success, van der Kemp and van Koppen (2007) summate that geographical profiling "*. . .has the ring of being very successful, but no study to date demonstrates that it is successful in helping police investigations in more than a small percentage of cases.*" As only a few cases seem to reach the threshold criteria (Rossmo 2000) for applying geographical profiling analysis, this may not be that surprising. For example, Rossmo argues that in order to establish a pattern, Rigel requires at least five related or linked crimes (Rossmo 2000). Research by Snook, Zito, Bennell, and Taylor (2005b) contest Rossmo's assertion, citing a lack of substantial empirical underpinning of the criterion. However, more recent research by Leitner, Kent, Oldfield, and Swoope (2007), replicating the work of Newton (1988) on serial murder, has shown that predictions of an offender's "haven" (e.g., a home base or anchor point) becomes successively more accurate after the fifth offense in a series in urban burglary data. Nevertheless, in reality, the point may be moot as recent research by Knabe-Nicol and Alison (2011) report that UK geo-profilers nevertheless provide investigative advice in a substantial amount of single offenses (39 % of cases from 2002 to 2007) often in which only one crime location is known.

The Man (e.g., heuristics) Versus Machine (CGP Systems) Debate

A publication by Snook, Canter, and Bennell (2002; later followed by Snook et al. 2004) called into questions the benefit of computerized geographical profiling (CGP) systems, such as Rigel, Dragnet, and CrimeStat. An academic debate emerged between Rossmo and Snook and colleagues, the latter presenting empirical evidence that students using simple heuristics could predict an offender's home base as accurately as a CGP system (Rossmo's Rigel CGP) using simple geo-profiling heuristics. Although this debate led to an important increase in research empirically scrutinizing CGP systems, it also spawned numerous research studies that sought to produce the most optimal distance-decay algorithm for use in CGP systems using a multitude of methodologies (see Kent et al. 2006, for review). However, it is suggested that the search for the most optimal method or algorithm for determining the home base of an offender from *only* x/y coordinates on a map perhaps misses the overall point of the GP – to examine the geographical movements and decision making of an individual offender for the purposes of identifying or prioritizing areas of interest or, even better, offenders. In other words, the pragmatic utility of using *only* a CGP system or *only* a heuristic approach and not considering the target type, distribution, or attractiveness (Bernasco 2007) is questionable on a number of compelling grounds (for further review, see Stangeland 2005). By the same token, the results of Paulsen (2006) are quite telling, no matter whether anchor point predictions were based on human judgment, geometric principles, or distance-decay functions, they were all still off the mark.

Pragmatic Use of Geographical Offender Profiling (Geo-OP)

Why Are Those Pins, in That Pattern on That Particular Map?

For some time, the act of (literally) "sticking pins on map" to indicate the x/y, northing-easting's, or GPS coordinates of crimes and crime series by police and researchers alike has been used to display and analyze geographical crime patterns of individuals and groups (see van Schaaik and van der Kemp 2009, for review). With regard to GP, much of the research focus has been on developing mathematical and computational models of serial offenders' "pins on the map" (e.g., offenses) to predict an offender's home base or anchor point (s) (Canter and Youngs 2008a). Yet, a major limitation of GP research has been that the crime location "map" (e.g., topography, transport routes, social nodes, etc.) has largely been neglected (Kent and Leitner 2009).

Further and perhaps of even greater relevance to GP is the fact that only a handful of studies have attempted to understand the psychological aspects of *why* the pins are where they are (e.g., Goodwill and Alison 2005; Rossmo 2000; Canter and Shalev 2000). It should be apparent from the discussion thus far that GP is a complex process and cannot be reliably reduced to the prediction of an offender's home base from x/y coordinates, irrespective of considering the influence of the geographic area, or the routine activity of the probable offender (e.g., *why* that "space"? *why* then? *why* that route? etc.). As Van der Kemp and Van Koppen (2007) postulate, using that information is potentially the best way to fine-tune geographical profiling. Therefore, in light of the limited research exploring the complexities and reliability of GP methods, one might question what it is that geo-profilers actually advise on, what that advice is, and how it is derived?

Beyond the Pins: Revealing How UK Geo-profilers Operate

Knabe-Nicol and Alison (2011) carried out the first detailed, qualitative analysis to explore and explain the various stages and demands of the decision-making processes of geographical profilers in the UK. Using Applied Cognitive Task Analysis (ACTA), Knabe-Nicol and Alison (2011) were able to explicate the different decision-making stages, their degree of difficulty, the most common errors that can be made, and the cue and strategies to counteract possible pitfalls in the geographical profiling process undergone by UK geo-profilers.

Importantly, Knabe-Nicol and Alison's (2011) research revealed that the analysis of spatial information by UK geo-profilers was not limited to simple x/y map location(s) analysis but more often involved identifying the activity space and routes of victims, offenders, and the general public. In other words, geo-profilers did seem to be more concerned with how individuals *use* the geographical space, what *influences* that use, and what that can tell us about a number of aspects of the offense or offender. Accordingly, they found that a fundamental part of the process used by geo-profilers was to examine offenses from an environmental criminology viewpoint: Did the offender meet his victim while carrying out a routine activity (e.g., the attack was somewhat opportunistic) or does he have intimate knowledge of that area from previous exposure (for whatever reason) to it and has returned to it to offend (e.g., there was an element of planning involved in the attack)? Geo-profilers would also scrutinize the various aspects of crime scene information, the locations of the offenses, and the behaviors observed based on the least-effort principle (as discussed in section "Geo-spatial Decision Making: Distance-Decay Theory"), such as why did the offender not take the shortest escape route?

This approach, far removed from the mathematical process of pinpointing the offender's home base based on x/y crime location coordinates, enables geo-profilers to offer advice on any offense or series of offenses, even those in which the offender may be a nonlocal "commuting" or "poaching" offender. However, it is still difficult to estimate the reliability or validity of their methods when one recognizes that there is a dearth of empirical research investigating the relationship between routine activity theory and GP. Again, this begs the question: Just what are they using to make their investigative recommendations? Further, are the UK geo-profilers unique in their approach or do geo-profilers from other countries use similar strategies? Although this initial research by Knabe-Nicol and Alison is compelling and tantalizingly insightful, it still leaves many questions unanswered and requires further investigation.

Offender "Hunting Style": The Potential for Behavioral Integration in Geo-OP

Although the research into the integration of routine activities and GP is still developing, a tentative theory on how sexual offenders may make geo-spatial decisions to locate and attack victims has been offered by Rossmo (2000). Rossmo proposed that offenders employ various "hunting patterns" based on their geo-spatial movement and behavioral characteristics – acknowledging that geo-spatial movement is a dynamic decision-making process. Rossmo delineates four types of hunting patterns the: hunter (a.k.a. marauder), poacher (a.k.a. commuter), troller, and trapper. Hunters, as the name implies, are offenders who actively seek out their victim. They tend to use their place of residence as an anchor point before engaging in crime. Poachers are also active in their pursuit; however, they tend to travel further distances, even to other cities, in order to find their victims. Trollers offend opportunistically, coming across their victims while they are engaged in non-predatory activities, and seizing the chance when they become aware of it. Trappers choose to situate themselves in positions that provide them with the largest accessibility to a particular victim type. These offenders choose to work in professions such as nursing or find means to lure victims into their homes.

It is important to note that although these hunting types are theoretically possible and may make some intuitive sense, they are still being empirically validated (Beauregard et al. 2010). As Beauregard, Rossmo, and Proulx (2007) point out: No explanation is provided as to why offenders choose one method over another. Nevertheless, as stated by van der Kemp and van Koppen (2007), the process of relating behavioral inferences to geo-spatial movement patterns will no doubt result in a more fine-tuned and accurate GP approach.

Geographical Offender Profiling Validity

As with most investigative methods, it is quite difficult to assess to what extent geographical profiles have actually helped in the investigation. For example, a geo-profile may help to define the area for door-to-door enquiries, it may indicate a potential linked crime to a series in question, and/or it may pinpoint an offender's residence or simply estimate an offender's activity space, among other geographical aspects and investigative uses (Rossmo 2000). However, some aspects of a report may help while other aspects may not and some may even hinder an investigation. Unless a geo-profile specifically names the offender, it is difficult to ascertain the extent to which it helped (or hindered) the investigation – and this is rarely the case.

In practice, a number of problems arise in estimating the accuracy of geo-profiles (see van der Kemp and van Koppen 2007, for a detailed discussion). For example, how to assess the accuracy of a geo-profile, that is succinctly and comprehensively based on compelling (e.g., state of the art) theoretical and empirical research when in actuality the offender deviates from the "norm"? Is a well-informed well-reasoned geo-profile "incorrect" if the offender lives outside the predicted area? Is it possible to be "correct" based on our current knowledge (e.g., the predictions are theoretically and empirically sound), yet, still, "inaccurate"?

Integrating Routine Activity Space in Geographic Offender Profiling

As discussed previously, research integrating routine activity theory into geo-profiling is sparse. Instead much debate has surrounded on how one should go about determining the likely home base of an offender based on the x/y coordinates of their crimes (see sections "Routine Activity Approach," "Rational Choice Perspective," "Theory Summation"). This line of research is likely to be futile in real pragmatic terms of aiding police investigations. For example, even if the "perfect" algorithm existed to pinpoint exactly where, theoretically, an offender should live to the utmost precision, it still may be inaccurate. The offender may live, work, play, somewhere else. The point is clear that crime locations offer investigators and researchers alike a chance to know one particular thing about the offender: The offender has been there, for some reason, and has offended. Thus, in line with Brantingham and Brantingham's (1984) crime pattern theory, we may now know something about the offender's *activity* and *opportunity* space.

Recently, several researchers have supported this view suggesting that GP analyses must be combined with other types of information, such as who utilizes the "space" around crime locations, to increase accuracy and reliability, and/or to ultimately *identify* an offender (Bichler et al. 2011; Goodwill and Alison 2006; Stangeland 2005; van der Kemp and van Koppen 2007). Importantly, this "other" information need not only be additional crime scene information but archival information in general: phone records, land registry ownership, hospital admissions, parking infractions, etc. Historically, police investigators combined geo-profiling home-base predictions with police records of previous convictions, using this information to focus their searches and enquiries around the "usual suspects" – those already known to the police. In addition, police would prioritize search areas for the assailant within the immediate vicinity of the crime(s) to conduct door-to-door interviews, pamphlet drops, and potentially DNA swabbing (Rossmo 2000). However, as Stangeland (2005) points out:

> An intelligent criminal, of middle-class background, is less likely to be found in police files. However, the possibility of tracking him down through other kinds of records increases. Precisely because he lives a normal life, he is more likely to be a homeowner, registered on the local census rolls, to have a mobile phone, credit cards, and a car in his name. The possibility to combine two or more known data on the person and perform a computer search in public or private registers can reduce the circle of suspects. (p.467)

The current authors suggest that it is precisely this combination of various types of information databases, most readily available and in the public or semipublic domain, that will enable investigators to identify which individuals are utilizing a specific area (around a crime location) or the entire area defined by a crime series. In other words, whose *routine activity space* do these crime locations represent?

Investigative Strategies: Developing and Prioritizing Suspect Lists Based on a Routine Activity Approach

As discussed throughout this entry, the advancement of GP will be as a result of the integration of information beyond x/y crime coordinates and other mere mathematical calculations (e.g., distances between crime sites, JTC distances, etc.). It is suggested that crime locations offer insight into the activity space of an offender and these are likely areas that the offender routinely visits. Recently, researchers have begun to recognize that identifying the routine activity space of offenders is an important aspect of geo-spatial analyses. Bichler, Christie-Merrall, and Sechrest (2011) suggest that activity space, specifically points of "social" focus (e.g., gathering points), may influence offender distance-decay functions and in turn GP and CGP systems.

Within a GP paradigm,with the aim to predict or prioritize *who* has committed an offense, it seems of great importance then to determine a) *who* uses that area and b) *what* that area looks like. In terms of *what* an area looks like, geographers and criminologists have a long history of investigating the topographic, social, and transportation features associated with that area, yet arguably those have not, as of yet, been integrated into mainstream GP research or CGP systems. In fact, in relation to GP research, the topographic characteristics of the area of the crimes are seldom considered, giving rise to the chance that home-base predictions will be in a lake or an airport runway (Santtila 2010). Importantly, recent JTC research has begun to integrate topographic features of the area under study to improve JTC estimates (Kent and Leitner 2009); however, improvements have been cited as "inconsistent."

In determining *who* utilizes the activity space surrounding a crime location, the obvious first step is to identify who lives (or perhaps works) in the area. In other words, who "belongs" or has reason to be in that area. Identifying who lives and works in the area can be achieved through various archival and public records as well as through door-to-door enquiries. Other information such as traffic violations, store receipts, hospital admissions, even information on who are walking dogs, or regular joggers in the area may help to determine who *routinely* uses that area. Archival records such as census enrolment, tax records, library card ownership, General Practitioners registrations, school enrolment and attendance, and even birth records (e.g., home-towns and links to the community) could establish links between the area(s) and who routinely is in it.

In an ideal situation, one could generate lists of individuals who are routinely using the activity space around each crime location of a linked series and cross-reference the lists to prioritize individuals. This is an admittedly lofty goal and in some cases may not generate or prioritize the individual responsible, but in arguably the majority of cases, the offender will be somewhere on those lists. It is then up to researchers and investigative expertise to develop methods to identify or prioritize the offender responsible.

Concluding Comments on the Need for a Routine Activity Integrative Approach to GP

As discussed throughout this chapter, current GP research and supporting CGP systems may help us to make estimates and judgments about the activity space (e.g., home base and/or anchor points) of an offender. However, greater GP accuracy and precision in identifying the unknown offender will undoubtedly come from research that integrates analysis of crime locations (e.g., x/y coordinates), features of the geographic location (e.g., topography, routes, and social nodes), and the routine activity of offenders. Pragmatically, geo-profilers must utilize all manner of other types of information relating to the activity space surrounding crime locations to identify links to other crimes or series and to identify who is utilizing that particular activity space. In conclusion, the current authors advocate that the integration of environmental criminological theory, particularly that of routine activities, into current GP research and CGP systems is a necessary next step in advancing geographical offender profiling.

Overview

Constant changes in the technology of computers and small-scale digital devices create a number of challenges for computer forensic examiners and the law enforcement community. Two of these challenges are the identification of devices and media and the retrieval of the data from these devices coupled with having the proper training in forensic techniques to recover digital data properly. Automated tools and command-line-driven techniques, known as manual forensics, are the two methods used to retrieve digital evidence from these devices. Today's automated tools are often a more efficient method for forensic examiners to collect and analyze digital evidence than command-line procedures, which gain the same result. Depending on the situation and the type of device and media, different forensic methodologies are used. The computer forensic process is the identification, collection, preservation, analysis, and reporting of evidence recovered from computers and small-scale digital devices. This entry looks at collection of digital data in three categories: (1) on-scene collection of digital devices and media, (2) on-scene collection of digital evidence, and (3) in-lab collection of digital evidence. Standards and Best Practices require examiners to perform analysis from a bit-by-bit copy of the original data to ensure data integrity. This bit-by-bit copy is commonly referred to as a forensic image. Depending on the circumstances an examiner is confronted with, forensic analysis can be performed at the logical or physical level of the device or media. Traditional command-line techniques and automated tools each have their own purpose during forensic examinations. Time constraints, type of examination, and exigent circumstances are some examples of why a particular methodology might be appropriate to use during an examination.

Introduction

Computer forensics is the identification, collection, preservation, analysis, and reporting of evidence found on computer hard disk drives (HDD) and other small-scale digital devices and various storage media. This type of evidence is commonly referred to as digital evidence (Department of Justice 2004). Digital evidence is not only recovered from HDD but also CDs, DVDs, USB drives, SIM cards, etc. Small-scale digital devices such as cell phones, readers, IDevices (IPod®, IPhone®, IPad®), game boxes, GPSs, and even vehicle computers are commonly examined to recover digital evidence. The driving force for the evolution of computer forensics is the investigative needs of law enforcement and the rapid growth of the microcomputer field (Dixon 2005). Digital evidence was being collected and analyzed as early as the mid-1980s by the Federal Bureau of Investigation and certain military units within the Department of Defense. Law enforcement at the state and local level began to develop the expertise in the late 1980s and early 1990s.

In its infancy, computer forensics was accomplished using manual command-line-driven techniques, which evolved into suites of automated tools that are commonly used today. Microsoft's DOS™ operating system provided some basic tools for early practitioners. For example, examiners used list, dir, chkdsk (check disk), file copy, CD, etc., with switching to identify and copy files. Examiners created batch files in DOS to execute multiple commands to accomplish steps in a forensic examination. Simple commands using DOS could accomplish many of the functions needed to retrieve digital evidence during an examination. However, as technology became more sophisticated, forensic examinations needed to evolve on pace with the technology. This evolution to automated tools happened when software developers began creating suites of automated tools to interpret data and perform the forensic exam (Dixon 2005). Even though some comparatively sophisticated automated computer forensic tools are now commonly used, practitioners often still rely on manual methods using Linux to perform many forensic functions.

Fundamentals

Identification of Digital Evidence

In the 1980s and1990s, identification of devices that actually stored digital data was very simple. With the exception of mainframe computers – which used magnetic tape as a storage media – storage media was only in one form, floppy disks. Personal and business computers used floppy disks to access their operating systems as well as application and data storage. As technology advanced, the operating systems, applications, and user-generated data could be stored in two places: the HDD or on some configuration of floppy disk, that is, 5.25 in., 8 in., or 3.5 in. (Department of Justice 2004). As a result, law enforcement needed to know what an HDD and floppy disks of various sizes looked like. For those who were already working in the field of computer forensics, this was simple and straightforward because they were using HDDs, various kinds of floppy disks, and, although not as often, tape drives. However, very quickly, this simple task became much more challenging. Manufacturers began producing many different types (a veritable cornucopia) of storage media, Zip® disks, Bernoulli® disks, Jazz® disks, etc., which were capable of storing much more data. These new storage media were relatively expensive, and law enforcement often could not afford them. Another difficulty was that examiners might not have had the right equipment to read and image these media when the digital evidence was seized for examination in the lab.

Today's USB devices are a great example of storage media that have drastically changed. These devices are now made in hundreds of configurations from Santa Claus statutes to sushi, making it sometimes difficult for the untrained to recognize them as potential repositories of digital evidence. Add to this the number of new small-scale digital devices, cell phones, GPSs, gaming stations, cameras, readers, IDevices, etc. that might also contain digital evidence, and training in identification becomes even more critical. These new sources for digital evidence have also dramatically increased the level of training required by examiners as well as increased the caseload for computer forensics' laboratories. Additionally, storage schema and proprietary formatting continue to make forensic imaging of media a challenge and require specific training for examiners. Cell phone, GPS, and reader devices are other excellent examples of the diverse number of operating systems and storage schema being used by manufacturers, which now requires not only new tools and techniques to collect digital evidence but again specialized training for examiners.

All levels of law enforcement, from patrol officers to detectives and, of course, computer forensics examiners, are now expected to be able to identify devices and media that could potentially contain digital evidence; specific training in identification and seizure of digital media is now often a basic academy curriculum. This training is becoming standardized by organizations such as the National White Collar Crime Center (NW3C); however, these standards are not mandated. Further, although new automated tools and techniques have been and are being developed to keep pace with these challenges, training in their proper use is also required. Departments are always financially challenged to find the funding and time to keep officers properly trained in the various disciplines within the law enforcement field; computer forensics training at all levels is no less a challenge. (Refer to Open Questions for further discussion.)

Collection and Preservation of Digital Evidence

Digital evidence must be collected in a fashion that both preserves and protects the device, the media, or the record(s) so that the original evidence is preserved in its exact original state. Additionally, practitioners must be able to demonstrate that the copy used for examination is an exact copy of the original. Preservation begins with the first contact with the evidence, which may be as simple as maintaining the chain of custody, and in the case of an HDD, it is packaged in non-static cushioned wrap and care taken not to expose the HDD to extremes of heat or cold. The National Institute of Justice, in partnership with the National Institute for Standards and Technology (NIST), authored the *Electronic Crime Scene Investigation: A Guide for First Responders* (2008). This publication is still the definitive guide for law enforcement's collection of digital evidence today. These guidelines provide law enforcement with standards, guidelines, best practices, and strategies for collecting and preserving digital evidence.

For ease of discussion, collection is explained in three phases: (1) on-scene collection of physical devices and media, (2) on-scene collection of digital evidence, and (3) in-lab collection of digital evidence.

On-scene collection of devices and media simply means the proper marking and packaging and scrupulous documentation of chain of custody of the physical evidence. In the case of a computer that is connected to peripheral devices, such as a computer connected to a printer, router, mouse, and monitor, photographs and diagrams of all connected devices should be taken. These should be in such detail that the "system" could be reconfigured in court exactly as it was at the time of seizure (Department of Justice 2008; NW3C 2011). Digital evidence response training is now broken into three tiers: tiers I, II, and III. Generally, training required for identification and physical collection of digital evidence is tier I level training.

The second area is on-scene collection of digital evidence; tier II level training and expertise is required. There are a number of reasons that digital evidence might be collected on scene rather than in a computer forensics lab. Often the court requires that if a search warrant is being served at a business, for example, officers are required to collect or image the original media on scene and leave the business system up and running; this requirement usually depends on the size of the business. If the business is a relatively small operation, officers can use a forensic copy of the original HDD(s) to leave behind for the business to continue operations because an exact bit-by-bit image is made of the original media on scene. In other circumstances, when a large business operation is involved, examiners may be required to obtain forensic copies of files and folders (Schweha and Inch 2008).

On-scene collection of evidence may require that imaging be accomplished at a logical level as opposed to a physical bit-by-bit image level. A couple of examples that would require a logical level collection of digital evidence would be when encryption is encountered or exigent circumstances require immediate access to information because life or harm is eminent.

Data that is encrypted is not accessible once a computer is powered down without the password or phrase that allows re-accessing the encrypted volume, that is, file, folder, or disk. Normally, a computer that is being seized as evidence is powered down by removing the power source – power cord or battery – rather than using the operating system to turn the computer off (polite or soft shutdown) (Department of Justice 2004; SWGDE 2008). Powering down is not an option if encryption is running on a computer unless passwords or phrases are known. This circumstance requires either live imaging of the system using automated tools or copying files and folders manually from the computer.

A logical image is not a bit-by-bit image of the drive, but an image of files and folders on the drive. A logical image collects data based on the installed operating system, file system, and applications (Craiger 2005). A logical image does not copy unallocated or slack space, boot partitions, partition tables, etc. Automated tools will produce a forensically sound logical image because they perform hashes of the data at the logical level as they are being obtained during the imaging process. These hashes, which will be discussed later, ensure that the data copied from logical volumes are an exact copy used during on-scene or forensic lab examination and analysis of the evidence. In the case of exigent circumstances, a logical image may be the only method of obtaining the evidence. There are at least two software tools that allow forensic-acceptable logical imaging of on-scene digital evidence: EnCase® (EnCase Portable) and Access Data® (Live Response®). These two tools are commonly used for on-scene, live acquisition of digital evidence. If encryption is present, manual methods of accessing data cannot be used because they require that a system be booted from a powered down state before commands can be executed.

Forensic examiners work from a forensic image and use various algorithms such as MD5 or SHA to verify that the two pieces of evidence, the original and the forensic image, are mirror images of each other (Allen 2006). Hashing is referred to as the process of assigning “a mathematical algorithm against data to produce a numeric value that is representative of that data” (Department of Justice 2004, p. 40). Hash values change if the evidence is changed or altered in any way, thus assuring the integrity of the data (SWGDE 2006b). Hashing of the evidence is accomplished in two stages: when the original data is hashed and when the copy is created and hashed. These two hashes must match in order to confirm that an exact copy of the original data has been obtained for examination. If a bit is changed in the process of the hashing, hashes will not match. If hashes do not match, the examiner must be able to explain what happened that caused the alteration of the evidence, and the change must have been a viable change (Bell and Boddington 2010). Automated forensic tools do this seamlessly.

Using manual command-line techniques, examiners are able to copy bit-by-bit copies of files; however, the hash function is missing from the procedure. If the examiner knows that the DOS command-line “copy” command will result in a bit-by-bit copy of a file, a hash is only necessary to verify that an automated tool actually did what it was suppose to do – make a bit-by-bit image. A file could be hashed on the original drive in the exact location it is stored. The file then copies to another forensically clean media, and the file is again hashed. Those two hashes are compared for an exact match. This would confirm that the file on the original media was copied as an exact, mirrored, image to the copy media (Craiger 2005).

An important concept in the forensics process is the difference between a forensic examination and device interrogation. These two processes are performed on various devices and involve two different methodologies. Standard forensic examination of digital evidence requires that an exact, uncorrupted, bit-by-bit image of the data stored on a media be obtained and an exact copy is used to analyze the data to obtain evidence (Department of Justice 2004; Lewis 2008). Although examination of small-scale digital devices such as GPS devices and cell phones are often called cell phone forensics or GPS forensics, the methodologies used to collect data from these devices often cannot be done to forensic standards. These types of examinations are more accurately defined as device interrogations not forensic examinations. The proprietary nature of the operating systems and storage schema of handheld devices often negates the ability for a true forensics copy to be made of stored data as well as the operating and file system. Because many of these devices do not allow a forensic copy to be made, methods such as photographing individual screens and logical acquisition of stored data must be performed (SWGDE 2006a). Because of these limitations, often, the only methodology for collection of digital evidence is capturing photographic images (screenshots) and un-hashable data dumps of stored data on these devices, that is, contact lists, text messages, recent calls, calendars, and photos.

Another methodology for on-scene collection of digital evidence is triage. Triage tools access the computer from a boot disk and parse through files and folders at the logical level. There are a number of tools that use CD, thumb drives, and other bootable methods along with triage application that are specifically designed to assist the investigator in quickly and efficiently determining if there is obvious evidence on the computer. One of the most used triage tools is TUX4N6™ developed and distributed free to law enforcement by NW3C (NW3C 2010). Some of the other commercial triage tools are Blade™, EnCase Portable™, Drive Prophet™, LiveResponse™.

Prior to performing any triage examination on a computer, one key element is to recognize what files can be collected during the process. Because triage is done on the logical level, files and folders are accessible, not slack space, partition tables, and other areas of the media. Knowing what files to look at is key. Relevant locations to search commonly include My Documents, Desktop, Recents, Recycle Bin, Temp, Downloads, Internet Explorer®, or Firefox®, and Flash® usage histories, the "low hanging fruit" (NW3C 2010). This listing is certainly not all-inclusive, but simply some examples of the data locations that can be quickly searched for digital evidence. An advantage of using modern triage tools is that examiners can do both automated and manual searches of the media for evidence. Digital evidence collected using the triage application with automated or manual search techniques is forensically sound and can often be submitted in court without further forensic examination in the lab. On-scene as well as in-lab triage of computers has been a great help in decreasing the case backlog in many computer forensic labs around the United States.

The third area for discussion is examination and analysis in the forensic lab environment. Any evidence seized from the scene of the crime should be imaged, if possible, and the examination performed on a forensic image of the evidence. According to the working group that set forth the NIJ Analysis Guidelines (Department of Justice 2004), an image is "an accurate digital representation of all data contained on a digital storage device (e.g., hard drive, CD-ROM, flash memory, floppy disk, Zip®, Jazz®) which maintains contents and attributes but may include metadata such as CRCs, hash value, and audit information" (p. 40).

Working from an image is important for several different reasons. First, it is important that there are no modifications accidentally performed to the original evidence. This enables the evidence to stand up to authenticity if it is taken to court (Lewis 2008). Second, all tests performed on the evidence must be able to be replicated. This means that the defense counsel, or an outside examiner, must be able to reproduce all tests performed on the evidence in an attempt to reproduce the same results that the examiner received during the examination (Crozby 2001). Lastly, working from an image is always a fail-safe method in case the image becomes damaged for any reason in the process of examination. In any case, the examiner always has the original evidence to rely on once again to make another image (Department of Justice 2008; SWGDE 2006a).

Analysis of Digital Evidence

The analysis must conform to the scope of the search warrant (Department of Justice 2009). By example, a search warrant authorizing a search for images, that is, child pornography, may very well prohibit the examination and analysis of documents that may reside on the same hard drive.

Prior to performing the analysis on any evidence, the examiner must become familiar with the operating system and file structure of the device in which is being examined. Operating systems vary depending on manufacturer, and although the types of evidence will always be the same, the location of where it is on the machine or device will change. The Microsoft® operating system is updated often; this requires new training and expertise by examiners. Microsoft® is entirely different from a Linux or Macintosh® operating system. This is also true with different file systems (Britz 2009). While testifying in court, the examiner must be able to state which operating system was used and where that piece of evidence was found in the file structure. Changes made to operating systems and file systems require examiners to have updated training. Updated training for automated tools is expensive, and it is often very difficult for examiners to afford this training. The time away from their caseload for training, not to mention the time required in gaining expertise using the new tool capability, is another burden on examiners and their agency.

Solid-State Drives (see discussion in “Key Issues/Controversies”)

Performing keyword searching, data carving, and email examination are some of the data analysis functions that can be performed at the physical level both manually and by using automated tools. Keyword searches allow the examiner to look for items not related to the operating or file system (Department of Justice 2004). A keyword may be used to search for specific items that pertain to things such as images, documents, spreadsheets, and databases. An examiner can also search by file extension. Email searching falls into two categories: application-based and web-based email. Common email applications are those that are installed when Microsoft® is installed. Yahoo®, Gmail®, and Hotmail® are a few web-based email services that examiners will find in the temporary Internet folders. Data carving looking for deleted files in unallocated and slack space is another important element in physical analysis (Craiger 2005).

Reporting of Digital Evidence

Automated analysis tools have built-in reporting capabilities that establish an audit trail of most of the steps of an examination; this is critical for court presentation of digital evidence gleaned from examinations. In addition to these auto-generated report capabilities, when performing manual analysis or automated forensic examinations, it is also necessary to document other steps in the analysis process. In addition to automated reporting, standard policy requires that a separate examination report is prepared that documents steps taken that are not part of application-generated reports, that is, system documentation, peer review of analysis results, and chain of custody. An important element of reporting is to document that standards, best practices, and department policy were followed.

State of the Art

Various automated tools assist with computer forensic examinations during the imaging and analysis stages. Essentially, all these automated tools do for forensic examiners is to run multiple command-line functions on the computers and media looking for specific evidence. In comparison, this is what a manual examination is; however, it takes a much longer process, and the examiner has to execute one command at a time or create batch files to perform various forensic functions. Law enforcement must be able to prove that the automated tool or manual methods used in the examination process were forensically sound and did not jeopardize the integrity of the evidence that was collected during the examination. The National Institute of Standards and Technology’s (NIST) Computer Forensics Tool Testing project (2001) created validation and testing guidelines that tool developers can use in order to measure assurance for forensic requirements in judicial proceedings.

The automated tools available to law enforcement and forensic examiners can essentially be broken into three categories: imaging tools, triage tools, and analysis tools. Some of the more popular automated forensic tools used by law enforcement forensic labs include WinHex™, EnCase®, Access Data® Forensic Toolkit™, and various Linux tools; however, the availability of these tools relies on the budgets of the agencies (Allen 2006; Dixon 2005). Automated tools have even been developed to perform a variety of forensic functions such as triage, live system acquisition, and small-scale device interrogation. These tools are constantly updated and new tools developed because of the ever-changing varieties of cell phones and other small-scale or handheld digital devices.

Key Issues/Controversies

Changes in technology, such as data storage devices, new proprietary operating and file systems, and other advances, will cause forensic standards to always evolve. Funding for research, testing, and validation to organizations such as NIST is critical for law enforcement to have validated tools available for forensics examinations of these new and changing technologies.

A current example of evolving technology forcing a paradigm shift in computer forensics is solid-state drives (SSD). Files are written differently on HDD and solid-state drives. Some of the differences between the two types of drives are that SSD drives are faster and allow access to parts of data. Bell and Boddington in their research state, "A paradigm shift has taken place in technology storage and complex, transistor-based devices for primary storage are now increasingly common" (2010, p. 5). As a result of their research, the authors identify twenty-one critical areas that examiners must be aware of in their "Recommendations and Guidance" section. This research could indeed change the state of computer forensics as it applies to SSD. Further research will no doubt be forthcoming in this specific area of computer forensics.

Future Direction

There are several areas that are open for discussion in the field of computer forensics, including certification and accreditation, standards for forensic training for practitioners, and law and policy.

Practitioner Certification and Forensic Lab Accreditation

- As the Internet makes connectivity ubiquitous, law enforcement will be challenged in a number of areas. During a criminal investigation, how can law enforcement locate and collect the data generated by hundreds of Wi-Fi networks that will be commonly pushing communication to handheld devices such as cell phones, readers, and pads?
- Software tools used in EDiscovery are beginning to be used by law enforcement to assist in parsing large datasets, that is, email servers. Although these EDiscovery can be of great assistance, testing and validation of forensic soundness of the tools are not commonly done.
- Should live system acquisition and device interrogation be treated as the same type of forensic examination?
- The number of handheld devices has now exceeded the number of computers being purchased. Handheld devices are evolving to include much more capability and sophistication. The research and development required to develop training that keeps law enforcement abreast of these new technologies is a challenge now because of lack of congressional funding, and without long-term solutions, computer forensics will not keep pace with the quantum leaps that technology is making in the twenty-first century.

Standards for Forensic Training for Practitioners

Are colleges and universities keeping pace in their curriculum in the area of computer forensics to match the needs of the law enforcement, the intelligence community, private sector business, and industry? Although there are some excellent undergraduate- and graduate-level programs, private sector business and government are still challenged to find enough qualified graduates to fill their needs. Techno-based business often expresses a need for university curriculum focused on knowledge and skill sets that result in graduates being able to enter the field having the practical skills instead of having a degree based on theory and not practice.

Law and Policy

The list of legal issues surrounding computer forensics is endless, from ensuring that privacy is protected to outdated laws and regulations that were enacted decades ago for the telecommunications system that simply do not apply to today's Internet-driven society. Many heated debates have been raging for decades over jurisdictional issues as they apply to search warrants, subpoenas, preservation orders, etc. Is a digital search warrant that is accepted in all jurisdictions the answer? The Internet has no state, county, city, or even country jurisdictional boundaries, but the laws governing these issues certainly do. Legislation must be as nimble as the technology and the Internet. Crafting cogent regulations, laws, and policy that will live to the future is beyond challenging.

Although more and more potential evidence is now held by third parties such as Internet service providers and cloud services, the laws governing law enforcements' legal access to potential evidence are not keeping pace with these changes. How are law, policy, and regulation going to change to solve these issues?

Conclusions

Computer forensics is evolving rapidly for law enforcement due to the ever-changing growth of technology. Forensic examiners rely on two methods for analyzing data: automated tools and manual forensics. Automated tools evolved from command-line methods, producing a more efficient method of collecting data. Depending on the circumstances surrounding the forensic examination, that is, whether it is an on-scene device collection, on-scene data collection, live system acquisition, device interrogation, or lab examination, the most important concept during the examination is to maintain the integrity of the evidence. Identifying, collecting, preserving, analyzing, and reporting of digital data found on hard disk drives and small-scale digital devices are known as the computer forensic process. Automated and manual forensic exam principles are introduced at the collection stage and can be used throughout the remaining forensic examination process. Analysis can take place at both the logical and physical levels of a device. The goal of the computer forensic exam is to document the process (no matter whether automatic or manual methods were used), ensure evidence integrity, and maintain proper chain of custody in order to present the evidence in court.

Babies Behind Bars

Leana A. Bouffard
College of Criminal Justice, Sam Houston
State University, Huntsville, TX, USA

Overview

Although there has been massive growth in the number of women in prison in the USA and other countries, women remain a significant minority within correctional systems. In the United States, the number of women in prison increased by more than 800 % in the 30-year period between 1977 and 2007. In the United Kingdom, the female prison population nearly tripled in just a 12-year period from 1992 to 2004. Despite these increases, in most countries, women still constitute less than 10 % of the prison population (Alejos 2005). There have long been concerns that the correctional system, which was built around a need to house large numbers of male offenders, ignores, minimizes, and marginalizes female inmates and their specific needs, including medical needs.

In particular, statistics find that a large proportion of female inmates are mothers. One recent study in the United Kingdom reported that more than half of women in prison have children under the age of 16 and one-third of women have children under 5 years old (Edge 2006). Similarly, in the United States, more than half of state and federal inmates have an estimated 1.7 million minor children (Glaze and Maruschak 2008). In most cases, the women are the primary caregivers and had been living with their children prior to incarceration. The children of men who are imprisoned typically stay with their mothers during the father's incarceration; however, children whose mothers are incarcerated are much less likely to remain in their family home, often being placed with extended family. Additionally, incarcerated mothers are five times more likely than incarcerated fathers to report that their children were placed in foster care or other institutions during their incarceration (Glaze and Maruschak 2008). While the number of women who are pregnant, give birth, or have new infants while in prison is much smaller than the number who had children prior to incarceration, all of these women and their infants and children have specific needs that are often not addressed by prison policy, practice, or administration.

Legal Issues with Mothers and Children in Prison

In 1990, the United Nations Congress on the Prevention of Crime and Treatment of Offenders issued a resolution that the imprisonment of pregnant women should be avoided, stating that "the use of imprisonment for certain categories of offenders, such as pregnant women or mothers with infants or small children, should be restricted and a special effort made to avoid the

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

extended use of imprisonment as a sanction for these categories" (Alejos 2005, p. 13). There are a number of issues that arise in dealing with convicted women who are either pregnant or are mothers, especially to young children. For women (and men) who have children, applicable legal considerations include the Convention on the Rights of the Child, which specifies that children should not be separated from their parents against their will except in a case where it is in the best interest of the child (Alejos 2005, p. 14). The African Union's Charter on the Rights of Children, for example, specifies that noncustodial sentences should be considered first in cases of pregnant women and mothers of infants and young children and that the purpose of punishment should be reform and reintegration with family (Alejos 2005). In fact, the best interests of the child are indicated as the primary guiding factor, which raises the question of whether it is in a child's best interests to remain with their mother in a prison or to be separated from their mother in order to remain in the community.

In terms of pregnancy and childbirth in prison, the United Nations standard minimum rules for the treatment of prisoners specify that women should receive all necessary prenatal and postnatal care, that birth should occur in a hospital outside of the institution, and that a child's birth certificate should not list a prison as the place of birth. Additional criteria require that efforts should be made to maintain and improve relationships between prisoners and their family, which would presumably include children. While many international legal standards suggest that prison should only be used for pregnant women in extreme circumstances, for those women who are incarcerated while pregnant, additional legal considerations address the necessity of appropriate prenatal care, including nutrition, medical care, a healthy environment and exercise, and attention to any cultural or religious issues surrounding childbirth. Physical restraint of pregnant women should not be used except in extreme circumstances, and numerous international standards call for abolishing the practice of shackling or restraining women during labor and childbirth.

Children living with a parent in prison also present special legal challenges, and the management of these children varies widely by nation (Bastick and Townhead 2008). General international standards specify the need for monitoring mechanisms and the involvement of child welfare agencies in institutional decision-making that affects the child. Adequate accommodations should be available, including separate mother-child units that are removed from the general prison population, the provision of a safe and healthy environment, as well as appropriate facilities to house the children at times when their parent is participating in activities not appropriate for children. Underlying these general standards is a fundamental assumption that the child is not a prisoner and should never be treated as one.

Pregnant in Prison

Data compiled by the Bureau of Justice Statistics indicated that in 2004 in the USA, 4 % of female state inmates and 3 % of federal inmates were pregnant when they were admitted to prison. International standards require that pregnant inmates receive all appropriate medical care, nutrition, and assistance. In the USA, a number of medical organizations as well as the National Commission on Correctional Health Care have issued policy statements on appropriate health care for inmates in general and for pregnant inmates more specifically. These recommended guidelines include "timely and appropriate prenatal care, specialized obstetrical services when indicated, and postpartum care" (NCCHC). Specific issues that should be addressed among pregnant inmates include prenatal medical exams, nutrition, and counseling, along with diagnostic screening for high-risk pregnancies, including HIV testing. In addition, the NCCHC recommends that institutions should have written agreements with a local medical facility for delivery. Despite these policy guidelines and standards, research finds that pregnant women in prison do not receive adequate prenatal care and health screening (Edge 2006). Research with pregnant inmates in England finds that these women report being constantly hungry, being physically restrained with shackles and belly chains, and invasions of privacy with male guards present during medical exams and delivery.

In 2010, the Rebecca Project for Human Rights in conjunction with the National Women's Law Center conducted a state-by-state analysis of policies and practices for dealing with pregnant and parenting women in prison in the USA. According to this study, three-quarters of states do not have adequate (or any) policies in place for providing prenatal care for women who are pregnant during their incarceration. This may be especially problematic because female inmates typically are less likely than other women to have had routine health care prior to their incarceration. These women may have undiagnosed health conditions as well as higher levels of drug use, sexually transmitted diseases, and risk factors for HIV, which may lead to a higher proportion of high-risk pregnancies in this population. Incarcerated women are also more likely to have histories of neglect and victimization, including sexual assault. Some research has noted that since many women in prison receive short sentences, the rapid turnover of the female prison population may interfere with the ability of institutions to ensure adequate prenatal care and aftercare (Edge 2006). The failure to provide a high level of prenatal care may have implications for the pregnancy as well as short-term effects on the infant, including low birth weight or other birth complications, and long-term consequences for the health of both mother and baby.

Despite a great deal of increased attention to the issue recently, the practice of shackling female inmates during pregnancy, labor, and delivery remains an area of concern. The National Commission on Correctional Health Care (NCCHC), the American Congress of Obstetricians and Gynecologists (ACOG), the American Medication Association (AMA), and the Association of Women's Health, Obstetrics, and Neonatal Nurses (AWHONN) have all issued position statements arguing that the use of restraints for pregnant women should be avoided completely except in cases of extreme risk, and when restraints are judged to be necessary, the least restrictive method should be used. For example, the AWHONN (2011, p. 817) "opposes the practice of shackling incarcerated pregnant women...[which] should only take place if prison officials reasonably believe, after an impartial and thorough evaluation, that a particular individual may attempt to harm herself or others or presents a legitimate flight risk." In January 2012, the American Correctional Association (ACA) also issued a policy statement that pregnant women should be restrained in the least restrictive method possible, that waist and electronic restraints should never be used during pregnancy, and that leg restraints should never be used during labor and delivery. While efforts to restrict the use of physical restraints on pregnant and laboring women in prison are gaining momentum, more than half of the states do not have policies that comprehensively limit the use of restraints (The Rebecca Project 2010). As of 2012, only 17 states have adopted laws that limit the use of physical restraints for pregnant inmates, with four states addressing the issue in policy.

International Examples of Prison-Based and Community-Based Programs

While it is more common outside of the USA for babies born in prison as well as other children to reside in prison with their mothers, there is little information available and even less consistency in how institutions and nations deal with mothers and their children. For example, in Australia, a mother or primary caregiver may submit a request to the superintendent of the institution that her baby live in the facility with her for up to 12 months. Requests may also be made for older children to stay overnight. In France, however, the decision to keep a child in prison is left up to the mother with no approval necessary except for the agreement of the father, and babies may stay in the prison until they are 18 months old (Alejos 2005). In Finland, legislation allows both mothers and fathers to bring their children into prison with them. While there is no specific age limit, this typically involves children younger than 2 or 3 years old. Some countries, like

Germany and Spain, allow older children (in some cases, up to age 6) to live in prison with their mothers. In other countries, like Norway, children are not allowed in prisons at all.

There are a number of examples of the various ways that programs throughout the world manage babies, children, and their mothers in prisons and community-based alternatives. In England, the prison service has designated Mother-Baby Units (MBUs), which are described as separate living arrangements within a women's prison where women and their children may live together during her incarceration (Edge 2006). These units are designed with the rights of the child as the primary consideration. Children can stay with their mothers in prison up to a maximum of 18 months of age. Women must apply to participate in the program, and admission is determined based on what is in the best interests of the child. Mothers must be and remain drug-free, must be willing to take primary parental care of the child, and must have no physical and/or mental health or other concerns that would interfere with their ability to care for the child. Applications are taken system-wide, and women may be transferred to another facility if they are accepted. Because of the geographic distribution and isolation of facilities, placement in a Mother-Baby Unit may mean that a mother and baby are separated from the rest of their family, including any older children she may already have.

Canada also has an Institutional Mother-Child Program (Alejos 2005). Mothers who are categorized as either minimum or medium security and who are housed in institutions that provide the program are eligible to participate as long as the offense did not involve a child. In general, participants may request that their young children (up to 4 years old) live with them full time and that older children (up to 12 years old) may have part-time residence. Canadian policy specifies that the primary consideration in allowing women to participate should be what is in the best interests of the child, and the goal of allowing children to reside with their mothers is to maintain and support stable mother-child relationships. Interestingly, those reviewing applications for participation in the program are also directed, when feasible, to consider the wishes of the child in determining who will be accepted. If accepted into the program, mothers sign a parenting agreement, which may include parenting training, health-care plans, and other criteria. Program staff monitor a mother's compliance with program requirements and review cases after the first month and then every 6 months.

While women have long been allowed to keep young children in prison with them in Spain, Feintuch (2010) describes an institutional program implemented in 2004 with the stated goal of removing all children from prisons by 2012. These "external mother units" are designed for those women with longer sentences, who committed a nonviolent offense. In these units, women are housed in separate apartments with their children, and the women are responsible for the feeding and care of their children. Efforts are made to maintain a homelike environment, including the language used to describe the units, referring to a woman's "apartment" and "home." During the day, the children attend a community preschool, while the women participate in programs focusing on parenting classes, education, and job training. The women may also work in the community as long as the job does not interfere with their child's schedule. Cases are reviewed frequently to ensure the health and safety of the children, and as a child approaches 3 years of age, the mother's case is reviewed to determine whether she could complete her sentence in the community. The units have an age limit of 3 for the children, so older children are not eligible to live with their mothers in the units. There are only a few facilities in the country, which means that mothers may be located in a facility some distance from their other family, and this may also interfere with the involvement of fathers. Interestingly, Spain does have one family unit where families can live if both parents are incarcerated. Finally, the external mother unit program is also heavily dependent on help from nongovernmental organizations, so continued funding may be an increasing concern. Community-based programs are also available for convicted parenting women and their children. In addition to the "external mother units" described, Spain is increasing the use of community-based alternatives for nonviolent, parenting women with shorter sentences.

Children in Prison: US Examples

In contrast to the numerous examples from the international perspective, it is uncommon for imprisoned mothers in the United States to keep their children with them while serving their sentence. In the USA, it is common for mothers who give birth while incarcerated to be separated from their babies within a few days. While the mother returns to the institution to finish serving her prison term, the baby is placed in the community with family or social services. Mothers who have children prior to incarceration simply leave those children behind when they begin serving their sentence. Support for the use of prison nursery programs in the United States has varied over the years, and few states operate programs. There are, however, a few notable examples of programs ranging from prison nurseries to community-based sanctions. There are generally two goals associated with these types of programs: that allowing mothers and babies to stay together will foster positive attachment and bonding and, relatedly, that this environment will be rehabilitative for the mother and will reduce her chances of recidivism.

Within the past two decades, a minority of states have developed prison nursery programs, which allow children born during their mother's imprisonment to remain with the mother for a period of time following birth. The oldest program, operating since 1901, is located in New York. Other programs have been developed in Nebraska, Washington, Massachusetts, Illinois, Indiana, Ohio, California, West Virginia, and South Dakota. The Federal Bureau of Prisons also operates a program, Mothers and Infants Nurturing Together (MINT). Prison nursery programs in the USA are generally designed for women who give birth during their incarceration, who were convicted of a nonviolent offense, and who have no history of child abuse or neglect. The length of time that babies can stay with their mothers in the program varies from a low of 30 days in South Dakota to a maximum of 3 years in Washington. Most of the prison nursery programs in operation are housed in an area of the prison separated from the general population and incorporate parenting skills training.

The Bedford Hills Correctional Facility for Women in New York houses the nation's oldest prison nursery program, operating since 1901. Women who are pregnant when admitted to prison and who will give birth in custody are eligible for the program. Selection of participants is determined by a number of factors, including a consideration of who will have custody of the child, the length of the mother's sentence, and the type of crime she committed. If the mother will be discharged from prison within 18 months following the birth of her child, the babies can stay with their mothers the entire time. Otherwise, the maximum stay is 12 months. Mothers receive weekly nurse visits, and the program includes specialized children's activities, daycare, parenting education, family counseling, and assistance with child placement.

In 1994, Nebraska expanded an existing program for mothers and children into a prison nursery program modeled after the Bedford Hills New York program (Carlson 2001). Mothers in the women's prison in Nebraska give birth at a local hospital. For program participants, both mother and baby return to the nursery facility after discharge from the hospital. To be eligible for the nursery program, women must have less than 18 months left on their sentence following the birth of their child, must have no prior convictions for child abuse, and must sign a parenting program agreement. As part of that agreement, prenatal classes are required, in addition to parenting classes, educational programs, and employment. In its early stages, participating mothers reported strong support for the program, feeling that they have a better relationship with their child and that they are better mothers as a result of their participation and involvement in parenting classes (Carlson 2001).

More recently, the Washington Correctional Center for Women opened the Residential Parenting Program in 1999 for minimum security women who had committed a nonviolent offense and would have no more than 3 years remaining on their sentence following the birth of their child (Women's Prison Association 2009). In a separate unit within the facility, mothers in the program each have a private room with a bed for her child. The unit also includes indoor and outdoor children's play areas. Monthly pediatrician visits are provided to monitor the health and well-being of the children. Because children may stay with their mothers up to 3 years, the facility partners with a local organization to provide an early head start program for the children, which incorporates activities for the children, nutrition counseling, information about child development, and maternal depression screenings.

Alternatives to Incarceration in the United States

There is also a growing effort in the USA to develop alternatives to incarceration for convicted women with young children. More than half of the states have some form of family-based treatment as an alternative to prison. Summit House in North Carolina was one example of a model residential alternative to incarceration program for women with young children who were convicted of a nonviolent offense (Women's Prison Association 2009). Participation in the program for 12–24 months was a court-ordered condition of probation. With the goal of rehabilitating women while maintaining family bonds, the program included counseling, life and job skills training, substance abuse counseling, supportive housing, and parenting education. Like many alternative community-based programs, Summit House is a nonprofit organization with funding dependent on the current economic climate. Despite being recognized as a model program and evidence of substantial cost savings in terms of both reduced recidivism among the participants and reduced social service costs of dealing with the children, funding was cut substantially, and the program was forced to close in June 2011.

Another example is Drew House, described by Goshin and Byrne (2011), a newly designed program in New York that provides supportive housing to women charged with felony offenses and their children. The women in the program are typically charged with nonviolent offenses, although some women with violent felonies may be eligible if there was no serious injury and the victim agrees to the placement. The program uses a gender-responsive, relational model that promotes independence, and court-mandated conditions typically involve drug testing, educational and vocational training, efforts to find employment, as well as participation in parenting classes. Participation in the program typically lasts between 12 and 24 months. During program participation, the women and up to three children live in their own apartments, paying some or all of the rent. As with the Summit House program, availability of funding is also an issue with Drew House.

Results of Prison-Based and Community-Based Programs

Research on the effectiveness of prison-based and community-based programs for parenting women and their children is very limited. While knowledge about the consequences of the separation of mothers and their children due to incarceration is also limited, research does suggest that both the mother and their children can be adversely affected. For example, children separated from their mothers may experience attachment disorders, mental health problems, and behavioral problems. Others report academic failure and increased levels of criminal involvement among children of incarcerated women (Byrne et al. 2012). Thus, it is important to consider the effectiveness of these types of programs in terms of their impact on the mothers who are participating but also in looking at the long-term impacts on the children.

When sufficient resources are dedicated to prison nursery programs designed for convicted women and their children, results are generally positive, providing an environment that facilitates appropriate child development and allows mothers and their children to develop strong relational bonds. For example, studies in the UK indicate that pregnant inmates are more likely to reduce their levels of smoking, drinking, and drug use when presented with information about healthy behaviors during pregnancy (Edge 2006). Longitudinal research also suggests that mothers are likely to retain custody of their children following participation, and the women also demonstrate reduced recidivism (Byrne et al. 2012). Community-based alternatives to incarceration also appear to produce positive results related to mother-child attachment and recidivism rates (Campbell and Carlson 2012). Additionally, the children who participate with their mothers avoid placement in the foster care system, maternal separation, and the related negative repercussions.

Future Directions

With the increasing attention being paid to pregnant and parenting women in prisons, it has become apparent that there is very little information maintained to track the number of pregnant women, the outcome of those pregnancies, and the numbers of children born or housed within prisons throughout the world. Poso et al. (2010) refer to the "institutional invisibility" of these children and the policies and practices related to children and their parents. In the USA, research has found that correctional administrators are generally unfamiliar with prison nursery programs (Campbell and Carlson 2012). While these administrators expressed some interest in learning more about this type of program, they expressed reservations that would ever be implemented in their state or facility. At a minimum, facilities should consider focusing on ways to facilitate relationships between incarcerated mothers and their children, including creating visitation areas for children that provide a more homelike setting or allowing mothers to create audio-recordings of bedtime stories that they could send to their children (Bastick and Townhead 2008). Other community-based programs face issues with maintaining sufficient resources to serve the women and children who need them.

Most of the parenting women in prison-based programs are low risk and could reasonably serve their sentences in the community. The Women's Prison Association suggests increasing the use of community corrections and alternatives to imprisonment for parenting women. Whether in a prison-based or in a community-based program, these programs should address the needs of both the woman and her family and should offer educational and vocational services as well as education on parenting skills. More generally, there is a great need for additional research and evaluation to assess these programs, including the components that produce the greatest benefit to both the women and their children.

Overview

Bayesian updating – the principle that individuals update prior beliefs in light of observed data according to probability rules – has important substantive implications for criminology. Theoretically, this principle may help formalize key causal mechanisms of deterrence, rational choice, social learning, symbolic interactionist, and developmental perspectives of crime. Empirically, recent research linking individuals' perceptions of punishment risk to the objective certainty of arrest has developed formal models drawn from Bayesian updating. Such models help link macrolevel research on aggregate crime rates to microlevel research on individual risk perceptions and self-reported crime. This essay reviews empirical work on Bayesian updating of risk perceptions, points to theoretical and methodological challenges in this area, and outlines future research opportunities for perceptual dynamics and crime.

Introduction

Bayesian updating, or Bayesian learning, has become an increasingly important principle for specifying how human beings change their beliefs in light of new evidence. It has been applied to a variety of substantive topics, including machine learning, language acquisition, artificial intelligence, and dynamic systems. In criminal justice research, Bayesian inference has been applied to jury decision-making, as a rational way of accumulating evidence to reach a verdict (e.g., Robertson and Vignaux 1995). And in criminology, Bayesian updating has primarily been approached from a deterrence perspective, where individuals are argued to follow Bayesian processes when updating their perceptions of formal sanction risk in light of new evidence (Nagin 1998). Indeed, the link between Bayesian updating and deterrence theory is a useful place to begin the current essay.

Bayesian Updating, Deterrence, and Rational Choice

The deterrence doctrine is rooted in a rational decision-making framework. In his seminal work, *Essay on Crimes and Punishment*, the Italian Enlightenment scholar Cesare Beccaria ([1775] 1983:44) presented a utilitarian philosophy of criminal punishment that assumed actors weight pleasures and pains associated with behavior and seek to maximize pleasure and minimize pain. It follows that threatening citizens with punishments that are certain, swift, and proportional to the severity of crime would deter the public from violating the terms of the social contract. Beccaria argued that deterrence requires that punishment must be known in advance by all citizens, and therefore, written laws must clearly stipulate proscribed behaviors and unequivocally designate penalties for transgressors. Beccaria ([1775] 1983:44) further argued that formal sanction by the state is only effective insofar as citizens accurately perceive the cost of crime and apply this information to future offending decisions: punishments "ought to be chosen, as will make the strongest and most lasting impressions on the minds of others, with the least torment."

The deterrence doctrine of the classical school was later formalized by neoclassical economists, who assume that actors maximize expected utility subject to constraints. Drawing on von Neumann and Morgenstern's (1944) expected utility theory of risky decisions under uncertainty, Becker (1968:177) specified a utility function for criminal behavior that included the deterrent effect of punishment:

$$E(U) = (1 - p)\ U(Y) + p\ U(Y - F) \quad (1)$$

where $E(U)$ refers to expected utility, p is the probability of getting caught as perceived by the criminal, $(1 - p)$ is the perceived probability of getting away with crime, Y is returns to crime (both monetary and psychic), and F is the penalty. This utility function describes two states: getting caught or getting away with crime. When $p = 1$, the criminal expects to get caught with certainty and, therefore, $E(U) = U(Y - F)$; that is, the expected utility of crime is equal to the utility of the perceived returns to crime minus the punitive sanction (assuming that the criminal keeps her booty when caught). When $p = 0$, the criminal expects to get away with certainty and, therefore, $E(U) = U(Y)$; that is, the expected utility of crime is equal to the utility of the returns to crime. A person is assumed to commit crime when the expected utility of crime is higher than the expected utility of alternative legal pursuits (Taylor 1978). Moreover, Eq. (1) implies that, all else being equal, an increase in p, the perceived certainty of punishment will reduce the utility of crime, and thereby the probability of crime.

Both the classical and neoclassical models' emphases on the actors' perceived probabilities of punishment underscores the importance of information for deterrence and for decision-making in general. Because individuals' perceptions of sanction risk are not exogenously determined but rather are endogenously produced through social interaction, a rational choice theory of deterrence and crime requires a theory of information. Such a theory would specify how information about sanction risks are communicated and disseminated to individuals. Here, Bayesian updating can provide a mechanism for risk communication which is consistent with rational choice theory. Understanding Bayesian updating first requires an understanding of the basics of Bayesian statistical inference.

Bayesian Inference and Updating

Based on the probability theorem posthumously published by Thomas Bayes (1701–61), Bayesian updating refers to the general principle that subjective beliefs should change given exposure to new evidence (Bayes and Price 1763). Bayesian updating provides a rational and principled way of combining prior beliefs with new evidence using Bayesian inference. It begins with two assumptions: (1) Subjective hypotheses about the world can be expressed as degrees of belief, which in turn, can be expressed in terms of probabilities ranging from 0 to 1. (2) Human beings are able to use probability distributions to represent uncertainty in inference. Given these assumptions, actors can use probability theory to compute the degree of belief of a hypothesis, h_i, given some observed data d, where h_i is a member of the set of mutually exclusive and exhaustive hypotheses $\mathcal{H}$. Belief in h_i prior to observing the data d is defined as the *prior probability*, denoted as $P(h_i)$. The probability of observing datum d given that h_i is true is the *likelihood*, denoted $P(d|h_j)$. Bayes' rule can then be used to derive our belief in h_i after observing the data, which is the posterior probability denoted $P(h_i|d)$:

$$P(h_i|d) = \frac{P(d|h_i)P(h_i)}{\sum_{h_j} P(d|h_j)P(h_j)} \quad (2)$$

where $h_j \in \mathcal{H}$. The denominator is simply the sum of all possible hypotheses under consideration

Bayesian Updating and Crime, Table 1 Hypothetical Burglar Arrest Perceptions Given Observed Arrests

Prior probability $P(h_i)$	Likelihood $P(d/h_i)$	Posterior probability $P(h_i/d)$
P(certain) = .30	P(.80|certain) = .80	P(certain|.50) = .522
P(50/50) = .30	P(.80|50/50) = .60	P(50/50|.50) = .391
P(get away) = .40	P(.80|get away) = .10	P(get away|.50) = .087

which ensures that the posterior probabilities of all hypotheses sum to one. This equation describes a rational updating process in which new evidence is combined with prior beliefs to yield a new subjective belief. The posterior probability $P(h_i|d)$ is equal to the likelihood of the data given h_i is true $P(d|h_j)$ times the prior probability $P(h_i)$.

A simple example helps to illustrate how this equation produces Bayesian learning (see Table 1). For simplicity, assume there are only three prior hypotheses about the risk of arrest for burglary: certain arrest ($P = 1.0$), 50/50 ($P = .50$) and certain to get away ($P = 0$). The prior probability is .30 for certainty, .30 for 50/50, and .40 for getting away. Thus, given the opportunity, an actor would be expected to engage in burglary, since the highest probability is associated with getting away with the crime. The actor then observes new information or data, in which four of five burglars are arrested for the burglaries. Given the new data (that 80 % of burglars are arrested), the probabilities for our three hypotheses are as follows: .80 for certain arrest, .60 for 50/50, and .10 for getting away.

The updated probabilities become .522 for certain, .391 for 50/50, and .087 for get away (Table 1, column 3). Note that the highest subjective probability for the posterior is now getting caught (.552). Thus, all else being equal, after updating, the actor would be expected to refrain from burglary.

Bayesian inference assumes that the observed evidence or data are generated by some underlying process or mechanism, which has crucial implications for making inferences. The likelihood is based on a probability model of the mechanism by which the data were generated. In this way, Bayesian learning is a way of evaluating different hypotheses about the underlying process generating the data and making predictions about the most likely ones. For example, if the data on arrested burglars were generated from a random sample of the population of all burglars, and one views oneself as an average burglar, applications of Bayesian inference would be straightforward. However, if the data on arrested burglars were generated from a sample of very unskilled novice burglars, one would draw a different inference. Although the observed data are identical, this difference in the generation of the data will produce distinct likelihoods, altered posterior distributions, and different inferences. Thus, in applying Bayesian learning to substantive applications, careful attention must be paid to the generative process producing the data, a point returned to later in the essay.

The Heuristic Critique

Bayesian updating, as well as other rational principles of learning, has been subject to theoretical and empirical critique. Indeed, the emerging discipline of behavioral economics has as its focus the study of systematic ways human beings depart from rationality. Much of this research derives from the important work of Tversky and Kahneman (1974), who conducted a series of ingenious experiments that showed actors departing from rational updating in systematic ways, which they termed "cognitive heuristics" or "cognitive shortcuts." The assumption is that human beings have a limited ability to process information cognitively, and therefore, must rely on cognitive shortcuts. Based on results of their social experiments, Tversky and Kahneman (1974) outline four heuristic rules that individuals use to form perceived risks, and which could bring about departures from a Bayesian learning process. The first, representativeness, refers to a tendency to rely on stereotypes, while ignoring information on population distributions. For example, people are likely to overestimate the probability a mother is black when told that she is a teenage mother, thereby forgetting or ignoring the extent to which whites are disproportionately represented in the population. In the case of certainty of sanction, individuals are likely to rely on stereotypes depicted in the media, in which criminals are caught and arrested. Research suggests that naïve individuals with no experience with the criminal justice system tend to overestimate the likelihood that they will be arrested if they commit crimes. Tittle (1980, p. 67) termed this "the shell of illusion."

A second heuristic, availability, refers to the tendency to update based only on information that is easily or quickly retrieved from memory (Tversky and Kahneman 1974). Rare and mundane events are less likely to be recalled than common and vivid events. Moreover, the two could interact: events that are vivid, salient, and dramatic – as well as rare – could be brought to mind quicker than other events. The result can be bias due to differences in ease of retrieval, as vivid experiences or events trump other sources of information. For example, a dramatic event, such as being arrested for a crime, may swamp other sources of information in an individual's estimate of rearrest. A third heuristic, anchoring, refers to a failure to adjust initial probability estimates sufficiently in light of new information. For example, when individuals are given an initial probability estimate that is arbitrary or even randomly assigned, followed by additional accurate information with which to update, their new estimates are consistently biased in the direction of the initial estimate (Tversky and Kahneman 1974). The estimates are anchored at the initial value, rather than adjusted properly in light of the new information. Applied to updating perceived risk of formal sanction, anchoring could lead to an effect opposite from that of availability. Individuals may fail to adjust risk estimates appropriately in light of new information and instead anchor on their baseline estimates. Tversky and Kahneman (1974) mention a fourth departure from Bayesian learning: the gambler's fallacy. Stated simply, the gambler's fallacy occurs when one assumes that a departure from what happens in the long run will be corrected in the short run. For example, if seven coin flips in a row have come up tails, one might think one is "due" for a heads. Applied to updating perceived risk, this might cause individuals who continuously get away with crime to think they are "due" for an arrest, or those who experience a string of arrests think they are "due" to get away with crime (Pogarsky and Piquero 2003).

Although experimental evidence suggests that actors do depart systematically from rational updating, some scholars argue that the departures are relatively small in magnitude, given the overall decision-making process. Thus, Bayesian updating of perceived sanction risk may be present net of cognitive heuristics. The next section summarizes related research on deterrence and updating risk perceptions.

Research on Deterrence and Perceptual Updating

Early empirical tests of Becker's model used statistical models of aggregate crime rates, focusing on the deterrent effects of *objective* risk of punishment, using for example, risk of imprisonment (measured by imprisonment per capita) or risk of arrest (measured by arrests per crimes reported to police). Most notably, Ehrlich (1973) found deterrent effects of risk of imprisonment, but scholars criticized his simultaneous equation models for using implausible solutions to the identification problem – the problem of finding good instrumental variables to identify reciprocal effects between rates of imprisonment and rates of crime – such as assuming population age, socioeconomic status, and region have zero direct effects on crime (Nagin, 1978). Later work using aggregate data includes more plausible instrumental variables to address the problem of reverse causality and found deterrent effects. For example, Levitt (1997) employed the timing of mayoral elections as an instrument for the number of police per capita, under the assumption that such elections should have a direct effect on investment in the police force (as newly elected mayors seek to crack down on crime), but only an indirect effect on crime. For a review of aggregate deterrence research, see Nagin (1998) and Durlauf and Nagin (2011).

Tests of the deterrence hypothesis using aggregate data assume that aggregate clearance rates are good proxies for individuals' perceptions of formal sanction risk, which is the key explanatory variable. A few economists remain uninterested in directly measuring individual risk perceptions and instead assume that the models need not describe perceptual or cognitive processes so long as actors behave "as if they are rational" and the models make good predictions. By contrast, most scholars view the measurement issue as an empirical question and welcome research on the relationship between aggregate rates of objective certainty of punishment and perceptions of the risk of sanction. Subjective expected utility models replace the objective certainty of sanction with a probability distribution of subjective probabilities. Such models are still rational models because the statistical mean of the subjective probability distribution is assumed to fall on the value of the objective probability (Nagin 1998). Empirical research from a subjective expected utility framework uses survey methods to measure perceived risk of punishment directly from respondents, rather than inferring it from behavior through the method of revealed preferences (e.g., Kahneman et al. 1997). These studies of individuals have the potential of linking subjective risk of punishment measured with survey data and objective risk of punishment measured with police clearance rates.

Early perceptual deterrence research by sociologists used cross-sectional data, eliciting self-reports of delinquent behavior and perceptions of risk of arrest in the same questionnaire or interview. These studies generally found small but significant deterrent effects for certainty but not for severity. That is, youth who perceive a high probability of arrest for minor offenses (like marijuana use and petty theft) tend to report fewer acts of delinquency. Such research was immediately criticized for using cross-sectional data in which past delinquency is regressed on present perceived risk, resulting in the causal ordering of the variables contradicting their temporal order of measurement (Paternoster 1987). These criticisms led to panel studies in which individuals are followed over short periods of time and both risk perceptions and self-reported crime are remeasured repeatedly.

The initial panel studies surveyed two waves of undergraduate students and estimated cross-lagged panel models. Here, self-reported delinquency is regressed on lagged delinquency plus lagged perceived risk and then perceived risk is regressed on lagged risk plus lagged delinquency. These studies found that both perceived risk and delinquency were fairly stable over a 6-month or 12-month period. Moreover, they found little evidence of a deterrent effect of the certainty of sanctions: net of lagged delinquency, lagged perceived risk of punishment was not significantly related to delinquent behavior. They did find support for the opposite effect: net of lagged risk, lagged delinquency exerted significant effects on perceived risk. Paternoster et al. (1982) called this an "experiential effect," because it suggested that youth who experienced getting away with crime – arrest is fairly rare for the nonserious self-reported delinquent acts measured – reported lower risk of arrest. These findings were replicated on other two-wave panels of students. Furthermore, the results – a strong experiential effect and weak deterrent effect – were replicated in samples of disadvantaged adults in several cities at risk of serious crimes (Piliavin et al. 1986). The experiential effect was the first important empirical finding about the formation of individual risk perceptions. An experiential effect is consistent with a Bayesian updating model insofar as respondents have not been arrested between waves. If they had been arrested, that information must be included in any updating model.

Paternoster et al. (1985) found, for their two-wave panel of undergraduate students, experiential effects for minor property offender. They also found that students who were arrested between waves had higher perceptions of arrest risk. Horney and Marshall (1992) interviewed incarcerated felons and obtained their retrospective self-reported arrests and offenses. They computed, for a variety of offenses, the ratio of arrests to offenses and found that arrest ratios strongly related to perceived risk of punishment. This finding is consistent with a model of Bayesian updating. Subsequent research used prospective longitudinal designs to examine Bayesian learning of perceived risk. Pogarsky, Piquero, and Paternoster (2004) focused on changes in risk perceptions among a sample of high school students surveyed at the 10th and 11th grade. They found that students who experienced an arrest between the waves increased their perceptions of arrest certainty. This effect was most pronounced for offenders with an initially low-risk perception, which the authors attribute to these offenders having more room for change (i.e., a floor effect). Additionally, they found that individuals who reported higher peer offending had lower perceptions of risk, presumably because those friends avoided arrest. Stafford and Warr (1993) termed such a process vicarious punishment avoidance. This peer effect was greatest for non-offenders, consistent with the idea that naive individuals have a "shell of illusion" (Tittle 1980:67) regarding police effectiveness that is eroded through vicarious experiences.

Two recent studies incorporate Bayesian updating of perceived risk into deterrence models of subsequent offending. Matsueda, Kreager, and Huizinga (2006) examined changes in risk perceptions and offending with longitudinal data of adolescents from high-risk Denver neighborhoods. They found strong support for a Bayesian learning hypothesis for both property and violent crime: lagged ratios of arrest per offense – which they termed, "experienced certainty" – were monotonically (positively) associated with perceived risk of arrest. In addition, respondents' unsanctioned offenses were monotonically (negatively) related to perceived risk of arrest. They also found that perceptions of peer delinquency were negatively associated with perceived risk (see also Pogarsky et al. 2004). Each of these findings is consistent with Bayesian updating. Finally, Matsueda et al. (2006) also estimated a rational choice model of crime, finding that perceived risk of arrest was significantly associated with subsequent offending. Specifically, they found that, on average, a 10 % increase in perceived certainty of arrest was associated with a 3 % decrease in theft and violence. Lochner (2007) reported similar findings using data from the National Longitudinal Survey of Youth 1997 and National Youth Survey. He found that respondents in both surveys updated their risk perceptions in ways consistent with Bayesian expectations. Offenders who got away with crime reported lower risk of arrest, and those who got arrested reported higher risks. Lochner (2007) also found that naïve non-offenders held the highest perceptions of risk certainty. When comparing perceived certainty to actual offending, he strikingly found almost the exact same pattern as Matsueda et al. (2006): using the NLSY97 data, he found that a 10 % increase in perceived certainty of arrest was associated with a 3 % decrease in theft. The similarity of these results builds confidence in the deterrent effect of perceived certainty of arrest on future offending.

The most recent study of Bayesian updating, conducted by Anwar and Loughran (2011), examined serious juvenile offenders enrolled in the Pathways to Desistance Study. They found that offenders in their sample appeared to update their risk perceptions following a Bayesian model. Offenders who committed crimes and were arrested for them reported an average of 6.3 % higher-risk perceptions than those who committed crime but were not arrested. This is an important finding, as it suggests that risk perceptions remain malleable even among serious offenders, a population often written off as irrational or impulsive and thus outside policy intervention.

The weight of recent evidence thus supports Bayesian expectations when applied to updated risk perceptions and personal experiences of offending and sanctioning. As mentioned above, one might also ask if subjective sanction perceptions are rooted in objective rates of arrest and punishment. For example, does increased police arrest activity alter offenders' subjective arrest perceptions? Interestingly, Lochner (2007) observed that the risk perceptions of his NLSY97 sample were fairly unresponsive to county-level arrest-per-crime rates. Combined with his findings of individual experiential effects, the lack of a contextual effect suggests that proximate conditions are more important determinants of perceptual change than macro-contextual conditions. Kleck et al. (2005), in a phone survey of respondents in 300 counties, also found little correspondence between individuals' estimates of police clearance rates and the actual clearance rates in those counties. However, Apel, Pogarsky, and Bates (2009) did find an association between changes in a school's disciplinary regime and students' perceptions of discipline, suggesting that individuals' risk perceptions are responsive to contextual conditions in at least some instances. The limited and mixed findings in this area suggest that further research is required to connect objective sanction risk in a given geographic area to individual risk perceptions.

Extralegal Benefits and Costs

Research of the linkage between perceptual change and offending should also extend beyond formal sanctions. Theory and qualitative evidence suggest that other costs and rewards are equally, if not more so, related to criminal decision-making. As mentioned previously, Becker's (1968) criminal utility model includes both subjective costs and benefits in criminal decision-making. This utility calculus lies at the heart of rational choice theories of crime (Clarke and Cornish 1985). The relative neglect of crime's perceived returns, and how these perceptions are adjusted over time, is a serious omission both for etiological and policy reasons. Understanding crime's perceived benefits will likely provide valuable insights for understanding criminal motivation, while also pointing to potential interventions that downwardly adjust individuals' positive perceptions of crime over time.

In his phenomenological examination of violent and property crime, Katz (1988) provided perhaps the most detailed account of crime's "seductive" psychic and social rewards. He explored the "sneaky thrills" of shoplifting and the social status associated with the "badass" gang member. Such perceived benefits are intimately linked to the criminal event and may override the certainty, celerity, and severity of perceived punishment. Indeed, Matsueda et al. (2006) found that the perceived excitement and "coolness" of offending were stronger predictors of crime than perceptions of arrest. Missing from their analyses, and generally overlooked in empirical analyses of criminal perceptions, are the origins and dynamics of crime's perceived benefits as predicted by Bayesian learning.

Such analyses would appear particularly relevant for understanding individual trajectories of drug use. The objective risks of apprehension for drugs are low and likely swamped by perceptions of their psychic and social returns. In his classic *Becoming a Marihuana User*, Howard Becker (1953) described the learning process associated with marijuana initiation. In interviews of marijuana-smoking Jazz musicians, he found that users often entered their first marijuana experience uncertain of the drug's effects. Moreover, marijuana's psychopharmacological properties may result in potentially ambiguous physical effects, such as hunger, paranoia, dizziness, and euphoria, or no effects at all. Becker argued that the presence of more knowledgeable peers help the initiate translate these effects into a pleasurable experience worth repeating, or these peers may push the initiate to smoke again if he or she experienced no discernible effects the first time. In these ways, perceptions of fear and uncertainty are updated into fun and excitement. The change in marijuana's perceived rewards upon initiation thus provides a particularly fruitful context for studying Bayesian updating.

Costs other than formal sanctions may also be important for understanding criminal decision-making. McCarthy and Hagan (2005) argued that the proximal fear of physical harm likely overrides perceptions of punishment for offending decisions. In their qualitative and quantitative study of street youth living in Toronto and Vancouver, they found that perceptions of danger deterred youth from theft, drug dealing, and prostitution. Interestingly, they found little evidence for the threat of legal sanctions, but, consistent with Matsueda et al. (2006), they did find that perceived excitement predicted theft and drug dealing. Note, however, that the cross-sectional nature of their data did not allow them to directly address the Bayesian updating hypothesis. More work is required to test if repeated exposure to crime and delinquency increases or decreases perceived danger.

Life-Course Transitions and Cognitive Change

The growth in life-course theories and research has opened up new avenues for understanding Bayesian updating processes. An axiom of life-course perspectives is that life events can meaningfully alter individual behavioral trajectories. Although the dominant explanation for how events become "turning points" in criminal trajectories is through external social control mechanisms (Sampson and Laub 1993), cognitive change is increasingly the focus of life-course criminology. Giordano et al. (2002) provided a symbolic interactionist theory that connects life-course transitions, cognitive transformation processes, and criminal desistance. Their central premise was that desisters are likely to reflect on their past and present circumstances and create new conventional identities. Life-course transitions, such as marriage, incarceration, and parenthood, then become "hooks for change" in this cognitive process. Interpreted from a Bayesian perspective, significant life events should provide new evidence by which prior perceptions are updated to shape future behavior. As Maruna (2001) points out, however, whether such life events positively or negatively affect self-perceptions is extremely difficult to predict. For example, a drug addict may interpret a friend's overdose as (1) the final impetus needed to "get clean," (2) unrelated to their own fate, or (3) a reason to use drugs to manage the resulting grief. The subjectivity of experience, and the meaning of experiences derived in contextualized social interactions, complicates an understanding of perceptual change and use of formal models of Bayesian inference. Identifying the origins of such heterogeneity is challenging but worth future investigation.

Conclusion and Future Directions

Under many guises, Bayesian updating remains an influential concept for criminological theory and research. Within the deterrence literature, researchers have consistently documented the experiential effect of crime on reduced risk perceptions, while also documenting an association between sanction perceptions and future offending. Rational choice studies have extended the study of perceptual dynamics to extralegal domains, including changes in perceived excitement, social status, monetary rewards, and fear of physical danger. More recently, life-course research has explored the impacts of life events on cognitive changes and desistance processes. All of these research strands continue to produce contributions for both criminology and the understanding of individual perceptual dynamics over time.

The obstacles facing perceptual research also provide opportunities for scientific advancement. As mentioned previously, a continuous challenge facing research in this area is disentangling experiential from perceptual effects. For example, an individual's experiences in crime should change his or her perceptions of its costs and benefits, which should then impact his or her probability of future crime. Longitudinal designs are clearly necessary for distinguishing these reciprocal processes. One attractive strategy might be to design an experiment where individuals are randomly exposed to sanction risk information, such as local arrest statistics, to examine if their pretest arrest perceptions and behavioral intentions are updated upon receiving new information. Another potentially fruitful research avenue would focus on perceptual changes surrounding criminal onset. Prior to initiation, individuals must rely on less-than-optimal information sources – such as peers, the media, or experience with related behaviors – to formulate expectations for a novel behavior. But the inadequacy of prior information may result in actors initiating a behavior under extreme uncertainty. The situational contexts of initiation, and the physical experience of that event, are then highly influential in revising perceptions from uncertainty to increased clarity. The large amount of perceptual change potentially associated with initiation makes understanding this event critical for our knowledge of Bayesian updating. Although measuring the perceptions and contexts at the point of initiation would be difficult, it holds tremendous potential for broadening our insights of dynamic risk perceptions.

Future research is also required to order individuals' perceptions of crime's costs and benefits. Prior research has demonstrated that crime's perceived extralegal costs and benefits often exceed the effects of perceived formal sanctions in predicting future criminal behavior. What is needed is research that identifies the relevant subjective perceptions of crime and helps rank order or weight these perceptions while also examining how such orderings may change over time. For example, the perceived social benefits of drug use may be a strong predictor of drug initiation, but upon initiation, such perceptions may be overridden by the perceived fun and excitement associated with getting "high." Further, perceptions of pleasure may fade over time and be replaced by the perceived costs of heavy use. Bouffard (2007) has taken steps toward identifying preference orderings using subject-generated perceptions of criminal consequences, but more work is required to understand the dynamics of such orderings given individual experience.

More broadly, greater theorizing is necessary for the generative process of risk perceptions. Aside from personal exposure and vicarious experiences through peer networks, few studies have focused on the origins of offending perceptions and their changes over time. It is clear that non-offenders' perceptions differ greatly from offenders' perceptions, and that individuals transitioning from the former to latter typically experience substantial perceptual shifts. However, more research should center on the information sources associated with each status and how naïve perceptions are updated or negated with offending decisions or experiences. Such investigations have substantial implications for interventions aimed at manipulating perceptions to prevent initiation (general deterrence), or increasing offenders' perceived risks to prevent future offending (specific deterrence).

Finally, research should also continue to isolate the effects of salient life events (e.g., marriage, parenting, employment, military service, incarceration, etc.) on changing risk perceptions. Symbolic interactionist perspectives of desistance (Maruna 2001; Giordano et al. 2002) have taken strides in presenting theoretical models and qualitative evidence for how life events relate to cognitive transformation and desistance, but further quantitative evidence is needed to validate this line of inquiry and calibrate risk perceptions so that they may be formally analyzed using Bayesian inference. Prospective studies of sanction perceptions and prominent life-course transitions would add to an understanding of desistance while also testing the Bayesian learning hypothesis. Such investigations will provide greater clarity to the cognitive processes and decision-making associated with "knifing off" a criminal past and the construction of a conventional future (Maruna 2001).

Overview

Behavioral Investigative Advice represents the UK approach to the provision of advice and support to major crime investigations from a behavioral science perspective. Although the foundations of Behavioral Investigative Advice are built upon such precursor influences as criminal investigative analysis, offender profiling, and investigative psychology, the emergence of Behavioral Investigative Advice should be recognized more as a qualitatively distinct *profession*, than a variation of technique.

All such behavioral support to UK policing is delivered exclusively by a nationally funded cadre of professional Behavioural Investigative Advisers (BIAs) who have significantly widened the scope from the traditional, specific view of "offender profiling" to a discipline which now encompasses a broad range of scientifically based yet pragmatic activities related to supporting police investigations, based on replicable, transparent, and valid knowledge and research.

While elements of this approach and philosophy have begun to evolve within other (predominantly European) countries, it is emphasized that the formal recognition of Behavioural Investigative Advisers is a UK-specific initiative and should not be misinterpreted as any form of internationally recognized standard.

Brief Historical Overview

The term "offender profiling" was first regularly used by members of the FBI Behavioural Science Unit who defined it as the process of drawing inferences about a suspect's characteristics from details of his or her actions exhibited during the commission of a crime.

Critical review of these initial efforts however drew attention to the lack of systematic basis and empirical evidence supporting the claims made. David Canter, a UK psychologist, was highly influential in advocating a more robust scientific psychological approach to offender profiling, and in recognizing the broader utility of providing investigative support to serious crime enquiries from a behavioral science perspective.

In 1992, the Metropolitan Police service commissioned research into the investigative usefulness of such offender profiling, following concerns that despite over 200 British Police inquiries utilizing such services in the preceding decade, no reliable or valid scientific assessment has been conducted to evaluate its usefulness.

While the explicit focus of this research was directed toward the methodologies employed and the resulting usefulness of profiling, it also provided important signposts toward the challenges facing this emerging discipline within the UK, most significantly in the observation that no governing body for the regulation of professional or ethical standards existed, and that there was no formally recognized program for the training of UK practitioners in profiling techniques.

However, it was not until 2001 that a significant watershed in such endeavors occurred, most conspicuously evidenced by the replacement of the term "offender profiler" with "Behavioural Investigative Adviser" (BIA). A set of common standards and working conditions were introduced, making explicit the responsibilities of BIAs, including: administrative protocols, commitment to producing written reports, agreement to have work annually audited and evaluated, and acceptance that the results of such audits would determine the retention or removal of their authority to provide Behavioral Investigative Advice within the UK.

The introduction of these new working conditions had a twofold effect. In making explicit the need to document all advice provided, not only were quality assurance issues addressed, but the true extent of behavioral science provision to UK investigations could be known for the first time, allowing for detailed qualitative and quantitative analyses of all aspects and supply and demand. The availability of such management information led to a formal strategic review of UK Behavioral Investigative Advice in 2010, which provided a clear overview of the current status of the discipline, clarified current and potential future demand, made explicit the current and anticipated threats to the effective delivery of the service and considered regulatory and governance issues, including minimum performance standards. It concluded with a proposed model of management and delivery of Behavioral Investigative Advice which significantly changed the landscape of such activity within the UK.

Today, all behavioral science contributions to major crime investigations are delivered exclusively by a nationally funded cadre of full-time professional Behavioural Investigative Advisers (BIAs).

International Perspectives

While one of the key successes of the UK approach to Behavioral Investigative Advice is the effective integration of the BIA into the investigative arena, the UK model differs significantly from many of its international contemporaries in the philosophy of individual specialism within a multidisciplinary approach. Whereas in many countries, the "profiler" assumes the role of investigator, whose behavioral science knowledge and expertise represents but one facet to an overall "investigative consultancy" role, in the UK, such expertise is far more discrete. The BIA is concerned only with contributions based on behavioral/psychological principles, and integrates such expertise with other specific experts, including those focused exclusively on investigative doctrine. An additional benefit of such approach is that unburdened by the same training and experiences of police investigators, the BIA has the benefit of a more objective and "different" view of the case. While approaches in which seasoned investigators are "trained" in behavioral science have their own merit, the UK's approach favors the behavioral scientist gaining a sufficient and relevant understanding of the investigative process, but delegating the more "traditional" investigative advice to an "expert" investigator.

Investigative Contribution

Behavioral Investigative Advice has the potential to contribute to many aspects of the investigative process and may take many forms throughout the life of the enquiry. While all of the products and services available offer tactical or strategic solutions in their own right, all are underpinned by a broader philosophy of adding value to the decision-making of the Senior Investigating Officer (SIO), through an enhanced understanding of the offense and offender from a perspective different from that routinely employed within major crime investigation teams. Such differences in perspective can be broadly characterized as evidence (SIO) versus understanding (BIA), although both are directed at supporting the single goal of case resolution. It is this additional perspective and associated expertise which should be recognized as the critical success factor of Behavioral Investigative Advice.

While the prediction of those facets of an unknowns criminal's background which are amenable to investigative action serves as a great asset in major crime enquiries, this does not represent the only contribution of contemporary BIAs. Analysis of the type and scope of reports produced by the national cadre of UK BIAs reveals a steady decline in producing "offender profiles," from over 60 % of all operational activity at the launch of the unit over a decade ago to a little over 10 % in 2009. Such figures do not however imply that such inference generation regarding offenders is no longer undertaken on a routine basis, but rather that such inferences often form the basis of a more bespoke service to SIOs, tailored to their specific investigative needs.

However, the implicit assumption that all the additional services provided by BIAs are dependent upon such prescriptive predictions concerning the unknown offender is also inaccurate. Many of the products and services, as outlined below, are wholly independent of any such speculative inferences regarding the type of unknown person who has committed the offense in question.

Crime Scene Assessment and Hypothesis Generation

Critical to the provision of many BIA products and services is a fundamental understanding of the offense, and hence the offender(s), from a behavioral perspective. This is achieved through crime scene assessment (CSA) and hypothesis generation. This involves a thorough examination of the criminal event and generating hypotheses based upon the available information. Support for or against each of the possible hypotheses is then forwarded with reference to psychological theory, relevant research findings, and experiential knowledge, with information gaps identified that will further enhance the process. The benefits of such an approach are that specific hypotheses regarding the offense can be tested in a systematic, reasoned, and objective fashion, based upon sound supporting rationale. Such a methodology is consistent with, and provides a tangible product of the investigative philosophy promoted within national policing guidance. Recent practice advice advocates the application of scientific principles and methods as core investigative doctrine to be adopted across the UK police service (ACPO 2005).

Offense Linkage Analysis

In the absence of any physical evidence linking a number of crimes, the contribution of a behavioral analysis may be significant. Research into behavior exhibited by offenders during the commission of their crimes has led to a greater understanding in consistency and variability of offenders when committing a series of offenses. Through national mandates to collect and analyze a range of sexually motivated offenses throughout the UK, BIAs have access to the largest collection of data of its kind in the UK and one of the largest in Europe via the ViCLAS (Violent Crime Linkage Analysis System) database (the collection criteria cover homicide, serious sexual assault and abduction offenses, including attempts). The creation of such large datasets allows for validation of initial hypotheses regarding linkage, as well as providing statistics with regard to the frequency of individual behaviors, and more significantly, combinations of behaviors.

Predictive Profiling

Drawing inferences in relation to a particular offender on the basis of a comprehensive crime scene assessment is a process commonly referred to as predictive (or offender) profiling. However, it is important to recognize that in contrast to its media portrayal, the focus of modern day predictive profiling is very much on investigative utility rather than psychological interest. Perhaps the most widely held misconception regarding the role of the contemporary BIA surrounds the insistence that speculative predictions concerning the unknown criminal's *personality* are routinely made. They are not. Not only is such activity lacking scientific reliability and validity, in itself it serves very little, if any purpose in assisting police officers to identify the offender. Despite the tabloid appeal of psychological musings over traits such as narcissism, misogyny, introversion, and the like, the lack of any police database recording such facets of the criminal population makes them somewhat limited in terms of investigative utility.

A BIA will endeavor to make accurate assessments in relation to objective and verifiable elements of an offender's background. Consideration will be given to the likely age of the offender, whether he is likely to have previous police convictions and if so what these may be, and where he may reside or be based. The goal of the BIA in this process is to allow the SIO and the enquiry team to focus on areas of investigation most likely to identify the offender. It is perhaps only in the form of investigative suggestions and interview strategy development where BIAs may on occasion consider more trait-based interpretations and their associated behavioral implications at the investigative level (see below).

Nominal Generation

An extension to predictive profiling, suspect generation may be undertaken by the investigation under the guidance of a BIA. By taking the predictions made in relation to an offender's likely background characteristics, it is possible to utilize local crime and intelligence databases as well as the Police National Computer (PNC) in order to generate pools of potential suspects. Outside of the criminal arena, in some cases, it may also be possible to highlight additional potential suspect pools on the basis of advice offered by a BIA, such as those from housing lists, voters register, employment records, and so on. This will always be evaluated by the BIA on a case-by-case basis.

Prioritization Matrices

Again, an extension of the predictive profiling process, a prioritization matrix takes the individual predictions made in relation to the proposed background of the unknown offender and integrates them in the form of a matrix. Each facet of a potential suspect will be given a numerical value such that nominals within an enquiry can be objectively scored and ranked in terms of how well their background characteristics fit with those proposed for the unknown offender. This process is of particular utility if an investigation wishes to undertake an intelligence-led DNA screen or is seeking to prioritize many hundreds of potential suspects from a cold case enquiry or mass media appeal. Where possible, a suspect prioritization matrix will be developed so as to integrate the behavioral predictions (in relation to an offender's background) with a geographic profile in relation to their most likely area of residence.

Investigative Suggestions

In line with the BIAs intention to make their report as investigatively focused as possible, it is normal practice now for BIAs to offer direct investigative suggestions on the basis of the information supplied to them. It should be recognized that while the BIA role is very much an "advisory" one, they do typically possess significant experience of major criminal investigations (the national cadre of BIAs have an accumulated experience of over 1,000 cases). This experience combined with their ability to draw logical inferences on the basis of an offender's behavior means that they will offer investigative suggestions to the SIO as a routine part of their report. Suggestions are made strictly on a case-by-case basis and should always be accompanied by a clear supporting rationale.

Interview Advice

Contributions from a behavioral perspective can provide a significant enhancement to the development of interview strategies. Such contributions can be classified as either interviewee-specific advice or crime-scene-specific advice. With respect to the former, more traditionally recognized interviewee-specific advice, an identification of salient behavioral characteristics of the individual to be interviewed can inform strategies to maximize interaction and the quantity and quality of information disclosed and minimize confabulation and fabrication. The more contemporary contribution from a crime-scene-specific perspective provides additional guidance to interviewing officers in understanding the offense; will identify any gaps, inconsistencies, and ambiguities in the information; and provide a template against which investigative hypotheses can be systematically tested during interview. It is however essential that interview advice gained from a BIA is complemented with advice from an appropriate in-force or ACPO (Association of Chief Police Officers) Approved Interview Adviser to ensure compliance with relevant legislation and support of the overall investigative aims, objectives, and strategies.

Media Advice

In certain circumstances, it may be advisable to seek opinions from a BIA in relation to utilizing the media in major investigations. This advice is intended to maximize the use of the media when, for example, making appeals to the public or releasing information about an offense, but also to enable SIOs to better understand the potential effects of the media on the behavior of an offender.

Familial DNA Prioritization

The recently introduced technique of Familial DNA (fDNA) searching allows investigations to search for relatives of an unknown offender in cases where a full DNA profile is available at the crime scene that does not match anyone on the National DNA Database (NDNAD). It works on the general principle that people who are related are likely to have more DNA in common than those who are not, and thereby seeks to identify individuals on the NDNAD who have a greater genetic similarity to the unknown offender and hence a greater potential to be related. The BIAs can utilize a sophisticated process that allows the resulting lists from forensic science providers to be re-prioritized with respect to age and geographic association. By adjusting the genetic prioritization to take into account an individual's age and geographic association, those individuals who are more likely to be relatives of the offender should become more readily identifiable from the more general backdrop of the lists, while still preserving the appropriate weight assigned to them through their genetic similarity.

Search Advice

BIAs may also be able to contribute to any search activity within an investigation. An enhanced understanding of the offense and/or likely offender can inform search parameters for forensic evidence, witnesses, CCTV, etc., and in combination with relevant research findings assist in prioritizing potential body deposition sites. Additionally, an enhanced knowledge of specific psychological or criminal dispositions may assist in broader search considerations, such as briefing search officers as to the potential significance (from an intelligence perspective) of items which may be observed within the course of more evidential searches.

Decision Support

As highlighted above, every contribution to the investigation of serious crime from a behavioral science perspective has the single underlying goal of supporting investigative decision-making. While the above provides a more prescriptive summary of the individual products and services that offer explicit tactical and strategic solutions in their own right, the more implicit role of the BIA on the decision-making process is perhaps a less obvious, but nevertheless critical contribution.

The field of decision-making is well established within the psychological literature and offers a multitude of well-established influences on decision-making. The focus of BIA contribution is directed toward those factors which are commonly encountered within major crime investigations, namely, heuristics and biases. It is cognizance of these factors within an investigative environment that underpins an implicit but often overlooked contribution from BIAs and further highlights the distinction between "traditional" paradigms of profilers assisting investigators with "offender profiles" and the contemporary UK approach of discrete, multifaceted, professional psychological expertise.

The ability for investigators to make rational decisions in serious crime enquiries is influenced by the same heuristics and biases that affect all of our day-to-day judgments. Base rate fallacies, representativeness heuristics, illusory correlations, clustering illusions, availability heuristics, anchoring and adjustment, belief persistence, confirmation bias, and selective information search, all have the potential to undermine even the most astute of investigators' decision-making capabilities. While such influences are by no means any more (or indeed less) prevalent among Senior Investigating Officers than among the general population, the consequences of error within a murder enquiry are of arguably greater consequence than the majority of more mundane daily decisions.

It is a critical role of the contemporary BIA to mitigate against such errors of decision-making through the implicit integration of such considerations within all advice and support offered. While such cognizance of these bias and heuristics does not form a "product" or "service" in its own right, it may be argued to represent one of the biggest contributions from BIAs, providing the foundations on which the goal of supporting investigative decision-making can be soundly built.

This requires a sound theoretical understanding of common biases and heuristics, an ability to recognize their presence and potential negative impact within the specific environment of a major incident, the capability to diplomatically address such errors, and an awareness of and access to relevant data and information to optimize subsequent investigative decision-making.

Working Practice and Process

All Behavioral Investigative Advice within the UK is provided upon request, and although advocated on Senior Detective training programs and within national guidance manuals, does not represent a procedural requirement, but rather a carefully considered investigative decision.

Once a BIA has been engaged by the Investigating Officer, a meeting takes place where an exchange of information and views leads to the agreement of explicit terms of reference. These terms are established in writing and clearly articulate what is expected of both parties. This is particularly important with regard to ownership of any material and confidentiality, which is expected in instances where a BIA might have privileged access to sensitive information about crime scenes and/or victims. This should, for example, inhibit disclosure of certain information to the media without the SIO's permission. Terms of reference should also provide similar assurances to the BIA that all relevant case materials will be made available, and any developments which may support, refute, or refine the advice proffered be communicated as soon as reasonably possible.

It is at this stage that the precise nature of any behavioral science support will be discussed and agreed. As has been made explicit above, the potential products and services from contemporary BIAs are far broader and more diverse than either the media or naive academics would proffer, and should not be regarded as the exclusive generation of inferred offender characteristics, either as a product in its own right or as the necessary foundation to other contributions.

In order for the BIA to undertake their behavioral analysis and provide timely advice, a variety of case materials will be required from the investigation. The provision of these assist the BIA to commence their analysis and return a detailed report to the investigation within a timeframe that maximizes the utility of the advice (i.e., as soon as practically possible, but with cognizance to the investigation's overall strategy and resourcing and competing BIA demands from other cases). Although by no means exhaustive, and with cognizance that different enquiries will generate different information and different products and services require different source materials, the following represents a summative overview of the material required and utilized.

- Full verbal case briefing and access to the SIO/ investigation team
- All relevant statements
- Crime report
- Any officers' reports/status reports
- Pathology and forensic reports/findings
- Full set of crime scene and postmortem photographs (where applicable)
- Available analysis (e.g., telephony, palynology, entomology, etc.)
- Relevant maps
- Visit to all relevant scenes

It is worth highlighting that the scene visit represents a critical component of the process as it allows the BIA to gain a fuller understanding of the decision-making process of the offender. Such information is not routinely available from crime reports, statements, or photographs, where often the evidential focus is too restrictive to provide the necessary "behavioral" perspective.

In addition, the scene visit is typically complemented by a visit to the incident room/ enquiry team, allowing the BIA to ask questions concerning the demographics and crime profile (i.e., the type, frequency, patterns, and interpretation of previous criminal activity) of the area, as well as to get a full briefing from the SIO or nominated member of the investigation team. It is therefore of great importance that in addition to making the necessary case documentation available to the BIA, officers who meet with the BIA and who accompany them to the scene(s) should have a good knowledge of the relevant areas and of the offense(s) for which the support has been requested.

Once this information has been collated, the BIA (except in rare circumstances involving critical incidences or "crimes in action") departs the incident room and returns to their place of work to critically review the information and begin report preparation. Establishing direct lines of communication with relevant officers within the enquiry removes any necessity to remain physically located within the incident room, which may be viewed as counterproductive when one considers the resources required by the BIA, the priorities of the investigative team, and the advantages of distanced objectivity. The BIA is reliant upon both the statistical information contained within relevant datasets (which for security reasons are not accessible outside of secure national policing premises) and the extensive academic research libraries they have collated to inform and support inference generation and investigative strategy development. The capacity to reflect and synthesize these resources with the known case material is greatly enhanced by such remote working, eliminating both the distractions and potential biases inherent in major incident rooms.

Once the analysis is complete, a report will be forwarded to the enquiry with the explicit recommendation that the document should not be viewed as the completion of the BIA's input, but rather provide the starting point for a dialogue between the investigator and the BI-A. This is critical to ensure the SIO's understanding of the inferences and recommendations made and to promote understanding that such conclusions should be continually evaluated against additional forthcoming information.

The importance of the BIA becoming part of an advisory team is emphasized by the BIA. This ensures all experts are aware of the findings, opinions, and advice of other members of the team, allowing for hypotheses to be supported, rejected, or refined, and to prompt searches for information in other directions. Discussions with specialists from other disciplines can also act as a useful safeguard against too narrow a focus in an investigation and can encourage officers to continue to look for alternative explanations for events.

Having decided to seek assistance, the SIO should remain critical and reflective of any information or opinion put forward by BIAs. He or she should be ready to explore and challenge assumptions made as well as pointing out any inferences that are inconsistent, contradictory, or logically incoherent. Only by thoroughly discussing the opinion in this way will the SIO be able to gage the validity of the BIA contribution to the investigation. The SIO should ensure that the BIA's opinion is fully explained in order to know what weight to assign to the information provided. Asking the BIA to justify the way in which they have developed their methodology and derived any inferences should ensure their involvement in any investigation is transparent and explicit. SIOs are urged to look beyond the psychological interest factor toward the investigative utility of the advice and are regularly reminded by BIAs to ensure any advice proffered achieves the highest possible standards of quality and effectiveness.

It is of utmost importance that any behavioral advice provided to an investigation is utilized in the manner in which it was intended. In particular, it should be remembered that advice is typically offered on the basis of what is most likely or what should be prioritized. Behavioral Investigative Advice does not deal in absolutes and as such advice from a BIA should always be evaluated carefully by the SIO to ensure that its impact on the investigation is proportionate.

Expert Evidence

Closely aligned to the above discussion, it is made explicit within BIA reports that they do not constitute expert evidence. BIA reports deal in probabilities, not certainties and provide the most likely "type" of individual in order to systematically prioritize lines of enquiry. Due to the probabilistic nature of the findings, while the majority of recommendations will prove effective for the majority of cases, it is to be expected that in a minority of cases, the individual responsible will demonstrate significant variance with the reported probabilities. Even if a significant overlap exists between the "profile" and defendant, the best that could be inferred is that the defendant has the characteristics which have been suggested as most likely from a behavioral analysis of crime scene and related information. This should be deemed insufficiently relevant and reliable and too prejudicial to be received by the court as evidence of the defendant's guilt. It is for this reason that it is made explicit that a BIA's report is not fit for purpose in attempting to provide evidence of an individual's involvement or guilt, or conversely as evidence that a specific individual cannot be responsible for an offense. This is not a failing of BIA advice, rather recognition of its investigative utility as a means of better understanding an event and informing and prioritizing investigative decision-making and actions. As such a "profile" should never be attempted to be used as evidence with regard to identity. However, the wider discipline of Behavioral Investigative Advice may, under specific circumstances, be able to contribute to the court process, although the exact parameters and process for such a contribution are at present unclear and may be found to fall foul of the same obstacles as "profiles" if tested (for a review of the evidential obstacles facing "offender profiling," see Omerod and Sturman 2005).

Conclusions and Future Directions

Behavioral Investigative Advice has developed in the UK over the past decade as a distinct profession which has significantly widened the scope from the traditional, specific view of "offender profiling" to a discipline which now encompasses a broad range of scientifically based yet pragmatic activities related to supporting police investigations, based on replicable, transparent, and valid knowledge and research.

It is acknowledged that while perceptions of such activity may be misguided and outdated, both predecessors and many contemporary practitioners are perhaps still guilty of enthusiasm over professionalism. However, such experiences are perhaps inevitable in any emerging discipline and should not continue to represent the stick that beats contemporary efforts into submission.

Such contemporary optimism is bolstered by many years of frontline experience, hundreds of case consultations, and, significantly, by the policing community. Over the past decade, Senior Investigating Officers have gone from blind acceptance of an unproven innovative technique, through suspicion and virtual dismissal, to the more balanced mid-ground of critically and judiciously evaluating the potential such contributions BIA's make within the overall investigative process.

This contemporary policing environment not only safeguards against the excesses and failures of the past, but demands the very evidence-based practice that contemporary BIAs have recognized as critical to the continuing development and professionalization of the discipline. This cannot be achieved by the practitioners alone. The research community has a key role to play in such endeavors, but activity must be focused on solution-oriented research of direct relevance to the practitioners. Historically, BIAs have had to rely on what has been published within disparate research domains (e.g., psychiatry, criminology, environmental psychology, forensic science, medical science, etc.) and tease out the small morsels of relevance to investigative application. What is required is a much more integrated approach where practitioners and academics better understand one another's aims and objectives and produce findings of direct relevance to real world application. It is acknowledged that many academics will view such bold proclamations as somewhat naive and fanciful, protesting that they have been advocating precisely the same intentions but that such rhetoric is never backed up with access to the masses of relevant data held by the police. This too is changing. The emerging investigative philosophy of a more scientific approach has led to not only the development of larger, centralized, and more sophisticated data collection processes, but also a greater willingness to share such data with the academic community.

In addition to broader knowledge and research strategies aimed at improving the way in which the police service create, assure, share, and use knowledge in support of practice and decision-making, greater access to data held within the various national databases together with clear articulation of specific research questions has began to develop such collaborative activity. It is hoped that such initiatives, viewed in tandem with an enhanced understanding of the contemporary philosophy of Behavioral Investigative Advice, will encourage further solution-oriented research and continue to inform future practice.

Behavioral Management in Probation

Faye S. Taxman
Criminology, Law and Society, George Mason University, Fairfax, VA, USA

Synonyms

Case management; Community supervision; Contingency management; Evidence-based supervision; Probation; RNR Supervision

Overview

Behavioral management is the newest framework for community supervision; it is a hybrid combining the traditional theoretical approaches of law enforcement (monitoring and compliance) and social work (resource broker and/or counseling). The social work perspective was more commonplace in the USA until the 1970s and is currently slowly eroding in other countries over the last several decades. The erosion is part of the diminishing support for rehabilitation-type programming for offenders as well as the increased concerns about offender accountability and public safety. Enforcement and compliance management are now the more predominant framework in the USA with other countries emulating this style of supervision given the emphasis on offender accountability. As a hybrid approach, behavioral management arms the probation officer with a new toolkit that recognizes the balance between offender change and accountability, and it offers new strategies for managing the offender in the community that incorporates evidence-based practices and treatments ("what works"). The behavioral management supervision model is based on a theoretical framework that offender change is due to a trusting, caring relationship between the offender and the officer where the emphasis is on structure and accountability. The officer facilitates offender change through therapeutic techniques of individualized case plans, cognitive restructuring, and graduated responses to positive and negative behaviors.

This chapter reviews the literature on the effectiveness of community supervision and then explores the concepts of behavioral management with examples from existing efforts across the globe. Next this chapter discusses the policies, programming, and developmental issues that affect the likelihood of behavioral management becoming predominant in supervision settings. This is critically important since a behavioral management framework requires organizational strategies to emphasize an altered mission and goal for the supervision organizations to encompass structure along with programs and services to alter offender outcomes.

Evolving Nature of Community Supervision Models

Community supervision is the broad category that refers to any correctional control in a community setting. This generally covers pretrial (preadjudication), probation (sentence that involves community control), and parole (post-incarceration) as well as case management of offenders in the community. Probation had its early roots as a humane method of dealing with alcoholics. John Augustus, the grandfather of contemporary probation in the USA, realized that alcohol abuse contributed to workers being unreliable. Probation was conceived as a court service designed to reduce the use of jail sentences for first-time offenders. The early era of probation was focused on alternatives to incarceration and assisting those with needs (mostly alcohol abuse). In the 1970s, more emphasis was placed on oversight (law enforcement) and enforcement of conditions in the USA as support for rehabilitation dwindled (Garland 2001). The current emphasis on enforcement of the conditions of release (i.e., generally reporting, informing the officer of their whereabouts, and other emphasis on controls) dominates probation services.

Probation supervision is built on suppressing criminal behavior through a contact approach. Contacts, or face-to-face meetings between offenders and community supervision officers, are the main tool of overseeing offender behavior. While on probation, the offender has a series of liberty restrictions that define the requirements of supervision. Some of these restrictions are imposed by the court (for probation or pretrial supervision) or the parole board (for parole). Others are part of standard supervision conditions such as limiting activities and curfews, requirements to report to the supervision officer, no possession of guns, and so on. That is, the offenders have a set of rules to guide their behavior. The purpose of supervision monitoring is to improve compliance with these conditions. The notion is that offenders will be deterred from further criminal behavior with the threat of incarceration (due to failure to comply with the conditions of release). The core component of supervision – contacts – has been empirically tested in a limited fashion, primarily with studies of intensive supervision (more contacts), where frequency of supervision has not resulted in improved results (MacKenzie 2006; Petersilia and Turner 1993; Taxman 2002). A recent study of low-risk offenders (i.e., offenders that have a low probability of further criminal justice involvement) found that increasing the number of contacts with supervision officers did not result in reductions in recidivism (Barnes et al. 2012). There have been no experiments or studies on whether being on probation (i.e., having required contacts between the probation officer and offender) or having no oversight has any impact on future offending behavior. This limits the ability to understand whether supervision suppresses offending behavior or how supervision leads to more desirable impacts on offender behavior. The question of what type of supervision is most effective has largely been unanswered except for a recent systematic review that favored the risk-need-responsivity (RNR) (behavioral management) model of supervision (Drake 2011).

A small body of literature has examined the impact of probation on per-person offending rates. MacKenzie and Li (2002) examined the rate of offending of probationers and found that during the period of supervision, their self-reported offending rates decreased slightly. They found that having more conditions of supervision or requirements did not impact offending rates or offending behavior. But there is caution that needs to be acknowledged given that this was a quasi-experimental design with no control group (no one was assigned to not being supervised by an authority of the state) or comparison group; instead the study examined pre-post self-reported behaviors of offending. MacKenzie and Li (2002) also raise questions about whether added supervision conditions are useful given that the additional conditions do not appear to have a deterrent effect.

Supervision studies have primarily focused on contact levels and caseload size. The premise is that the caseload size is used as a proxy for the amount of time that the officer can devote to each offender. Two outstanding questions are: (1) what is the optimal size of the caseload a probation officer can manage to increase the success on probation? and (2) what impact does increasing the contact between the probation officer and the probationer have on contacts? The question about caseload size was addressed in several randomized trials to assess whether a caseload of 25–40 (depending on the study) had any impact on offending behavior. The theory was that having too many probationers to supervise would reduce the effectiveness of supervision by reducing the time that the offender can spend with the officer (Taxman 2002; MacKenzie 2006). Of course, these studies did not consider the difference when caseloads were 100 or more as compared to prior studies when caseloads were under 40 offenders per officer. Most of the caseload size findings from these studies (examining smaller caseloads under 40 offenders) were null, meaning that the caseload size did not affect offender outcomes. Since the concept of size of caseload was not associated with a particular theory of supervision, the studies did not contribute to a better understanding of what the probation officer should do as part of supervision.

Dosage studies (i.e., "frequency of contact") were the next series of studies conducted to detect how much contact is needed to improve offender outcomes. This set of studies was built on similar theoretical deficits in that the studies did not examine different styles of supervision but instead examined how more contact between the officer and offender/probationer affected outcomes. Petersilia and Turner (1993), in the largest multisite randomized trial (13 sites for probation supervision and 2 for parole) in probation supervision, found that intensive supervision services (the amount of required contacts varied by site) served to increase technical violations (i.e., allowed officers to be aware of compliance issues) but had no impact on rearrests. Intensive supervision heightened the number of contacts between the officer and probationer, increased the use of drug testing to detect drug use, and increased conditions of release. Yet, it had no notable impact on offending behaviors of offenders. The increased contact model has been found to be ineffective in reducing criminal behavior, although it is acknowledged that the law enforcement component has the potential to actually increase technical violations (Aos et al. 2006; MacKenzie 2006; Taxman 2002).

The caseload size and dosage studies on supervision have not found any impact on these factors on improvements in supervision outcomes. That is, the law enforcement and monitoring approach does not appear to improve outcomes, but this can only be stated with qualifications given that insufficient studies have examined or compared different types of supervision strategies. A recent systematic review by Drake (2011) found that the RNR model of supervision has the greatest impact on offending, followed by supervision with treatment conditions. Other forms of supervision such as contact only or contacts and drug testing (controls) had no impact on outcomes. The RNR model of supervision allows supervision to be more "client centered," where the goal is to tailor probation conditions and style of supervision to the individual. This draws from the "what works" (evidence-based practices) literature, focusing on reducing the risk of the individual offending by attending to dynamic criminogenic needs through specific case plans and responsive treatment programs. A major component of the model – besides the hard technology of using standardized tools for screening, assessment, and placement in appropriate programming – is the emphasis on the "soft" technology of deportment or the relationship between officer and offender (Taxman 2002, 2008a; Taxman et al. 2004). The RNR model of supervision addresses the tension between enforcement and social work models of supervision by realigning the goals of supervision officers to be behavioral managers. The theoretical framework is that offender change is a function of attention to target, proximal behaviors that are crime reducing, and a trusting relationship between the offender and officer.

The RNR model draws upon the importance of probationers and officers having a working relationship to address the general factors that affect involvement in criminal conduct. Recent studies illustrate how improved working relationships (e.g., empathy, trust, care, voice) have a positive relationship with offender outcomes (Taxman and Ainsworth 2009). Probationers (with mental health conditions) who perceived their officer to be tough had more failures and higher numbers of violations than those that did not (Skeem et al. 2007). Thanner and Taxman (2003, 2004) found that when offenders reported that they had a "voice" (i.e., the probation officer allowed the offender to participate in deciding the type of sanctions for failure to comply with requirements), reductions occurred in arrests and positive drug tests. While recognizing the importance of the person-centered model in supervision, James Bonta and colleagues in Canada studied whether probation officers have the appropriate interpersonal skills, role modeling, and communication skills to work effectively with offenders in an evidence-based practices model of risk, needs, and responsivity. The general findings from their studies are that probation officers do not have these skills and, even if the officers have the skills, they do not use them in supervision of offenders (Bonta et al. 2011).

Within the field, the following principles are considered important to an evidence-based supervision system (Taxman 2008b; Taxman et al. 2004; NIC 2004):

1. *Manage risk levels*. Providing higher-risk offenders with more structured control and treatment services, it is possible to reduce recidivism. Using risk level to articulate a supervision policy based on providing more intensive services by risk level serves to use probation resources wisely and use treatment services in a fashion that generates the best results. A related finding is that low-risk offenders could be supervised with fewer resources, and by providing low-risk offenders with minimal services, one can obtain relatively positive findings. In a recent experiment with low-risk offenders, Barnes and colleagues (2010) found that minimal supervision (average of 2.5 contacts per year) had similar recidivism results as offenders supervised on a more traditional schedule (average 4.5 contacts per year).
2. *Treat dynamic criminogenic needs* (i.e., substance abuse, impulsive behavior, criminal peers, and criminal thinking). Offenders vary considerably in the factors that affect their criminal behavior. While risk level indicates the likelihood of further involvement with the justice system, criminogenic needs identify the dynamic factors that affect involvement with criminal behavior. These dynamic factors can be altered with the use of proper treatment programming and correctional controls. The criminogenic needs should be targeted to improve outcomes.
3. *Manage compliance*. The most difficult part of any behavior change is sustaining the effect. Probation agencies can assist with compliance with judicial or parole board mandates. Compliance is similar to monitoring offenders, but the key is to use short-term goals to allow offenders to achieve positive outcomes; short-term goals are stacked towards longer-term outcomes of reduced drug use and alcohol abuse and continued involvement with the justice system. Retention strategies are important to achieve longer-term impacts. The use of administrative sanctions (matrix of responses to different types of behavior such as drug use, failure to pay fees, etc.) is recommended to provide graduated, structured responses.
4. *Create an environment for offender change*. An important part of the EBP model is the creation of an environment to support offender change. A focus only on revocations is counter to the emphasis on behavioral change, which is long and difficult. More attention is needed to creating an organizational culture that supports trusting relationship on supervision. The working relationship between the offender and the probation officer is an important component of the change process in that it builds support for change (Taxman and Ainsworth 2009).

This constitutes the behavioral management model of supervision where therapeutic strategies are used to facilitate offender change. The toolkit for supervision officers includes motivational enhancements, cognitive restructuring for meeting criminogenic needs and compliance management, and targeted responses to behaviors; all of this must occur in an environment where behavioral change is expected to be slow and steady with some relapses. In fact, relapses are expected to be commonplace and provide the tools to build resiliency to further change.

Maryland Proactive Community Supervision Study

A recent systematic review found that the evidence-based practices model that emphasizes behavioral management reduces recidivism by 16 %, in contrast to enforcement supervision (no impact) and supervision with treatment (10 % effect) (Drake 2011). The question is whether an evidence-based supervision model can be implemented and can deliver the same expected results of reduced recidivism as the "what works." The Maryland Proactive Community Supervision (PCS) experiment was a test of this model (see Taxman 2008a). Taxman and colleagues (2004) translated the risk-need-responsivity (RNR) model into a model for probation supervision given that the original model of "what works" principles was primarily geared towards treatment-related programming. The core components of the probation supervision model were based on the following theoretical approaches that blend accountability with therapeutic interventions, as shown in Table 1. One key component is the role of the supervision officer in helping the offender facilitate behavioral change by using cognitive restructuring strategies into routine practices of risk and need assessment, case planning, and compliance monitoring. That is, officers were trained in using cognitive restructuring and motivational interviewing as part of how they address traditional offender processing procedures (e.g., assessment, case planning, treatment and control monitoring, and determination of progress). The PCS model was designed to address the tension between the law enforcement and social work frameworks, with the emphasis on using quality contacts as a conduit for offender change. The behavioral management components were designed to integrate cognitive restructuring and behavioral modification frameworks within supervision settings by having the officer use these techniques with offenders.

Behavioral Management in Probation, Table 1 Components of the PCS model

Components of the PCS model	Theoretical framework
Risk and need assessment;	Risk assessment
Prioritize moderate- and high-risk offenders in treatment programs	Treatment matching (responsivity)
Case planning and typologies for major criminogenic needs (specifying needs)	Treatment matching (responsivity)
Offender input into case plans	Motivational enhancement; Cognitive restructuring
Deportment (working alliance between officer and offender)	Motivational enhancement
Compliance management including sanctions and rewards	Enforcement; Boundary setting; Behavioral modification
Cognitive restructuring for offenders	Cognitive behavioral interventions
Officers as role models	Motivational enhancement

The PCS offender supervision process model consists of five major components (see Taxman et al. 2004 for more details). A five-item risk screener was used to determine initial assignment. Offenders scoring moderate to high risk are then involved in a lengthier assessment process involving the Level of Service Inventory–Revised, a third-generation risk assessment tool (Andrews et al. 2006). Officers also conduct a thorough review of the person's place of residence and social networks. As part of the process, the offender is asked about their desired goals during supervision. All of this information is used to assess the factors that affect criminal behavior, with attention to the specific typology of criminogenic behavior. The six typologies (and related goals) are disassociated (develop prosocial network), drug addiction (achieve abstinence and recovery), drug-involved entrepreneur (obtain prosocial employment), violent offender (address power and control issues), domestic violence (address relationship and control issues), mental health (continue treatment and address support network), and sexual deviance (achieve control over urges and manage behavior). The typology helps define the components of the case plan, including the appropriate type of treatment programming and controls applied, such as drug testing, curfews, house arrest, or other types of mechanisms to limit liberties. On a monthly basis, the offender and the supervision officer review progress on the case plan (see Taxman 2008a). The case plan is revised monthly based on the offender's progress in meeting goals and the offender's attitude. Offenders are given no more than three goals a month, with participation in treatment services prioritized as one of the key goals.

The process hinges on the offender's engagement to achieve ownership of the case plan through a positive working relationship with the supervising officer. The agency achieves the emphasis on engagement through a series of skill development sessions that emphasize (1) learning to use motivational interviewing strategies, (2) using cognitive restructuring strategies to assist offenders in problem solving to address their criminogenic needs, and (3) using performance measurements (e.g., drug tests, attendance) to assess offenders' progress. The skill development efforts provide officers with the ability to adapt and translate motivational interviewing, behavioral modification, and cognitive restructuring in a community supervision environment (see Taxman et al. 2004) into traditional functions of assessment, case planning, monitoring, and compliance assessments. These skill-building components provide the officers with new behavioral strategies to work with offenders.

The PCS model of skill development and refocus of supervision could not be accomplished without changes in the culture of the probation officer. The agency created a social learning environment (for staff and probationers) with an emphasis on building a probation culture that supported officers' use of the behavioral management strategies instead of traditional law enforcement techniques. The agency adapted core tenets of a social learning environment: greet offenders with proper salutations, shake hands with the offender upon entrance and exit, and maintain eye contact with the offender during all personal conversations. Additionally, the face-to-face contact of supervision is realigned. The traditional face-to-face contacts are altered to bilateral information exchange sessions where the goals of supervision could be assessed, refined, and restated. Assessment and other data collection exercises are shared with offenders to allow them to learn about their own behavior. Finally, performance measures for offenders, supervision staff, and PCS offices are used to reinforce the emphasis on behavioral management strategies such as number of offenders employed, number of goals achieved, and then attention to the accomplishments per typology. Officers and probationers reviewed the target goals in each section as part of the behavioral contract and these accomplishments are used to build future target goals. The emphasis on target goals is to gradually improve the probationers' success on probation. This is the process that defines the behavioral management framework used in a responsive face-to-face contact system.

In a place-based experimental design where four probation/parole offices in Maryland implemented the behavioral management supervision model (PCS) and four similar offices used the traditional law enforcement supervision style, logistic regression results found that, controlling for length of time on supervision and prior criminal history, offenders that were supervised in the behavioral management style were less likely to be rearrested (30 % for the PCS and 42 % of the non-PCS sample; $p < 0.01$) and less likely to have a warrant issued for technical violations (34.7 % of the PCS group and 40 % for the non-PCS group; $p < 0.10$). The study also included a process evaluation to assess the degree to which the key components of the model were implemented. The assessment inventory (LSI-R) was implemented in 70 % of the cases and the typologies were used in 56 % of the cases. The typologies were used as a vehicle to identify short-term goals to improve outcomes, and for those that were assigned typologies, a greater percentage were placed into appropriate programming and controls than in the control group. Some officers did not implement the model as planned which resulted in some cases with no typology assignment. In these cases, fewer services were obtained for the probationer. Several replications of the application of the risk-need-responsivity model of supervision have confirmed reductions in recidivism (Drake 2011).

Further Work on Behavioral Management (RNR) Supervision Models

Trying to disentangle the effective mechanisms of supervision is the subject of a growing body of research. The focus of attention has been on (1) specialized caseloads, (2) different collaboration between probation agencies and treatment providers, (3) the use of graduated sanctions to manage offender behavior, (4) "light" supervision for low-risk cases, and (5) improving the problem-solving skills of officers.

Specialized Caseloads. Very little research has been conducted on the impact of specialized caseloads, or the concentration of offenders with like criminogenic needs with one officer. The available research has been on offenders with mental health disorders or domestic violence. In a national survey of specialized caseloads, special mental health units were distinguished by (1) caseloads consisting of clients with mental disorders, (2) reduced caseload sizes, (3) trained officers in mental health issues and behavioral management problems, (4) integration of probation and community mental health resources, and (5) use of problem-solving strategies to address treatment noncompliance. Three separate evaluations of specialized caseloads for probationers with mental illness have found a tendency towards positive outcomes of reduced technical violations or rearrests, although these studies are not conclusive given their weak research designs and measures (Epperson 2009). Specialized units for domestic violence caseload have shown similar results to intensive supervision programs with increased contacts that have lead to increased violations. The emphasis of most domestic violence research focused on enforcement and control of offenders, which has the same outcomes of other intensive supervision studies – that is, the specialized caseloads led to greater probation violations.

Collaboration Models Between Probation and Treatment Providers. Most community correctional agencies in the USA do not provide treatment services directly by the probation agency. Instead, the offender is referred to treatment programs provided by publically funded treatment programs or the probation agency contracts for services in the community. Increasing the access to treatment services has been a long-standing challenge for probation and community corrections agencies in that the services are seldom designed specifically for an offender population. The specialized case management services, commonly referred to as Treatment Accountability for Safer Communities (TASC), are designed to provide a bridge between justice and treatment agencies. The five-site evaluation of the TASC case management model found that case management did not result in reduced recidivism or technical violations and did not improve access to treatment services. In the sites where positive findings occurred, the service agency also provided treatment services and therefore directly improved access to treatment (Anglin et al. 1999). This is a common theme regarding case management; agencies that provide both case management and treatment are more likely to improve outcomes.

In contrast to a brokerage model of service linkage, Taxman (1998) developed the concept of a policy-driven seamless system of care. The concept was built upon information sharing across the spectrum of service delivery: assessment, drug testing, treatment access and participation, supervision requirements, and outcomes. The goal was to have probation officers and treatment providers jointly share information that would be useful in their efforts to assist offenders. The study results vary considerably, mainly based on the features of the seamless system that are present. For pretrial supervision focusing on testing, treatment, and sanctions, a randomized trial found reductions in rearrest rates for higher-risk offenders (Harrell et al. 1998). In another study of probation that used a person-centered model of probation supervision, the findings are also mixed. An assessor in the probation office would screen for substance abuse disorders and then target offenders to appropriate treatment. Treatment should be 9 months in duration with two levels of care (generally a step down to outpatient but it could be from in-jail treatment to outpatient care, drug testing, and sanctions). The probation/parole officer's role was as a resource broker, working with the treatment counselor on treatment access, monitoring compliance with drug treatment requirements, and responding to positive drug test results. The study resulted in increased access to treatment services and increased days in treatment, but the seamless intervention was more costly to deliver and did not result in reduced recidivism for some higher-risk offenders (Alemi et al. 2006; Taxman and Thanner 2006). For higher-risk offenders, there was a reduction in arrests and opiate drug use (Thanner and Taxman 2003; Taxman and Thanner 2006). A more recent study used a slightly different seamless framework but added a manualized cognitive behavioral therapy treatment sessions offered in the probation office. Again, there were increases in treatment access, and the study found improvements in outcomes for moderate-risk offenders, but not for high-risk offenders (Taxman and Belenko, 2011). The provision of treatment in the probation office did not universally improve outcomes for offenders, but the study found that certain treatments are more effective for some offenders. Overall, the study found that offenders with drug dependence disorders tended to have less positive outcomes than those with abuse disorders. It appears that the outpatient treatment is not as effective for those with dependence disorders.

Another study focused on probation/parole officer and treatment provider working together in a collaborative model of care. The Step 'n Out study, conducted in six sites, required the officer and treatment provider to work together on a collaborative behavioral management (CBM) process of accessing treatment needs, reviewing treatment progress, and using a structured reward schedule to incentivize offenders for positive behavior (Friedmann et al. 2008). CBM is modeled after contingency management, which focuses on providing rewards for positive behaviors (see Stitzer et al. 2011). The study found a treatment effect for offenders with substance use disorders, particularly those that did not use hard-core drugs (e.g., opiates, cocaine, methamphetamine) (Friedmann et al. 2012). In this model, the probation officer and treatment provider have frequent meetings to review the progress of offenders.

Use of Graduated Responses. Supervision officers have tremendous discretion regarding the handling (and managing) of offender outcomes. As drug treatment courts and the seamless system evolved, the emphasis was on using gradual responses to offender noncompliance, commonly referred to as graduated sanctions. The notion is that sanctions need to be swift, certain, and severe (increasing in intensity based on the number and type of violation behavior). Sanctions can be delivered by probation or parole officers, or they can be delivered by judicial or parole board authorities. The former is referred to as administrative sanctions and the latter as sanctions. Swiftness means that the sanction occurs in a period of time close to the noncompliant event. Certainty means that the sanction is delivered as it was indicated. Severity refers to the type of response and whether it involves liberty restrictions such as incarceration. Paternoster (1987), in a study of perceptional deterrence, found that swiftness and certainty are more likely to influence offending behavior. While there has been general support for probation and parole officers using administrative sanctions (a set regulatory procedure) or a matrix of noncompliant behavior and type of responses, there are relatively few empirical studies of the degree to which administrative sanctions reduce offending behaviors. In a non-experimental study examining the use of graduated sanctions on parolees during the first year after release from prison, researchers found that graduated sanctions could alter the offending behaviors of offenders. The use of graduated sanctions in a manner that features swift, certain, and severe can enhance the suppression effect of parole on criminal behavior. Steiner et al. (2012) did not examine the use of any specific sanction schedule and used the sanction mechanism as a proximity for severity of response (i.e., supervising officer gives a privilege restriction, parole board or a hearing officer, placement in a halfway house, and formal revocation hearing where it was possible the offender may have been returned to prison). They found that sanctions were effective regardless of offender risk level, but younger offenders did not respond as well to sanctions.

Another graduated response is the use of rewards. Following the model of contingency management in the substance abuse treatment literature, rewards are to be delivered swiftly, certainly, and severely (progressively increasing in value). Rewards tested in drug treatment programs demonstrate that offenders respond well, with rewards impacting drug use and treatment retention. Marlowe and colleagues (2009) found that rewards were very successful for young offenders in a drug court setting in terms of reducing offending behavior. Rudes and colleagues (2011) outlined how rewards could be adapted in justice-type settings and used as part of a progressive behavioral management scheme. Rewards create an environment for probation that is consistent with the efforts to facilitate offender change. That is, recognizing that offenders respond to acknowledgment about positive steps during probation facilitates positive outcomes.

Low-Risk Offenders. The risk-need-responsivity model focuses attention on moderate-to high-risk offenders. The triage model indicates that low-risk offenders should not have the same oversight or monitoring as other offenders, presuming that their criminogenic needs are minimal (similar to their low criminal justice risk status). This principle is based on the lower recidivism rates of low-risk offenders. Barnes and colleagues (2012) conducted an experiment where low-risk offenders were supervised on administrative caseloads (caseloads averaging 400 offenders per officer with requirements of two in-person contacts and two phone contacts a year) or traditional supervision (monthly in-person contacts). The study found that offenders assigned to traditional supervision are more likely to abscond from probation (partially a function of the traditional supervision defining absconding as missing for 2 months of contacts, whereas the experimental group had to not have contact in 3 months). There were no statistically significant differences in the rearrest rates or drug test positive rates. In examining the comparative effectiveness of the two models for supervising low-risk offenders, the experiment confirms that there is a slight advantage in reducing contact levels in that there are fewer absconders. Similar to intensive supervision, which finds that increased attention is likely to denote more compliance-related issues, this study found that low-risk offenders can be managed with less supervision. These findings are important for policy considerations in that risk level is an important consideration for managing offenders in the community.

Skill building of Officers. The behavioral management approach to supervision has yielded attention to an important part of the equation to achieve more positive offender outcomes: the skills of the officers supervising offenders. Officer skills are important because the model, as described above, relies upon officers to create an environment where change can occur, to engage offenders in the change processes, to use cognitive restructuring techniques in working with offenders, and to use problem solving and other strategies to address compliance-related issues. The notion that officers need to be trained on the basic premises of the behavioral management principles (including RNR) was evident in the MD PCS study (cited above), which recognized that preservice training and ongoing in-service training did not include the basic principles of managing risks and attending to criminogenic needs. The MD PCS project designed and built three training programs: Officer Engagement skills (based on principles of motivational enhancement and interviewing), “Sizing Up” (based on applying the risk and need assessment tools), and in-office refresher training (see Taxman et al. 2004). More recent attention has been given to enhancing the training of officers through similar curriculums that focus on structuring sessions, relationship-building skills, behavioral techniques, cognitive techniques, and effective correctional skills (Bonta et al. 2011; Robinson et al. 2011). The premise is that in order for officers to use the RNR principles, their work flow needs to be adapted to the principles of their work environment, including attention to intake and assessment, monitoring compliance, monitoring treatment compliance, and reinforcing cognitive restructuring.

Without training in applying the RNR principles, it is unlikely that officers will discuss procriminal attitudes or cognitions with offenders and even more unlikely to use cognitive intervention techniques with their clients. Bourgon et al. (2011) found that the Canadian STICS training, which included review tapes, improved officers' discussion about procriminal attitudes and results in increased utilization of cognitive techniques (namely, helping the offender to examine their own behavior and outline options). In a cox regression model, the authors also found that the use of cognitive techniques reduced offending rates. Bonta and colleagues (2011) had similar findings when most probation officer-offender contacts focused on probation conditions and noncriminogenic factors (e.g., work, sports). The increased training improved the focus on procriminal attitudes among the experimental group with more attention to attitudes and employment and educational issues. Offenders supervised by officers using the skills were also significantly less likely to reoffend.

Conclusion

The behavioral management model of supervision is currently being implemented in the USA as well as other countries. The recent systematic review confirmed that the RNR supervision model had better outcomes than other supervision approaches (Drake 2011). However, probation officers are not aware of how the risk-need-responsivity (RNR) principles apply to supervision, and therefore, the successful implementation of this model will depend on the technology transfer strategies that are used. The "what works" model (RNR) has primarily been targeted to treatment programs, but as learned in the MD PCS demonstration, it is possible for supervision officers to use the RNR principles. The challenge is to adapt RNR to align with supervision. RNR relies upon principles of behavioral management in terms of recognizing that there are boundaries that need to be in place (enforcement) but also that therapeutic techniques of individualized care, cognitive restructuring, and graduated response are useful to achieve improvements in supervision outcomes. The advent of various training protocols (i.e., STICS in Canada, STARRS in federal probation, EPICS in other supervision models) illustrates the complexity of the transfer process and the need to import RNR principles into supervision practices. The proliferation of these curricula illustrates that there is a need to improve the skill sets of officers to use the RNR principles, especially given that few officers are trained in social work or counseling skills. This becomes the challenge to implementation in that supervision staff need to develop new skills to work with offenders in a different manner.

The other challenge is the development of policies to support the use of behavioral management strategies. An important part of the model is to use the risk level to allocate resource levels so that moderate- and high-risk offenders receive ongoing (and more intensive) care than low-risk offenders. While this is an intuitive policy, it is actually more challenging to implement since officers tend to find lower-risk offenders easier to supervise (e.g., they tend to be less resistant). But other policies that are important to put in place have to do with collaborations with treatment providers and using graduated responses. The collaboration with treatment providers is an important policy issue. The working relationship between supervision and treatment agencies should be defined at the office level to ensure that treatment providers use evidence-based treatments and that information is shared between the two disciplines. The creation of policy-level agreements will avoid probation officers having different agreements with treatment providers and having different expectations from the treatment providers. The use of graduated responses – both negative and positive – is another policy issue in that the agency needs to determine what can be used as reinforcers both in terms of liberty restrictions (sanctions) and liberty enhancers (rewards).

This discussion of behavioral management supervision has not included another dimension that is being integrated into the workspace of supervision: temporally and spatially based supervision. The increasing awareness that some offenders are concentrated in certain neighborhoods has spurred an interest in community-based probation models that focus on ameliorating the risks of the individual and the place. These models are based on the premise that concentration of offenders into typically resource-deprived communities only serves to undermine supervision; the demands of the community override the requirements of supervision. Byrne (2009) also points out that targeting supervision at high-risk times – generally referring to the early part of the supervision period or the first 90 days – is a sound strategy for reducing recidivism. During this early period, offenders are more likely to fail (MacKenzie and Li 2002; MacKenzie and Brame 2001), and officers have an opportunity to set expectations about the behavior of offenders under supervision. The early period of supervision is when offenders are going to test the conditions of release. Little research has been conducted on different methods for improving compliance during this early period of supervision, but it is an important factor.

Behavioral management offers a solution to the age-old debate about supervision being enforcement vs. social work. Since the behavioral management (RNR) model incorporates a balance between compliance-focused supervision and working on offender change issues, it offers a model of supervision that fulfills the multiple goals of sentencing. Moreover, behavioral management helps assist officers in learning strategies to facilitate offender change. The test over time will be whether behavioral management supervision can be successfully implemented and what the scaled-up version will have an impact on offenders' outcomes.

Behavioral Science Evidence in Criminal Trials

Jenny McEwan
School of Law, Exeter University, Exeter, Devon, UK

Overview

Expert witnesses are by no means always scientists, but they must know something the judge or jury do not. The judge will decide whether or not that is the case. For the behavioral sciences, this approach tends to favor the clinical end of the spectrum; even there, however, lawyers have been known to be skeptical of the value of such evidence in a criminal trial. Such reservations are often founded on ignorance of the culture, purpose, and circumstances that form the background against which experts make behavioral assessments. Courts should be aware of the requirements of diagnoses for clinical purposes. The length of observation period normally necessary for diagnostic purposes is unlikely to be available in the context of preparation for trial. A relatively short period of contact possibly makes it easier for a mental illness to be faked. In any event, a retrospective analysis of how an observed condition would have affected past events inevitably involves much speculation.

Behavioral sciences such as psychology, sociology, or anthropology do not fit comfortably within conventional perceptions of expert scientific evidence. There is, within these disciplines, extensive disagreement about questions of central importance, such as methodology. This makes it more difficult to persuade judges that witnesses specializing in these areas of scholarship have an expert opinion of evidential value. Even more problematically, to some extent behavioral sciences represent a challenge to the power of a tribunal of fact, whether judge, juror, or magistrate, to determine the ultimate issue, the matter to be determined in reaching a verdict. Frequently the central or ultimate issue in a criminal trial requires a determination of how an individual, often the defendant or victim, responded to a particular situation. This decision by the trier of fact tends to be based to some extent on intuitive or heuristic judgments about human behavior. Many lawyers would defend such decision-making as an essential element in the role of the lay jury as the representative of popular sentiment, bringing community moral and practical judgments into the criminal court. This role, and the way in which it has traditionally been performed, insofar as it consists of assessments of human reactions and motivations, occupies the very area of expertise claimed by behavioral science. Unlike "hard science," therefore, where courts defer to specialist knowledge, behavioral science is seen as trespassing on the fundamentals of the jury's responsibility and rationale. Lay finders of fact and behavioral experts are effectively pitted in competition against each other in terms of their ability to understand and evaluate human nature.

Admissibility of Behavioral Science Evidence

Where a potential witness can contribute expertise indubitably outside the experience of the tribunal of fact, such as a psychiatrist or clinical psychologist in relation to the defenses of diminished responsibility or insanity, the expert may, even in jurisdictions which prohibit expert opinion on the ultimate issue, give evidence as to the presence or absence and nature of the condition in question and whether it satisfies legal requirements. In most cases, however, behavioral science evidence occupies a problematic middle ground between acknowledged scientific expertise, such as clinical diagnosis, and the kind of "common sense" or everyday perceptions and generalizations of human behavior that are considered properly to be the province of the jury. Given that, essentially, the common law approach to the admissibility of expert opinion evidence is one of laissez-faire insofar as the question is left to the trial judge in the particular proceedings (Roberts and Zuckerman 2010, pp. 482–493), the admissibility of behavioral science evidence is determined on a case-by-case basis. However, courts are jealously protective of the role of the finder of fact as the arbiter of everyday life. In the Court of Appeal of England and Wales, Lord Justice Lawton famously observed:

> The fact that an expert witness has impressive scientific qualifications does not by that fact alone make his opinion on matters of human nature and behaviour within the limits of normality any more helpful than that of the jurors themselves; but there is a danger that they may think that it does....Jurors do not need psychiatrists to tell them how ordinary folk who are not suffering from any mental illness are likely to react to the stresses and strains of life. (*R* v *Turner* [1975] 1 All ER 70, 74)

A concern to protect the role of the jury in interpreting events and applying their own standards of reasonableness may prompt courts to distinguish "normal" behavior, preempting expert opinion evidence, from "abnormal" mental states. This sharp distinction is a legal invention. In psychiatry, the difference is a matter of degree rather than kind, and as medical knowledge advances, the blurry line between them shifts over time. "Medical expertise lies along a line between the predictive technological know-how of the physical science and the loose generalizations of social science practice" (Smith 1985, p. 69). Nevertheless, legal jurisdictions may develop their own typologies of mental states indicating which will be deemed pathological or normal as far as the law of that jurisdiction is concerned. This will determine whether the jury require expert help to decide what the effect of the disorder might have been. And, while psychological research on memory in "normal" adults would be generally excluded from evidence, child development will usually be regarded as an established scientific discipline upon which a specialist could assist the court. Explaining developmental aspects of children's memories and how a particular child compares with the norm does not usurp the function of the jury, as long as the expert does not say that a particular child is telling the truth; that would be for the court to decide.

As "gate-keepers" determining whether or not particular expert evidence is admissible in a given case, judges arbitrate between areas of psychology in which it is possible to draw on specialist expertise over and above the everyday experiences of lay jurors. Obscure or recently identified conditions are more likely than familiar ones to be regarded with hostility. The judge has to accept both that the claimed expertise exists as a discipline and that the particular witness is sufficiently acquainted with it. A second aspect of the "gate-keeper" role is the possibility that the judge will exercise some kind of reliability standard in deciding whether or not the opinion evidence should be admitted. In England and Wales, however, there has been concern that a "culture of acceptance" of purportedly scientific evidence could be creating miscarriages of justice. A generous approach is likely to be founded on the belief that cross-examination by opponents is an effective tool to unmask any bogus science or scientist. True, the anxiety in England and Wales about "junk science" expressed in recent case law, the academic literature, and a significant official report (Law Commission 2011) has arisen in the context of "hard," nonbehavioral scientific evidence on such matters as the reliability of "earprint" evidence (*R* v *Dallagher* [2002] EWCA Crim 1903), or shaken baby syndrome (*R* v *Harris* [2006] 1 Cr App R 5, [2005] EWCA Crim 1980). However, the Law Commission's recommendations for an explicit reliability standard to regulate the admission of all expert opinion evidence in criminal proceedings would, if implemented, apply to "soft" science, too. This approach has caused problems in the United States, where judicial attempts to evolve a workable reliability test have been accused of favoring dated theories and militating against the admission of reliable and pertinent behavioral science evidence.

Defining Reliability Standards

An influential reliability test, deriving from *Frye* v *US*, 293 F 1013 (DC Cir 1923), is that the discipline commands "general acceptability to the scientific community." A general acceptance criterion could be thought to discriminate against any developing science, and is likely to exclude any discipline where there is substantial controversy among practitioners. An Australian test, inquiring "whether the subject matter of the [expert's] opinion forms part of a body of knowledge or experience which is sufficiently organized or recognized to be accepted as a reliable body of knowledge or experience" (*R* v *Bonython* (1984) 38 SASR 45) is along similar lines. The alternative American test, advocated by *Daubert* v *Merrell Dow Pharmaceuticals*, 113 S Ct 2786 (1993), aims to enable the courts to be more responsive to scientific innovation, while at the same time demanding that sufficient reliability is demonstrated. Trial judges are enjoined by *Daubert* to consider factors such as whether the technique in question has been subjected to peer review, whether it has been generally accepted, and whether the theory or technique can be or has been tested. Another factor that may be considered is the falsifiability of the opinion, which means that its plausibility depends upon whether the theory or concept on which it rests is capable of being shown to be false. Any proposition incapable of being verified in this way should, on the *Daubert* test, be treated with great suspicion by the courts.

The difficulty for the social and behavioral sciences, economics, sociology, and psychology, is that they do not fit easily into this portrait of a body of knowledge consisting of a set of propositions which have been demonstrated to hold in all circumstances. The English Law Commission proposes a new test for reliability which would force judges to decide whether or not the purported science is soundly based. Trial judges should consider a number of factors in making this judgment, the most significant for behavioral science being: whether or not any relevant hypothesis has been sufficiently scrutinized, the nature of the data on which the opinion is based, where the expert's opinion relies on the results of any measurement or survey, and whether the opinion takes proper account of matters such as the degree of precision or margin of uncertainty in data collection (Law Commission 2011).

Reliability Standards and Behavioral Science Evidence

Evidence given by experts in behavioral or social sciences is not easily accommodated within a *Daubert*-style test for admissibility. Falsifiability is not an appropriate technique in the social sciences. Controlled experiments are virtually impossible: "we correctly refuse to abuse a child for the sake of research" (Graham 1998). Aware of such practical and ethical constraints, many American judges have, sidestepped *Daubert* on the grounds that the test does not apply to "soft" science. They have proceeded to admit evidence of false confessions and suggestible personalities, post-traumatic stress disorder (PTSD), and repressed memory syndrome (Slovenko 1998). Meanwhile, Canadian courts have allowed expert evidence on "learned helplessness" to be adduced to dispel any jury myths about battered women (see *R* v *Lavallee* (1990) 55 CCC (3d) 97).

The reception of "syndrome evidence" has not met with universal approval. For instance, controversy surrounds the reception in rape trials of evidence of rape trauma syndrome. This is offered to demonstrate that the complainant's behavior is consistent with her allegation that she was raped. Critics suggest that the alleged syndrome is based on inconclusive research and could consequently cause great prejudice to the defendant. It has not been established whether rape trauma syndrome is a subset of post-traumatic stress disorder. It lacks specificity, in that many kinds of behavior appear to fall within its compass; the victim may be afraid to be indoors, or she may be afraid to go out of doors, depending on where the rape took place. Notwithstanding considerable skepticism, evidence of rape trauma syndrome has been admitted in some courts in the United States. Some American judges, however, allow it only as rebuttal evidence after the defense has argued that the complainant's behavior indicates fabrication. Given the adverse effect on the fact finder where a rape complainant displays no emotion, expert evidence to preempt the complainant's superficial serenity from being misconstrued may be advisable (Frazier and Borgida 1992). It appears, however, that expert evidence on general aspects of rape trauma syndrome has less impact on a jury than expert testimony linking rape trauma syndrome to specific features of the case (Brekke and Borgida 1988).

It has been argued that courts are being bombarded with an escalating number of novel afflictions, such as "urban survival syndrome," which could be derided as "trash syndromes." Over-willingness to accept syndrome evidence could lead to miscarriages of justice (Mosteller 1996). Repressed memory syndrome has been a particular target for criticism; it has been said that according to the falsifiability criterion, claims for repressed memory are not based on valid science. Yet there are psychiatric disorders, such as multiple personality disorder and attention-deficit hyperactivity disorder, listed in professional diagnostic manuals and commanding respect as legitimate medicine, which could equally be said to lack scientific validation (Richardson et al. 1995). One of the problems here is that techniques and theory developed for one purpose are being considered for use in a very different context. Conditions such as child sexual abuse accommodation syndrome or theories of repressed memory, developed originally for therapeutic purposes and therefore characteristically evaluated within their scientific communities in terms of alleviation of symptoms, are being scrutinized by judges for a level of objectively established reliability never sought or claimed for them. Courts which understand this, and mindful of the presumed ability of cross-examination to expose any overstated claim, tend to allow such evidence on the basis that *Daubert* permits a flexible approach and does not require general acceptance in the scientific community. To apply the *Daubert* test strictly would deprive fact finders of relevant bodies of knowledge. Yet to abandon any admissibility threshold or critical screening process in relation to expert evidence on behavioral issues would expose courts to the risk that plausible "junk science" would warp decision-making in criminal proceedings.

One might attempt to distinguish evidence presented as scientific knowledge, requiring compliance with *Daubert*, from specialist knowledge based on experience. The "experiential" category would include, for example, lip-reading expertise (*R* v *Luttrell* [2004] 2 Cr App R 31, CA), knowledge of black market drug prices (*R* v *Hodges* [2003] 2 Cr App R 247, CA), and handwriting comparisons. In cases involving testimony regarding battered woman syndrome, the evidence would have the beneficial effect of countering potential jury prejudice, but would not be masquerading as proven science. This is, effectively, the pragmatic strategy of many American courts (Renaker 1996). But if "junk science" is to be excluded, judges are left searching for a true test of genuine experience and knowledge. American and British judges appear to have found no alternative, where "soft science" is concerned, to reliance on their own intuitive assessment of the alleged field of expertise. Thus, while an American court may allow evidence of "psychological autopsies," retrospectively assessing the alleged murder victim's state of mind and tendency to suicide on the basis of medical records and interviews with family and friends (*State* v *Huber*, 62 Ohio Misc.2d 237), English courts remain unpersuaded: *R* v *Gilfoyle* [2001] 2 Cr App R 57, CA.

The work of criminal profilers, although heavily featured in film and television drama and, arguably, of use during police investigation, seems to be another area on which judicial opinion is divided – as is the expert community itself. From an objective point of view, psychological profiling seems to be an area of behavioral science far too undeveloped for use in a criminal trial. Profiling does not enjoy universal support among the ranks of psychologists, some of whom regard it as little more than a professional sideline with dubious scientific credentials (Gudjonsson and Copson 2000). It is likely that decision-makers who became aware of earlier criminal or other discreditable behavior by an accused person will be readier to convict (Tanford and Penrod 1984; Wagenaar et al. 1993), and so such evidence is particularly problematic when offered as an indicator of guilt as part of the prosecution case (Roberts and Zuckerman 2010, Chap. 14). Conversely, defense profile evidence was excluded from a rape trial on the ground that there was no proof that rapists have particular mental characteristics, or that psychiatrists could, by examination of a person, determine the presence or absence of these supposed characteristics: *State* v *Cavallo*, 88 NJ 508; 443 A (2d) 1020, (1982).

Behavioral Science Having Significant Legal Effect

The most well-known area in which the findings of behavioral scientists have influenced criminal trials concerns eyewitness evidence. Where identification is a contested issue in a trial, the ability of an eyewitness to link the accused person to the offense is a potentially invaluable asset to the prosecution. Direct observation by an individual of the perpetrator committing the offense is just about the best evidence that can be presented to the court. The true value of such evidence is, however, in considerable doubt following the findings of psychological experiments testing eyewitness reliability. According to these experimental simulations, accuracy of description varies between 65 % and 75 %, and decreases somewhat over time (Shepherd et al. 1982). Given that most developed legal systems demand prior identification in the relatively clinical conditions furnished by an identification parade before the witness can identify the defendant in court, the more significant data relate to the accuracy of recognition. Here, little reassurance can be offered to criminal lawyers. Although recognizing someone is easier than describing them, the accuracy of recognition is also alarmingly low. Across the multiplicity of studies, it varies between 35 % and 60 %. Although practical difficulties affecting the observation, such as lack of light or a short-lived event affording only a fleeting glimpse, exacerbate the problem, good observation conditions and prolonged observation periods make little difference to overall accuracy. High levels of error in recognition remain.

Identification parades provide only limited safeguards against wrongful identifications. If a parade is held at which the real actor is not present, there is a one-third likelihood of the eyewitness selecting a volunteer (Pigott et al. 1990). It appears that the eyewitness, anxious to choose *someone*, will select the line-up member who, compared with the other members of the line-up, most resembles the culprit (Wells 1993). If there is a familiar face in the line-up, it may be confused for that of the offender, the witness forgetting the context of a previous acquaintance. This is known as the "transference effect." Similar mistakes can be made where the person the witness saw resembled someone familiar, such as a well-known TV personality. There are extra layers of unreliability in identifications across races (Shepherd et al. 1974) and, more debatably, across genders and age groups (Jalbert and Getting 1992). In 1984, a black man was convicted of rape in the United States on the basis of an identification by the white female victim, who picked him out from a line-up. In 1995, DNA evidence established that another man had carried out the attack (Memon and McDaid 2000). The witness had been confident of the accuracy of her recognition throughout. Research indicates that eyewitness confidence is no guarantor of accuracy (Deffenbacher and Loftus 1982). The forensic impact of such confidence may be profound, however. Jurors' common sense presuppositions support the existence of a significant link between witness confidence and accuracy (Wells et al. 2002), and so an eyewitness who insists on the reliability of their memory may exert a very powerful influence on the outcome of the trial.

One way for the problem of eyewitness inaccuracy to be accommodated in a trial setting is to allow an expert witness to explain to the jury that identification evidence may be considerably less reliable than it appears, and to draw attention to any factors in the particular case that would cast doubt on the accuracy of the recognition in question. Uninstructed, jurors seem to be impressed by identification evidence, particularly if there is more than one witness. Judicial warnings apparently do little to moderate juror enthusiasm for eyewitness evidence (Cutler and Penrod 1995), so courts in some US states have attempted to amplify its effect by allowing expert testimony to explain the unreliability of identifications. Whether greater judicial attention should be devoted to the voluminous psychological literature on the accuracy of identification turns partly upon the extent to which it is possible to extrapolate directly from laboratory findings to real-life situations. In one naturalistic study, eyewitnesses interviewed following an armed robbery and fatal shooting in the street achieved strikingly high rates of accuracy. In follow-up interviews, accuracy did not decrease, but new information, also accurate, was offered. The recall of those who suffered the most stress was not adversely affected by their trauma (Yuille and Cutshall 1986). In any event, it would be unwise to dismiss all eyewitness evidence as equally unreliable. Certain individuals may have a good track record for recognition (Cutler and Penrod 1995). It is possibly misleading to claim that eyewitness confidence is no indicator of accuracy whatsoever, since the issue may be more complicated than some research literature allows. Eyewitnesses may legitimately feel confident about the accuracy of some of the details they recall while being less confident about others (Stephenson 1984). Also, there is a significant difference between a confident delivery and actually believing that one's identification is undoubtedly correct (King 1986). However, most of the relevant research focuses on subjects' beliefs in the correctness of their identifications rather than upon the personality or demeanor of particular eyewitnesses.

Another vital evidential issue illuminated by behavioral science research concerns the probative value of admissions made by suspects under criminal investigation. Admissions of guilt are regarded as key items of evidence for the prosecution, but have come under critical scrutiny from researchers. The result is increasing recognition of the extent to which the readiness to confess to a crime may be influenced not only by improper pressure from police officers, but by personality traits peculiar to the individual which may cause him or her to make false admissions. This may occur without any impropriety on the part of investigators. The vulnerability of some suspects, such as those with low or borderline IQ, may be clear to courts and can be taken into account when considering the reliability of their admissions. In some cases, however, factors indicating that a confession should be viewed with caution are less obvious. This does not necessarily mean that courts will routinely accept expert evidence on the reliability of a confession. They tend to be most receptive to such evidence where the defendant has a personality disorder or learning difficulties, that is, at the more overtly scientific end of behavioral science typically involving clinical diagnosis. Yet even in a nonclinical case, there may be powerful personality factors indicating that the suspect's confession should be treated with skepticism.

The psychological characteristics which need to be addressed are interrogative *suggestibility* and *compliance*, which are traits that may cause false admissions to be made once in police custody, even during perfectly proper and legitimate questioning by police officers. Suggestibility is a tendency to accept uncritically information communicated during questions. It is most pronounced in people of low intelligence. Gudjonsson (1992) has devised what he considers to be a reliable scale to assess suggestibility as a continuing condition, while allowing suggestibility may be aggravated by circumstances. Gudjonsson defines compliance as a tendency to go along with requests made by a person perceived to be in authority, even though the subject does not necessarily agree with or wholeheartedly endorse them. Building on these foundational concepts, Gudjonsson (1992) advanced a useful threefold classification of false confessions.

First, "voluntary" confessions are not induced by the police in any way; often there is no interview. The confession may constitute a response to publicity for a serious offense. Certain individuals are well known to their local police station for attempting to take responsibility for a whole series of crimes reported in the media. This kind of behavior may be motivated by a desire for notoriety, or to relieve a general feeling of guilt, or reflect an inability to distinguish fact and fantasy. A second kind of unreliable confession is the "coerced-compliant," a false confession motivated by the desire to escape from a highly stressful situation, such as police custody The immediate gain, frequently nothing more than the need for short-term resolution and predictability of future events, becomes a more powerful influence on the subject's behavior than the more uncertain long-term effects of the confession, even if the allegation concerns a serious offense. The majority of false confessions encountered in practice are coerced-compliant. Wagenaar concurs that common occasions for false confessions include the suspect taking an apparently easy way out, not anticipating the long-term consequences, perhaps thinking it will be possible to retract later, or choosing the only conceivable way out because the suspect is unable to cope with immediate pressures, for example, of confinement and interrogation, or a situation where the suspect is simply outwitted by the questioner – a not inconceivable event in the inevitably oppressive atmosphere of police custody (Wagenaar et al. 1993). A third category of false confession is the "coerced-internalized." People who do not trust their own memory may begin to accept the suggestions of apparently authoritative and knowledgeable individuals, like police investigators. Such suspects may become temporarily persuaded that they might have, or did indeed, commit the crime. Such a confession is more likely to be elicited by gentle, rather than aggressive, interviewing. It may be retracted later on, although the subject is more likely to stick to internalized admissions than is the coerced-compliant confessor who never truly accepted responsibility in the first place. Even if a confession is later withdrawn, the subject's memory may be permanently distorted (Wagenaar et al. 1993) and the confession itself might still be admissible in court.

Some legal jurisdictions recognize the risks involved in attributing significant evidential weight to confession evidence even in the absence of illegitimate pressure from the investigating authorities. Elsewhere, the psychology of false confessions is simply not recognized (see, e.g., Hodgson 2000's depictions of French criminal process). In Scotland and the Netherlands, no one can be convicted on the strength of a confession alone. In some US jurisdictions, a police station confession by the defendant, without corroboration, is not considered sufficient to sustain a conviction. In jurisdictions without a general corroboration requirement, there may be particular protections for vulnerable suspects, as in England and Wales, but they tend to allow weak corroboration, such as the suspect's "special knowledge" of circumstantial details that only the perpetrator of the crime would know, to support the admissibility of the confession. However, the notion that the suspect's guilt is reliably confirmed by his awareness of facts not communicated to the public is a dubious method of corroborating confessions. There are documented instances of suspects who confess in apparent knowledge of such information, only later to be proved innocent in the light of further revelations. They must have become aware of the relevant facts at some point during the period of detention, possibly through careless "confabulation" whereby police interviewers unwittingly feed information to the suspect (Kassin and Wrightsman 1988).

In prosecutions of domestic violence, theories of learned helplessness in consequence of domestic abuse have been influential in developing defenses or partial defenses, for example, in murder cases where prolonged exposure to domestic abuse has apparently caused the victim to respond by killing the abuser. Colloquially known as "battered woman syndrome," this psychological disorder is said to establish a causal relationship between the pattern of abuse suffered by the defendant, her psychological reactions to it, and her perception of her subsequent conduct. There is some evidence that lay persons, and therefore potential jurors, tend to consider that victims of domestic violence should leave home to escape it. This rationalist interpretation of behavior appears to be a powerful influence on jury reasoning, relatively impervious to expert evidence explaining why the obvious escape route is not employed in many such cases (Dodge and Green 1991). It is difficult to communicate to nonspecialists that prolonged experience of a highly controlled situation and exposure to violent sanctions for disobedience can reduce to vanishing point a person's subjective free choice. A battered partner might have genuinely (and sometimes even reasonably) believed that deadly force was the only way to escape from a perilous situation in which his or her own life was in mortal danger (Ewing 1987).

Future Directions

Behavioral science research and expertise have influenced many aspects of criminal investigation and the way evidence is presented to the court. Psychological autopsies and offender profiling have assisted the police in some cases. Sociological and psychological research has established that the emphasis on orality of testimony has had a markedly detrimental effect on a whole range of witnesses who have in the past struggled with the performance elements of the adversarial trial. In many jurisdictions, the evidence of vulnerable witnesses is now facilitated by technological innovations such as "live link" videoconferencing or videorecording (see, e.g., Roberts and Zuckerman 2010, Chap. 10). Criminal courts owe much to researchers in these fields. In addition, some aspects of behavioral science research are gaining ground in terms of providing evidence that may assist in reaching a verdict. Greater use of expert evidence in rape cases, in particular to dispel commonly held assumptions about the likely effect of having been raped upon a person's demeanor and likely response, could be very useful.

However, behavioral science is not yet ready to assist the court with the most problematic and the most crucial of the judgments that the jury has to make, namely, whether someone is speaking the truth or telling lies. Experts are not allowed to testify as to the credibility of a particular witness, although they may be able to explain the effect of a mental disorder on sufferers in general. At the same time, the literature on what, if any, exhibited behaviors constitute evidence of lying is at best inconclusive (Vrij 2000). Some years ago naïve faith in technological development encouraged flirtations with truth drugs and lie detector machines, but experience has since shown that they are not reliable indicators of dishonesty. Simple devices measuring levels of moisture on the palms of the hands may indicate nervousness, and nothing more (Saxe 1991). Polygraphs are used in criminal investigations in Canada, Israel, and Japan, but nowhere more than in the United States; albeit that courts in some US states will still not accept polygraph evidence (Patrick and Iacono 1991). In the United Kingdom, a working group produced such a devastating report on polygraph machines that the Government of the day abandoned any attempt to introduce them as a source of evidence in criminal trials (Working Group of the British Psychological Society on the Use of Polygraphs 1986).

The only conclusions to be drawn from the voluminous psychological literature on lying, credibility, and demeanor is that, first, neither laymen nor machines are accurate in recognizing liars or lies. Secondly, there is no valid scientific reason to believe that there is any observable indicator of lying behavior that an expert could use to identify it on behalf of fact finders in criminal adjudication. If the consequence of successful cross-examination in court is to produce behaviors commonly associated with lying but equally consistent with nervousness or confusion, the only inferential conclusions are negative. Behavioral science research certainly casts doubt on various familiar categories of evidence and challenges many commonly held lay assumptions capable of frustrating the courts' truth-seeking function. Unfortunately, however, it cannot provide much in the way of positive information as to where the truth of the case lies. The credibility of a witness, or the weight to attach to their evidence, lies in the two issues of reliability, depending on memory, and truthfulness. Behavioral science can tell us only of generalities, not specifics. Were it otherwise, jury dominance over the ultimate issue could be challenged. Unless and until our understanding of human conduct and thinking develops into a demonstrably convincing and coherent scientific discipline affording positive, case-specific guidance to fact finders, jurors (and victims and defendants) will be left at the mercy of their "common-sense" perceptions of behavior – prejudices, stereotypes, myths, and all.

Overview

This entry will address the issues associated with police racial and ethnic bias, including research findings, research limitations, and policy issues related to reducing racial and ethnic disparities.

Introduction

Why are racial and ethnic minority citizens overrepresented at every stage of the criminal justice system? Answers to this reality are not clear or straightforward. While all criminal justice actors enjoy a degree of discretion in their decision-making, it is particularly important to determine whether bias is present in the early stages of the criminal justice process because initial biases can cause reverberations throughout the entire criminal justice process. The differential treatment patterns and practices of police in their decision-making have historically manifested itself in several ways (e.g., sexism, ageism) and garnered widespread attention. More specifically, a well of skepticism exists among citizens, scholars, legislatures, and the judiciary in response to the overrepresentation of racial and ethnic minorities at every stage of the criminal justice process. In response to the appearance of racial and ethnic animus in police decision-making, voluntary, legislative, and judicial data explorations of racial and ethnic biases in police discretionary decision-making have been encouraged.

The following manuscript addresses several issues associated with racial and ethnic bias among police. First, decision-making is contextualized as it relates to bias among policing discretion. Second, the difficulties of measuring bias-based policing are discussed within the context of future research endeavors. Third, research findings across various police decision-making points, including the use of force, the decision to arrest, and automobile stops, are presented. Fourth, commentary on contemporary manifestations of bias-based policing is set against a post-9/11 America. Fifth, bias-based policing results are tempered by some of the acknowledged limitations of prior research. Finally, a policy framework for reducing racial and ethnic disparities among officer discretionary decision-making is advanced.

Discretionary Decision-Making

Discretionary decision-making has been defined as "informal decision-making or [a] judgment by professionals based on unwritten rules, their training and their experience" (Samaha 2005, p. 10). Discretionary decision-making stands in opposition to mandatory acts, such as obeying the law and following departmental policies. Davis (1969) contextualized the relationship between law and discretion as "where law ends, discretion beings" (p. 3). Although this absolute dichotomy is false (see Walker 1993), law and discretion are related to the concept of procedural justice. Procedural justice refers to processes of fairness (Sunshine and Tyler 2003). Police discretionary decision-making is perceived to be fair when it is based on facts. Rarely is the legitimacy of fair outcomes called into question. Alternatively, discretionary decision-making is problematic when the judgments of police are seen as unfair, not based on law, and/or based on personal biases. This lead Walker (1993) to conclude that "[t]he problem is not discretion itself, but its misuse" (p. 4). More specifically to the topic at hand, bias-based policing or the selective/differential enforcement patterns and practices of police on minorities have the appearance of abuse.

Contrary to folklore, research indicates police receive overwhelming support from the public, and this support has been stable over time (Tuch and Weitzer 1997). There is, however, some variability in police support across races and ethnicities. These differences are most pronounced in African American and Hispanic communities (Withrow 2006). African Americans and Hispanics consistently report higher rates of dissatisfaction with police when compared with Whites (Ramirez et al. 2000). Although explaining the satisfaction gap between racial and ethnic groups is beyond the scope of this entry, one source for the disparity may be police differential treatment of minorities during encounters. Minorities believe police are more punitive during their encounters with police (Lundman and Kaufman 2003; Eith and Durose 2011). Beckett and Sasson (2004) noted that perceptions of being singled out impact attitudes of procedural justice and may explain "African Americans' growing alienation from the institutions of criminal justice" (p. 126).

When looking at the prevalence of actual police-citizen encounters, a disconnect between perceptual and actual disparities becomes apparent. The Bureau of Justice Statistics (BJS) has collected and reported on the racial and ethnic composition of police-citizen encounters every triennial since 1999. In the most recent report titled *Contacts between Police and the Public*, Eith and Durose (2011) estimated that 16.9 % of the population, 16 or older, will have some sort of face-to-face interaction with police (p. 1).

Among the 40.0 million citizens who encountered the police through citizen- and police-initiated contacts, 14.2 % were African American and 15.2 % were Hispanic (Eith and Durose 2011, p. 5). These statistics nearly mirror the proportion of racial and ethnic minorities in the general population.

Taken together, it appears as though the quality of interactions between police and racial and ethnic minorities may be the driving force behind differences in support. There are two observations on this issue. First, isolated instances of police misconduct usually have a bigger social impact than expected. For example, media sensationalism surrounding incidents like Rodney King, Abner Louima, and Amadou Diallo has the potential to generalize individual incidents of police misconduct to all law enforcement officials. Despite the isolated nature of events, racially and ethnically motivated events are, to a certain degree, vicariously experienced by all minorities. Second, bias-based policing may be more pronounced than these statistics indicate because contextual nuances are rarely expressed in national surveys. This is explored further in the following section (Walker and Meyers 2000).

Contextualizing Bias-Based Policing

Despite evidence of racial and ethnic neutrality among police, identifying race- and/or ethnicity-based police patterns and practices is a much more difficult task (Eith and Durose 2011). First, race and/or ethnicity are rarely absolute influencers of police behavior. Rather, bias typically manifests itself in other more subtle ways. The importance of race and/or ethnicity varies on a spectrum in which race and/or ethnicity is more or less influential among other exogenous factors (Higgins et al. 2008). Relevant factors have typically been found to fall within the following typologies: environmental, organizational, officer, and situational. Environmental factors suggest that the physical location in which the police-citizen encounter occurs has bearing on police decision-making. Organizational factors prescribe that departmental norms, culture, and structure differentially impact police decision-making. Officer factors charge that the characteristics of the officer, such as the age, race, ethnicity, experience, training, and rank of the officer, may influence decision-making. Situational factors, including citizen demographics and the reason(s) for police interaction, are also said to have pull in police decision-making. Finally, it is important to note that race and/or ethnicity may interact with each of these factors. Research found that minorities were significantly more likely to be arrested than nonminorities (Smith et al. 1984). The impact, however, vanished when the suspects' demeanor was taken into consideration and concluded that while race and/or ethnicity is influential, it does not have a direct impact on police decision-making. Similarly, other research found that police use significantly more force during encounters with minorities, yet the relationship between race and the use of force dissipated after controlling for neighborhood disadvantage and crime rates (Terrill and Reisig 2003). These examples highlight the complex nature of identifying bias within police decision-making.

The use of race and/or ethnicity may also be motivated by legally accepted practices (Schafer et al. 2006). These practices include drug courier profiles and "race out of place" policing. Drug courier profiling is a set of characteristics, including the race and/or ethnicity of the citizen, thought to be typical among persons carrying illegal drugs. Although highly subjective, police may stop, question, and under some situations search citizens fitting the drug courier profile. In choosing to engage citizens, race and/or ethnicity may be one of many factors contributing to police decision-making. Alternatively, "race out of place" policing indicates that race and/or ethnicity is the sole determining factor for police engagement with citizens. "Race out of place" policing refers to the legal practice of police engaging citizens based on a perceived inconsistency between the racial and/or ethnic identity of the citizen and the racial and/or ethnic composition of the ecological or neighborhood context (Ramirez et al. 2000). Each of these instances demonstrates the importance of distinguishing legal and extralegal factors when identifying race- and/or ethnicity-based policing patterns and practices. Given the contextual uniqueness of bias-based policing, the influence of race and/or ethnicity cannot be considered within a vacuum. Rather, many nuanced factors can be said to be important in police decision-making.

Measuring Bias-Based Policing Through Discretionary Decision-Making

Measuring police discretionary decision-making has been a difficult task because racial and ethnic animus is likely to be concealed within police behaviors that have low visibility. Since there is a great deal of difficulty in observing low-visibility police behaviors, the bulk of bias-based policing research has focused on systematic difference in decision-making outcomes. Furthermore, a host of discretionary decision-making outcomes with a variety of analytical approaches have been studied. The three most prominently featured discretionary decision-making points among bias-based policing focus on the use of force, the decision to arrest, and automobile stops. Each of these decision-making points provides measurable aspects to the cognitive processes of police discretionary decision-making.

The capacity to use coercive force is one of the defining features of police work. Racial and ethnic minorities consistently report the use of force against them is excessive. Among the people who contacted the police, only 1.4 % had force threatened or used against them (Eith and Durose 2011). Among threats and the use of force statistics, the most frequently cited type was being "pushed" or "grabbed" (53.5 %) (Eith and Durose 2011, p. 13). Although the threat and use of force is uncommon, African Americans and Hispanics are overrepresented among these instances. In fact, African Americans were more than twice (3.4 %) as likely to have force threatened or used against them than the national average (Eith and Durose 2011, p. 12). African Americans are also overrepresented among deadly force statistics.

Although consequences for the use of force are more immediate to citizens, the consequences of "arrests have a far more pervasive effect on peoples' lives" (Walker 1993, p. 39). An arrest occurs when a person is taken into custody for the purpose of criminal prosecution or interrogation. The evidentiary threshold for determining the appropriateness of an arrest is probable cause. Unfortunately for citizens, probable cause does not provide safeguards against arrest harassment or police failure to make an arrest. Further complicating the issue is the unreliability of arrest data because the point at which an individual is arrested is hard to identify and highly influenced by departmental norms. Some jurisdictions report arrests when citizens are formally restrained. Other jurisdictions, however, report arrests when citizens are formally booked. The difference between each reporting threshold represents a "dark figure" of arrests in which bias-based policing may be concealed (Erez 1984). Despite sporadic arrest reporting, official arrest statistics indicate that African Americans are overrepresented. Tillman (1987) estimated that nearly two-thirds (65.5 %) of African American males and one-third of African American females (29.6 %) will be arrested before the age of 30. This rate is nearly two times the rate of White males (33.9 %) and three times the rate of White females (10.1 %) arrested before the age of 30. While there is some indication that race and ethnicity may be an indirect cause for the decision to arrest, the equitable application of the probable cause standard appears to be a myth.

The final discretionary decision-making point measures automobile stop outcomes. Racial profiling, a phenomenon also known as "driving while Black/Brown," has gained parlance in American vernacular to represent the bias-based treatment patterns and practices of police on minorities during automobile stops (Alpert et al. 2007). Automobile stops present three unique opportunities for measuring the discretionary decision-making of police: stop initiation, searches, and the punitiveness of automobile stop outcomes. Research on automobile stop initiation focuses on the racial and/or ethnic composition of drivers stopped by the police. The bulk of drivers are stopped by the police for traffic enforcement-related issues, but more discretionary stops, such as investigatory stops, are also often captured. Among the citizens that encountered the police during automobile stops, 8.4 % were White, 8.8 % were African American, and 9.1 % were Hispanic (Eith and Durose 2011, p. 7). The relative parity of these statistics does not demonstrate the full dynamics of police-citizen automobile stops. Additionally, some researchers indicate that stop initiation poorly represents instances of bias-based policing because police officers can "only determine the race of the driver prior to the stop approximately 30 % of the time" (Alpert et al. 2007, p. 48). In response to these issues, researchers (Fallik and Novak 2012) have suggested that post-stop decision-making provides better indications of the presence of bias.

The second measured outcome from automobile stops concerns the officers' decision to search the driver, vehicle, passenger(s), or a combination of some or all three entities. African American drivers (12.3 %) were approximately three times more likely to be searched than white drivers (3.9 %) and approximately two times more likely to be searched than Hispanic drivers (5.8 %) (Eith and Durose 2011, p. 10). Despite being searched at a greater rate than Whites, minorities are no more likely to possess illegal contraband (Engel and Calnon 2004; Lundman 2004). Predicting searches becomes even more complicated when race and ethnicity are considered among other exogenous factors. Some researchers have concluded that race and/or ethnicity was one of numerous search predictors (Williams and Stahl 2008). Alternatively, while race remained a consequential predictor for Smith and Petrocelli (2001), Whites were nearly two and half times more likely to be the subject of consent searches. Consent searches are the most discretionary type of search legally permissible. Others found that the influence of race and/or ethnicity is neutralized once search types or typologies are specified (Fallik and Novak 2012; Schafer et al. 2006). There are eight search types permissible by Supreme Court precedent and police procedures: (1) searches incident to arrest, (2) inventory searches after a vehicle has been impounded, (3) searchers based on the presence of an existing search warrant, (4) probable cause searchers, (5) searches where contraband was discovered in plain view, (6) searches following a drug-sniffing dog alert, (7) "Terry" stop or pat-down searches, and (8) searches subsequent to the driver or passenger(s) given consent. When identifying typologies, each of the search types is typically categorized by the level of discretion required to execute the search, such as highly discretionary or non-discretionary. Finally, some researchers have discovered that race and/or ethnicity is not a significant predictor of searches (Higgins et al. 2008).

Similar nuanced inconsistencies can be said to exist for automobile stop punitiveness. Some research indicates that African Americans are more likely to be treated harshly by police sanctions (Engel and Calnon 2004). Alternatively, a more contextual awareness of less punitive outcomes among police-citizen encounters in that African Americans and Hispanics were less likely to receive punitive sanctions from the police but were more likely to be stopped for highly discretionary reasons, such as equipment violations and failure to signal (Novak 2004). This suggests that police may be using minor traffic violations as a pretextual motive for engaging minority drivers in automobile stops. An additional measure for an automobile stops' punitiveness considers how long citizens are detained. This body of research lacks consistency in the nature, strength, and sometimes presence of bias-based policing (Withrow 2006).

Contemporary Examples of Bias-Based Policing

Although most bias-based policing research has primarily focused on African Americans, other racial and ethnic groups have also been the targets of bias-based policing patterns and practices. Arab Americans, persons of Middle Eastern decent, and Muslims became the targets of bias-based policing. After September 11, over 12,000 Arab Americans, persons of Middle Eastern decent, and Muslims were "detained and held indefinitely" on suspicion of terrorism (Nguyen 2005, p. XVII). Furthermore, public opinions for the use of racial and ethnic profiling changed due to the fear society felt toward terrorist and terrorism. Prior to September 11, national opinion polls generally reported opposition to the use of race and/or ethnicity in policing, but after September 11, the majority of society supported the targeting of Arab Americans, persons of Middle Eastern decent, and Muslims in airports (Nguyen 2005) leading one scholar to explain, "after 9/11 the rules changed and everything we had learned about the social costs and ineffectiveness of racial profiling was largely ignored" (Withrow 2006, p. 244).

In response to terrorism threats at home, the US Justice Department began pressuring local and state authorities to enforce and enact immigration laws. Hispanics were particularly victimized by these efforts because of the loose US-Mexican border. Post September 11, political leaders "framed the border as a critical front in the war on terror" (Nguyen 2005, p. 92). For example, Arizona enacted the "Support Our Law Enforcement and Safe Neighborhoods" Act – also known as Senate Bill 1070 – which was designed to discourage illegal immigration in the United States. The bill required that police, during the course of lawful citizen contact, determine the immigration status of the people they encounter when there is reasonable suspicion to believe that the individual is an illegal alien, encouraging police to target Hispanic populations. Although the law never took effect, due to a federal injunction and a Supreme Court decision in 2012, it remains uncertain what the future will hold on this issue.

Research Limitations

Despite researchers' best efforts to explain the etiology of bias-based policing, two methodological controversies have arisen from this body of literature that are important to consider when drawing conclusions regarding the breadth and depth of bias in policing activities. First, there is some concern for officer self-reports measures of bias-based policing. Concern stems from the fact that officers may be aware of how their accounts of situations are being used and they may fear that accurately reporting some or all of their encounters with citizens may reflect poorly on them or the department. In automobile stops, research indicated that this may result in officers "ghosting' their data or recording race and ethnicity incorrectly to create the illusion of equitable stop and search procedures" (Williams and Stahl 2008, p. 231). This type of reactivity or Hawthorne effect greatly threatens the external validity of results. Alternatively, others found few signs of officer disengagement in his time-series analyses of encounters once it was announced that data collection would begin (Novak 2004). Given these inconsistencies, researchers should measure officer reactivity when using self-report data.

Second, measuring bias-based policing patterns and practices requires that benchmarks for performance be set. Benchmarks enable researchers to determine if police behavior matches expected decision-making outcomes. Deciding on an appropriate benchmark can be problematic with illusive and transitory populations. Related to automobile stops, "given a group of citizens stopped by the police (the numerator), what could be used as a denominator to conclusively determine whether certain drivers were stopped at a disproportionate rate?" (Schafer et al. 2006, p. 187). Over time, a variety of benchmarks have evolved, including census or modified census population estimates, information from drivers' licenses, not-at-fault accident data, blind enforcement data, systematic social observations of violator populations (e.g., "rolling surveys"), and internal comparisons. Despite the ecological fallacies found in all of these benchmarks, coverage error – from the benchmark to the expected outcome – is more pronounced under certain research contexts. Bias-based researchers should select the benchmark that minimizes coverage error within the research context while recognizing that all benchmarks have their own limitations.

To address both of these issues, future research must tie theoretical rationales to understandings of police discretionary decision-making by using multiple data sources, ideally coming from a triangulation of sources, including "police-reported, citizen-reported, and observer-reported data" (Lundman 2004, p. 343). Single source data explorations are often riddled with invalidity, inconclusiveness, and, worst of all, biases. A triangulation of data sources has the best potential to address each of these methodological issues. Efforts should be coupled with research that examines equitable and lawful policing that results in compliance by citizens (Piquero 2009). The etiology of police discretionary decision-making is best achieved from these methods.

Policy Implications

The improper use of race and/or ethnicity places the legitimacy of all law enforcement agencies in jeopardy, but efforts to curb the abuse of discretion must weigh individual rights against crime control objectives. To control the use of discretionary decision-making, several evidence-based practices have been proposed and implemented (Davis 1969; Gottfredson and Gottfredson 1988; Walker 1993). Four typologies have emerged among these strategies: structure, confinement, checking, and options.

Structural policies are rules, regulations, and guidelines that identify appropriate behaviors. An example of a structural policy geared toward bias-based policing is mandatory reporting. Mandatory reporting policies require that officers document every encounter they have with citizens. Although some mandatory reporting initiatives have been court ordered, many of these policies are agency initiated. By documenting the nature of encounters, departments have developed early intervention systems (EIS) to address issues of bias-based policing (Walker and Katz 2008). EIS is a tool used to identifying individual officers who disparately engage racial and ethnic minorities. These officers are more commonly known as "bad apples." The use of EIS has been encouraged by the shift toward electronic record keeping.

Confinement policies are rules, regulations, and guidelines that limit police behaviors. Examples of confinement are easily found in Supreme Court decisions. For example, the Supreme Court in *Whren v. United States* ruled that an officers' initial decision to engage citizens during automobile stops has to exceed the reasonable suspicion threshold. This ruling attempted to limit officer racial and ethnic pretextual motivations for stopping citizens. Although *Whren* may have encouraged police to hide behind minor traffic infractions when using race and/or ethnicity inappropriately during automobile stops, it confined police-initiated contacts to the reasonable suspicion standard.

Checking refers to the review of discretionary decision-making which can occur before, during, or after a decision is made. In order to be effective, the person or entity doing the checking must have a direct influence on the decision-making process. An example of a checking policy initiative used to combat bias-based policing is community review boards (CRBs). CRBs vary in the nature of the citizen input, review substance, breadth of the jurisdictional issues addressed, organizational structure, and operating policies. Functionally, CRBs provide external accountability to police-community-related issues. Police departments with CRBs have improved community-police relations, and cities with CRBs have higher rates of reporting. Both of these research findings indicate that communities with CRBs have greater confidence in police and the justice process. In essence, CRBs increase the visibility of citizen-reported police misconduct by providing an external review of instances in which an officers' discretionary decision-making may have gone awry (Walker 2001).

Perhaps the most radical policy suggestion presented in the research literature is the abolition of discretionary. While abolition has typically been focused on court discretionary decision-making, few supporters of abolition contest that police discretionary decision-making should remain unaffected. However, many researchers feel as though abolition is "unrealistic and ill-advised" (Gottfredson and Gottfredson 1988, p. 51). One of the extra option policy initiatives jurisdictions are moving toward would include issuing summons to appear in court, tickets, or fines for possession of person use marijuana.

Since drug crimes disproportionately affect minorities, the extra option – other than arrest – reduces the racial and ethnic disproportionality among arrest statistics (Johnson et al. 2008). Providing extra options may not address bias-based policing directly, but it has the ability to shift the disproportionality of discretionary decision-making to less punitive outcomes, thereby reducing the prevalence of more punitive outcomes. Furthermore, it allows researchers to more easily identify instances of bias in more punitive response outcomes.

Finally, although the ability to use coercive force may be the sine qua non of policing, extralegal police aggression – also known as police brutality – is not without safeguards (Holmes and Smith 2008). Each of the aforementioned strategies for reducing discretionary decision-making (i.e., structure, confinement, checking, and options) can be found in recent use of force policy responses. First, police training began incorporating the use of force continuum into their curriculum. The use of force continuum is a structural tool that teaches officers proper responses to escalating threats of violence. Second, the Supreme Court rulings in *Tennessee v. Garner* (1985) confined the use of deadly force to instances where a reasonable person would have acted on the threat of death or serious physical injury posed by a suspect. The check on the use of force occurs after the fact. When an officer discharges their weapon, departments often require that the officer explain the circumstances that precipitated the discharge of their weapon in a formal report. Supervisors review these reports before determining if it was a "good" or "bad" shot. Finally, police departments nationally began issuing and training officers in the use of nonlethal weapons, such as pepper spray, Tasers, and rubber bullets. Additional options allow police to apply the appropriate amount of force to the level of escalation each situation requires. While each of these typologies uniquely addresses discretionary decision-making, when combined they have reduced the racial and ethnic disparity of persons killed by police (Sherman and Cohn 1986).

Summary

Bias-based policing conjures up raw emotions. It is a complex social question rooted deeply within the historical and structural conditions of America. Acknowledging the existence of bias-based policing potentially compromises the legitimacy of the police in a democratic society. Ignoring or minimizing bias-based policing does not provide relief to targeted populations and does not hold individuals or organizations accountable. Research on the extent and impact of bias-based policing yields inconsistent conclusions. Furthermore, the impact of policies designed to address bias-based policing is difficult to determine. Given the current state of bias-based policing, the most productive conciliatory path is to join others in calling for further examination into the extent to which race and/or ethnicity impacts discretionary decision-making.

Bicycle Theft

Aiden Sidebottom and Shane D. Johnson
Department of Security and Crime Science,
University College London, London, UK

Overview

Bicycle theft is defined as the unauthorized removal of a nonmotorized pedal cycle. This usually refers to the theft of an entire bicycle but can also include theft of component parts and accessories such as lights, seats, and wheels. Bicycle theft can take many forms, reflecting the range of motivations of bicycle thieves. Some cycles are stolen for transportation purposes, others to joyride or to trade in for cash or drugs; *specific types* of bicycle may be stolen to order; a cycle may be stolen to facilitate another crime – an example of a *crime multiplier*; or a bike may be stolen in response to an offender’s bicycle being taken, thus comprising part of a *crime chain*. Awareness of the heterogeneity of cycle theft is important; different forms of cycle theft are likely to demand different preventive responses.

Several studies suggest that bicycle theft is a common problem. However, compared to other high-volume property crimes, bicycle theft has been the subject of limited academic research, whether in criminology or related fields such as transport and urban planning. This is often attributed to the incompleteness of relevant police-recorded crime data where reporting rates and detection rates are both low. Failures to report may be explained by victim expectations that the chances of either detection or recovery of the bicycle are slim. Most lacking is reliable evaluations of what works to reduce cycle theft.

The spiraling obesity rates experienced in many industrialized regions in recent years (OECD 2011) have, among other things, prompted government agencies to promote cycling as a healthier alternative to motorized transport. Opportunity theories of crime would predict that increases in the population of cyclists will be associated with increases in the opportunities for cycle theft. This is a concern given that research suggests that bicycle ownership (a proxy for opportunities), measured at the country level, is strongly correlated with national levels of cycle theft. Moreover, the risk of cycle theft, real or perceived, is found to be a significant barrier to cycling (Rietveld and Koetse 2003). Cycle theft hence threatens to jeopardize strategies to better integrate cycling as a sustainable, health-promoting form of transport. Enriching our knowledge of cycle theft and determining effective ways to reduce it are therefore of social as well as academic importance.

This entry sets out what we know about cycle theft and the progress made in reducing it. It begins by describing the extent of cycle theft internationally and articulates challenges associated with measuring it. Next, some of the harms caused by cycle theft are outlined, particularly theft as a potential barrier to cycling uptake. Third, the major known correlates of cycle theft victimization are addressed. This is followed by a discussion of efforts to prevent cycle theft, and we conclude by outlining as yet unanswered research questions.

The Extent of Bicycle Theft

Several studies suggest that bicycle theft is a common problem and that levels are highest in countries where cycling is popular. For example, using data from the International Crime Victim Survey (ICVS) and the European Survey on Crime and Safety (EU ICS), Van Dijk et al. (2007) report that bicycle ownership levels are strongly correlated ($r = 0.76$, $n = 30$, $p < 0.05$) with national levels of bicycle theft. They find that the risks of cycle theft are considerably higher in Northern Europe, where cycling is widespread, than in North America and Australia where cycling is less prevalent. To illustrate, the 1-year victimization prevalence rates for 2003/2004 in Holland were 6.6 per 100 population, whereas in Australia, the figure was only 1.2. Despite this variation, across countries cyclists were consistently found to be around three times more likely to have their bike stolen than car owners their car or motorcyclists their motorbike (Van Dijk et al. 2007).

In the USA, the ICVS indicates that levels of cycle theft remained stable between 1998 and 2004, with a mean rate of 2.8 victims per 100 population. In terms of official crime statistics, the FBI classifies bicycle theft as an example of “larceny-theft,” alongside offenses such as shoplifting and pocket-picking. In 2009, bicycle theft constituted 3.4 % of all incidents of larceny, equating to over 200,000 offenses. This likely underestimates the true extent of the problem as many thefts fail to reach the police because of underreporting. Data from the ICVS, for example, suggest that roughly half of all bicycle thefts are reported to the police (Van Kesteren et al. 2000). The US National Crime Victimization Survey showed a fivefold difference between cycle thefts that are reported to the police and those that actually occurred in 2008.

A similar picture is observed in England and Wales. Police-recorded crime data indicate only minor yearly fluctuations in the levels of cycle theft since 1997, with around 100,000 thefts recorded in 2010/2011. This contrasts sharply with estimates from the British Crime Survey (BCS) which suggest that over the same year, around 526,000 incidents occurred. Moreover, while recorded crime figures depict cycle theft as largely static over the past decade, for the same interval of time, estimates from the BCS suggest an upward trend both in the volume of cycle theft and rates per 10,000 bicycle-owning households. The true figures are probably higher still given the BCS excludes those aged under 16 from the survey sampling frame. Furthermore, viewed against a backdrop of general reductions in property crimes (for both data sources) in England and Wales since 2002/2003 (and elsewhere in the world), the increase in bicycle theft relative to changes in other types of acquisitive crime is more dramatic than the absolute change.

Explanations for the "dark figure" of cycle theft are varied. Interviews with cycle theft victims (Bryan-Brown and Saville 1997) reveal that many fail to notify the police because they believe they are unlikely to apprehend offenders or recover stolen cycles. Insofar as available data can be used to examine this, this notion appears to be justified. For example, police detection rates for bicycle theft are consistently low. In Sweden, where cycle theft is common, only 1 % of cycle thefts result in an arrest (Bra 2008). In England and Wales, sanction detection rates in 2008/2009 were marginally better at 5 % (Walker et al. 2009) but still low compared to other types of offenses. Poor police detection rates may partly be explained by the fact that for many bike thefts, there is little relationship between the offender and the victim, and thus identification of suspects is difficult. Another factor is the proof-of-ownership problem. Many cyclists cannot provide adequate proof that they own their bicycle. A study conducted by the London Metropolitan Police Service found that of the 836 cyclists surveyed, over three quarters did not know their cycle frame registration number (see Halliwell and Brown 2011). This frustrates reunification efforts because should stolen cycles be recovered by the police, there is often insufficient evidence to pursue the case and detained offenders will often be released without charge. Even when offenses are reported, Gamman et al. (2004) argue that many fail to be processed further because bicycle theft is considered a low police priority. A similar observation is made in China where Zhang et al. (2007) claim that the police tend to limit their attention to repeat bicycle thieves.

The Harms of Cycle Crime: Theft as a Barrier to Cycling

In many urban settings, current levels of obesity as well as road congestion and traffic-related air and noise pollution are generally considered to be excessive. Various initiatives have been proposed to reduce automobile dependency and encourage the use of bicycles. These include changes to infrastructure (such as the creation of cycling lanes), better integrating cycling with other forms of public transport (such as increasing cycle parking facilities at transport nodes), and increasing the provision of cycles (such as bike-sharing schemes). At this time the results appear mixed. While cycling remains relatively rare in many industrialized nations (compared to motorized transport), other countries have seen encouraging increases involving a small fraction but quite large numbers of individuals. Cycling in London, for example, has increased by 91 % since 2000 (TFL 2008). Similar trends, albeit less dramatic, have also been observed in several European cities (Oja and Vuori 2000) and in parts of the USA (Xing et al. 2008).

Commentators argue that cycle theft poses a threat to attempts to increase cycling rates – one that presently has received inadequate attention (see Sidebottom et al. 2009). Research finds that theft, and the fear of cycle theft, is a barrier to cycle use. Experience of theft can deter individuals from cycling due to an inability to replace the stolen bike or due to (justified) apathy that it may happen again. This is supported by interviews with cycle theft victims that find a sizable portion of cyclists do not replace their bicycle once stolen and/or cycle less frequently (Davies et al. 1998; Mercat and Heran 2003). Direct or vicarious experience of theft may also increase the likelihood of cyclists' purchasing cheap, low-quality cycles and associated protective measures (such as locks) due to an assumption that theft is an inevitable "occupational hazard." Tentative support for this comes from a study by Mercat and Heran (2003) in which half of all cycle theft victims who purchased a replacement bike opted for a second-hand rather than a new cycle.

Reducing cycle theft may also yield wider social benefits. A review of numerous programs to increase physical activity internationally reports strong evidence that as the number of cyclists and pedestrians increases, the frequency of collisions between those groups and motorists *decreases* (Jacobson 2003). The putative mechanism underlying this pattern is that motorists modify their driving behavior when they expect or encounter cyclists and walkers. To slightly overstate the point, effectively reducing the risks of cycle theft may indirectly contribute to improvements in the safety of cyclists.

The Bicycle as Crime Target

Bicycles are attractive targets for theft. They fit Clarke's (1999) CRAVED model which outlines the attributes commonly associated with frequently stolen items. Johnson et al. (2008) suggest that bicycles are:

Concealable – Widespread availability of cycles in many urban settings enables cycle thieves to remain inconspicuous when riding away on a stolen bicycle, rendering the crime concealable.

Removable – If poorly locked, bicycles are easy to remove. With respect to theft *from* cycles, quick-release features (such as wheels or seat posts) that are inadequately secured also require little effort to steal.

Available – More bikes provide more opportunities for cycle theft, as well as a greater demand for bicycles and component parts.

Valuable – While many bicycles are available cheaply, others can cost in advance of $3,000 dollars, thereby constituting a desirable crime target. There is also often an imbalance between the value of the bike and the value of the security measures used to protect it.

Enjoyable – Bicycles offer utility as a form of transport, particularly in regions where public transport is inadequate and/or expensive. From an offender's perspective, a stolen cycle can also facilitate further crimes through increasing the speed and area in which they can forage for crime targets.

Disposable – Thieves can easily sell stolen bikes, either "whole" or "piecemeal." Abundant buyer's markets for stolen bikes, swelled by the internet, may also provide an incentive to steal.

Correlates of Victimization

Research has identified several factors that are reliably associated with the risk of cycle theft. Consistent with the national trends described above, opportunity plays a central role. Cycle theft is found to concentrate at locations where opportunities are plentiful. Common examples include in and around the victim's home, at university campuses, or at transport hubs. Estimates from the BCS suggest that over half of all reported cycle thefts in England and Wales occur immediately outside the victim's home (i.e., bikes stored in sheds or gardens), thereby constituting the most common location for cycle theft. University campuses often house a large proportion of high-performance and expensive bicycles that attract bicycle thieves. A study by Lovejoy and Handy (2011) at the University of California, Davis, shows that 19 % of sampled cyclists report experiencing cycle theft on campus during their tenure, with 9 % suffering a theft in the previous year. A regular supply of opportunities in the form of parked bicycles also explains why railway stations are common locations for theft. Data from the British Transport Police, who are responsible for policing the railway system of England, Wales, and Scotland, show that recorded cases of theft and damage to bicycles increased by 74 % between 2002/2003 (3,277 offenses) and 2006/2007 (5,686 offenses) and have remained at comparatively high levels since (in 2010/2011 there were 5,859 offenses). Other forms of vehicle theft and criminal damage fell considerably over the same period.

The way in which cyclists lock their bicycles is a further factor. Several studies report that stolen bicycles are often locked insecurely (Mercat and Heran 2003; Roe and Olivero 1993). A study comprising over 8,500 observations of cycle locking events in the UK found "secure" locking techniques – therein measured as instances where both wheels and the frame were attached to parking furniture – to be atypical; other (less secure) ways of parking a bicycle were dominant (Sidebottom et al. 2009). Such findings are important in highlighting the potential limitations of schemes that aim to increase the use of robust locks but neglect to provide guidance as to how they should be applied.

Insecure locking behavior is also likely to be a function of what a cycle is locked to. In urban settings many bicycles are *flyparked* (Johnson et al. 2008): fastened to street furniture not designed for that purpose (i.e., railings, parking meters, and trees). Flyparked cycles may be at greater risk of victimization because such furniture affords little scope for secure locking (as defined previously). While this is yet to be systematically tested, recorded crime statistics from the London Borough of Camden, England, indicate that of all bicycles reported stolen between 2004 and 2005, 72 % were flyparked. From a town planning perspective, high levels of flyparking may indicate insufficient or inappropriate (poorly positioned) formal bike parking opportunities.

In one of the few empirical studies not to employ Anglo-American data, Zhang et al. (2007) assessed household- and area-level determinants of residential cycle theft victimization in the city of Tianjin, China, using data collected as part of a household survey. Informed by the routine activity approach, they find, among other things, that the risk of cycle theft is positively associated with neighborhood-level crime and deviance, therein taken to be a proxy measure for exposure to offenders. The number of adults per household (a proxy for guardianship) was found to be a significant protective factor against cycle theft.

Research across many crime types demonstrates that previous victimization is a reliable predictor of future victimization. While the evidence for repeat cycle thefts is limited, those studies that are available suggest the same patterns are also apparent. Analyzing survey data from the Netherlands, Wittebrood and Nieuwbeerta (2000) report that prior victimization was significantly associated with the probability of further incidents of bicycle theft. This is consistent with data from Melbourne, Australia, which indicate that under a third of bicycle theft victims accounted for 60 % of all thefts reported (Johnson et al. 2008). Put differently, a small proportion of cycle theft victims disproportionately account for a large number of cycle theft victimizations. Extending this concept further, Johnson et al. (2008) show that the risk of cycle theft victimization displays a contagion-like quality across space and time. Analyzing recorded crime data from Dorset, England, they find that in the wake of a cycle theft and for a period of around 4 weeks, further incidents were more likely to occur at locations nearby and up to a distance of about 450 yards.

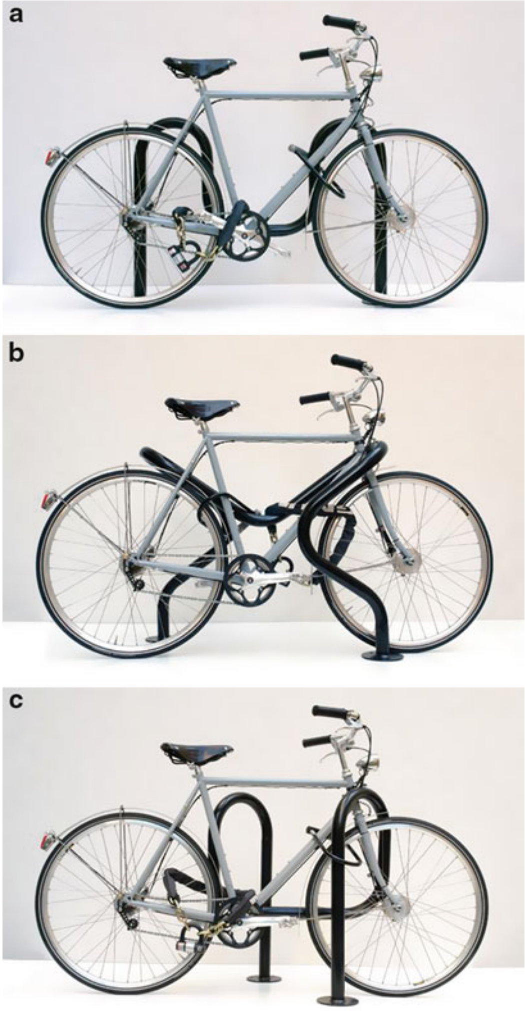
Prevention

Johnson et al. (2008) provide a review of various interventions designed to reduce cycle theft and categorize them as follows: (1) interventions which seek to catch bicycle thieves *in the act*, (2) initiatives designed to deter bicycle thieves through focusing on the registration and recovery of bicycles (thereby making stolen bicycles more risky to dispose of), (3) schemes to improve the security of bicycle parking facilities (both cycle parking furniture and parking facilities as a whole), and (4) interventions which try to increase the security of locks and/or the manner in which they are applied.

Despite various interventions being implemented, few robust evaluations of attempts to reduce cycle theft are available. Situational measures designed to prevent (rather than detect) bicycle theft through altering cyclists' behavior in ways that increase the effort and risk associated with stealing cycles have yielded positive results. Two studies evaluating situational measures warrant mention. The first concerns a targeted publicity campaign in which stickers – designed to improve cyclists' locking practice by depicting how to lock a bicycle securely – were attached to a series of bicycle parking stands in on-street public cycle parks in the UK (Sidebottom et al. 2009). Pre- and post-intervention observations found modest albeit statistically significant improvements in the security of cyclist's locking practices at bicycle parking stands where the intervention was fitted compared to the control sites. Importantly this pattern was consistent across two different settings. Sidebottom and colleagues conclude that communication strategies of this kind might constitute a cheap, scalable "quick win" against cycle theft.

The second intervention concerns the design of bicycle parking furniture. As alluded to previously, how secure a cycle is parked is partly a function of what it is locked to. The common Sheffield (or ∩-shape) stand, for example, makes it difficult for cyclists to lock the frame and both wheels. Many only lock the top crossbar of their bicycle as it runs parallel to the horizontal bar of the Sheffield stand. Alternative designs have therefore been developed in an attempt to encourage more secure locking styles. An example is the caMden M-shaped stand, which is designed in such a way so as to remove the opportunity for cyclists to lock the crossbar to the stand, encouraging the cyclist to instead apply a more effective locking practice, such as securing both the wheels and frame. Thorpe et al. (2012) describe a study in which the impact of seven prototype parking stands designed to increase securer locking practices was evaluated (some examples are in Fig. 1). Using data gathered through 3,563 observations, they report significant improvements in locking practice at the prototype bicycle stands compared to the control (Sheffield) stands. They also report considerable variation *between* the prototype stands in terms of their effectiveness and popularity.

A limitation in the above studies is noteworthy. Both evaluations use locking practice as an intermediate outcome measure which is hypothesized to precede the ultimate outcome measure of interest (a reduction in bike theft). In both studies, it was important to conduct an intermediate outcome measure evaluation because if the interventions are not found to change the locking practice of cyclists, then there would be no reason to expect an impact on levels of cycle theft. The reason the study authors did not conduct an ultimate outcome measure evaluation was due to shortcomings in the recorded crime data available, specifically the level of geographical resolution associated with incidents of bicycle theft. Briefly, many recorded bicycle thefts are often reported as having taken place at landmarks, shops, or streets rather than specific locations, and consequently the exact site of the theft



Bicycle Theft, Fig. 1 Examples of the prototype bicycle parking stands (Source: Thorpe et al. 2012) event cannot easily be determined. This lack of information may, in part, reflect the low priority status that some suggest the police attach to cycle theft. This lack of specificity is problematic because the interventions described in the above studies were implemented at *specific* cycle parking sites located on streets where other – nonintervention – cycle parking opportunities are also available. This presents an obvious problem for analysis because it would be unclear whether stolen bicycles were fastened to "treatment" street furniture or elsewhere (be that control parking stands or flyparked). This brings forth two issues. First, such problems are likely generalizable to other settings and should be considered in advance of conducting comparable studies. Second, further research is needed to determine whether, as hypothesized, positive changes in the locking practice of cyclists are associated with reductions in cycle theft.

Future Directions

We began this entry by highlighting the lack of bicycle theft research hitherto. Various areas of relevance to policy and practice remain unexplored. The following are considered to be some of the most important. They are outlined with the intent of stimulating the reader to initiate further research.

The Stolen Bike Market

It is a widely held assumption that many bicycles are stolen with the intention of being resold for profit. Indirect evidence in the form of low recovery rates of stolen cycles lends support to this claim. It follows that disrupting the market for stolen cycles holds much potential for effectively reducing the problem. Evidence on the use of *market reduction approaches* (see Sutton 2005) to reduce other forms of acquisitive crime suggests that such strategies are promising. These schemes employ various tactics to make the buying and selling of stolen goods riskier for offenders. Regrettably, little is known about the market for stolen bicycles, specifically the role of online (legitimate) auctions as a means of disposal. The proof-of-ownership problem implies that few bicycles could easily be identified as stolen, which aids the resale of stolen bikes and reduces the risk of apprehension. Research concerned with better illuminating the dynamics of stolen bike markets is therefore required.

Cycle Hire Schemes: Criminogenic or Criminocclusive?

Cycle hire schemes are increasingly common in many urban settings. The rationale is that increasing the availability of cycles may lead to increases in the number of individuals cycling – the sought-for objective. As already mentioned, increased cycle usage – particularly as an alternative form of urban transport – may generate increases in the levels of cycle theft. Alternatively, cycle hire schemes may lead to reductions in theft by providing secure storage facilities and (as is often the case) by requiring cyclists to register their personal details, including banking information, before they can access cycles thereby reducing anonymity which would otherwise facilitate cycle theft. Furthermore, where financial details are required to use the cycles, this should reduce the rewards associated with stealing hire cycles.

Successful cycle hire schemes could reduce bicycle theft in other ways. For example, if such schemes result in an increase in the number of cyclists, and if the parking facilities for cycle hire schemes are located near to other cycle parking facilities, this may provide additional natural surveillance at such facilities throughout the day. Furthermore, the components used to manufacture cycle hire bikes can often only be used for that type of bicycle. For example, the London cycle hire scheme uses bicycles constructed of oversize, non-common parts which are incompatible with non-hire bikes. An advantage of this is that such cycles are unlikely to be stripped for parts (see Johnson et al. 2008) as they are not typically the sort of bicycle that would be attractive to own, largely because they are designed so as to be clearly identifiable as for-hire bicycles, thereby making them unattractive to thieves who might seek to steal them, or those who might want to purchase a second-hand bike.

To our knowledge, no published research has explored the impact of cycle hire schemes on the levels and patterns of cycle theft. Such research could usefully guide prevention efforts as well as inform the operation of cycle hire schemes.

Residential Cycle Theft

Victimization surveys maintain that the majority of bicycles are stolen from in and around the victim's home. Yet the research which is available on bicycle theft is overwhelmingly concentrated on theft of bicycles from public locations. This asymmetry may relate to the ease with which agencies (and individuals) with the ability to influence the conditions conducive for cycle theft can be mobilized to behave differently; there is arguably greater scope, through levering public agencies responsible for crime prevention and community safety, to manage and reduce opportunities for cycle theft in public places than to persuade individuals in or around their homes to modify their behavior. Either way, there is much to be gained by analyzing the patterns of residential cycle theft with a view to determining practical ways to tackle it.

The Broken Bike Effect

Abandoned bicycles are common. In calculating the volume of cyclists at the University of California, Lovejoy and Handy (2011) estimate that 23 % of total rack capacity was taken up by abandoned cycles. The relationship between abandoned bikes and theft is yet to be empirically examined, but observational research by Gamman et al. (2004) suggests that bicycle parking stands adjacent to damaged or abandoned bicycles are less popular among cyclists, even when located closest to the destination served. Two outcomes are envisaged, both leading to increases in cycle theft. First, they argue that on encountering abandoned bikes, cyclists may be provoked to park their cycles elsewhere, possibly leading to an increase in flyparking (which as described often affords less secure parking opportunities than street furniture which is designed with bike parking in mind). Second, they suggest that cycle parks containing damaged or abandoned bicycles may signal to offenders that this is an area lacking in guardianship thereby constituting a conducive location in which to offend. Gamman et al. (2004) refer to this phenomenon as the "broken bike" effect, invoking the mechanism underpinning the well-known broken windows theory (Kelling and Wilson 1982).

The broken bike effect is yet to be empirically tested, but could be. For example, in a recent study Keizer et al. (2008) examined broken windows theory using an experimental manipulation. Briefly, they observed peoples' behavior in a real-world setting for a range of conditions. In one experiment, leaflets were attached to cyclist's parked bicycles, and for one condition other leaflets were scattered (by the experimenters) on the floor nearby. In the "control" condition, no leaflets were littered in this way. The empirical question was whether the way in which cyclists' would dispose of the leaflets was affected by the experimental condition. That is, would those who discovered the attached leaflets in the presence of litter also be more likely to litter than their counterparts? The results of the study were quite conclusive, clearly demonstrating that where litter was present, cyclists were also more likely to litter than when it was not. While there may be ethical issues associated with conducting an analogous experiment; that is, by seeing if cycles are more likely to be stolen where "broken bikes" are introduced at a parking facility and when they are not, it would be possible to see if the removal of existing damaged or abandoned bikes has an effect on rates of cycle theft.

In closing, it is evident that cycle theft is a considerable problem. Relative to other property that people are likely to own, such as an iPad, they are also valuable. However, they are routinely left unguarded around the home and in public spaces thereby making them attractive targets to thieves. Recent studies have focused on the problem of bicycle theft, but it is quite clear that more research is required if we are to understand how to prevent this type of crime. As has been discussed, if cycle theft continues to increase, it is possible that this will be an impediment to the uptake of cycling and hence the sustainable transport agendas of many countries.

Biological Geographical Profiling

Mark Stevenson and Steven Le Comber
School of Biological and Chemical Sciences,
Queen Mary, University of London,
London, UK

Overview

Geographic profiling was originally developed as a statistical tool in criminology, where it uses the spatial locations of linked crimes (e.g., murder, rape, and arson) to identify areas that are most likely to include the offender's residence. In criminology, geographic profiling uses these crime locations to create a probability surface that is overlaid on the study area to produce a geoprofile. Geoprofiles do not provide an exact location for the criminal's home, but allow the police to prioritize investigations by systematically checking suspects associated with locations in descending order of the height of these locations on the geoprofile, facilitating an optimal search process based on decreasing probability density. The technique has been extremely successful in this field, and it is now widely used by police forces and investigative agencies around the world. Recently, the same techniques have begun to be applied to biological data, initially in the field of animal foraging and hunting behavior, but also in epidemiology and invasive species biology, where geographic profiling can be used to locate the sources of infectious disease or of invasive plants and animals as a prelude to targeted control efforts. As the technique has now been shown to be useful in such divergent scenarios from those for which it was originally developed, it raises the intriguing possibility that geographic profiling could be a useful general tool for studying spatial patterns in biological data. Here, we review the work in this area, and suggest further avenues for future research. We go on to consider ways in which this highly successful transfer of ideas from criminology to biology might also work in the opposite direction.

Introduction

Geographic profiling is well established in criminology, with a proven track record of success. It has recently begun to be applied to biological data. In this entry, we will first of all outline the basic ideas underlying geographic profiling (section "Introduction"), before reviewing the existing studies of biological data using geographic profiling, and considering how these differ from the model's application in criminology (section "From Criminology to Biology: Applications of Geographic Profiling to Biology"). Having discussed how ideas from geographic profiling have fed into biology, we will suggest ways in which ideas from biology might in turn feed-back into geographic profiling in general, and criminology in particular (section "From Biology to Criminology: Future Developments").

Geographic Profiling

Geographic profiling is a statistical technique used in criminology to prioritize large lists of suspects in cases of serial crime, such as murder, rape, or arson. The need for such a technique arises because criminal investigations often generate too many, rather than too few, suspects; for example, the enquiry into the Yorkshire Ripper murders in the UK between 1975 and 1980 generated 268,000 names (Doney 1990). Obviously, it will frequently be impractical to follow up all but a handful of these names. Clearly, any technique that allows police forces to prioritize such lists of suspects is likely to be of enormous value.

In essence, the model is simple and depends on two concepts: (1) distance decay and (2) the buffer zone (Rossmo 1999; Le Comber et al. 2006). The first concept relies on the fact that, because traveling incurs costs in time, effort, and/or money, most crimes occur relatively close to an "anchor point" (usually the criminal's home or workplace) (for instance, 70 % of arsons occur within two miles of the arsonist's home (Sapp et al. 1994)). However, the anchor point is also typically surrounded by an area (the buffer zone) in which offenses are relatively rare. This buffer zone arises partly because of increases in detection risk related to reduced anonymity within the criminal’s local neighborhood, and partly because the number of criminal opportunities increases geometrically with distance traveled from home. The size of the buffer zone is specific to an individual criminal and location, since it will be affected by the criminal’s willingness and ability to travel, and also the underlying distribution of opportunities for crime (the “target backcloth” (Rossmo 1999)).

Geographic profiling uses the opposing effects of distance decay and the buffer zone to calculate the probability of offender residence for each location within the study area, producing a three-dimensional probability surface (called a jeopardy surface). Locations in which it is more likely that the offender might live are indicated by higher points on the jeopardy surface. Overlaying the 3-D jeopardy surface on to a search area map produces a geoprofile. Hence, geoprofiles do not provide an exact location for the criminal’s home, but they allow the police to prioritize search locations by starting with the highest point on the jeopardy surface. Systematically checking locations in descending order of their height on the geoprofile probability surface describes an optimal search process based on decreasing probability density. Therefore, the better the geographic profiling model performs, the shorter the search before the real location of the offender’s home is found (Rossmo 1999).

Because geographic profiling seeks to describe an optimal search, the model’s performance can be assessed simply by asking how high up the jeopardy surface, the true anchor point lies. This measure, which is expressed in terms of the hit score percentage (HS%), is the proportion of the study area (in criminology, this is usually the area bounding the crimes, plus an additional 10 % of the area surrounding this, to allow offender source locations to come from outside the area of the crime sites) that must be searched before the true anchor point is found. The smaller the HS%, the more accurate is the geoprofile. A hit score of 50 % is what would be expected from a nonprioritized (i.e., random or uniform) search; thus, a hit score of 10 % describes a search which is five times more efficient than a random search (Rossmo 1999).

From Criminology to Biology: Applications of Geographic Profiling to Biology

Although geographic profiling was originally designed to apply to crimes such as murder, rape, and arson, it has had numerous success in other areas, including burglary, counter-insurgency and piracy (see, e.g., Kucera (2005) and Rossmo and Harries (2011)). Based on its applicability to a range of problems in a variety of different fields, its application to biological data was an obvious next step. Given the similarities between criminal hunting behavior and animal behavior, it is perhaps not surprising that the first paper to apply geographic profiling in a biological context looked at animal foraging (Le Comber et al. 2006).

Geographic Profiling and Animal Foraging

Geographic profiling was introduced to biology in a 2006 paper in the *Journal of Theoretical Biology* (Le Comber et al. 2006). In this study, the authors used data from radio-tracking studies of two species of bat, the common and soprano pipistrelles (*Pipistrellus pipistrellus* and *P. pygmaeus*) in north-east Scotland. A previous study had identified both roost sites and foraging sites, and the authors fitted Rossmo’s criminal geographic targeting (CGT) model (Rossmo 1999) for each bat and showed that the fitted model parameters (*B*, *f*, and *g*) could be used to locate roost sites, using foraging sites as input, analogous to crime sites. Interestingly, the fitted values differed between the two species, despite their close genetic relatedness. This probably reflects their different foraging strategies; *P. pygmaeus* forages preferentially in riparian habitats (i.e., along the edges of rivers and lakes) that support higher numbers of insect taxa (Gressit and Gressit 1962; Townes 1962), while *P. pipistrellus* is more generalist. This specialization in *P. pygmaeus* is likely to mean that this species must forage over greater distances to locate sufficient prey items to satisfy its energetic demands. This was an intriguing result, suggesting that when anchor points such as nests, roosts, or dens are known, fitted CGT model parameters could provide a concise way of describing complicated foraging patterns.

The bat study was followed by a second study of animal foraging, this time in bees, but using laboratory data rather than field data (Raine et al. 2009). Bees were allowed to enter a flight arena approximately 1 m square, via a central hole, and allowed to forage on artificial flowers containing a sucrose solution. Again, the CGT algorithm successfully located this entrance. Fitting model parameters in the same way as in the bat study also showed that when the artificial flowers were presented at higher density, the size of the buffer zone decreased. This was of interest because, in criminology, little may be known about the target backcloth, since law enforcement agencies will have information on crimes committed, but not always on potential crimes that were not.

Another interesting extension of this study involved using "virtual" bees, in a similar experimental design to the real bees, using a variety of plausible foraging algorithms (including spiral searches, nearest-neighbor methods, and a variety of others). Just as the fitted model parameters could be used to differentiate between the foraging patterns of the two bat species, they could be used here to distinguish between different foraging rules. Crucially, for biologists, these could also be compared to the behavior of the real bees, allowing the authors to rule out some of the suggested foraging algorithms as inconsistent with the patterns observed in the real bees.

At about the same time, Martin et al. (2009) used geographic profiling to study great white shark predation on seals off the coast of South Africa. Again, much of the interest of this paper derived from aspects tangential to the main purpose of geographic profiling, that is, identifying sources for point pattern data. In this case, the study identified a well-defined search base or anchor point 100 m seaward of the seal's primary island entry-exit point. This is not where the chances of intercepting seals are greatest, and the authors suggested that it represented a balance between prey detection, capture rates, and competition. In addition, the different geoprofiles observed for sharks of different ages showed that smaller sharks exhibited more dispersed search patterns and had lower success rates than larger sharks, suggesting either that hunting success improved with experience or that larger sharks excluded smaller sharks from the most profitable areas.

Geographic Profiling and Epidemiology

As noted above, animal foraging behavior has much in common with criminal hunting behavior. The extension of geographic profiling to epidemiological datasets, however, involves several important differences, notably the increased importance of multiple sources, and the possibility, for some diseases, of secondary sources. These issues are discussed in section "Differences Between Biology and Criminology."

The application of geographic profiling to epidemiological data fills a surprising gap in epidemiology. As Buscema et al. (2009) pointed out, classical epidemiology tends to model the spread of infectious epidemic diseases, and few attempts have been made to identify the origin of the epidemic spread. This is surprising because, as Le Comber et al. (2011) noted, in many diseases, infection sources can be highly clustered: For example, malaria parasite transmission is strongly dependent on the location of vector breeding sites, and most transmission only occurs within short distances of these sites; in Africa, these distances are typically between a few hundred meters and a kilometer, and rarely more than 2–3 km (Carter et al. 2000). Because of this clustering, untargeted control efforts are highly inefficient. Although source reduction of mosquito larval habitats can dramatically mitigate malaria transmission (Yohannes et al. 2005; Gu et al. 2006; Walker and Lynch 2007; Gu and Novak 2009), the transient nature and diversity of potential vector breeding sites makes the identification and control of breeding sites difficult (Carter et al. 2000). As a result, evidence-based targeting of interventions is more efficient, environmentally friendly, and cost-effective than untargeted intervention. This, of course, is exactly why the problem geographic profiling was designed to solve.

The first attempt to apply geographic profiling to epidemiological data was by Buscema et al. (2009). This study examined Chikingunya fever, foot and mouth disease, and cholera, but concluded that geographic profiling was less efficient than the authors' preferred artificial intelligence method, the H-PST (Hidden-Pick and Squash Tracking) Algorithm. However, this study mistakenly used the distance between the peak of the geoprofile and the correct source as a measure of model performance. As Rossmo (1999) was careful to point out, geographic profiling does not attempt to provide a point estimate for the anchor point (here, the infection source), as methods such as spatial mean, spatial median, and center of minimum distance seek to do; rather, it describes an optimal search strategy. Because of the complexity of jeopardy surfaces, the distance from the peak of the geoprofile to the anchor point is irrelevant; what matters is what percentage of points within the study area have higher Z values than the anchor point. In fact, when there are multiple sources of infection (e.g., the malaria cases examined by Le Comber et al. (2011)) this is an important advantage of geographic profiling over the H-PST algorithm, since methods that provide point estimates of sources will typically perform poorly when there is more than one source. When Le Comber et al. (2011) revisited one of the case studies in the Buscema paper (John Snow's data on the 1854 London cholera outbreak (Snow and Frost 1936)), geographic profiling performed extremely well.

Geographic Profiling and Invasive Species Biology

Another promising area for the application of geographic profiling to biological research concerns the spread of invasive species, an area with more in common with epidemiology (e.g., multiple and secondary sources) than with animal foraging. The issue is not trivial; invasive species are now viewed as the second most important driver of world biodiversity loss behind habitat destruction and have been identified as a significant component of global change (Vitousek et al. 1996; Wilcove et al. 1998). The cost of invasive species can run from millions to billions of dollars per occurrence (Mooney and Baker 1986; Pimentel et al. 2001), and invasive species have been shown to affect native species through predation and competition, modify ecosystem functions, alter the abiotic environment, and spread pathogens (Strayer et al. 2006; Ricciardi 2007). In addition, the problem is likely to get worse as climate change and anthropogenic influences lead to increased range shifts (Hulme 2007). For these reasons, prevention and control of invasive species has been identified as a priority for conservation organizations and government wildlife and agriculture ministries globally (Mooney and Baker 1986; Hulme 2006).

Although only one study has looked at invasive species and geographic profiling, the results are promising. Stevenson et al. (2012) analyzed historical data from the Biological Records Centre (BRC: http://www.brc.ac.uk/) for 53 invasive species in Great Britain, ranging from marine invertebrates to woody trees, and from a wide variety of habitats (including littoral habitats, woodland and man-made habitats). For 52 out of these 53 datasets, geographic profiling outperformed spatial mean, spatial median, and center of minimum distance as a search strategy. The study also compared fitted parameter values between different species, groups, and habitat types, with a view to identify general values that might be used for novel invasions where data are lacking, with some success.

Differences Between Biology and Criminology

The first applications of geographic profiling to biology involved fairly straightforward mapping of the basic concepts from criminology: In these studies, animal foraging sites were used to identify animal roosts (or other home locations) in the same way that crime sites are used to identify probable areas of offender residence in criminology. However, later extensions, and most notably studies of invasive species biology and epidemiology, differ in a number of areas.

In criminology, the application of geographic profiling will usually (or at least often) deal with the crimes of single individual with a single anchor point, often (hopefully!) over a short period of time. In contrast, biological data can involve multiple organisms (and hence multiple anchor points), secondary anchor points, and extended time periods.

Multiple Anchor Points

In criminology, although jeopardy surfaces may have several peaks, relating perhaps to the criminal's home, work place, or a relative's home (or, in the case of the Hillside Strangler, the two homes of the two cousins who committed the crimes together; Rossmo (1999)), it is usually assumed that the crimes are linked; that is, they are carried out by a single individual (some applications of geographic profiling to terrorist activities may be an exception). In invasive species biology or epidemiology, it is usually impossible, or at least impractical (e.g., perhaps requiring expensive genetic testing to identify particular strains of virus, or genotypes of individual plants or animals), to link events to individual sources. For example, the malaria cases in Le Comber et al. (2011) were treated as a single group of "crimes," although it is possible that six or more *An. sergentii* breeding sites were involved. In this case, data was simply pooled and the heights of each potential source on the geoprofile examined separately; Stevenson et al. (2012) took a similar approach with invasive species. At this point, no studies have explicitly examined the effect of multiple sources on geographic profiling model performance, although the data in Le Comber et al. (2011) and Stevenson et al. (2012), along with some simulation data (unpublished), suggest that geographic profiling's performance relative to simple measures of spatial center tendency (spatial mean, spatial median, center of minimum distance) will increase as the number of sources increases.

Secondary Anchor Points

Murder victims do not go out and commit murders; victims of arson do not go out and burn down other buildings. Similarly, in the context of animal foraging, seals predated upon by great white sharks do not then predate upon other seals. However, the sites of new biological invasions can go on to act as sources for further waves of invasion; similarly, in many disease systems, infected individuals will go on to affect other individuals. These secondary sources/anchor points may dramatically alter the spatial patterns observed.

Extended Time Periods

In criminal investigations, the persistence of a series of linked crimes over a number of years obviously represents a failure of law enforcement; cases such as Jeffrey Dahmer (1978–1991) or the Yorkshire Ripper (1975–1980) (Rossmo 1999) are, hopefully, an exception. In biology, this need not be the case, and longer-term datasets may in fact be highly desirable. Ecological datasets in particular can span decades or even centuries (Stevenson et al. 2012), and can involve multiple "outbreaks," while criminal cases typically span shorter periods of time. In this sense, biological data may offer a distinct advantage over criminological data. Invasions and disease outbreaks have long histories and repeated outbreaks, so assuming that repeated invasions follow similar histories, previous outbreaks (perhaps with known sources) can be used to validate the geographic profiling model. Future spread can then be predicted using parameters established from the organism's own invasion history.

From Biology to Criminology: Future Developments

Clearly, geographic profiling has already made important and interesting contributions to biology, in fields including animal foraging, invasive species biology, and epidemiology. In this section, we will consider how insights from biology might feedback into geographic profiling theory, and criminology generally. Broadly speaking, these fall into three classes: (1) mathematical developments; (2) spatial methods; and (3) experimental methods.

Mathematical Developments

The underlying mathematics of geographic profiling has recently attracted attention, notably from O'Leary (2009, 2010). Here, we will briefly discuss four areas of interest. These are (1) incorporating a Bayesian framework; (2) fitting model parameters; (3) incorporating explicit models of behavior; and (4) considering different mathematical distributions in addition to the exponential functions used in the Rossmo model (Rossmo 1999).

Bayesian Statistics

Recent papers on the mathematics of geographic profiling, notably those of O'Leary (2009, 2010), highlight two different approaches to the subject. Because of its origins in criminology, one of these approaches is highly practical, concentrating on the model's use as a tool in investigations of serial crimes such as murder, rape, and arson. Most applications of the model within biology to date have taken a similar approach, with the main results of the various studies (Le Comber et al. 2006; Martin et al. 2009; Raine et al. 2009) being to demonstrate the applicability of the model to different types of data. O'Leary's papers take a different tack, considering the underlying mathematics themselves, with less attention paid to the model's practical utility. It might be argued that these are two parallel avenues of research that are unlikely to intersect. However, our view is that it might be possible to bring these two strands together. The acid test, of course, will be whether different mathematical approaches (e.g., embedding the model within a Bayesian framework, or considering other underlying spatial distributions such as the Cauchy distribution (see below)) can improve the model's performance.

Fitting Model Parameters

Rossmo's (2009) model uses three parameters, *B*, *f*, and *g*. *B* is the width of the buffer zone, while *f* and *g* together determine first the increase in the probability of a crime occurring moving outward from the anchor point toward the edge of the buffer zone, and second the decrease moving further beyond this. In criminology, the width of the buffer zone is typically set at half the mean nearest-neighbor distance, with *f* and *g* set at 1.2. To date, studies in biology have either adopted this method (Martin et al. 2009; Le Comber et al. 2011), or attempted to fit spatial data to known anchor points (Le Comber et al. 2006, 2011; Raine et al. 2009). This may matter because multiple sources (see above) could lead to different patterns of "crime sites," depending on their number and proximity to each other; there may also be some use in using fitted model parameters as descriptors of more complex spatial patterns, as in Raine et al. (2009). Thus, the issue of precisely how model parameters are fitted may be come of interest. Although to date published studies have used only simple methods (see, for instance, (Le Comber et al. 2006; Raine et al. 2009)), an obvious approach is to use Markov Chain Monte Carlo (MCMC) methods to explore parameter space. In our view, this is likely to be an interesting area of development, although care will have to be taken to avoid well-known problems of over-fitting (Hawkins 2004).

Incorporating Explicit Models of Behavior

Current geographic profiling models are generic. They express simple geometric patterns such as exponential or normal decay. The Rossmo model incorporates *B*, an explicit parameter for the buffer zone, but *f* and *g* remain as exponential decay functions. Rather than fitting a generic statistical model, the aim of mathematical modeling is to find true relationships that underlie the data. Ideally we should have models that have parameters that explicating relate to some aspect of predator behavior, invasive species dispersal, or epidemic spread.

Distribution Models

Models of offender behavior will obviously depend on the precise spatial distribution of crime sites. Canter and Hammond (Canter 2006) examined logarithmic, exponential, and quadratic functions, while the Rossmo model (Rossmo 1999) uses an exponential function, as does CrimeStat (Levine 2009). O'Leary (2010) introduced the idea of alpha as a single parameter from a normal distribution, suggesting that it could be used as a predictive parameter to represent average offense distance; the optimized parameter *B* in (Stevenson et al., 2012) fulfills similar criteria if *f* and *g* are fixed in the Rossmo model. In a later study, O'Leary (2010) compared single- and two-parameter normal, and single- and two-parameter exponential functions, concluding that there was no difference between normal and exponential in the single-parameter models in Baltimore county burglaries; neither of the two-parameter models performed as well as the single-parameter models.

The distribution models appropriate for offender behavior are likely to be substantially different to models appropriate for disease and animal dispersal. Invasive species dispersal is likely to be strongly nonnormal; dispersal includes both short local dispersers and long escalated movements: for example, Levy flight (see, e.g., (Viswanathan et al. 2000; Viswanathan and Bartumeus 2002; Bartumeus 2009)). This type of dispersal is described by a Cauchy distribution (Viswanathan et al. 2000). The Cauchy distribution is related to normal distributions, in that dividing one normal distribution centered on zero by another centered on zero will yield a Cauchy distribution. In fact, the Cauchy distribution can be made to resemble a smoother version of the Rossmo distribution, but avoiding the latter's sharp peak at the radius of the buffer zone. In addition, Cauchy distributions also allow the inclusion of a width or thickness parameter, gamma, which describes the "fatness" of the distribution's tail, relating to the amount of longer dispersal events. A Cauchy distribution could also be used in criminology, and would relate to the occurrence of two different types of jumps already documented in the criminology literature, prowlers, and commuters (Rossmo 1999).

Running Models Forward in Time

Finally, one intriguing possibility following O'Leary's work (2009, 2010) is that of running models forward in time – rather pleasingly, this would link current models of spatial epidemiology such as risk mapping (Leung et al. 2002) with geographic profiling, which is essentially retrospective in nature. O'Leary suggests using integration to generate a function that can then be used to predict future spread. The possibility of producing risk maps for offenders to predict possible sites of future burglaries or even more serious crimes is a real possibility, even when based on a small number of data points, in contrast to current hot spot mapping.

Spatial Developments

In the same way that mathematical studies are beginning to feed-back into geographic profiling, it seems likely that techniques from spatial epidemiology may offer interesting avenues for research; in fact, as noted above, O'Leary's proposed approach (2009, 2010) may go some way toward allowing techniques from spatial epidemiology and spatial ecology to feed-back into geographic profiling.

One fruitful area is likely to be ecological niche mapping. Ecological niche mapping is used in invasion biology and macroecology to predict species spread based on associated habitat types (see, e.g., Kaschner et al. (2006)). Species found in particular ranges are associated with particular ecological factors; these can then be mapped to new ranges to predict spread based on these niche factors. We suggest that this type of modeling can be used to generate priors or hyperpriors for a Bayesian model of geographic profiling. True prediction requires knowledge of not only where the species is now and where it is dispersing to, but also what habitat is suitable for it to live in. Our prior estimation of where a species is capable of dispersing to will inform the geoprofile to produce a surface that includes both types of information. Obviously, this approach could also be applied to criminology, using information about neighborhood quality, street lighting, open spaces, frequency of police patrols, and so on.

Experimental Developments

One advantage the biologist has over the criminologist is that, in biology, experiments are far easier, and certainly less ethically problematic. For example, Raine et al. (2009) were able to manipulate the target backcloth in a study of bee foraging behavior that would simply not be possible in the context of crime. Thus, biology might be better placed to explicitly test some of the underlying assumptions and methodologies of geographic profiling.

A related point, alluded to above, is that in biology datasets, long-term datasets are more abundant, and replication is more exact: For example, in invasive species biology, it is possible, and even common, to have (1) repeated invasions of the same geographical area by the same species; (2) repeated invasions of different geographical areas by the same species; (3) repeated invasions of the same geographical area by different species. A rigorous comparison of these different cases may help to disentangle those aspects of any observed spatial patterns that are due to the invader's behavior and/or biology, and the habitat's own attributes. The analogous exercise – understanding what aspects of spatial patterns of crimes are due to the criminal's behavior, and what aspects are due to the peculiarities of the target backcloth – is much more difficult.

Conclusions

Although the application of geographic profiling to biological datasets is still relatively new, the early indications are that the method's considerable success in the field of criminology may be replicated in areas as seemingly diverse as animal foraging behavior, epidemiology, and invasive species biology. This is encouraging because, despite the obvious similarities between criminal hunting behavior and animal foraging behavior, there are several key differences that can arise in biology, notably the importance of multiple and secondary anchor points. To date, most studies using geographic profiling in biology have concentrated on demonstrating the method's utility. In contrast, much of the mathematical research has pursued a parallel line of enquiry, ignoring the method's application. Future work may bring these two seemingly distinct approaches closer together, and we suggest that, just as methods from criminology have proved of use in biology, some techniques from biology – for example, niche modeling, Levy flight, and optimization methods – may prove useful in criminology.

Biometrics; Border control; Migration policing; Technology

Overview

This entry examines the role of biometric technologies and databases in border policing. It commences with a definition of biometric technology and then proceeds to discuss the political economy of the biometric industry since the attacks of 9/11. Drawing upon a range of critical scholarship, a number of theories are discussed which interrogate the changing nature of citizenship and identity in relation to biometric databases. The entry also discusses some of the critiques raised by civil libertarians in relation to the assemblage of large-scale and frequently transnational databases. The discussion concludes by considering the constitutive role of biometric technologies in broader processes of the securitization of mobility.

Key Issues/Controversies

Over the past decade borders and border enforcement have become the subject of intense scholarly interest within criminology, and more generally within the social sciences. In 1996 Saskia Sassen presciently identified border crossing as a "strategic site of inquiry about the limits of the new order" (xvi) under conditions of globalization. The drive – most readily apparent in states of the global north – to secure seamless circuits of capital, trade, and skilled migration, while fortifying national boundaries against perceived threats of organized crime, terrorism, and illegal migration, has resulted in considerable political, technical, and financial investment in border control (Aas 2011). The "informatization" of the border has been a crucial component of such developments – with a proliferation of databases, records, and files on citizens, migrants, business visitors, asylum seekers, and cross-border workers. Biometric identifiers are key elements of these proliferating databases which seek to control flows, identify risks, and banish threats (van der Ploeg 2006). This entry will detail key areas in the study of biometrics and border policing. While there is a technical literature in this field, primarily concerned with implementation (e.g., Woodward et al. 2003), this entry will focus on key issues and controversies that arise from critical scholarship. It will commence with a definition of biometrics, and then discuss the political economy of biometrics in relation to the security industry. The entry will then proceed to position the study of biometrics and border policing within wider debates about the changing nature of borders and mobility under conditions of globalization.

At the outset it is important to provide a brief explanation of what is under discussion in the scholarship surrounding "biometrics." In general, biometric technology involves the collection of digital representations of physiological features unique to an individual, such as fingerprints, pattern of the iris, the retina, or voice patterns. Digital representations are then normally transformed into binary code by means of an algorithm to construct a template. These templates are accumulated in a centralized database that is accessed when, on subsequent occasions, the finger, hand, face, eye, or voice is presented to the system. If a matching template is found, the person is acknowledged and counts as known to the system. In some instances the representation may be stored on a chipcard rather than a template. The user then has to present the chipcard and requested body part to prove they are the legitimate user of the card (van der Ploeg 1999, p. 37).

Biometric technology uses two main methods for identity checks: verification and identification. Verification is essentially confirming people are who they say they are, and is achieved through one-to-one matching. One-to-one matching is used, for example, in the identification of people traveling on false passports, but might also be used to facilitate more rapid immigration procedures for those possessing the designated biometric documents. Biometric technologies are also increasingly utilized in identification (that is determining who the person is, or in some instances is not) through one-to-many matching. The clearest example of one-to-many matching is evident in the use of facial recognition technology matched to CCTV cameras. Air passengers can have their faces scanned and checked against a database of "terrorists" or other "wanted" people (Lyon 2003).

In the wake of September 11, 2001 (hereafter9/11), and the subsequent "war on terror" hi-tech solutions to problems of security — such as facial recognition technology, iris and retina scans, and smart identity cards — have proven incredibly persuasive and ascendant (Van der Ploeg 2003; Zuriek and Hindle 2004). The proliferation of biometric technologies has been most evident at the borders between nation states, where the use of biometric passports matched with surveillance tools such as face and iris recognition technologies is being rapidly deployed at airports and other land and sea border posts. It is important to note that the security industry was already expanding prior to the attacks of 9/11. As Garland (2001) noted, late modern societies had witnessed an expansion of the commercial security sector that frequently fueled public anxieties in relation to crime control while claiming to allay them. Nevertheless, the already expansionist trajectory of the security sector received a massive boost from the climate of heightened anxiety following 9/11, and later compounded by the 7/7 bombings on the London Underground and the Madrid bombings. Mike Davis predicted in 2001 that "the 'Fear Economy,' as the business press has labelled the complex of military and security firms rushing to exploit the national nervous breakdown, will grow fat amidst the general famine" (p. 45). Later commentators have suggested Davis' prediction materialized. Webb (2007) has argued for the emergence of the "corporate-security complex" post 9/11, while Hayes (2010) outlines the emergence of a "security-industrial complex."

Prior to 9/11 biometrics was a fringe element of the security industry widely regarded as being of limited application and subject to significant errors. However, post-9/11 the biometric industry has grown considerably in size (Zuriek and Hindle 2004; Wilson 2006; Webb 2007). Moreover, particularly in the US, government expenditure on security technologies accelerated in the wake of the attacks of 9/11 and the subsequent "war on terror." In 2003 the Bush Administration earmarked $38 billion in new spending for homeland security, while security budgets in Europe and Australia also ballooned (Zuriek and Hindle 2004). In this climate the biometrics industry has been well organized to claim market share and gain "brand recognition" for biometrics as a security technology. Security technology companies were aggressively marketing their wares to airport officials within days of the 9/11 attacks (ACLU 2004, p. 27). Within a fortnight of 9/11 the International Biometrics Industry Association (IBIA), an advocacy organization representing major biometric companies in the US, issued a press release highlighting the role of biometrics in the fight against terrorism. Visionics – a US manufacturer of facial recognition technology – suggested in a white paper entitled *Protecting Civilization from the Faces of Terror* that airport security, in the US the responsibility of the Federal Government, "demands substantial financial resources" to develop "technology that can be implemented to immediately spot terrorists and prevent their actions." Boarding a plane, the white paper suggested, should no longer be considered "a right granted to all, but as a privilege accorded to those who can be cleared of as having no terrorist or dangerous affiliations" (cited in Zuriek and Hindle, p. 122). The political economy of biometric technology is constituted of complex networks of research laboratories, venture capitalists, and transnational corporations both stimulating and responding to expanding security markets that are both public and private (Walters 2010).

Biometric technologies have been heavily promoted as infallible despite their actual efficacy remaining highly questionable. At Palm Beach International Airport in the US, a trial of facial recognition technology failed to recognize participating airport employees 53 % of the time (Wilson 2006). Results of independent evaluations of facial recognition technology in other locations suggest similarly dismal results (Clarke 2003). Accuracy rates for facial recognition and fingerprint scanning remain problematic, and a Japanese researcher was able to fool a system by using a gelatin-based fake finger (Lyon 2003, p. 71; Zuriek and Hindle 2004, p. 120). Even some within the security industry are uneasy about the rapid pace with which untested and poorly researched biometric technologies are being deployed (Wilson 2006, 2007). Nevertheless the appeal of biometric technologies may reside in their symbolic resonance rather than in any technical efficacy, a point to which this entry will later return.

Automated systems, it might be suggested, reduce questions of discretion and discrimination to the abstracted question of whether one is granted or denied access. Technological discourse frequently constructs biometrics as a neutral security tool enacting abstracted processes of authentication and verification. As Muller notes "why biometrics is so successful in concealing its exclusionary and discriminatory character is the way in which it tries to hide the question of identity behind the preoccupation with authenticity" (2004, p. 286). Nevertheless, while biometric technology may appear to do little more than enact automated functions of verification and authentication, critical scholars have argued that it heralds new forms of control and exclusion. Gilles Deleuze (1992), for example, has argued that contemporary societies are "societies of control" where surveillance is detached from discipline and is primarily concerned with the distribution of entitlements on the basis of identity. Nikolas Rose (1999) has argued that contemporary shifts represent the "securitization of identity" whereby the exercise of freedom requires proof of legitimate identity.

The concepts of "societies of control" and the "securitization of identity" suggest that biometric technologies are far from neutral but are rather deeply imbricated within new modalities of power. Digital biometric identifiers become vital tokens of contemporary citizenship, and an integral aspect of what Jones (2001) terms "digital rule." "Digital rule" refers to the capacity of control agents to assign access and authorization. Punishment increasingly takes the form of "withdrawal of access privileges." This is a form of remote rule based upon databases and codes. The capability of remotely granting or denying access through biometric technologies linked to databases thus contains the capacity to deepen and widen social discrimination. Biometric technologies are hastening processes of what Lyon (2003) has termed "social sorting" where populations are digitally categorized as worthy and unworthy, included and excluded.

Similarly, scholars such as Graham and Wood (2003) have argued that these technological systems are far from neutral and abstracted, but are rather actively formed through social practices and decisions. As they note of digital surveillance systems, while they may be characterized by flexibility and ambivalence, and contingent upon judgments of social and economic worth built into their design, they are "likely to be strongly biased by the political, economic and social conditions that shape the principles embedded in their design and implementation" (2003, p. 229). Pugliese (2010) also argues that the categorizations of biometric systems are inherently racialized. Biometric systems, Pugliese suggests, are "calibrated to white," whereby Whiteness is configured as the universal gauge determining the technical limits for image capture. Categories of racialized exclusion are therefore embedded within the technological infrastructure. Several scholars have examined biometrics through the prism of Foucaldian notions of biopower (Pugliese 2010). Alternatively, Didier Bigo (2006), drawing upon Agamben's notion of the "ban" has suggested the concept of the "banopticon." David Lyon neatly summarizes this concept noting that "the majority of mobile citizens of the global north are normalized travelers who accept the need security passes for fast-tracking through the airport as they accept the need for frequent flyer cards to get access to the club lounges, a focused surveillance is reserved for the *sans-papiers*, the potential terrorist, the refugee – those 'trapped in the imperative of mobility'" (2008, p. 44).

Biometric technologies are thus not neutral but both constitutive and symbolic of transformations in power and social classification and exclusion. By their very nature, biometrics form components of technological systems that imply the assembling of digitized databases on an unprecedented scale. Scholars such as Lyon (2008) remain concerned that such databases are being assembled amidst a "state of exception," whereby nation-states increasingly enact decisions based upon political will rather than the constraints of normative law (Agamben 2005). Thus it could be argued that biometrics are deployed within a social context and organizing logic that inevitably heads towards exclusionary rather than inclusionary functioning. The potential for "actuarial justice" where the objective is risk management rather than rehabilitation and where predictors of dangerousness are engaged to preemptively target "problem" populations becomes amplified.

While a substantial scholarship has emerged around the issue of borders, the principal focus here is on how biometric systems connected to databases have facilitated the "delocalized border" (Bigo 2002). Aas (2005, p. 207) has observed that new technologies "seem both to transform the traditional space of government and to disrupt territorial boundaries," as well as appearing to provide the most efficient solution to problems of risk and security. The borders of the global north are fast becoming high-tech borders, "capable of materializing in different sites around the globe" (Walters 2006, p. 197). Actuarial logic requires that containment measures be applied *before* any harm results (Wilson and Weber 2008). Risk thinking in relation to border control therefore leads inexorably to temporal, and hence spatial, displacement of the border. Thus the delocalized, technologically realized border is "performed" rather than drawn as a line on a map, is functional rather than physical (Weber 2006), and significantly reorganizes the spatiality of power (Walters 2006).

The logic of exclusion inherent in border - control, coupled with mentalities of "risk reduction" and corresponding information technologies, produces strategies of "preemptive immobilization" aimed at certain categories of travelers who conform to set criteria. These risk profiles are constructed using aggregate information about suspect populations, and applied through information technologies accessed by immigration authorities and their agents on or before the border. Surveillance technologies therefore expand the potential codes and categories of risk (O'Malley 2006). Nevertheless, border control is underpinned by more than a simple exclusionary logic. States have been seeking migration flows that are simultaneously accelerated for some and fortified against others, most often expressed as a binary opposition between "facilitation" and "security." Scholars have variously described this bifurcation of mobility – broadly equating to the increasing economic chasm between the global south and the global north – as the widening divide between "global tourists" and "global vagabonds," the sorting of mobile bodies into "kinetic elites" and "kinetic underclasses," the "mobility rich" and the "mobility poor," and "two-speed citizenship" (Bauman 1998; Adey 2004; Aas 2011).

For nation-states the engagement of biometric technology at physical borders bears a signification that neatly encapsulates the paradoxes of state sovereignty under conditions of globalization. Biometric technology offers the possibility of rapid flows of capital and global elites through borders while simultaneously fortifying the border against unwanted intrusions from "deviant" outsiders. The technology becomes instrumental in processes of global social classification in which "low risk" travelers are granted unimpeded access and mobility while "high risk" travelers from the Global South, compelled to travel with limited or no documentation, are excluded and blocked. Registered traveler programs highlight this two-tiered system of mobility emerging in the post 9/11 context. Privileged passenger programs facilitate the rapid and unimpeded movement of elite travelers from the global north. Simultaneously those from the global south are increasingly blocked from entry. In a global economy where mobility is equated to participation the consequences of this discrimination are enormously significant. In the US as such these systems of preferential mobility are encouraged in law. The *Aviation and Transportation Security Act 2002* provides that the Under Secretary of Transportation for Security may establish requirements to implement trusted traveler programs. Registered Traveler Programs are intended not only to provide selected travelers with expedited processing at border points, but also to "target security resources to those travelers who might pose greater security risks."

Such systems have however been in place for some time. The US Immigration and Naturalization Service Passenger Accelerated Service System (INSPASS) a hand geometry system used in seven US and two Canadian airports has been in operation since 1993 (GAO 2003). Amsterdam's Schiphol Airport was the world's first airport to employ an automatic border control system using iris recognition technology for travelers. The "Privium" system, installed in October 2001, is intended to fast track passengers carrying an iris data-embedded smart card through passport control (Woodward et al. 2003, pp. 295–296; Lyon 2003, p. 71). Similar projects have also been undertaken in other locations. At Tokyo's Narita airport frequent customers of Japan Airlines are enrolled in a comparable system, has have been selected passengers at London's Heathrow airport and at Toronto and Vancouver (Wilson 2006). Biometric border control systems thus serve to exacerbate the trend identified by Bauman as "the extraterritoriality of the new global elite and the forced territoriality of the rest" (2000, p. 221). Biometric technology is therefore both a powerful signifier and a formative element in the widening chasm between a small global elite possessed of mobility and capital and the many in the global south geographically confined and impoverished.

It has been argued that states with diminished control of economic and social questions within their national boundaries increasingly turn to border security and migration control as key "performances" asserting their continued relevance and strength (Wilson and Weber 2008; Wilson 2006). Political scientist Wendy Brown suggests that border construction projects are "hyperbolic tokens" that attempt to signify resurgent nation-state sovereignty, despite the reality that they are often expressions of the withering of the nation-state and "the waning relevance and cohesiveness of the form" (Brown 2010, p. 24). For the truncated nation-states of late modernity, biometric technologies are potent signifiers of a reinvigorated sovereign power with the capacity to assert impermeable borders. Iris and fingerprint scanners, passport kiosks, and smart cards are, from this perspective, integral props in the theater - of statehood.

Such a theater of statehood is nowhere more in evidence than in the increased securitization of airports. The 9/11 attacks, and earlier instances such as the TWA flight crash in 1996, have been instrumental in facilitating heightened security measures in airports, and in embedding airports in public consciousness as filters of risk (Adey 2004). As border posts airports thus have substantial symbolic capital. As a report on Australian airport security noted "perhaps as important as their contributions to transportation and the wider economy is the symbolic significance attached to airports. They embody the modern world in all its complexity, since few other places bring together our most advanced technological creations and the intricate interconnected systems we have devised to serve both those creations and ourselves" (Wheeler 2005, p. 5). As highly symbolic nodes of modernity, airports become crucial platforms through which the power of the state to include and exclude is enacted. The centrality of securitizing airports in the post 9/11 environment then has powerful signifying functions. Mike Davis suggests that airports may function as microcosmic spaces of wider security and surveillance trends, noting that "the security regime of the airport departure lounges will likely provide a template for the regulation of crowds at malls, shopping concourses, sports events and elsewhere" (2001, p. 45). Biometric identification systems are integral elements of the intensified security regimes evident in airports (Zuriek and Hindle 2004, p. 129).

The signifying and political functions of biometric technology are also evident in its incorporation within the international passport system. Passports are the primary document for identifying, regulating, and tracing mobile individuals. The passport is, as Salter suggests, "a modern heuristic device which serves to link individuals to foreign policy, and according to which government agents classify travellers as safe or dangerous, desirable or undesirable, according to national, social or political narratives" (2004, p. 72). The spread of biometric passports has largely been dictated by US legislation, and offers a tangible expression of US hegemonic power in the post 9/11 global order. Section 302 of the *Enhanced Border Security and Visa Entry Reform Act 2001* requires "a visa waiver country, in order to maintain program participation, to certify by October 26, 2003, that it has a program to issue to its nationals qualifying machine-readable passports that are tamper proof and contain biometric identifiers."

The hegemonic power of the US is therefore instrumental in leading and setting the final standards for the global introduction of biometric passports (Wilson 2006). The International Civil Aviation Organization (ICAO), the organization governing international civil aviation, has been examining the issue of biometric passports since 1995. However, until recently national and regional legislation protecting privacy and civil liberties mitigated against their adoption. In May 2003, the G8 countries (Canada, UK, France, Japan, Italy, Russia, Germany, and the US) entered into an agreement to implement a biometric passport system. Civil libertarians remain troubled that passports will utilize face recognition, not only among the least reliable of biometrics but also one that can be used at a distance to track individuals without their knowledge. Moreover the passports are to include RFID (Radio Frequency Identification) tags. These are tiny computer chips that, when receiving a radio signal from an RFID reader, use that power to transmit the data they store. And in US passports this information would include name, date of birth, place of birth, and a digital photograph and digital face recognition template. Organizations such as the American Civil Liberties Union maintain that this raises substantial privacy and security issues and significantly intensifies the potential for the surveillance and tracking of individuals.

Critics maintain that biometric passports are a proxy for a global database. The International Campaign Against Mass Surveillance, for example, argues that biometric passports represent one avenue of obtaining "nearly universal registration of everyone on the planet" (cited in Wilson 2006). For critics the potentially ominous ramifications of this development reside not in the documents themselves but in the possible databases linked to them and the tracking and classification potential they unleash. The assemblage and mobilization of large-scale government databases in relation to visa applications and the tracking of "non-citizens" was evident in the detention of hundreds of Muslim non-citizens in the wake of September 11. US authorities systematically registered and created dossiers on nearly every male over the age of 15 with origins in a list of countries (mostly Muslim) traveling in the US. Individuals on the list were required to report to the government to be fingerprinted, photographed, and questioned. Those who failed to register risked deportation and criminal penalties. This was carried out under the aegis of a program called the National Security Entry-Exit Registration System (NSEERS) (Wilson 2006).

The registration that occurred under NSEERS has been expanded via a program called US-VIST to most visitors to the US. A similar system in the EU, the Visa Information System (VIS) has been developed in the EU to capture and store information – including biometric information – from all visa applications to EU member states (Wilson 2006). The storage of this data and its linkage across databases will facilitate surveillance and monitoring on an unprecedented scale. The integration of biometric technologies into the international passport and visa system is then both a signification and realization of new forms of power. The technologizing of the border via biometrics betokens a renewed capacity of nation-states to police their boundaries. Technologized means of exerting control over movement form elements of "processes of statecraft" whereby the sovereignty of the state is enacted through processes of inclusion and expulsion. Such expressions of sovereignty have significant repercussions on the ground, as expanding databases facilitate new and powerful forms of cataloging, coding and filing individual identities. Increasingly too, databases are globalized through the incorporation of biometric identifiers in the international passport and visa system, an architecture forged by the US that some have suggested opens up the possibility of a global ID.

Post 9/11 questions of migration and mobility are increasingly interpreted through the prism of security (Guild 2009). States of the global north have assessed the specter of uncontrolled migration as a threat to sovereignty. Within this rhetoric asylum seekers and refugees are increasingly cast as "folk devils" in moral panics fuelled by law and order politics (Wilson 2006). The demonization and criminalization of asylum seekers has been accompanied by coercive measures such as indefinite detention and forced deportation. In the nation states of the global north such coercive measures are elements of more sustained processes of criminalization whereby the act of seeking asylum is itself constructed as a "crime of arrival."

Consequently it is perhaps unremarkable that biometric identification systems have initially been deployed on asylum seeker populations, where they serve as technological signifiers of the securitization of migration. Biometric identification systems involving fingerprinting those seeking asylum have become increasingly common and are in use in the UK, the Netherlands, and Australia (Woodward et al. 2003; Wilson 2006). The United Kingdom's Home Office has adopted a biometric solution in the identification of asylum seekers within the UK. Asylum seekers are issued an Application Registration Card that carries a template of the bearer's fingerprints, as well as their photograph, name, date of birth, and nationality (Home Office UK, 2002). The ARC is designed to facilitate rapid identification of asylum seekers following initial processing at ports of entry or at the Asylum Seekers Unit in Croydon. The objective of the card is to facilitate identification of asylum seekers by authorities. In so doing the ARC firmly inscribes and secures a "non-citizen" identity on individual asylum seekers. The system is designed not so much to facilitate access to services as to deny them, one stated purpose of the system being to counter fraud through the claiming of services under multiple identities (Woodward et al. 2003, p. 290.)

Similar schemes are also initiated in the EU, US, and Canada. The countries of the European Union have established EURODAC, an automated fingerprint identification system. In the Convention of Dublin, June 15, 1990, the member states of the European Union agreed that the first country where the applicant arrives was to be responsible for their application. This was to preclude one country passing asylum seekers on to another, as well as asylum seekers submitting multiple applications in different member states (Van der Ploeg 1999, p. 298). EU ministers responsible for immigration established a Community wide system for the comparison of fingerprints of asylum applicants in 1991, while the agreement to build a central fingerprint database of asylum seekers was established in 1997 by the European Council. EURODAC was tested in 2002, and from January 15, 2003, asylum seekers fingerprints have been taken whenever they seek asylum, whether inside or outside the EU's borders. Fingerprints are then digitally transferred from member states to a central EURODAC unit for comparison against the existing database. Fingerprints of asylum seekers can be stored for up to 10 years, or immediately erased if an applicant is granted nationality in a member state. In addition to asylum seekers, EURODAC is also a biometric database of "persons who have crossed an external frontier of the Community in an irregular manner." These "foreign nationals" have their biometric data retained for 2 years or immediately erased if they receive a residence permit or leave the territory of the EU (Wilson 2006).

EURODAC was justified by the EU Council in terms of the need to accelerate decisions on asylum bids. Another powerful rationale behind the establishment EURODAC was a perceived need to stem "asylum shopping" across member states of the EU and separate those categorized as "legitimate" asylum seekers from other categories of migrant. Across nation-states of the global north biometric technology is being extensively deployed to demarcate and signify identities of "non-citizens." This process is intertwined with the wider securitization of migration as a political issue and the attendant discursive criminalization of migrant identities. International relations scholars have noted the significance of policing borders not only to preserve the integrity of the nation-state but as a marker and arbiter of state sovereignty overall. Increasingly the identity of the asylum seeker has been configured as a site on which state sovereignty is enacted. The capacity to establish legitimacy, confirm identity, and expel those deemed "illegitimate" has thus been a pivotal "performance of sovereignty" (Pickering 2005).

The particular focus upon asylum seekers in biometric deployment is intertwined with the securitization of migration and the criminalization of persons seeking to move from the global south to the global north. The issuing of smart entitlement cards and the targeting of "illegal" migrants with biometric technologies serves to wend discourses of terrorism, organized crime, and migration as a single coherent threat to national sovereignty. The need for biometric data incorporated into travel documents is most often cited as "national security" – meaning security from "illegal" migrants and terrorists. However, in practice such documents inscribe on those seeking asylum the identity of "non-citizen." Fixing these "non-citizen" identities through biometric documentation and "entitlement" cards serves to heighten exclusion and reinforces the notion of migration as a problem of security.

Biometrics has become a pivotal technology in a range of security domains but most evidently in border control. Its ascendancy has been partially due to the expanding security market – both public and private – in the post 9/11 global north. Critical scholars, however, dispute the claims of the technical literature which frequently asserts the neutrality of the technology. It is argued that biometric databases are integral to processes of social sorting that distinguish between the eligible and ineligible, the included and the excluded, the banished and the admitted. Moreover biometric databases have deterritorialized the border, creating a situation in which the border is – quite literally – everywhere. Biometric technologies have also played an instrumental role in facilitating the enhanced mobility of a privileged elite from the global north through trusted traveler programs while impeding the movement of those from the global south through risk profiles and categorizations of dangerousness.

British Crime Firms

Dick Hobbs
University of Essex, Essex, UK

Overview

Historically organized crime is a relatively new phenomenon in Britain that was only formally recognized by politicians and law enforcement in the 1980s and 1990s and emerged as a social problem that was heavily associated with transnationality (Hobbs 2013). However, there were precursors to this obsession with “transnational-organized crime,” which warrant attention, and they were very much home grown and embedded in the class relations and political economy of industrial society. The criminal firm emerged from the cultures of the urban working class as a form of localized organized crime that was central to the economies and cultures of traditional working class communities and were particularly prominent in London among those communities lacking the strict disciplines of industrial life.

History

Working class London was made up of, “a social patchwork of intensively localist culture and sentiment” (Robson 1997, 7), that lacked the homogeneity of cultures created by a single mode of production (Hobbs 1988, 87). London’s economic base was diffuse, and as a consequence the capital’s proletariat evolved as a complex and highly individualistic amalgam of class specific identities gleaned from localities sharing little in common with their neighbors other than socioeconomic deprivation. Even dock work, upon which vast swathes of south and east London were reliant, created working cultures dependant upon semiautonomous groups of workers hired by the day before shifting to another cargo, possibly on another ship, maybe in a different dock (Hobbs 1988, 109–111). The localism of Londoners manifested itself in a tendency to regard territories beyond their own with deep suspicion, maintaining exposure to those residing in adjacent neighborhoods to a minimum.

The strictly defined territorial parameters of industrial working class communities produced clusters of youthful collaborations who utilized territorial identity as a vehicle for recreational transgression before morphing seamlessly into adult pursuits, and if we take some of the better known criminal brands of the mid-twentieth century, youthful conflict was certainly important in forming identities, creating reputations, and molding communal distinctiveness in the face of opposition. These territorially based groups occupied spaces or interstices between sections of the urban fabric and were frequently situated within "delinquency areas" where youthful deviant collaborations were organized around working class territorial imperatives defined by the experiences of low income, poor housing, and poor health. It is here where criminal careers are nurtured and where youth formulate criminal associations. Then as now neighborhood-based groups abounded in working class London, territorial imperatives featuring individual, local, and family reputations were forged in youthful combat that was ideal preparation for the world of acquisitive gangsterism, where fractious networks came to define much of what came to be regarded as organized crime in the twentieth-century London.

Throughout the industrial era generations of youths forged reputations in defense of their neighborhood, as groups of young men drifted into adjacent territory in order to provoke violence. However, these groups emanated from a domain that was shaped, refined, and restrained by elements of social control that were lodged in the pragmatic realities of the local political economy and its associated cultures and institutions. For most participants these were temporary collaborations before engagement with the local employment market-enabled maturation into an unambiguously proletarian society where crime was normal (Hobbs 2013). However, certain individuals, groups, and families on establishing a monopoly of informal violence would commodify this monopoly and via the finely grained differential between security and extortion, exploit businesses, and individuals within their home territory. While most groups stayed within the cultural and economic frameworks provided by the industrial neighborhood, the most competent and ambitious sought out and colonized adjacent territories where the object was to create "protected enclaves" (Arlacchi 1986, 195), via the maintenance of a viable threat.

Examples of crime firms who succeeded in breaking out of the local neighborhood to occupy adjacent territories can be found in the three following cases.

Three Crime Firms

After the First World War, there was a boom in horse racing and many who wished to gamble were drawn to the opportunities for lawful betting at racecourses. However, groups of men with violent reputations exploited the numerous extortionate opportunities available at the racecourses, and these coalitions of violent men are significant for their willingness to pit local reputations within a national arena. The Sabini family emerged as defenders of Clerkenwell's "Little Italy," resisting incursions from equally deprived areas of the capital, and they soon commodified their growing reputations by organizing a moderately lucrative extortion business. However, the racecourses offered the richest prize to any group who could transcend the restricted opportunities of the working class territory where their reputations were formed and to enable this transcendence the Sabinis formed alliances with Jewish bookmakers and criminals, as well as some significant figures in the police (Hill 1955, 3).

Eventually, against a backdrop of considerable violence, the Sabinis established something approaching a monopoly at most of the major racecourses in England, progressing into the affluent West End of London, and "Bottle parties, clubs, public houses, cafes, restaurants, even ordinary shops had to pay protection money to the Sabini extortionists" (Hill 1955, 5). However, further progress was halted by the outbreak of the Second World War and the interment of many of the "Italian Firm" and the Sabinis never fully recovered their power. The Sabinis were a powerful criminal group who transcended their immediate neighborhood, briefly succeeded in dominating a wide territory that included most major English racecourses, as well as the affluent west end of London, and as a consequence Darby Sabini was "the nearest Britain got to an organising gangster" (Pearson 1973, 30. For further details of the Sabinis, see Hobbs 2013).

The Kray twins who emerged from the East London neighborhood of Bethnal Green during the post-Second World War era also utilized violent reputations forged in adolescence before commodifying this violence and extorting from local businesses. Changes in the British gambling laws opened up new opportunities in adjacent territories, and they were soon competing with neighborhood crime firms from across London for a portion of the lucrative West end market (Pearson 1973, 16–18, 27–28). Mental illness plagued the Kray firm, and delusional fantasies based upon the replication of Gangster scenarios with origins in Hollywood restricted their progress. Eventually reckless violence and murder made the Krays firm difficult to ignore, and by the end of the 1960s the police had imprisoned the entire firm, the twins making more money from nostalgia, bogus charity events, books, and a film than they ever did from crime (Hobbs 2013).

Charlie and Eddie Richardson were born into a traditional south London working class family, and like their East London counterparts the brothers endured a wartime childhood, enjoyed the vibrant streetlife of working class London and developed as talented young boxers and prominent street fighters. However, unlike the Krays, both Charlie and Eddie Richardson were hard workers and made good money from the postwar scrap metal trade. The Richardsons established an extortion business across a wide south London territory and moved into a number of disparate commercial areas, including wholesale chemists and mineral mining. The honey-pot of the West End brought them into limited conflict with the Krays and the Richardons diversified into long firm fraud (Levi 1981, 76–77), gaming machines, pornography, scrap metal yards, a perlite mine in South Africa, and control over car parking at Heathrow Airport. The Richardson firm was eventually closed down by the police after a fatal shooting at a club, a bizarre "torture" trial and Charlie Richardson's dalliance with the South African Secret service (Hobbs 2013).

These three examples indicate the manner in which the British crime firm emerged from working class neighborhoods with commercially viable violent reputations forged in youth. The foundation of the crime firm is extortion or "protection," and the elite were able to apply their reputations to colonizing adjacent territories. However, the local working class neighborhood was the platform that formed the reputations upon which subsequent operations depended, and when this territory was obliterated, the neighborhood firm was forced to adapt.

Deindustrialization eroded the traditional working class milieu from which the traditional crime firm emerged, and the fragmentation of working class neighborhoods created arenas that have made it difficult for family-based crime firms to establish the kind of parochial dominance they once enjoyed in the 1950s and 1960s. The new arenas for criminal activity are entrepreneurially orientated and consist of "…flexible, adaptive networks that readily expand and contract to deal with the uncertainties of the criminal enterprise" (Potter 1994, 12), and as a consequence, the family firm has had to adapt (Hobbs 1997). Although we should not assume that this constitutes redundancy, Lambrianou reminds us, "Brothers were your strength" (1992, 29).

Suburbs

The postindustrial drift of London's traditional working class communities away from its urban heartlands was enabled by both public housing policy and the private housing market and resulted in the colonization of rural space, bloating the periphery with new towns and extending the suburbs with a rash of housing projects. Those involved in criminal enterprise were merely part of this migration, and the key to understanding their change of address rests not with their criminality, but with their status as part of a proletarian diaspora whose trajectories out of the working class city can encompass a wide range of possibilities. Yet the shift out of the old neighborhood is seldom total, for the restructuring of the old industrial neighborhood has created new opportunities for money making, and pubs, clubs, and gyms make good investments that will always benefit from being associated with an old established brand (Hobbs 2013).

As geographical location becomes a somewhat ambiguous concept around which to base an illegal business, criminal labor has taken on increasingly transient, characteristics. The ever-mutating interlocking networks of opportunity created by the late modern city (Ruggiero and South 1997), in common with its legitimate counterpart, features interactions negotiated within networks of small flexible firms that are characterized by short-term contracts and lack of tenure, where the workforce can be "...hired/fired/offshored, depending upon market demand and labor costs" (Castells 1996, 272).

Understanding local housing policies is crucial to reaching an understanding of the distribution of various forms of delinquency, and the emergence of potent postindustrial forces that have "emptied out" marketable labor from communities formed around the assumptions of traditional cultures has relocated criminal coalitions within decentered, unpredictable, and relatively fragile economies. As a result of the sanctioning of the sale of two million homes in the UK, working class council tenants were able to buy their homes at a massive discount before selling at a profit and heading for London's periphery, which combined with deindustrialization, effectively drained working class London of much of its established human capital (Hobbs 2013). Municipal housing policy, along with the London's private housing market combined with deindustrialization to relocate criminal coalitions within decentered, unpredictable, relatively fragile economies, spread over a wide, and at times seemingly inappropriate, terrain. By the late 1970s the traditional neighborhood had been decimated by regeneration, and most of the traditional family firms had become at least partly ensconced within London's periphery, establishing new business ventures, and in particular engaging with the drugs trade (Hobbs 2013).

However, deindustrialization is not a homogenous process, and in an examination of the serious crime community in another part of Britain, housing policy deliberately retained traditional neighborhood structures, and as a consequence key aspects of the locales cultural inheritance such as the neighborhood family firm, along with the cultural territory that spawned them, remained relatively intact. These firms have of course adapted to the new market place, occasionally expanding beyond the old neighborhood, while striving to retain the traditional order through traditional means (Hobbs 2001).

Discussion

Within the new serious crime community, relations between individuals vary according to demographic dispersion, familial composition, ethnic distribution and integration, commercial practice, trading routes and patterns, the economic backcloth of the legitimate culture, and the particular use of space (Soja 1989). As a consequence serious crime networks have been extended across time and space, its members residing upon an anonymous terrain that is apparently indistinguishable from that of the legitimate economic sphere. Yet these networks stand in stark contrast to their predecessors, particularly with regard to their dynamism, and the extent to which they impact globally via their ability to both exploit and undercut traditional cultures. This ambiguity that is located within the new family firm is highly instrumental and typified by "vertically disintegrated networks of small firms engaged in transaction rich linkages of market exchanges" (Lash and Urry 1994, 23). The family firm is historically and cognitively positioned among a habitus incorporating multiple chains of legitimate and illegitimate opportunity networks to exploit these linkages to the full. The scope and extent of their activity depends upon the degree of connectivity established between groups and individuals, and it is this connectedness rather than corporate identity that forms the structural connotation inherent in "organized crime." The at times confusing list of the family firm's contemporary activities, especially compared to the one dimensional nature of their forefather's criminal clout, is indicative of the families' ability to establish interactions that consist of infinite mutations that exploit geographic space without being confined to territorial imperatives.

The same mechanisms that contrive in the destruction of traditional communities are also liable for the creation of new forms of locality and identity, and the neighborhood firm is essentially a constantly evolving social system (Ianni 1971, 35), whose strength and longevity is derived from its continued identification with territory that retains a deep and enduring well of historical sentiment. For even when the material base for such a community is removed, and crime is located within loose collectivities of ad hoc groupings, the family firm survives as a functional touchstones of competence and honor (Hobbs 1997).

The sense of "retrospective unity" (Bauman 1992, 138) that is exploited by the family firm is reliant upon a generalized recipe of locality (Robertson 1995, 26) that enables a highly durable system of transposable dispositions, from which emerge practices that reproduce "the objective structures of which they are the product" (Bourdieu 1977, 72). The flexibility of contemporary serious crime collaborations, licenses engagement with new markets, and particularly when they are at least part populated by powerful individuals and proven practices from previous eras, they become somewhat more difficult to locate and pigeonhole than their predecessors. For while they may be steeped in traditional criminal cultures established and maintained by the precedents of indigenous markets, the contemporary criminal firm is not restrained by the parameters of specific neighborhoods, for they inhabit a universe that prioritizes the ability to perform successfully within a local class milieu that has not disappeared, but realigned according to the dictates of global markets.

Criminal career trajectories are no longer restricted to highly specific and essentially redundant geographic and cultural spaces within an urban "underworld" but are located "…all over the main streets and back alleys of the global economy" (Castells 1996, 168). The result is the creation of criminal firms typified by flexibility and unpredictability, operating within multilayered, networks of opportunity, "small, fragmented, and ephemeral enterprises (which) tend to populate illegal markets-not large corporate syndicates" (Potter 1994, 13). The illegitimate economic sphere now features interlocking networks of small flexible firms, which like all aspects of contemporary capitalism, is typified by versatility, and a degree of flexibility that were inconceivable during the industrial era (Lash and Urry 1987). While this is contrary to the popular notion of transnational crime corporations (Williams 1993), as Robertson (1992, 1995) has indicated, globalization has improved the viability of locality as a generator of a discrete social order. Indeed the dialectic between the local and the global brings to the fore markets where alliances between global and local spaces created enacted environments where "the methodologies for the integration of organised criminals into civil society are established" (Block 1991, 15).

This brings the family firm back into the spotlight, for by perpetually realigning local precedents in the context of global markets, some kind of continuity and long-term viability can be maintained (Hobbs 1995, Ch. 5). Globalization should not be allowed to override the particular (Ferguson 1992), for the result, as we see from any critique of transnational organized crime (Hobbs 2013), is an a-historical theory built upon a rigidly structured view of economic life drained of cultural resonance. Indeed such a concept could not possibly reproduce faithfully the experiences of the family firm, whose enacted environment is a blend of the local and the global, constituting a highly effective vehicle that enable both individuals and groups to move between these two interlocking spheres. For criminal career trajectories are no longer restricted to highly specific and essentially redundant geographic and cultural spaces within an urban "underworld" but are located "…all over the main streets and back alleys of the global economy" (Castells 1996, 168).

Serious crime should be understood in terms of interlocking networks which are metaphors for relationally and manifested as amalgams of family, neighborhood, region, and nationality. Indeed, kinship in itself should be regarded as a highly instrumental trust variable, assuring loyalty by appealing to something other than self-interest (Lupsha 1986, 34). This is particularly relevant to the family firms continued use of violence, which remains a tactic of the increasingly blurred personal and commercial domain, and serves to stress the importance of trust for, “The everyday presence of violence prevents personal and effectively neutral trust relationships. Where violence is paramount, interpersonal ties must necessarily be strong, intense and affectively connoted” (Catanzaro 1994, 273). The continued use of violence to create, protect, and maintain a slice of the market within a densely populated sector inhabited by a multiplicity of networked interfaces (Arlacchi 1986, 195) is an enduring characteristic of the serious crime market place (Arlacchi 1998, 205).

Conclusion

Criminals do not experience the world globally or transnationally, for these are essentially fields devoid of interpersonal relations, and although it has undergone major configurations and relocations during post-industrialism, the firm is far from obsolete. The firm operates both in the “inherited basic architecture” (Castells 1996, 146) of the industrial neighborhood, in their new suburban idyll, and across regional, national, and international boundaries (Hobbs 2013), constituting the embodiment of Rose’s belief that the individual, “can within the limits permitted by the culture define for himself somewhat new patterns suggested by the variation among the old ones” (1962, 14).

British Crime Survey; BCS

Overview

The Crime Survey for England and Wales (CSEW), until 1 April 2012 known as the British Crime Survey (BCS), is a victimization survey of the population resident in households in England and Wales. The primary motive for launching the survey, over 30 years ago, was to assess how much crime went unreported in official police records. Today the survey has a high profile and has become a key social indicator charting trends in crime experienced by the general population. Its quarterly results receive considerable media attention, and politicians debate the implications of its findings.

However, from its inception, the survey was not designed to be merely a social indicator. One of its strengths has been that it has provided a rich source for criminological research and for informing policy development. Analysis of the survey has been instrumental in shedding more light on the nature and circumstances of victimization. The survey has not stood still and has continued to evolve and develop its methodology and content to respond to emerging issues.

The survey was first commissioned by the UK Home Office (the Government department responsible for crime and policing), but responsibility for it has recently transferred to the central Office for National Statistics. This move raises questions about the future role of the survey and whether it can continue to effectively balance its role as a key social indicator on the one hand with a continuing role as an invaluable research tool on the other.

Origins

The Home Office, the Government department responsible for crime and policing in England and Wales, started collecting statistics on crimes recorded by the police over 100 years ago. The numbers of crimes recorded by the police grew inexorably from less than 100,000 crimes per year at the turn of the twentieth century to half a million in the 1950s, a million in the 1960s, and two million in the 1970s. By 1981, over three million crimes a year were recorded by the police. Many criminologists were skeptical that this scale of increase represented a real rise of such magnitude in crime.

The first attempts to derive alternative measures of crime, based on sample surveys of the general population, started to develop in the United States (US) in the late 1960s. The first surveys of this kind were carried out for the US President’s Commission on Crime which in turn led to the establishment of the National Crime Survey (NCS) program and subsequently the National Crime and Victimization Survey (NCVS).

This and the development of small area victimization surveys in the UK inspired analysts working in the Home Office to press for a national victimization survey to be developed. The discussions around the case for such a survey within the Home Office has been outlined by some of those closely involved in the decision back in the late 1970s and early 1980s (Hough et al. 2007). A strong part of the case for the creation of the BCS, as it later became known, was to yield an assessment of what was referred to at the time as the “dark figure” of crime, that is, crimes which escaped official police records. Indeed the first published report of the survey’s findings refers to one of its main aims being to provide an “index of crime as a complement to the figures of (police) recorded offences" (Hough and Mayhew 1983).

The decision to commission a national survey of crime in England and Wales was taken by the Home Office in mid-1981, and the Scottish Home and Health Department (the Government department responsible for crime and policing in Scotland, at the time) decided to fund an extension to cover Scotland shortly thereafter. A contract for data collection was awarded to an independent survey organization, Social and Community Planning Research (SCPR) which has subsequently become the National Centre for Social Research (NCSR).

However, from its beginnings, the survey was conceived as being more than merely an instrument for counting crime. The survey was seen as providing a rich source of data about the characteristics of victims of crime, the nature, and consequences of victimization experiences. This contrasted with the police-recorded statistics which yielded little more than aggregate counts of offences by area. In addition, the survey was able to include questions on public attitudes to crime and crime-related issues, and again, this provided a rich new vehicle for criminological research.

Methodology

An annual technical report covering the survey methodology is produced by the survey contractor each year, and the latest version, at the time of writing, covered the 2010/2011 survey year (Fitzpatrik and Grant 2011). Below, a brief summary of the key aspects of methodology and how it has developed over time can be found.

Population Coverage, Sampling, and Weighting

The BCS was conceived as a survey of the population resident in households and, as such, was never intended to capture the victimization experiences of other groups (e.g., those permanently resident in institutions) or organizations (e.g., commercial victims). The survey was designed to yield results for a nationally representative sample of the adult population (defined as those aged 16 years and over). In more recent years, the sample has been extended to cover the experiences of children aged 10–15 years (see below).

While the survey covered the whole of Britain in its early years, it soon became restricted in its geographical coverage to just England and Wales. Thus, for most of its history, the BCS was something of a misnomer, and following the transfer of responsibility for the survey from the Home Office to the Office for National Statistics (see below), the survey was renamed as the *Crime Survey for England and Wales* on 1 April 2012 to better reflect its geographical coverage.

Since the first survey in 1982, the CSEW has randomly selected one adult per household sampled to take part in the survey. The sampling frame used to draw the original sample of households/adults has evolved over time from the electoral register (a record of those adults entitled to vote) for the first three rounds of the survey to the small-user Postcode Address File (a record of residential addresses maintained by the Royal Mail) ever since. The sample design has been subject to a number of modifications with high-crime areas over-sampled in the early years when the annual sample size typically ranged between 10,000 and 15,000 adults. The 2000 BCS was the only survey to adopt a fully proportional sample (i.e., with every area selected with probability proportional to size).

Following the expansion of the sample size thereafter, and the need for the survey to yield a number of key estimates at police force area level, the survey has moved again to a disproportionate sampling but this time with less populous (and thus lower crime areas) over-sampled. The sample design has been refined in recent years to move to a partially clustered sample design involving an unclustered sample of addresses being drawn in the most densely populated areas, with more clustered designs in the medium population density and low population density areas.

Throughout the history of the survey, appropriate weighting systems have been developed to adjust for the different selection probabilities involved in the respective designs. An independent review was commissioned by the Home Office in 2009 to examine the impact of the changes in sample design on the reliability of BCS crime trend estimates (Tipping et al. 2010). This showed that no bias had been introduced to the survey from changes in the sample design and that all designs examined had generated estimates of victimization with low levels of variance. The authors concluded that changes in the sample design had not affected the ability of the survey to identify trends in victimization reliably.

Crime Reference Period and Victimization Measures

The data collection period for the first BCS took place in the first few months of 1982 and asked respondents about incidents that had happened since 1 January 1981. For the purpose of analysis and reporting, all incidents occurring in 1982 were excluded so that respondents had a common crime reference period of the 1981 calendar year. A change to the crime reference period was required with the move to a continuous survey, with data collection taking place throughout the year, from 2001/02. The survey then moved to asking respondents about crimes that had been experienced in the 12 months prior to interview. This resulted in the development of a rolling reference period with, for example respondents interviewed in January asked about crimes experienced from the previous January to December, those interviewed in February asked about crimes experienced between the previous February and January of the year of interview, and so on. Respondents were additionally asked for information on the month in which an incident took place or, if they could not recall the exact month, the quarter. This allows analysts to retrospectively splice data from multiple years to construct crime rates on the basis of calendar years if they should wish to do so (see (Tipping et al. 2010).

Since the survey began, the basic approach to obtaining information on victimization experiences has not changed. Respondents are asked a series of screener questions designed to ensure that all incidents of crime within the scope of the survey, including relatively minor ones, are mentioned. The screener questions deliberately avoid using legal terms such as “burglary,” “robbery,” or “assault,” all of which have a precise definition that many respondents will not know. The wording of these questions has been kept consistent since the survey began to ensure comparability across years.

Depending upon individual circumstances, a maximum of 25 screener questions are asked covering:

- Vehicle-related crimes (e.g., theft of vehicle, theft from vehicle, damage to vehicle, bicycle theft)
- Property-related crimes (e.g., whether anything was stolen, whether the property was broken into, whether any property was damaged)
- Experience of personal crimes (e.g., whether any personal property was stolen, whether any personal property was damaged, whether they had been a victim of force or violence or threats)

All vehicle-related and property-related crimes are considered to be *household* incidents, and respondents are asked about whether anyone currently residing in their household has experienced any incidents within the reference period. For respondents who have moved within the last 12 months, questions on household crimes are asked both in relation to the property they are now living in as well as other places they have lived in the last 12 months. *Personal* incidents refer to all crimes against the individual and only relate to things that have happened to the respondent personally, but not to other people in the household. Weights are created to allow analysis at either household or personal level.

All incidents identified at the screener questions are then followed through in a series of detailed questions. The first three victimization modules include detailed questions relating to each incident; the last three victim modules are shorter modules, designed to be much quicker to complete to avoid respondent fatigue during the interview. The order in which the victim modules are asked depends on the type of crime – less common crimes are prioritized in order to collect as much detailed information as possible. A total of up to six victimization modules can be completed by each respondent.

Most incidents reported represent one-off crimes or single incidents. However, in a minority of cases, a respondent may have been victimized a number of times in succession. At each screener question where a respondent reported an incident, they are asked how many incidents of the given type had occurred during the reference period. If more than one incident had been reported, the respondent was asked whether they thought that these incidents represented a "series" or not. A series is defined as "the same thing, done under the same circumstances and probably by the same people."

Where this was the case, only one set of detailed victimization questions are asked in relation to the most recent incident in the series. There are two practical advantages to this approach of only asking about the most recent incident where a series of similar incidents has occurred. First, since some (although not all) incidents classified as a series can be petty or minor incidents (e.g., vandalism), it avoids the need to ask the same questions to a respondent several times over and thus reducing respondent burden. Secondly, it avoids "using up" the limit of six sets of detailed victimization questions on incidents which may be less serious.

In subsequent analysis and reporting, the convention has been for single incidents to be counted once and *series* incidents to be given a score equal to the number of incidents in the series occurring in the reference period, with an arbitrary top limit of five. This procedure was introduced in order to ensure that the survey estimates are not affected by a very small number of respondents who report an extremely high number of incidents and which are highly variable between survey years. The inclusion of such victims could undermine the ability to measure trends consistently. This sort of capping is consistent with other surveys of crime and other topics. However, the decision to cap series incidents at five has led to some criticism with it being claimed that this has served to mask the extent of chronic victimization and harms experienced by the most frequently victimized (Farrell and Pease 2007).

The first BCS developed an Offence Coding System to enable incidents reported by respondents to be assigned a criminal offence code (e.g., burglary or robbery) that approximated to the way in which incidents were classified by the police. This offence coding process takes place outside of the interview itself using a team of specially trained coders who determine whether what has been reported represents a crime or not and, if so, what offence code should be assigned to it. Apart from some minor changes, the code frame and the instructions to coders for the core survey have remained stable since the first survey.

Mode of Interview

The 1982 BCS was conducted in respondent's homes with trained interviewers collecting data via a paper-and-pencil-administered interviewing (i.e., interviewers filled in paper questionnaires by hand with extensive post-interview data keying and editing process). In 1994, the BCS moved to computer-assisted personal interviewing (CAPI) which brought improvements to data quality as it was possible to automatically route respondents through the questionnaire, without relying on interviewers following written instructions, and to incorporate logic and consistency checks on data entered in different parts of the questionnaire. CAPI also allows date calculations and text substitutions which help the interviewer ensure the interview flows smoothly.

The move to laptop computers provided further opportunities for innovation with self-completion modules introduced to cover sensitive topics. The use of self-completion on laptops allows respondents to feel more at ease when answering questions on sensitive topics due to increased confidence in the privacy and confidentiality of the survey.

Self-completion modules were first included in the 1996 BCS to obtain improved estimates of domestic violence (Walby and Allen 2004), and a similar module has been included since the 2004/2005 survey. A paper self-completion module on illicit drug use was included in the 1994 BCS though a change in the way in which these questions were asked when it was reintroduced with CASI means that comparable figures are only available from 1996. A separate annual report on the findings from the drugs self-completion continues to be published by the Home Office with the latest one at the time of writing relating to the 2011/2012 survey year (Home 2012a).

The self-completion modules are restricted to those respondents aged 16–59 years (the decision to exclude those aged 60 and over was an economy measure). In the 2008/2009 survey, a 6-month trial was conducted to examine the feasibility of raising the age limit to 69, but this proved unsuccessful (Bolling et al. 2009).

Regularity of Survey Fieldwork

Following the first BCS in 1982, a second survey took place in 1984 with fieldwork taking place early that year and with the preceding calendar year (1983) acting as the reference period. Subsequent surveys were repeated on the same basis in 1988, 1992, 1994, 1996, 1998, 2000, and 2001.

In the late 1990s, the value of the survey for policy purposes was recognized by the Home Office which planned to move the survey onto an annual cycle and to increase substantially its sample size. These moves were designed to as a means of increasing the frequency with which survey-based estimates could be published, while the increase in sample size was motivated by a desire to increase the precision of certain estimates. The latter was related, in part, for the need to use the survey to provide key performance indicators to assess the performance of the police.

The Home Office commissioned an independent review by leading experts in survey methodology and this reported in 2000 (Lynn and Elliot 2000). They recommended a number of major changes to the survey including:

- A move to a continuous fieldwork with the crime reference period being the 12 months ending with the most recent completed calendar month
- Expansion of the sample to obtain a minimum achieved sample of 600 or 700 interviews per year in each police force area
- Introduction of nonresponse weighting to incorporate both sample weighting (which was already being done) and calibration to population totals (i.e., to correct for potential additional nonresponse bias).

These recommendations were accepted, and the change took place with the 2001/2002 survey. There being 43 territorial police forces in England and Wales, this required a large increase in the annual sample size of the survey from around 20,000 in 2000 to around 33,000 in the 2001/2002 survey. Over the next few years, further demands for the BCS to provide key performance indicators led to further boosts to the annual sample size, which increased to over 36,000 in 2002/2003, some 38,000 in 2003/2004, and over 45,000 by 2004/2005.

More recently, it has been announced that due to cuts in government funding, the sample size of the survey will reduce with the 2012/2013 survey cut back to a sample of around 35,000 per year (Home 2012b). Nevertheless, it is a sign of the importance of the survey and the value in which it is held that in a period when other surveys have been stopped, the BCS continues to run with a sample some three times larger than the first survey in 1982.

Extension of Survey to Children

The survey was restricted to the experiences of adults except for a one-off exercise in 1992 when a separate sample of children aged 12–15 were interviewed (Aye Maung 1995). This previous exercise did not attempt to replicate the methodology of the adult survey or to combine estimates from the adult and child surveys.

Following recommendations in two related reviews of crime statistics (Smith 2006; Statistics Commission 2006), the BCS was extended to children aged 10–15 from January 2009.

The Home Office commissioned methodological advice on the feasibility of extending the survey to children (Pickering and Smith 2008), and following an extensive period of development and testing work during 2008, live data collection started in January 2009.

Children aged 10–15 are interviewed in households that have taken part in the main survey; where an eligible child is identified (according to age), one is selected at random to take part. Extending the survey to encompass children's experience of crimes raised some difficult issues with regard to classifying criminal incidents; e.g., minor incidents that are normal within the context of childhood behavior and development can be categorized as criminal when existing legal definitions of offences are applied. Four different methods for counting crime against children were examined and subject to user consultation (Millard and Flatley 2010). Following consultation, two main measures were adopted. The first, called the "broad measure," is one in which all incidents that are in law a crime are counted. This will include minor offences between children and family members that would not normally be treated as criminal matters. The second, referred to as a "preferred measure," is a more focused method which takes into account factors identified as important in determining the severity of an incident (as judged by focus groups with children).

Methodological differences between the adult and children's survey mean that direct comparisons cannot be made between the adult and child victimization data, although these estimates are now presented in the published quarterly crime statistics (Office for National Statistics 2012) to provide a better understanding of victimization experiences among adults and children resident in households.

Methodological Limitations

The CSEW is viewed as a gold-standard survey of its kind in terms of its methodology and response rate (the survey has continued to obtain a response rate of 75 % during the last decade when other voluntary household surveys in the UK have experienced falling response rates). However, as with other sample surveys, there are a number of inherent methodological limitations, some of which have already been touched on above.

The most obvious of these relate to sampling error and the inherent imprecision around survey estimates. There are other sources of survey error, such as related to respondents' ability to recall events and report them to the interviewer accurately. Some incidents may be forgotten or events beyond the reference period brought into scope. Respondents may be embarrassed or unwilling to disclose some information to interviewers. Questions may be misinterpreted by respondent, and interviewers themselves may make mistakes in recording information given to them, and coders may make errors of interpretation when assigning incidents to offence codes. The survey contractors go to great lengths to minimize these errors through careful training of interviewers, testing of questions, and quality assurance of all aspects of the survey process.

The Influence of the Survey on Criminological Thinking

The CSEW is now part of the UK National Statistics system with results from the survey reported on a quarterly basis alongside the police-recorded crime figures to provide a complementary and more comprehensive account of crime in England and Wales (Office for National Statistics 2012). The survey charted a rise in the volume of crimes covered by the survey through the 1980s reaching a peak in the mid-1990s. In line with the experience of many other industrialized economies, the survey described a fall in crime over the next 10–15 years with a generally stable trend in more recent years. However, the survey has had wider influence on criminological thinking, and it is this which is touched on below.

Victimization Risks Including Repeat and Multiple Victimization

The first BCS report highlighted the relative rarity of serious criminal victimization but also the fact that a small segment of the general population was particularly prone to falling victim (Hough and Mayhew 1983). At the time, the fact that it was younger adults, rather than the elderly, who were more likely to be victims of crime was a striking finding.

More detailed analysis of the dimensions of risk followed (Gottfredson 1984) including area-based analysis. For example, secondary analysis of the 1982 BCS revealed significant differences between high- and low-crime areas (Trickett et al. 1992). This showed a strong relationship such that the number of victimizations per victim rose markedly as the area crime rate increased. Further analysis showed similar patterns during the 1980s with a small number of areas hosting a disproportionate amount of crime (Hope and Hough, 1988). Further work examining the extent of repeat and multiple victimization includes one study of the BCS showing that 70 % of all incidents were reported by just 14 % of respondents who were multiple victims (Farrell and Pease 1993).

Such studies were influential in suggesting that a large proportion of all crime might be prevented if repeat or multiple victimization could be reduced and that crime prevention policy should focus on reducing the repeat victimization experienced by the most vulnerable people and in the most vulnerable places.

Sexual and Domestic Violence

The BCS has been groundbreaking in its approach to the measurement of sexual and domestic violence. A self-completion module on domestic violence was included in the 1996 BCS (Mirrlees-Black 1999) and on sexual victimization in both the 1998 and 2000 surveys. The 2001 BCS included a more detailed self-completion questionnaire on both these topics. It was designed to yield national estimates of the extent and nature of domestic violence, sexual assault, and stalking including the first ever such estimates of sexual assault against men (Walby and Allen 2004).

This showed that interpersonal violence affected around one-third of the population at some time in their lives with women suffering higher levels of victimization than men. It also demonstrated that such victims suffered high levels of repeat victimization, in particular of domestic violence. While these findings were not surprising to experts in the field, they quantified a phenomenon which helped to challenge others to seek to tackle these forms of violence.

Fear of Crime and Perceptions of Crime and Antisocial Behavior

Fear of crime has been a topic included in the survey from its very beginnings. It is a concept which is complex and difficult to measure. Over the years, the survey has deployed a range of questions, and researchers have sought to explain the key drivers and relationships (see, e.g., Allen 2006). Other researchers have used BCS questions to explore the frequency and intensity of fear of crime (Farrall and Gadd 2004). It has been suggested that few people experience specific events of worry on a frequent basis and that “worry about crime” is often best seen as a diffuse anxiety about risk, rather than any pattern of everyday concerns over personal safety (Gray et al. 2011).

The survey has also been used to describe two types of “perception gap”: one related to differences between what is happening to crime nationally and in the local area and, the second, the difference between perceptions of crime and actual crime levels. New questions added to the 2008/2009 survey revealed that the perception gap between changes nationally and in the local area were greater for the more serious violent (and therefore rarer) crimes and smaller for acquisitive crimes suggesting personal experience was more likely to play a part in the perceptions of the more common crimes while perceptions of rarer crime types are likely to be influenced by media reporting. In addition, analysis of small area police-recorded crime data showed a clear linear relationship between actual levels of crime and perceptions of the comparative level of crime in the local area (Murphy and Flatley 2009).

Antisocial behavior has become a major focus for government policy and practitioners since the late 1980s. Questions were added to the 1992 BCS to ask people about their perceptions of antisocial behavior in their area, and these have been revised and expanded over time to include personal experiences as well as perceptions and what such perceptions were based on (see, e.g., Upson 2006).

Public Attitudes to the Police and Criminal Justice System

The coverage of policing issues has expanded in the survey over time with specific modules of questions being included on contact with the police and public attitudes to the police (see, e.g., Skogan 1994). Analysis of the experience of ethnic minorities with the police has also been a focus of BCS analysis (see, e.g., Clancy et al. 2001). In more recent years, the focus on neighborhood policing and on police performance has led to questions being more routinely included on police visibility and public attitudes towards the police (see, e.g., Allen et al. 2006; Moon and Flatley 2011).

The BCS included questions on public attitudes to sentencing in the 1982 and in a number of subsequent rounds of the survey which has made an important contribution to the understanding of such issues. The 1996 BCS included a range of specific questions on attitudes to punishment and revealed a rather jaundiced view of sentencers and sentencing thinking them to be too lenient (Hough and Roberts 1998). This analysis showed that public disaffection was partly a result of ignorance of judicial practice and, ironically, when people were asked to prescribe sentences for actual cases, their sentencing tended to be in line with current sentencing practice.

New Types of Crime

Throughout its life course, the survey has sought to adapt to emerging issues, and below are some examples of how the survey has evolved to meet changing information needs.

Following the Stephen Lawrence inquiry in 1999, the survey included questions on racially motivated crimes, and in recent years, the module of questions has been expanded to ask victims of crime if they thought the crime had been religiously motivated. Other strands of "hate crime" have also been added to the survey more recently (see, Lader 2012).

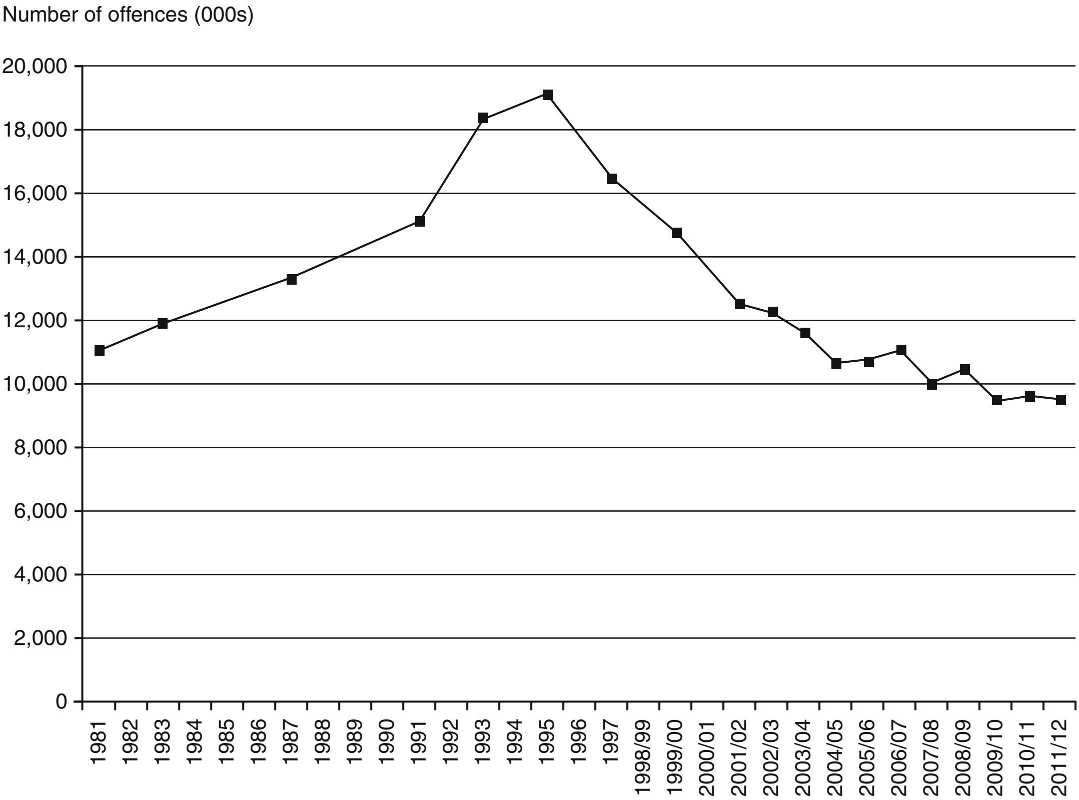
Responding to changes in technology, a mobile phone theft module was added to the 2001/2002 survey to examine levels of such thefts. Subsequent analysis has explored the extent of mobile phone theft which showed the increased risk of such victimization among children and young adults (Hoare 2007).

Similarly, a module covering fraud and technology crimes was first introduced in the 2002/2003 BCS. This covered the extent to which people had been victims of debit and credit card fraud, their computers had been infected with viruses or hacked into, or they had been sent harassing emails. An Identity Theft module was introduced to the BCS in 2005/2006 (Hoare and Wood 2007).

Future Directions

As has been described above, responsibility for the CSEW has recently transferred to the Office for National Statistics. In a piece written to mark the 25th anniversary of the birth of the BCS, the founders of the survey described the tensions within the Home Office between the researchers (who promoted the survey) and the statisticians (who were more skeptical of its value).

As shown in Fig. 1, the survey has charted the rise in crime from the early 1980s through to the mid-1990s and the subsequent crime drop that has also been seen across other developed economies. As the survey has become institutionalised as a key social statistic in the UK, responsibility for it has passed from the researchers to the statisticians (first, following a structural reorganization in the Home Office in April 2008 and more recently with the move to ONS). Perhaps inevitably this has resulted in a subtle shift in priorities. However, up to now the survey has managed to combine its social indicator and research tool functions.



British Crime Survey, Fig. 1 Trends in crime estimated from the Crime Survey for England and Wales

One of the key challenges for the ONS going forward is to ensure the continuation of both these functions to ensure the rich legacy of the survey as key resource for criminological enquiry continues.

British Police

Paul Lawrence
Department of History, The Open University,
Milton Keynes, UK

Overview

The development of policing in Britain prior to 1918 can be loosely divided into three phases.

From the early modern period until around 1850, the "old" police, a system of amateur or semiprofessional parish constables and night watchmen, were involved in the enforcement of laws and social norms. They shared this duty with a broad range of privately paid individuals and community groups, but, from c.1750 onwards, the efficacy of these localized and (relatively) informal mechanisms of policing was increasingly called into question. A variety of new initiatives were trialled, and, following on from the establishment of the Metropolitan Police in London in 1829, the so-called "new" police forces of the nineteenth century – uniformed, salaried, and preventive – were developed. These new forces did not initially mark a distinctive break with past practices and personnel, and there was a protracted period of overlap and reform. By about 1870, however, all administrative areas of Britain had instigated new, more "professional" institutions of policing. During the course of the nineteenth century, these new forces developed increasingly sophisticated policing techniques. Yet, while popularly depicted as a "golden age," policing in the later nineteenth and early twentieth century was typified as much by the persistence of police violence, scandal, and discontent as it was by the spread of new standards of order and control. In addition, regional variations across Britain further complicate any simplistic depiction of gradual and consensual reform.

Policing Before the "New Police"

Historical Antecedents

The presence of a uniformed and salaried police service is now so woven into the fabric of daily life that it is easy to forget that this is an institution of recent (in historical terms) advent. In Britain, the role of the central state in everyday life was relatively marginal prior to the nineteenth century, and the role of the individual and the local community in crime control, prosecution, and punishment was correspondingly greater. Indeed, the term "police" was not much used in Britain before 1800 and, even when in use, implied a much broader set of activities than just the prevention of crime and the detection of criminals (Dodsworth 2008).

This does not, however, mean that there was no "policing." During the early modern period, official policing duties in Britain were carried out by parish constables and urban watchmen. Under legislation dating primarily from the thirteenth century, constables were appointed locally, usually for no more than a year, and were charged with maintaining the King's peace in the district and reporting felons, miscreants, and nuisances to the local court. The efficacy of these parish constables was variable. There are some well-documented claims of negligence and inefficiency in apprehending offenders but there is also evidence that some served several terms of office, thereby gaining valuable expertise and authority. However, parish constables were not obliged to do anything which would take them beyond the boundaries of the jurisdiction they served, and there was no expectation that they would investigate all offenses which occurred in their locality (although they were expected to search premises or make arrests in instances where a magistrate's warrant was issued). Watchmen were recruited and funded locally to act as a deterrent to theft, usually in urban areas. They walked established beats at set times (usually at night), checking that doors and windows were locked. Watchmen made occasional arrests if they chanced across offenders, but were also not usually expected to seek out or track offenders after an offense had been committed.

In addition to parish constables and watchmen, there were a range of other, private arrangements made to safeguard property. Game keepers, private armed guards on mail coaches, individuals paid to watch barns and haystacks, and toll-gate keepers all had a role to play in the mixed economy of regulatory activity, and a significant amount of court cases resulted from apprehensions under such arrangements (King 2000, p. 63). In addition to these private policing initiatives, the role of the individual (whether as prosecuting victim or as helpful friend or neighbor) was crucial in early criminal justice processes. Individuals were expected to press (and pay for) charges, if the identity of the offender was known, and would often investigate crimes themselves or offer rewards for the recovery of stolen property.

Activities which would now be termed policing were thus carried out via a mixed regulatory economy, a rudimentary patchwork composed of limited state involvement, private initiative, business and community sanctions, and above all local enforcement of both legislation and social norms. Despite some tensions between the demands of magistrates and the norms of local communities, parish constables and watchmen maintained a broadly effective system of policing up until the end of the seventeenth century (Kent 1986).

The Bow Street Runners

From the 1690s onwards, successive governments attempted to encourage the apprehension of offenders (particularly highwaymen, burglars, and forgers) by expanding the system of rewards offered for successful prosecutions. However, as well as encouraging victims to prosecute, these incentives also served to multiply the number of private, entrepreneurial "thief-takers," many of whom were involved in corrupt practices such as encouraging (or even facilitating) robberies in order to claim the reward for subsequent arrests. With the bill for reward payments rising, the novelist and Bow Street magistrate Henry Fielding was granted a financial subvention in 1749 to enable him to establish a more organized body of men to confront violent offenders on the streets and highways around London. After Henry Fielding's death in 1754, this group was developed over subsequent decades by his blind half-brother John Fielding, one of the most innovate magistrates of the eighteenth century, into the Bow Street Runners. Sir John shaped these individuals into a well-known and stable group of officers with recognized expertise in investigating crimes, tracking and arresting offenders, and presenting evidence in court. While the men had no official title, because their role had no official standing, they were an innovation in policing in being both proactive in seeking out offenders (prompted either by orders from a magistrate or by a fee paid by the victim of a crime) and in gaining a degree of proficiency and continuity of service hitherto unmatched.

As part of their working practices, the Bow Street officers developed one of the first enduring systems of record-keeping relating to criminals and a range of rudimentary forensic techniques (e.g., ballistic and medical analyses). Thus, the "runners" can be thought of as "the first detectives," although the word itself was not used until the nineteenth century (Beattie 2012, p. 2). Indeed, some "principal officers" (a term they employed to differentiate themselves from the more junior patrolmen of the Bow Street magistrate's office) became highly sought-after professional investigators. John Townsend, for example, who had previously worked as a street vendor, gained such notoriety after a string of detective successes that he developed a close friendship with the Prince Regent and remained in popular demand among those who could afford his services.

The work of the principal officers was not, moreover, confined to London. Unlike parish constables, they were not bound to operate in any particular jurisdiction and, from the 1780s onwards, Bow Street officers were increasingly engaged by employers across the country, to the extent that they might be considered in some ways a precursor to a national police force (Cox 2010). The provincial magistracy, in particular, often required Bow Street assistance in the hunt for offenders, and principal officers often traveled significant distances in pursuit of felons. Because it was primarily the wealthy who engaged the services of Bow Street, this did mean that the officers primarily investigated crimes damaging to commercial interests (such as forgery, arson, and fraud) and there is certainly no sense that this was a police force acting to enforce the law uniformly and in the interest of all members of the public. Moreover, while there is little doubt that many of the principal officers were energetic and effective thief-takers, they were less effective as a preventive force and their numbers were arguably insufficient to make a significant impact on daily life in London, let alone further afield.

Debate and Reform from 1750

During the latter half of the eighteenth century, policing was thus by no means wholly unsatisfactory in many urban areas of Britain. The significance of London as a center of population and commerce meant that policing here was the most well developed in the nation. In addition to the Bow Street Runners, many districts operated their own locally controlled police services (Paley 1989), and many parishes also paid for and operated sophisticated watch systems (Reynolds 1998). There has been comparatively little research into the policing of the rural counties, but it is likely that the quality of policing here depended primarily on the personal inclination and ability of local justices of the peace and parish constables. However, from the mid-eighteen century onwards, significant national debates took place about the desirability of developing new modes of policing which might curtail local control and variability in the field of law enforcement. These debates were centered on London, as the most significant (and rapidly developing) urban center in the period, but also generated strong views from local authorities concerned about the implications of new forms of policing for their power to govern.

A number of factors prompted a focus on policing reform from the 1750s onwards. There was a public concern about the increasing incidence of certain types of crime (including theft, highway robbery, and rioting), but this concern has to be seen as part of a broader anxiety about how to cope with a period of rapid social change in which a mobile laboring class was developing. Equally, the expansion of the ambitions of the state during the later decades of the eighteenth century led to tensions over the correct relationship between central and local authority, and debates over policing reflected these tensions. There were also specific debates over the efficacy of existing policing arrangements as Fielding's view that crime was best prevented by an efficient detective force came under attack from others (such as Patrick Colquhoun) who believed that a preventive police (operating primarily via the patrol of predetermined beats) would be a better solution to the problem (Neocleous 2000).

Attempts to reform policing in London began in the 1780s when the City of London (the administrative division at the wealthy heart of the capital) organized a small, regular patrol for the city's streets. This patrol was uniformed from 1791 and gradually increased until it numbered 24 in 1824. In other areas of London, reform attempts began in 1785 when Pitt the Younger introduced the Westminster Police Bill, which was designed to put in place a centrally controlled police force for the whole city. This bill was defeated, but a far more moderate alternative was passed in 1792 and established seven new police offices in the city, each staffed by three stipendiary (salaried) magistrates, with six constables attached to each office. Further reforms followed, with a privately funded police force established by Act in 1798 to protect goods at London's docks. In 1800, this force was publicly funded as the Thames River Police. Private involvement in crime control remained significant. The Bank of England, for example, developed sophisticated nationwide mechanisms for apprehending and prosecuting forgers (McGowen 2005). The situation in London was unique, however, and most of the country, outside the large towns, "relied for their basic law enforcement on unpaid, part-time constables aged 30 or over" (Philips and Storch 1998, p. 5). Thus, while a variety of debates and reforms were already underway before the advent of the "New Police" in 1829, these were very much focussed on London and the larger cities (notably Glasgow), with much of Britain still policed lightly by systems which had been in place for centuries.

The "New Police"

The Metropolitan Police Act 1829

The most obvious outcome of the debates around policing which took place in the period 1780–1820 was the formation of the Metropolitan Police in London in 1829. This force was the most significant element of the so-called "New Police" of the nineteenth century. This shorthand term, which came into regular use in the decade after 1829, is now used as a useful descriptor for what many have seen as a wholesale reorganization of policing in Britain between 1829 and 1870. It refers to any of the new forces set up in response to the Police Acts of 1829, 1839–1840, and 1856 or, collectively, to all of them.

The Metropolitan Police Act was introduced to parliament by Sir Robert Peel in 1829. When Peel took over as Home Secretary in 1822, he argued the need for a new system of police – uniformed and supposedly both more efficient and more professional than their eighteenth-century counterparts and able to control the capital's new suburbs where the old system was weak. Although the validity of the statistics Peel used to "prove" his case in 1829 (by showing a tide of rising criminality) was probably minimal, he handled the political sensitivities of the issue adeptly, concealing the fact that he had already made up his mind what the reformed police should look like (Philips 1980, p. 186). Given an easy ride through parliament because of the attention being directed to the issue of Catholic emancipation, the subsequent act established the Metropolitan Police, neatly sidestepping concerns expressed by the City of London Corporation (which was worried about infringements on its authority) by leaving it outside the jurisdiction of the measure.

Thus, in 1829, the Metropolitan Police Improvement Bill was passed, and the new force of 3,000 uniformed constables took to the streets between September 1829 and May 1830. Throughout the 1830s, there was vociferous criticism of Peel's new force. Many commentators felt the uniforms of the new police betrayed their essentially "military" character, associating them with the gendarmeries of the continent, which were seen to serve political ends. Others complained about the cost of the new system, which was more expensive than the old and often put fewer men on the streets, but which still had to be paid for out of local taxes. In addition, there was considerable overlap with the existent forces policing London. The new police initially operated in tandem with 300 or so constables operating out of Bow Street and other police offices, under the direction of magistrates (loosely supervised by the Home Office). While these constables were primarily a detective force, and the new Metropolitan Police were primarily preventive, there was obviously overlap in their activities. This was investigated by a number of parliamentary select committees during the early 1830s and, in 1836, the Horse Patrol was amalgamated into the Metropolitan Police, with the Bow Street constables being absorbed in 1839. The 1833 Select Committee on the Metropolitan Police did also recommend that the separate jurisdiction of the City of London be abolished, but eventually the city introduced its own police force, via a private bill which precipitated fierce debate (Harris 2004, p. 132–53). As a legacy of this, the City of London still maintains its own police force distinct from that of the rest of metropolitan London.

Thus, the introduction of the Metropolitan Police was the result of a complex process of gradual and contested reform and did not necessarily mark the distinct and sharp break with previous practices that the epithet "New Police" might suggest. Such a large, uniformed force (dressed in top hats and blue tunics with high, stiff collars), firmly based on the preventive principle of beat policing (and initially featuring no detective division), was an innovation. The fact that this new force's commanders (two Commissioners of Police and a Receiver responsible for financial matters) were appointed by the Home Secretary and ultimately responsible to Parliament was also a departure from previous practice. Despite this, the new metropolitan force had considerable continuities of working practice with previous law-enforcement bodies, and there was also a considerable overlap in personnel, with many "old" police constables finding work within the Metropolitan Police.

National Police Reform

Outside of London, by the late 1820s, members of the provincial ruling class were also increasingly discussing the presumed inadequacy of existing policing arrangements (Philips and Storch 1994). This did not mean that reform followed swiftly, however. After the success of his 1829 Act, Peel devised plans for a "national" network of policing managed by stipendiary magistrates controlled by the Home Office. A bill along these lines was nearly introduced in 1832, but plans were shelved when it became apparent that local authorities were primed to resist on grounds of cost and the erosion of local control. Central control was imposed in some areas where fears of public disorder were particularly acute. In 1839, for example, Birmingham, Bolton, and Manchester had the control of policing taken out of local hands due to fears of political agitation. In general, however, the legislation which was successfully passed in the 1830s was primarily permissive – allowing for policing reform under local control but not requiring it. The national Lighting and Watching Act of 1833, for example, paved the way for urban policing reform by providing borough authorities with the means to improve their daytime watches and night patrols. The Municipal Corporations Act of 1835 specified that watch committees be set up to appoint and direct urban police forces. For rural areas, the recommendations of the rather one-sided 1836 Royal Commission on a Constabulary Force led to the Rural Police Act of 1839 (and a further amending act in 1840). This permissive act left the decision on whether to establish a rural police (as well as the control of that force) in the hands of the county magistrates.

While 24 counties had implemented the 1839 Act by 1841, and a further 11 did so in the next 15 years, around a third of counties still had not implemented any reforms by the mid-1850s. For this reason, another Select Committee was appointed in 1853 to consider the expediency of adopting a more uniform system of police. The resultant police bill, introduced in 1854 against a backdrop of extensive public order problems in the north of England, proposed that boroughs with less than 20,000 inhabitants would cede control of their forces to the counties and that there would be greater Home Office interaction with Chief Constables. These proposals again encountered stiff opposition, primarily from boroughs, with strong support from the City of London, and the bill was withdrawn. A subsequent bill introduced in 1856, which left local control of the police intact, was more favorably received, partly because of the ending of transportation to Australia, which elevated public concern over ex-convicts remaining at large in Britain. The resultant County and Borough Police Act of 1856 made the establishment of police forces a requirement at local government level in all counties and boroughs and allowed for part-funding from central government funds via a grant which the force would only receive if it passed an annual inspection (Parris 1961).

By c.1870 almost all provincial authorities had established new police forces but, overall, police reform in the nineteenth century was a complex, evolutionary process. Most counties and boroughs recognized the need for change but feared the loss of their authority to central government. The process of reform was further complicated by the fact that some new forces around the country were actually set up in advance of the national legislation, as a result of local initiative. In Gloucestershire, for example, the parish of Dursley had created its own force in 1814 in a way which prefigured later, national interventions. Thus, the idea that the Metropolitan Police Act served as an example to other areas of the country cannot be wholly sustained. A further layer of complexity is added by the fact that other national legislation passed during the period (such as the Parish Constables Act of 1842 and the Superintending Constables Act of 1850) in fact allowed rural parishes to appoint constables on the model of the "old" system, an allowance that many availed themselves of (Philips and Storch 1998, p. 213–19). Thus, while the police forces introduced as a result of the police acts passed between 1829 and 1856 were "new" insofar as novel legislation compelled the implementation of new structures locally, the debates, delays, and diversions around this implementation meant that the "New Police" did not necessarily represent a sharp break with the past. This statement is equally true in terms of police practice, where continuities with older mechanisms of policing were also in many ways also apparent.

The Practice of Policing

The Process of Professionalization

By the latter quarter of the nineteenth century, recognizably modern structures of policing were in place in England and Wales (with Scotland and Ireland, as outlined below, being policed under separate arrangements). In some senses, these "new" police forces were professional from the outset. In contrast to the "old" police, they were salaried, uniformed, and paid pensions after retirement. However, initially at least, many forces had considerable problems with both the enforcement of discipline and high staff turnover, with many constables fined or dismissed for drunkenness and inefficiency. This was partly due to key differences in the expectations the new forces had of their employees. In particular, the establishment of close supervision of the body of the constable (via drill, beat monitoring, and instruction), combined with the novel forms of time discipline required, meant that many "old" police constables found it hard to make the transition to the newer forces (Williams 2013). There were also periodic petitions in some cities for better pay and conditions. While a Chief Constables Association was formed in 1893, the clandestine Police and Prison Officers Union, which sought to represent the rank and file and organized a police strike in 1918/1919, was swiftly outlawed. British police officers have been barred from joining trade unions ever since.

Gradually, however, police forces matured as employers. The Metropolitan Police was one of the largest work organizations of any kind in nineteenth-century London, employing almost 22,000 men by 1914 (Shpayer-Makov 2002). Yet, from the outset, the Metropolitan Police (as with other British forces) was essentially a meritocracy, with all but the top 11 positions being filled from those who had risen through the ranks. This, combined with good pension provision (unusual for working-class employees during the nineteenth century), meant that the labor force of the new police gradually bedded in and the high turnover rates of the early years eventually subsided. The size, nature, and working practices of the new forces were far from static, however. As police forces matured, so new elements of professional practice were continually added to the policing repertoire, a key element of which was plain clothes detection.

Because of public fears that the new police could easily become a political "spy" police such as that believed to operate within many European countries, there were initially no detective departments or specialized detectives within the new police forces. While there were some officers who worked in plain clothes, it soon became clear that dedicated detection activity was a necessary part of police work. The Metropolitan Police set up a detective division in 1842, and the City of London and some larger cities and towns followed suit. Yet detective activity remained a surprisingly small element of police work. There were only a few hundred police detectives in the mid-nineteenth century, although this number had more than doubled by 1918 (Shpayer-Makov 2011). Britain did also, eventually, develop a "political" police of sorts. The secretive Special Branch, initially the Special Irish Branch, was set up in 1883 to combat Irish terrorism on the British mainland, but eventually extended its activities to encompass the surveillance of a wide range of individuals, including those with known left-wing political views (Porter 1987).

The identification of suspects was another important element of police work which underwent significant development. In an age before routine identification documents such as passports, knowing whether a person held in custody was a repeat offender was a complex problem, and the new police were quick to put emerging technologies to good effect. Photography was in use in British prisons as early as 1847 but was not common practice within police forces until the 1871 Prevention of Crime Act, which set up a central registry held at Scotland Yard (the headquarters of the Metropolitan Police). By 1886, this registry contained c.60,000 photographs of known offenders, showing the police as early and enthusiastic adopters of the technology (Stanford 2002). The crucial aid to the identification of suspects was the fingerprint bureau set up at Scotland Yard in 1901. Fingerprinting rapidly became the default means of identification in use in Britain and was much emulated around the world. The technology was not developed in England, however, but rather in India in the 1890s (by the Inspector General of Police in Bengal, Edward Henry), before exported back to the metropole (Cole 2002).

Novel technologies were certainly useful to the practice of policing but much police work was (and still is) based on routine bureaucracy and this, too, is worthy of consideration. The development of sophisticated systems for sharing information of all kinds marks part of the process of professionalization of the police. Internally, from the outset, the new police forces ran themselves via interlocking systems of reports and returns, which subjected the actions of each level to the surveillance and control of those above them. In relation to crime control, the 1871 Prevention of Crime Act set up a register of "habitual criminals," and from this register, the Home Office prepared an annual register of distinctive marks for circulation to all police forces. In addition, the Metropolitan Police maintained its own sophisticated archives which enabled better tracking and identification of suspects. Other regional forces had similar mechanisms for circulating information about increasingly mobile criminals in an era before widespread telephone communications. Such everyday practices as keeping files and circulating information in a timely and effective manner were the product of considerable thought and design and came to form an integral element of modern policing (Williams 2013).

The Limited Power of the State

Although police forces were larger and better trained than ever by the turn of the twentieth century, there were always limits to the capabilities of the police. Just as the narrative of institutional police reform was a convoluted one, so the story of the development of policing practice is not just one of increasingly sophisticated techniques of control. On the one hand, despite a public rhetoric which presented the British policing as consensual and the individual constable as simply "a citizen in uniform," the new forces undoubtedly acted to some extent to enforce new, middle-class standards of decorum. In some districts, the new constables were termed "a plague of blue locusts" due to their role in regulating drinking, gambling, and other working-class leisure activities (Storch 1975). Street offences (such as public drunkenness, vagrancy, and begging) took up an inordinate share of police time, with a similarly large focus devoted to the prevention and investigation of property crime. White-collar crime (a term coined in 1939 to describe fraud and other financial crimes committed by those in positions of authority) was not something which occupied the police particularly during the nineteenth century. The new police could, therefore, be viewed as "a new engine of power and authority," helping to manufacture an orderly working class suitable to the modern, capitalist economy (Philips 1980).

In reality, however, it was always impossible for the police (as for contemporary forces) to accomplish everything which might be required of them. While the police may have been granted extensive legislative powers and been asked to intervene frequently in the fields of popular morality and public behavior, this does not mean that they always did. Prevalent street culture remained resistant to police control, and the two Metropolitan Police Commissioners (and other chief constables around the country) often found themselves, of necessity, having to tread a path midway between the demands of local authorities and pressure groups, on the one hand, and the practical necessity for good relations with the populations they policed, on the other. Overall, policing practice in the nineteenth century was often designed to establish minimum standards of public order without provoking social conflict by aiming at unattainable standards. The role of discretion on the part of both individual officers (and senior commanders) in deciding what offenses to prioritize was always significant in the operation of policing. While the new police undoubtedly did spend a great deal of their time concerned with minor property crime and street offenses, these duties were often undertaken with sympathy and a degree of understanding (Lawrence 2004), and the police were in some ways a social mechanism which could be engaged by all classes (Davis 1984).

Consideration of the social backgrounds of police officers is a useful key to understanding some elements of policing practice during the period to 1918. English policemen (and they were exclusively male until the First World War) came from a range of backgrounds, but were overwhelmingly drawn from the unskilled and semiskilled working class (Emsley and Clapson 1994). This meant that some officers were at times understandably reluctant to enforce what appeared to many of them to be pointless attempts at social engineering. Moreover, the acquisition of social status through physical strength and aggression remained a key element of working-class culture during this period, and this meant that many police officers strove to be "as hard as the local hard men" (Emsley 2009, p. 149). Violence on the part of the police was a recognized (although not celebrated) facet of policing practice for much of the nineteenth century. Public order policing (particularly the regulation of political demonstrations and trades unions meetings) remained a key part of policing and here, too, violence on part of police also far from unusual.

Overall, it is apparent that the way the police were organized and the duties they were given meant that they were more likely to come into contact with members of the working class than other social groups. It was not until the advent of mass motoring that the middle classes really came into extensive contact with the police. However, any consideration of the operation of the new police in the nineteenth century needs to recognize both the novel demands made of constables and the pragmatism and discretion with which they mediated these demands.

Regional Variations

The policing of the outlying areas of Britain reveals both similarities and differences with England. Wales had the same legal system as England during the nineteenth and early twentieth century, and hence policing developments there followed similar patterns. Initial resistance to reform on the grounds of cost and the erosion of local control was followed by gradual acceptance. While the new police in Wales were involved in the imposition of new standards of social order, the size and composition of forces (particularly in rural areas) very often impeded the efforts of elites to impose certain aspects of social regulation (Jones 1982).

Scotland had its own legal system, yet there has been relatively little research focussed specifically on Scottish policing. What is evident is the significance of the English model, but also the ways in which it was tailored to local conditions (Barrie 2008). Scotland emerged from the age of improvement with a modern, professional police, but constabularies were initially administered under a dual control system whereby elected police commissions shared responsibility for the administration of forces with town councils and magistrates. Scottish police forces, as was the case in England and Wales, customarily adopted a pragmatic approach to the many demands placed upon them. More significantly, as in the English case, some elements of working-class culture, such as heavy drinking, remained more resistant to the new police than both police commissions and town councils would have liked.

Ireland, despite having the same legal framework as England from 1801 to 1922, had particular social, economic, and political circumstances which made issues of law and order (particularly public order policing) especially significant. As in England, an "old" police existed in Ireland at the turn of the nineteenth century. Parochial constables had no uniform or training and were usually only policemen in their spare time, but were tolerably effective in some areas (Malcolm 2006). Reforms introduced by the government in London were implemented in 1822 via the Irish Constabulary Act, which established a new force in each barony with chief constables and inspectors general under the control of Dublin Castle (the seat of British power in Ireland). The duties of these forces were in many ways similar to those of the new constabularies in England but they were paramilitary in nature. Armed from the start and divorced from local civil control, the police in Ireland had a much more prominent role in the maintenance of public order than forces in mainland Britain.

Following the Police Reform Act of 1836 and under the command of James Shaw Kennedy (who had originally been offered the commissionership of the Metropolitan Police by Robert Peel), the Irish Constabulary (which gained the prefix "Royal" in 1867) wore bottle-green uniforms, were armed with short-barreled carbines and sword bayonets, and lived in barracks. Dublin itself was policed by a separate civil force – the unarmed Dublin Metropolitan Police. While the RIC gradually became more representative of the Irish population, largely due to sustained efforts to recruit more Catholics into the rank and file, this process took decades, and the turnover among police personnel remained high. Thus, as with the English case, the nineteenth century saw a gradual evolution of recognizably modern mechanisms of policing in Ireland. Although the public order issues raised by Ireland’s complex relationship with mainland Britain, and the armed and national nature of the RIC, meant that there were distinct differences, it is also obvious that constables in both England and Ireland faced many of the same challenges and also undertook very similar sorts of duties on a daily basis.

Conclusions and Future Research

The advent of the “new police” in nineteenth-century Britain did not represent the sudden or total shift in institutions and practices which historians once assumed. The “old” police was in many ways a tolerably effective system in some areas, and there was significant continuity in both practices and personnel as new forces were set up post-1829. Police reform and changes in operational practice during the nineteenth century were extensive but were also often gradual and cumulative, rather than sudden or decisive. By 1918, policing in Britain and Ireland was very different to the pre-1829 era, but even in the 1880s and 1890s, many remnants of older, private, or informal mechanisms of policing still survived.

Despite 30 years of sustained academic research into British police history, however, there are still numerous unexplored topics. In particular, while significant attention has been lavished on London (rightly so, given its significance in the reform process) and a few other major cities, there is relatively little research which looks in detail at how policing was conducted in the rural areas and smaller towns of England. In addition, Wales, Scotland, and Ireland require considerable research to establish the extent to which developments in England are generalizable to those areas also. The interaction of the new police with the many other interest groups and agencies which were involved in the regulation of social life in the nineteenth century is another area requiring further attention. The significance of policing for any true understanding of the social history of the recent past hopefully means that these areas will not be lacking research for long.

Incivilities thesis; Order maintenance

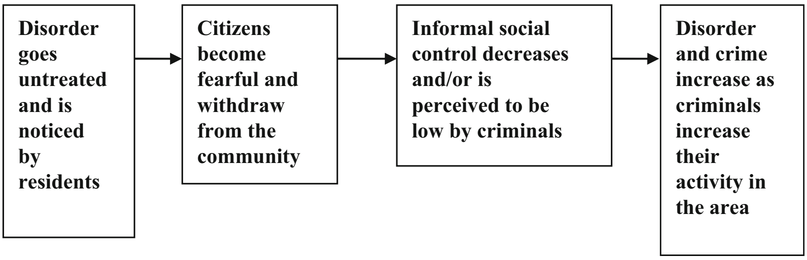
Overview

Few ideas in criminology have had the type of direct impact on criminal justice policy exhibited by the broken windows thesis. From its inauspicious beginnings in a nine-page article by James Q. Wilson and George Kelling in *The Atlantic Monthly*, the broken windows thesis has impacted policing strategies around the world. From the "quality of life policing" efforts in New York City (Kelling and Sousa 2001) to "Zero Tolerance" policing in England (Dennis and Mallon 1998), police agencies around the world have embraced Wilson and Kelling's idea that focusing on less serious offenses can yield important benefits in terms of community safety and prevention of more serious crime. Despite this broad policy influence, research on the theory itself has been relatively weak and has produced equivocal findings as will be detailed in this entry.

The Broken Windows Model

In a nutshell, the broken windows thesis (Wilson and Kelling 1982) suggests that police could more effectively fight crime by focusing on more minor annoyances which plague communities – hereafter referred to as disorder (some works also label these issues as "incivilities"). Disorder includes both rundown physical conditions in the form of litter, dilapidated buildings, graffiti, etc. as well as social nuisances such as panhandling, loitering, and public drinking. Their idea that crime could be prevented through targeting these issues was based on their thesis that such social ills eventually lead to community decline if left untended.

This process essentially has four key steps and begins with disorder not being dealt with in a timely manner. Trash is not picked up; loiterers are not asked to move on; people are drinking in public without being warned away. In time this invites more trash being thrown in the street, more loiterers to gather, and more people to start drinking in public. As this disorder accumulates, it sends a message to residents that things are getting out of control and that social



Disorder goes untreated and is noticed by residents
Citizens become fearful and withdraw from the community
Informal social control decreases and/or is perceived to be low by criminals
Disorder and crime increase as criminals increase their activity in the area

Broken Windows Thesis, Fig. 1 The broken windows thesis

controls have failed in their neighborhood. The key here is that residents perceive this untended disorder accumulating. It will likely have little impact if residents are not aware of the disorder in the community. In turn, the next step of the process is that residents who perceive worsening disorder problems eventually become fearful and begin to withdraw from the community. They spend less time outside, become less likely to intervene and ward off disorderly people, and, in the extreme, "good" residents may move away.

This leads to the third step of the process, which is a lowering of informal social controls. The community withdrawal results in fewer watchful eyes on the street, and the area is now less able to regulate behavior through informal social controls. As such disorder and minor crimes continue to flourish in these areas. Finally, this brings about the fourth step, in which criminals take these signs of untended disorder as a cue that such a neighborhood is a good place for them to work with relative impunity as they perceive their chances of being arrested in such areas to be slim. In Wilson and Kelling's terms, such neighborhoods are vulnerable to criminal invasion. It is not inevitable, but such places are much more likely, in their view, to see an increase in crime than neighborhoods which exert control in regulating the occurrence of disorder. Once crime occurs, residents also notice this and the cycle of fear and withdrawal is likely to worsen as the process is essentially a feedback loop. The steps of the community decline cycle outlined by broken windows thesis can be visualized as shown in Fig. 1.

As such, a main thrust of Wilson and Kelling's argument was that police could fight crime more effectively by dealing with disorder. If they stop disorder from accumulating and prevent neighborhoods from reaching the tipping point where they become vulnerable for criminal invasion, they can have a large impact on crime. Wilson and Kelling do not discuss what police may do in neighborhoods already past the tipping point and fully invaded by criminal behavior, but one could imply that cleaning up disorder would still play a role in restoring informal social control in such neighborhoods and helping residents take back the streets. As with any theory about crime, the broken windows thesis can be more readily understood by examining the research that influenced its formation.

Theoretical Development of the Broken Windows Thesis

While Wilson and Kelling are credited with developing the broken windows thesis, they were not the first to examine the role disorder played in communities. In the area of criminology, concern over disorder can partly be traced to early research on fear of crime. One issue that drove interest in the topic was a body of research that consistently found that fear of crime had seemingly little to do with crime. For instance, most studies found that females and the elderly reported the highest levels of fear of crime, yet the National Crime Surveys conducted by the Bureau of Justice Statistics consistently showed young males to have the highest rates of victimization. Thus, fear of crime did not appear to be driven by actual victimization risk, and these findings naturally led criminologists to question what was driving fear of crime if not crime itself.

A number of studies turned to disorder to explain fear of crime. For example, James Q. Wilson first noted in 1975 that people were troubled not only by crime but also by:

> The daily hassles they are confronted with on the street – street people, panhandlers, rowdy youths, or 'hey honey' hassles – and the deteriorated conditions that surround them – trash strewn alleys and vacant lots, graffiti, and deteriorated or abandoned housing – inspire concern. (p. 66)

Similarly, Garofalo and Laub (1978) stated that "...what has been measured in research as the 'fear of crime' is not simply fear of crime" (p. 245) and tied fear to quality of life and concern for the community. Ideas closely related to the broken windows thesis are most clearly seen in work by Hunter (1978). Hunter suggested that disorder affected both fear of crime and actual crime through a process in which disorder signaled to residents that local controls had failed and caused them to become personally at risk of victimization. He suggested that this would increase crime and further increase fear. His work can easily be seen as an early version of the broken windows thesis.

Finally, Wilson and Kelling's ideas were greatly influenced by a social-psychological experiment conducted by Stanford psychologist Philip Zimbardo in 1969, as indicated by the detailed discussion of the experiment in their broken windows article. Zimbardo abandoned a car with its hood up in two places – the Bronx in New York City and on the Stanford Campus in Palo Alto, California. The car in the Bronx was vandalized within 10 min, and within 24 h everything of value was removed. The car in Palo Alto, however, was not touched for more than a week. Zimbardo then smashed the windshield with a sledgehammer, and from that point on, people passing by saw the activity and the damaged car and joined in the destruction. This is where the broken windows metaphor came from for Wilson and Kelling and, combined with the above work on fear of crime and disorder, formed the basis for their ideas that untended disorder is what eventually leads to a neighborhood becoming crime plagued. Just like the broken window on the car in Palo Alto invited more vandalism, untended disorder is a visual cue in a community which invites more disorder and eventually more serious crime.

While the theoretical underpinnings of the broken windows thesis can clearly be seen in this early work on fear of crime and the Zimbardo experiment, the law enforcement portion of Wilson and Kelling's ideas was directly influenced by earlier research they had conducted on policing. Most notably, this is seen in the work of Wilson and Boland (1978) who noted that aggressive policing can reduce crime. Their main point was that the police may reduce crime not by how many are on patrol but rather by *what* they do while on patrol. They suggested that if police are aggressive in arresting criminals, they can have more of an impact on crime. Their study used traffic citations for as a proxy for aggressive policing and found a negative relationship between police aggressiveness and crime rates.

George Kelling was also greatly influenced by his earlier work on policing. In particular, the broken windows article repeatedly makes reference to his experience working on an evaluation of foot patrol in Newark, New Jersey (Kelling et al. 1981). In the Broken Windows article, Kelling elaborates on how his experiences on this study showed him that by being active in the community, the police could maintain order and make residents feel better, which could have positive impacts even if the police strategy was not directly reducing crime.

The above discussion lays out the theoretical foundation for Wilson and Kelling's broken windows thesis. It is clear how work both on causes of fear of crime and studies of specific police practices laid the groundwork for their ideas that police could fight crime by tackling smaller problems – the disorder in a community that made residents fearful and uneasy. In the quarter century since its inception, the broken windows thesis has had a profound impact on policing and continues to be a subject of theoretical debate in scholarly journals. The sections below provide an overview of evidence on the validity of the broken windows thesis itself.

Testing the Broken Windows Thesis

For a theory that has had such a large impact on police practice, the broken windows thesis has received relatively little research attention in terms of testing the theoretical propositions the broken windows thesis itself. As this section will show, there are a number of studies which have examined individual propositions of the broken windows thesis (often with no direct connection to or mention of broken windows), but few studies have set out to explicitly and directly test the entire broken windows thesis.

Looking at the broken windows thesis outlined above, one can see that there are three main theoretical propositions that make up the path from disorder to more serious crime. First, disorder must increase fear of crime among residents. In particular, perceptions of disorder are most relevant here. If residents are unaware of disorder on their block, it is unlikely to impact their levels of fear. Secondly, residents who become fearful must withdraw from the community, thus lowering informal social controls/ collective efficacy. Third, crime must increase in the area in response to this withdrawal as criminals perceive the area to be a place to commit crimes with relative impunity.

Does Disorder Cause Fear of Crime?

Wilson and Kelling (1982) suggested that disorder's first effect was increasing resident fear of crime. A number of studies have explored this issue by testing the connection between disorder and fear of crime, and a selection of these studies are reviewed here. A neighborhood-level study by Covington and Taylor (1991) found that both objectively measured disorder, as well as survey measured perceptions of disorder, were related to fear of crime. Moreover, their perceived disorder measure was the dominant effect in the model. Another study involving a panel interview of residents in Baltimore found that between the two surveys, those whose perceptions of disorder increased reported less satisfaction with the block they lived on, as well as showing greater increases in feelings of vulnerability and fear of crime (Robinson et at. 2003). Also of note, some research has suggested that social disorder has a stronger relationship with fear of crime than physical disorder (LaGrange et al. 1992).

More recent research has also supported the link between disorder and fear. One study tested a variation of the broken windows/decline hypothesis similar to the model in Fig. 1 using a sample of neighborhoods from three waves of the British Crime Survey (Markowitz at al. 2001). Their findings suggested the model was correct. Of particular interest to the current research, they found that "the dominant effect in the cycle is the effect of disorder on fear" (p. 310). The authors thus concluded that their findings were consistent with the broken windows/decline hypothesis as they show that disorder may increase crime indirectly by increasing levels of fear which in turn reduce the level of social cohesion which may then lead to crime.

On the other hand, some research has suggested that the relationship between disorder and fear may not be straightforward. Taylor and Shumaker (1990) found a relationship between disorder and fear of crime, but noted that it may not be linear. Their findings suggested a quadratic relationship where disorder does increase fear, but as disorder gets higher, the strength of the relationship weakens. They note that perhaps people in high disorder areas get somewhat inoculated to disorder, just as people living in areas plagued by natural disasters may fear earthquakes or hurricanes less than people from other areas. In short, some people may be accustomed to disorder and not bothered by it as much. Additionally, a few studies have not found clear evidence of a link between disorder and fear of crime. For instance, Taylor's (2001) well-known study in Baltimore found that incivilities measured in 1981 and 1982 were not related to changes in fear of crime in these neighborhoods between 1982 and 1994.

Overall, the studies reviewed above illustrate that the link between disorder and fear of crime has generally been supported in past research, with a few exceptions. Thus, there is reason to believe that Wilson and Kelling (1982) and those before them (e.g., Garafalo and Laub 1978; Hunter 1978; Wilson 1975) were correct in asserting that signs of disorder make people feel uneasy and even fearful of being victimized by crime in their neighborhood. Moving on to the next proposition, what does the research say about the link between fear of crime and withdrawal from the community?

Does Fear of Crime Lead to Withdrawal?

As with the link between disorder and fear of crime, there has been work examining whether fear of crime leads to community withdrawal. Again, most of this work was done without explicit reference to broken windows, but there are studies of the topic in other areas such as tests of variables related to social control or collective efficacy (Sampson et al. 1997). A review of these studies is relevant to understanding the evidence on the broken windows thesis as informal social control/collective efficacy can be viewed as analogous to Wilson and Kelling's (1982) discussion of the ability (or inability) of a community to regulate behavior.

A study by Garafalo (1981) found that fear of crime was related to a host of social outcomes related to collective efficacy such as heightened interpersonal distrust, withdrawal of support for formal control agencies and decreased social interaction. The Markowitz et al. (2001) study cited above which found a link between disorder and fear also found that fear in turn reduced social cohesion. Thus, as with the link between disorder and fear, a review of the research on the link between fear and withdrawal/collective efficacy (and related constructs) is generally supported in past research. The majority of the studies reviewed find that increases in fear of crime are tied to reductions in things such as neighborhood cohesion, social involvement, and interpersonal trust. Moving to the final theoretical proposition, what does the research say about the impacts of withdrawal and reductions in social control/collective efficacy on crime?

Does Withdrawal/Weakening of Social Controls Lead to Crime?

This link of the broken windows thesis really gets at the notion that reductions in informal social lead to increases in crime. This topic has received a fair amount of research attention in work examining the impact of social control/collective efficacy on crime, as well as work on social disorganization theory. This brief review will focus on research on collective efficacy, as that is the specific theory of informal social control that is at the center of current debates over the broken windows thesis. Collective efficacy refers to the notion that crime can be controlled in a community where there is a high level of social cohesion/social ties and willingness to intervene for the common good (Sampson et al. 1997). Places with higher levels of collective efficacy are more able to effectively regulate behavior and thus have lower crime rates.

In general, the collective efficacy literature has been supportive of this inverse relationship between collective efficacy and crime rates. For instance, in the work first advancing the concept, Sampson et al. (1997) found that collective efficacy was negatively associated with violence after controlling for individual factors and prior violence. A study by Sabol et al. (2004) found that collective efficacy reduced youth violence, child maltreatment, and intimate partner violence. Ford and Beveridge (2004), in looking at illegal drug sales, noted that collective efficacy can prevent drug sales not only by resisting undesirable factors (like drug dealers) but also through increasing the capacity to attract positive factors (i.e., legal businesses).

However, a study by Morenoff et al. (2001) found that collective action for social control was negatively related to homicide, but found little support that social ties mattered. Thus, it appears to be important that communities have shared goals and that residents are willing to intervene for the common good, but that social cohesion/social ties may not necessarily be a key component of collective efficacy. What matters is whether a community can work together to solve crime and disorder problems. Residents may not have to have strong social ties/cohesion to share mutual goals for the community and be willing to intervene to achieve these goals. These findings fit with the broken windows thesis as Wilson and Kelling's (1982) work focused on the notion that disorder led people to become fearful and less willing to intervene in the community. Social cohesion was not explicitly focused on in their work, as they focused more on the notion of people being too afraid to intervene and/or even moving away in response to rising untended disorder in their neighborhood.

In short, work looking at the relationship between collective efficacy and crime has generally been supportive and builds on the social disorganization literature which has a long history of showing that a community's ability to exert informal social control is a powerful predictor of crime rates. As such, the final link of broken windows has been supported with a long history of criminological work which suggests that withdrawal and other factors that reduce informal social control, collective efficacy, etc. are likely to lead to increases in crime.

The Current Empirical Status of the Broken Windows Thesis

The above review shows is that there is a fair amount of support for the individual theoretical propositions behind the broken windows thesis. However, this support comes largely from a body of unrelated studies, few of which examine more than one step of the broken windows model, and even for the individual propositions, there are still mixed findings at times. In turn, there is still a great deal of debate about the validity of the broken windows thesis. While some authors have strongly advocated the model and/or broken windows policing (e.g., Bratton and Kelling 2006; Kelling and Coles 1996; Kelling and Sousa 2001), some recent research has challenged the broken windows thesis by suggesting that the relationship between disorder and crime is spurious and explained by collective efficacy (see Sampson and Raudenbush 1999).

A Direct or Indirect Relationship Between Disorder and Crime?

A study by Sampson and Raudenbush (1999) sparked considerable debate over the broken windows thesis. Sampson and Raudenbush set out to test the broken windows thesis and collective efficacy theory using data collected as part of the Project on Human Development in Chicago Neighborhoods (PHDCN). These data included systematic social observations of physical and social disorder which were collected by videotaping segments with video cameras mounted to a vehicle which drove through study areas at 5 mph recording both sides of the streets. The tapes were then coded by members of the PHDCN research team to record levels of social and physical disorder on the study blocks. Collective efficacy and other individual-level variables were obtained through a resident survey, while crime was measured through official police data (and survey measured victimization in some models).

Sampson and Raudenbush used weighted regression analysis and measured variable path analysis in their study and found that disorder was positively related to crime. However, when they added collective efficacy to the model, they found that the relationship between disorder and crime disappeared – except for robbery where it remained significant. As such they concluded that the broken windows thesis was not supported as disorder and crime were only spuriously related – their results showed both to be a result of low collective efficacy. They argued that disorder and crime were simply different degrees of the same problem with the same underlying cause, rather than being causally related as the broken windows thesis suggests. As such, they concluded "....that neighborhoods high in disorder do not have higher crime rates in general than neighborhoods low on disorder once collective efficacy and structural antecedents are held constant" (p. 638).

Other studies have also examined this notion of a direct link between disorder and crime and produced findings that challenged the broken windows thesis. A study by Taylor (2001) found that disorder measured in 1981 was not strongly related to crime in 1994 after controlling for initial neighborhood structure. A more recent study found that neither collective efficacy nor disorder was a sufficient explanation for crime (St. Jean 2007). While high collective efficacy and low social disorder (physical disorder did not matter) explained low crime rates, places with low levels of collective efficacy and/or high levels of social disorder were found to be about equally likely to have high or low crime rates. Finally, in another study using 16 years of census block-level data collected in Seattle, Yang (2007, 2010) found that the trends between violent crime and disorder were correlated. The direction of causation, however, was opposed to what was suggested by the broken windows thesis. The results from Granger causality tests generally showed no causal relationship between disorder and violence, and in a few places, the causality appeared to run from violent crime to disorder.

On the other hand, a recent social-psychology experiment conducted in the Netherlands did find some support for a direct link between the presence of disorder and minor criminal behavior (Keizer et al. 2008). The study manipulated the levels of disorder in places (graffiti, trash, etc.) and tested whether it had an impact on behavior among passersby. Most of the tests looked at the spread of disorder – for instance, one of the experiments which was part of this study found that the presence of graffiti in a researcher-manipulated area led to a higher likelihood of people littering (throwing a flyer attached to their bicycles on the ground) compared with another area where the researches did not place graffiti (but also attached flyers to bicycles). However, one part other experiment examined minor theft. This experiment involved placing an envelope with a small amount of money clearly visible sticking of a mailbox. In the control setting, there was no graffiti or trash around the mailbox, and in the two experimental conditions, there was graffiti on the mailbox in one setting and trash strewn around it in the other. In both cases, passersby in the conditions with disorder present were significantly more likely to steal the envelope than those in the control condition. Of course, it is impossible to say from this study if the presence of disorder could lead to more serious crimes as the broken windows thesis suggests, or if it is just another example of how disorder spreads (which was the main focus of the study) given the very minor nature of the crime in question.

While the methodologies of these studies are sound, and the negative results of all but the Netherlands study seem to be a large challenge to the tenets of the broken windows thesis, this body of work has been criticized as an unfair test of broken windows. The challenge to this work comes from its assertion that crime and disorder are *directly* related – that disorder directly leads to crime. Some scholars, including Kelling himself, have denied that broken windows ever implied a direct relationship between disorder and crime (Bratton and Kelling 2006; Gault and Silver 2008; Xu et al. 2005), arguing that it has always posited an *indirect* relationship between disorder and crime.

A reading of Wilson and Kelling's (1982) article would seem to support Bratton and Kelling's (2006) assertion that they have always posited an indirect relationship between crime and disorder. For instance, Wilson and Kelling stated "…at the community level, disorder and crime are usually inextricably linked, in a kind of developmental sequence" (p. 31). A developmental sequence does not imply a direct relationship. In fact, going back as far as Zimbardo's 1969 experiment, the broken windows thesis has been a social-psychological theory. It has never suggested that disorder in a community directly causes crime. Rather it has always posited that perceptions of disorder, created through visual cues of untended disorder in a community, increase fear and lead to residential withdrawal which leaves communities vulnerable to criminal invasion. Studies that look for a direct relationship between observed disorder and crime ignore the social-psychological foundation of the broken windows thesis and thus are not complete tests of the theory.

Given this flaw, the impact of Sampson and Raudenbush's study, and other work testing for a direct relationship between disorder and crime, is challenged. If Sampson and Raudenbush had specified their model in accordance with the propositions and social-psychological foundation of the broken windows thesis, their data may have actually supported the broken windows thesis. A correct specification would test whether perceptions of disorder were positively related to levels of fear and then test whether fear in turn was negatively related to collective efficacy (the informal social control portion of the broken windows thesis) and whether collective efficacy was related to crime. Given that they found collective efficacy inversely related to crime, a finding that disorder, through increased fear of crime, reduced collective efficacy would be supportive of the broken windows' notion that disorder erodes informal social controls and leads to increases in crime.

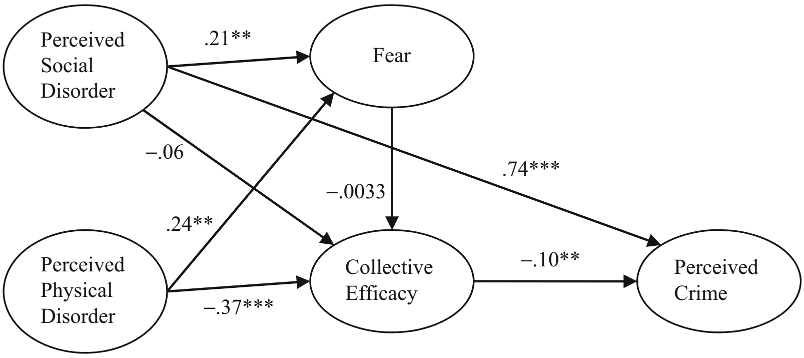
Sampson and Raudenbush (1999) themselves even made some statements that are supportive of a true reading of broken windows. For instance, in their conclusion, they state that "[e]radicating disorder *may* indirectly reduce crime by stabilizing neighborhoods. . . ." (p. 648). This is likely based on an analysis presented in passing on page 636 in which they found that "[t]he results indicated that observed disorder increases perceived disorder, which in turn reduces collective efficacy. The significant reciprocal relationship between violence and collective efficacy nonetheless remained intact. . ...." Thus, if Sampson and Raudenbush had set up their study to test the *indirect* link between perceived disorder and crime as outlined above, their conclusions likely would have been very different, as others have noted (Gault and Silver 2008; Xu et al. 2005).

Some recent research has aimed to address this issue by testing models that are more faithful to Wilson and Kelling's conceptualization of the broken windows thesis. Xu et al. (2005), in their study of community policing, found that perceived disorder had strong direct and indirect impacts on perceived crime after controlling for collective efficacy (Xu et al. 2005) and thus challenge the assertion made by Sampson and Raudenbush. However, Xu et al. also did not model the relations in the specific order suggested by the broken windows thesis and thus limited the ability of their study to test the theoretical propositions behind the broken windows thesis. Specifically, collective efficacy is only included as an exogenous variable in their structural equation models. Collective efficacy (along with community policing variables) is said to affect disorder and crime, which in turn affect fear of crime and perceptions of quality of life which then affect satisfaction with the police. As outlined above, a true test of the broken windows thesis as outlined by Wilson and Kelling (1982) would test the impact of disorder on fear of crime, which should in turn affect collective efficacy and crime.

A recent study aimed to shed light on this issue by using structural equation modeling to test the relationships between perceived disorder, fear of crime, collective efficacy, and perceived crime specified by the broken windows thesis (see Fig. 1 above) using structural equation modeling (Hinkle 2009). This study used perceptual data measured through resident surveys and found support for both direct and indirect pathways between perceived disorder and perceived crime in the best fitting model (see Fig. 2 below). While caution is needed in interpreting these findings due to the study using perceptual measures of disorder and crime from the same survey, the results nonetheless suggest that theories dealing with the relationship between disorder and crime may be overly simplistic if they only consider either direct or indirect pathways between these two variables. Additionally, the final model from this study challenged the centrality of fear of crime to the broken windows thesis. Once disorder was allowed to have direct impacts on collective efficacy and crime, the relationship between fear and collective efficacy hypothesized by the broken windows thesis was no longer statistically significant. The implications of these findings are elaborated on in the concluding section below.

The Future of the Broken Window Thesis

This review of the broken windows thesis essentially points out two key issues about the topic. First, it is an idea that has had a very



* =p <.05; **p <.01; ***p <.001; n=773; df=405
SRMR=.066; RMSEA=.047; CFI=.97

Broken Windows Thesis, Fig. 2 Testing the broken windows thesis (Final model from Hinkle 2009)

large impact on policing policy and practice. Second, despite this impact, the thesis itself has not received much direct empirical research attention. While there is a good deal of evidence on the individual relationships between disorder, fear of crime, collective efficacy/informal social control, and crime, there are hardly any studies which examine all of these variables simultaneously in one model with the relationships tested in a manner consistent with Wilson and Kelling's (1982) hypotheses.

As such, we still know little about the validity of the idea behind the policing model, and thus, debates over the thesis have been a hot topic in academic circles in recent years as outlined above. Given this dearth of empirical research explicitly testing the broken windows thesis, the future of the idea is very much up in the air. What is clear is that we need a substantial amount of empirical research testing the broken windows thesis. The study by Hinkle (2009) outlined above is one example and can serve as a starting point for a discussion of where future research on the broken windows thesis should begin.

A first takeaway point from that study is that future research should ideally consider both direct and indirect pathways from disorder to crime when testing the broken windows thesis. Future studies would be aided by including hard measures of crime in addition to perceptual measures. A second takeaway point was that fear of crime did not have the expected impact on collective efficacy once disorder was allowed to have direct impacts on efficacy and crime. While this is only one study, and this finding should thus be interpreted with caution, it does challenge the centrality of fear in the broken windows framework and suggests the need for theoretical elaboration on Wilson and Kelling's model.

For instance, while the results from this study challenge the role of fear of crime, it may also be unlikely that disorder and collective efficacy are truly directly related as the model in Fig. 2 shows. It may be more likely that there are other intervening variable besides fear of crime which mediate the impact of disorder on levels of informal social control. Maybe instead of untended disorder increasing fear and scaring off residents who care, it is more a matter of residents getting annoyed or frustrated and thus they give up intervening or even move away. Or perhaps over time some residents simply become used to the disorder and are not bothered by it as Taylor and Shumaker (1990) argued – in which case residents may become apathetic over time and thus stop intervening for the common good. Future theoretical work should consider these types of issues and attempt to elaborate on the broken windows thesis. It is up to such work to put forth more elaborate models based on theoretical propositions which clearly outline the relationships between disorder, crime, and whatever mediating variables are hypothesized to lie between these two constructs. These models can then be tested with SEM and other techniques to gauge whether they are supported empirically.

Finally, a key in sorting out these debates over the validity of the broken windows thesis will be testing the idea with longitudinal data. Most of the studies discussed above have tested the model with cross-sectional data. While such studies offer valuable insight into the broken windows model, it is nonetheless a theory of neighborhood decline that occurs over time. As such, it is best tested using data that covers a number of years. There have been some longitudinal tests of the theory by researchers such as Taylor (2001) and Yang (2007, 2010), and these tests tended to challenge the relationship between disorder and crime. However, these studies only tested for direct relationships between disorder and crime and thus were not full tests of the broken windows thesis.

Bullying

Maria Sapouna
School of Social Sciences, University of the West of Scotland, Hamilton, UK

Overview

The study of bullying has flourished in recent years, reflecting the growing recognition of the negative long-term effects this type of aggressive behavior can have on victims and bullies. There is now a considerable body of cross-sectional and longitudinal research that has informed our understanding of what bullying is; who it is most likely to affect; what consequences it can have for victims, bullies, and the peer group; and what can be done to reduce its occurrence. This entry attempts to shed some light on these questions by reviewing key empirical research conducted in this field over the last three decades. The piecemeal and theoretically unsystematic way in which much of this evidence has been produced, however, makes it difficult to reach a clear and coherent conclusion on why bullying happens and how it can be effectively prevented. Readers of this review should be aware of these research limitations, which, to some extent, reflect the complexity of the bullying phenomenon that precludes straightforward, one-size-fits-all conclusions.

Bullying Defined

Bullying has received worldwide attention in the last 30 years as a form of aggressive behavior that can have a significant negative impact on the physical, emotional, and academic development of victims. The first major contribution to the academic study of bullying was made by Dan Olweus, who wrote the first scholarly book in English to deal with bullying. The book was written in response to the suicide of three bullied boys in Norway and reported a high prevalence of school bullying (20 % of Norwegian children reported having some involvement) as well as discussed the success of the world's first bullying prevention program (Olweus 1993). Olweus' work opened the way for an explosion of research on bullying, which expanded from an initial interest in schools to include broader contexts such as the workplace, prisons, and sibling relationships. While much of this work is of interest, showing that bullying has the potential to affect a significant proportion of the population, this review focuses on school bullying, as this is the area that has attracted the most research interest to date.

The international literature is repleted with definitions of school bullying, most of which seem to accept that bullying is any type of negative action intended to cause distress or harm that is repeated and targeted against individuals who cannot defend themselves. When research on bullying started in the 1980s, bullying was perceived to comprise only episodes of physical or verbal aggression where the victim was physically attacked or called names. In recent years, the definition of bullying has broadened to include other forms of aggression that are relational in nature and aim to damage the victim's peer relationships and their social status such as spreading of malicious gossip and social exclusion. Fighting between people of approximately equal strength, a one-time attack, or a good-natured teasing and play fighting are not counted as bullying.

The advent and widespread use of electronic means of communication such as mobile phones and the Internet has made it easier to bully anonymously, through the use of pseudonyms and temporary accounts, at any time and in any place involving a wide audience. This development has meant that the definition of bullying has had to be expanded to account for what the literature refers to as "cyber-bullying" or "electronic bullying." A nationally representative survey of 7,508 adolescents in the United States in 2005 found that 8.3 % had bullied others and 9.8 % had been bullied electronically at least once in the last 2 months (Wang et al. 2009). In the same year in England and Wales, a survey of pupils aged 11–16 found that 22 % had been cyber-bullied at least once or twice in the last couple months (Smith et al. 2008). The most common form of cyber-bullying internationally is sending threatening and/or nasty text messages.

Prevalence and Continuity

National Variation

There are large variations across countries in the prevalence of bullying perpetration and victimization. In an international survey of health-related symptoms among school-aged children, the percentage of students who reported being frequently bullied during the current term ranged from a low of 5 % to 10 % in some countries to a high of 40 % in others (Due et al. 2005). The prevalence of bullies in primary school ranges, in most countries, between 7 % and 12 % and remains at those levels in secondary school (around 10 %). It is unclear whether these differences in prevalence reflect genuinely different levels of engagement in bullying among countries or, at least partly, result from different meanings of the term "bullying" in different countries and differences in methodologies and samples used.

An example of why valid comparisons between countries are not possible is Portugal where the bullying rate is high compared to other countries. Berger (2007) in her analysis found that one detail of educational policy in Portugal may account, among other things, for this higher rate of bullying. In Portuguese schools, children are asked to repeat sixth grade unless they pass a rigorous test. This practice results in at least 10 % of all sixth graders (more often boys) to be held back 2 years or more, and these older, bigger children are almost twice as likely to bully compared to the class average. This suggests that the difference in prevalence rates between countries may be, at least partly, accounted for by external factors including national differences in school policies and environments but also differences in the methodologies used (self-reports vs. peer and/or teacher reports), students' differing levels of cognitive ability, cultural differences in reporting, and different meanings of the term "bullying" in different countries.

The Importance of Age

Despite variations in prevalence, it is a universal finding that bullying victimization is more frequent among younger children and steadily declines with age. A range of explanations have been put forward to explain these age differences (Smith et al. 1999a, b). Compared to older children, younger children are less likely to have developed the appropriate skills and coping strategies to deal effectively with bullies and avert further victimization. Younger children are also less likely to refrain from bullying others due to socialization pressure. Finally, there is evidence that younger students adopt a more inclusive definition of bullying when responding to prevalence surveys, and this may, at least partly, account for the higher reported frequency of bullying victimization in primary school. For example, younger pupils might find it more difficult to distinguish between bullying and fighting, broadening the use of the term bullying to include aggressive behaviors that involve no imbalance of power. Within the general trend of decreasing bullying victimization over time, researchers have observed an abrupt increase in bullying during the transition from primary to secondary school which may reflect some students' attempts to establish dominance hierarchies in the new school environment. Relational forms of bullying take precedence over physical modes of attack as children grow older and their social skills improve.

Stability of Bullying Roles

There is some controversy in the literature as to the stability of bullying victimization in primary school. Some studies have reported that bullying victimization is relatively stable over a period of up to 4 years in primary school and often continues in secondary school. Other studies have found that only a relatively small proportion of children (around 4–5 %) are victimized repeatedly over time in primary school.

In secondary school, the stability of both bully and victim roles is considerably higher than in primary school according to teacher, peer, and self-reports. It is estimated that two out of three male bullies remain in their role over a 1-year period. Despite the moderate to high stability of the victim and bully roles in secondary school, prevalence rates are lower than in primary school. This suggests that a small number of victims are targeted consistently and systematically in secondary school.

Stability in bullying victimization has been explained in two ways. Firstly, it has been observed that victims select social environments that reinforce the risk of victimization, for example, they are more likely to have friends who are less accepted by the peer group and often victimized themselves. Secondly, victims often lack the social skills to break through in new environments, and this increases the risk that they are labeled as victims and locked in that role over a long period of time. It is important, therefore, to acknowledge that although for some children bullying victimization will be situational, for others it will develop into a trait.

Gender Differences

The view that males are more likely to bully and be bullied than females has been dismissed in recent years following a better understanding about the different forms aggressive behavior such as bullying can take. Although males are more likely to engage in physical forms of bullying such as pushing and hitting, females are, according to some studies, more adept at employing relational forms of aggression (e.g., social exclusion, spreading of nasty rumors) against their victims especially during adolescence. No consistent gender differences have been identified in the use of verbal bullying (e.g., calling names, nasty teasing). This suggests that overall gender differences are not as pronounced as originally thought and that bullying is not a male problem.

Characteristics of Children and Adolescents Involved in Bullying

The Bully

There is some controversy in the literature about the profile of bullies. Initially, studies described children who bullied others as insecure, anxious individuals who have low self-esteem, are unpopular among their classmates, and use aggressive strategies to resolve conflicts. This stereotype was later disputed by research that suggested bullies are socially competent and have superior theory of mind skills (i.e., awareness of others' mental functions and states) and good levels of social intelligence, knowing how to attain goals without damaging their reputation. Linked to this, there is also debate concerning whether bullies lack empathic skills. Some research suggests that bullies understand the emotions of others but do not share them. The inconsistencies across studies may be, at least partly, due to different definitions of bully status and different methodologies employed. Studies which have distinguished between "pure" bullies and bully/victims have revealed that "pure" bullies have few conduct problems, perform well at school, are popular among their classmates, and do not suffer from physical and psychosomatic health problems.

The Victim

There is more consensus on the profile of "pure" victims. Research has identified that "pure" victims exhibit elevated levels of depression and anxiety, low self-esteem, and poor social skills. Hawker and Boulton's (2000) meta-analysis found that peer victimization is more strongly concurrently associated with depression than with anxiety, loneliness, or self-esteem. Another meta-analysis by Card (2003) found that the strongest correlates of the victimization experience are low self-concept, low physical strength, low school enjoyment, poor social skills, and high internalizing and externalizing problems. It was unclear from these reviews of cross-sectional studies, however, whether internalizing problems lead to victimization or vice versa.

The recent body of longitudinal research on bullying and peer victimization more widely suggests that the relationship between internalizing problems such as depression, anxiety and loneliness, and victimization is more likely to be reciprocal, that is, internalizing problems contribute to victimization and vice versa. A meta-analysis of 18 longitudinal studies examining associations between peer victimization and internalizing problems in children and adolescents concluded that internalizing problems both precede and follow peer victimization experiences (Reijntjes et al. 2011). It is worth noting, however, that the path from psychological maladjustment to victimization has not been replicated in all studies. For instance, Bond et al. (2001) found no support for the hypothesis that emotional maladjustment invites victimization.

Recent work suggests that bullying might arise out of early cognitive deficits, including language problems, imperfect causal understanding, and poor inhibitory control that lead to decreased competence with peers, which over time develops into bullying. Research does not support the assertion that physical appearance (e.g., wearing glasses) is a risk factor for being bullied at school. The only physical characteristic that has been associated with an increased risk of victimization is low physical size and strength. There is less evidence on how equality characteristics influence victimization. There is no consistently robust evidence to suggest that ethnic minority children are more at risk of being bullied at school. Sexual orientation has rarely been investigated in longitudinal studies as a possible risk factor of bullying victimization, but there is some, mainly qualitative, evidence of sexual minorities being targeted in secondary schools. There is stronger evidence that children with disabilities are particularly vulnerable to victimization in mainstream settings, although it might be other characteristics of disabled children that make them more vulnerable to victimization such as lack of friends rather than the disability per se.

The Bully-Victim

Olweus (1993) was the first researcher to identify a small proportion of victims of bullying that he called "provocative victims" or "bully-victims," who bully other children as well as being bullied by them. Research has identified that bully-victims are the most troubled group among children and adolescents involved in bullying incidents. This group displays the highest levels of internalizing problems, including depression, anxiety, low self-esteem, and loneliness. At the same time, they score high on externalizing problems such as aggression, impulsivity, hyperactivity, and conduct problems. Other research has shown that bully-victims display higher levels of neuroticism and psychoticism than either bullies or victims. Bully-victims use aggressive strategies to cope with stressors at school that increase the risk of further victimization and rejection from peers.

The Peer Group

Besides the traditional roles of bully, victim, and bully-victim, research has identified that all students take on a role when bullying episodes emerge. Salmivalli et al. (1996) distinguished between six different roles children can take in bullying situations: the bully (leader), the reinforcer (encourages and provides audience), the assistant (follower/helper, e.g., holds the child down), the defender (helps the victim and/or tells bullies to stop), the outsider (stays away from bullying situations), and the victim. Subsequent research established that the three roles of bully, reinforcer, and assistant are closely correlated with each other and, therefore, cannot usefully discriminate between children. In kindergarten, the three most commonly held roles are those of the bully, the victim, and the defender. Fewer students are defenders by middle school, and the majority becomes witnesses or bystanders when bullying takes place. Such passive behavior, although not directly encouraging of bullying, provides a permissive context for bullies that allows them to continue harassing their victims.

Environmental Influences

Parenting and Home Environment

There is clear evidence that parenting styles are related to bullying behavior. Studies indicate that bullies are more likely to have parents who are authoritarian and punitive, disagree more often, and are less supportive. The parents of bullies are more likely to have been bullies themselves when they were young. Victims, on the other hand, are more likely to have been reared in an overprotective family environment. Bully-victims tend to come from family backgrounds that are exposed to abuse and violence and favor the use of harsh, punitive, and restrictive discipline practices. This group reports little positive warmth in their families and more difficulties in communicating with parents.

Family characteristics are related to bullying victimization in different ways for boys and girls. Boys are more prone to victimization when the father is highly critical or absent in his relationship with his son, thus failing to provide a satisfactory role model. Victimization in boys is also associated with maternal overprotectiveness which may hinder boys' search for autonomy and independence, whereas victimization in girls is more strongly related to maternal hostility which may lead to anxiety and decreased sense of connectedness in relationships.

Very little research has examined longitudinal associations between early home environment and subsequent bullying behavior. The few studies that exist suggest a link between low emotional support and subsequent bullying behavior at school. Parents who are disagreeable, hostile, cold, or rejecting tend to have children who are at risk of becoming aggressive in the future. In a small longitudinal study, Schwartz et al. (1997) found that bully-victims at 10 years were significantly more likely than the other groups to have had experiences with harsh, disorganized, and potentially abusive home environments 5 years earlier. Mother-child interactions at 5 years were characterized by hostile, restrictive, or overly punitive parenting. They were significantly exposed to higher levels of marital conflicts and more likely to come from marginally lower socioeconomic backgrounds. Bullies were found to be exposed to adult aggression and conflicts, but not victimization by adults, and were from lower socioeconomic backgrounds. These findings need to be replicated in larger samples before any safe conclusions can be drawn.

Sibling Relationships

More recently, there has been interest in how sibling relationships affect the development of bullying behavior. There is international evidence that children who are victimized at school are more likely, compared to other groups, to be victimized by their siblings at home. Wolke and Samara (2004) found that more than half of victims of bullying by siblings (50.7 %) were also involved in bullying behavior at school compared to only 12.4 % of those not victimized by siblings, indicating a strong link between intrafamilial and extrafamilial peer relationships. Those who were both victimized at home and at school had the highest behavior problems and were the least prosocial. Similar evidence exists in relation to bullying perpetration, suggesting that those who bully at school tend to exhibit similar behaviors towards their siblings at home.

School Factors

A number of school factors have also been implicated as correlates of bullying behavior. One of the most consistent findings in the international literature is that the number and quality of friends at school is one of the strongest, if not the strongest, protective factor against bullying victimization. Having friends is not sufficient in itself to protect against victimization. For instance, when at-risk children have friends with internalizing problems, who are physically weak or who themselves are victimized, the relation of children's behavioral risk to victimization is exacerbated.

More recent work on the role of class structure and climate on bullying has shown that variations in peer structure and dominance hierarchies influence the stability of bullying victimization. For example, victims in primary school classes with a more pronounced hierarchical structure are less likely to escape their victim role compared to those in classes with less clearly marked hierarchies (Schäfer et al. 2005).

Consequences

There has been a growing interest in recent years to investigate the long-term effects of bullying involvement on children's and adolescents' social, emotional, behavioral, and academic development using longitudinal samples. The results of these studies suggest that victims and bully-victims manifest more adjustment problems than bullies. Victims and, especially, bully-victims are more likely to show elevated levels of depression, anxiety, and loneliness; perform less well academically; and display conduct problems. The only negative long-term outcome that has consistently been reported in the literature for bullies is their involvement in later offending. There is also some initial evidence that bullying perpetration is a significant risk factor of poor academic performance.

Internalizing Problems

Several cross-sectional studies have demonstrated negative associations between peer victimization and a range of internalizing problems, including loneliness and low self-esteem. A meta-analysis of 23 cross-sectional studies of the association between peer victimization and psychological maladjustment found that peer victimization was more strongly concurrently associated with depression than with anxiety, loneliness, or self-esteem (Hawker and Boulton 2000).

Over the last decade, research on bullying is increasingly reliant on longitudinal methodologies to disentangle whether victimization contributes to internalizing problems or vice versa. It has been argued, for example, that children who display internalizing behaviors (e.g., anxiety or shyness) are more at risk of being targeted by peers due to their inability to cope effectively with provocation. The majority of longitudinal studies investigating associations between peer victimization and psychological maladjustment have found evidence for both directions.

Academic Performance

There is some longitudinal evidence that bullying involvement has a negative impact on academic performance, although more studies are needed to reach a definitive conclusion. A US longitudinal study that began in 2002 with a sample of about 1,700 adolescents found that being a bully had a stronger negative effect on self-perceived academic competence over time than being a victim after controlling for demographic background variables and baseline academic competence (Ma et al. 2009). Furthermore, only bully status predicted lower self-reported grades.

Delinquency and Criminality

Despite showing fewer adjustment problems than victims and bully-victims, bullies are at an increased risk of later delinquency and criminal offending. A recent meta-analysis of studies measuring school bullying and later offending found that school bullies were 2.5 times more likely than noninvolved students to engage in offending over an 11-year follow-up period (Ttofi et al. 2011). The risk was lower when major childhood risk factors were controlled for, but remained statistically significant. The effect of bullying on later offending was especially pronounced when bullying was assessed in older children. The longitudinal association between bullying perpetration and later offending has been replicated in many countries, including Australia, Canada, and Europe.

Impact Beyond Victims

Finally, there is evidence that bullying and victimization have a negative impact not only on the individual children involved but also on bystanders. Children who witness bullying incidents report increased anxiety, less satisfaction with school, and lower academic achievement.

There is also evidence that in school classes where a lot of victimization is taking place, school satisfaction among students is low.

Interventions

Following the development of the first anti-bullying program by Dan Olweus in Norway in the 1980s, a considerable number of anti-bullying interventions have flourished around the world to reduce bullying behaviors and protect victims. These fall under four broad categories: curriculum interventions generally designed to promote an anti-bullying attitude within the classroom; whole-school programs that intervene on the school, class, and individual level and address bullying as a systemic problem; social and behavioral skills training; and peer support programs including befriending and peer mediation. A systematic review conducted in 2004 evaluated the strength of scientific evidence in support of anti-bullying programs (Vreeman and Carroll 2007). The review concluded that only a small number of anti-bullying programs have been evaluated rigorously enough to permit strong conclusions about their effectiveness.

Whole-school interventions were found to be more effective in reducing victimization and bullying than interventions that focused only on curriculum changes or social and behavioral skills training. Targeting the whole school involves actions to improve the supervision of the playground, having regular meetings between parents and teachers, setting clear guidelines for dealing with bullying, and using role-playing and other techniques to teach students about bullying. The success of whole-school interventions, relative to other stand-alone approaches, supports the view that bullying is a systemic, sociocultural phenomenon derived from factors operating at the individual, class, school, family, and community level. Hence, interventions that target only one level are unlikely to have a significant impact.

A more recent systematic review of school-based anti-bullying programs found that, overall, these programs are effective in reducing bullying perpetration and victimization by an average of 20–23 % and 17–20 %, respectively (Farrington and Ttofi 2009). The interventions that were found to be most effective were those that incorporated parent training/meetings, disciplinary methods, and videos; targeted older children; and were delivered intensively and for longer. There is less robust evidence on the effectiveness of peer support programs that include activities such as befriending, peer counseling, conflict resolution, or mediation, and a systematic review suggested their use may lead to increases in bullying victimization.

More recently, there has been a growing interest in the use of virtual learning environments to reduce bullying at schools. The basic feature of these programs is a computer-based environment that creates a highly believable learning experience for children who find themselves "present" in the situation that causes emotional distress and, as a result, learn experientially how to deal with school problems. An example of such a program is "FearNot," an intervention that was developed to help victims of bullying explore the success or otherwise of different coping strategies to dealing with bullying victimization through interactions with "virtual" victims of school bullying. The evaluation of this intervention found that the victims that received the intervention were more likely to escape victimization in the short term than victims in control schools who did not interact with the software (Sapouna et al. 2010). These results suggest that the use of virtual environments might be an engaging and useful component of whole-school anti-bullying policies that merits further testing. A key finding that emerged from this research is that interventions are more likely to be successful if they have the support of teachers and other school personnel and there is a strong commitment to reduce bullying in the school community. This is considered to be one of the reasons behind the huge success of the Olweus' prevention program that has not been replicated to date.

Future Directions

Although an abundance of knowledge has emerged in recent years regarding the correlates of bullying behavior, there is still relatively little known about the causal processes and mechanisms associated with the bully and victim status. Longitudinal studies, which track bullies and victims over time, offer one of the best chances of disentangling the antecedents of bullying perpetration and victimization from its consequences, and these should form a key part of future research in this field. Another approach which shows much promise is the cutting-edge attempt to unravel the causes of bullying behavior made by researchers investigating biological and environmental influences and the way these influences interact.

One of these studies, involving 1,116 families with 10-year-old twins, found that the tendency for children to be bullied was largely explained by genetics (73 % of variance) and less so by environmental factors that were unique to each child (Ball et al. 2008). Another study of 506 six-year-old twins found that variance in victimization was accounted for only by shared and non-shared environmental influences (29 % and 71 %, respectively) and was not related to the child's genetic predisposition (Brendgen et al. 2008). These discrepancies might be explained by differences in methodologies used, as studies drew on different informants to assess bullying victimization (mothers and peers, respectively). Although results to date have been contradictory, future breakthroughs in this area have the potential to transform radically the study of bullying.

To understand more fully how bullying behaviors develop, future research will also need to investigate in more depth how individual and classroom level factors interact to cause involvement in bullying. It is not currently understood whether the relationship between risk factors and bullying is the same across different school and class environments or the extent to which consequences of bullying and victimization are dependent on class- and school-level factors.

Finally, another area that would benefit from more attention is the investigation of resilience to bullying. Some initial evidence suggests that maternal warmth has an environmental effect in protecting children from negative outcomes associated with victimization (Bowes et al. 2010). However, we still know relatively little about the factors that promote resilience to bullying and victimization among at-risk children, and also what role bullying has to play in increasing resilience. We also know little about the factors that help victims cope better with the effects of victimization.

To conclude, what the recent flurry of research activity has highlighted is how complex the bullying phenomenon is and that, although much has been learned to date, there is clearly a great need to understand how variables describing the family, school, class, and community environment interact with individual characteristics to determine who gets bullied and who bullies others. Research should neither be blind to nor discouraged by these complexities.

Overview

In this entry contemporary methodological issues in bullying prevention research are considered. The findings of extant systematic reviews and meta-analyses of school-based bullying prevention programs are assessed and integrated, with the aim of drawing clearer and more differentiated conclusions regarding their efficacy. Conclusions are drawn based on six reports, of which two included a systematic review but no meta-analysis, two included a systematic review and a meta-analysis, and two were not based on systematic searches of the literature but included some level of meta-analytic assessment. Based on a careful screening of all available meta-analytic investigations, it is concluded that bullying prevention programs are effective in reducing bullying and victimization. However, research users should be careful in identifying those intervention components and implementation procedures that are associated with a reduction in bullying. The entry concludes by identifying important challenges currently faced in the field of bullying prevention and highlighting areas for future research and implications of this work for psychologists and social scientists in general. The findings from this review of reviews are intended to inform both policy and public health practice related to bullying prevention.

Introduction

Research on school bullying has expanded considerably over the past two decades. It is now acknowledged as an established international research program, with worldwide coordinated efforts in founding a concordant methodological terminology for the explanation of this phenomenon (Smith et al. 2002). To a great extent, the strong scientific interest in bullying has been linked to the detrimental concurrent effects of school bullying for both perpetrators and victims. Notably, previous research has also established the long-term significant association of school bullying with internalizing (e.g., depression) and externalizing (e.g., offending and violence) problems (Ttofi et al. 2011a, b, 2012).

It comes as no surprise that a great deal of research has been invested in intervention efforts targeting the school environment (e.g., Waasdorp et al. 2012). Ideally, at the level of primary research, social scientists and research users should aim to draw conclusions from the most successful intervention studies always in line with explicit methodological quality standards. At the level of secondary research, a number of reviews of bullying prevention programs are also available. Ideally, these reviews should critically assess and synthesize the existing evaluation research, with the final aim of minimizing bias in the conclusions on which policymakers and practitioners are based. However, bias is not only the province of primary studies – it may also exist at the level of a review (Wilson 2009).

This is also true in the case of anti-bullying research (with a marked number of competing bullying prevention programs available), and it lays further weight on the importance of carefully assessing and utilizing *evidence-based* bullying prevention programs. It is for this reason that this entry focuses primarily on summarizing and juxtaposing what is methodologically the most high-quality evaluation research, with the final aim of drawing conclusions about what has been learned and what needs to be done next in the bullying prevention field. These aims will be accomplished by taking into account existing findings at the level of secondary research, namely, via systematic reviews and meta-analyses.

Methods

Bullying prevention could be seen as a form of early crime prevention as well as a form of early health promotion initiatives (Ttofi et al. 2012). This is true, however, only in the case of efficacious interventions. In an attempt to make suggestions about the most *scientific* and *evidence-based* bullying prevention programs, this synthesis of reviews of current evaluation studies is based on explicit inclusion criteria set in advance, namely, (a) reports presenting a systematic review of evaluations of bullying prevention programs aimed to reduce the level of school bullying perpetration and victimization (and not other outcome measures) or, ideally, (b) reports presenting both a systematic and meta-analytic review of the relevant literature. Reports that present some level of meta-analytic synthesis are also reviewed, although they may not be based on systematic searches. Reports that assessed bullying prevention programs based on narrative reviews are excluded, because this type of research carries a high risk of bias. An extensive search was conducted in order to obtain all relevant systematic and meta-analytic reviews.

Results

To date, a growing number of school-based bullying prevention programs have been developed and evaluated, but relatively few attempts have been made to synthesize the relevant rigorous outcome-based research findings (see Table 1). An extensive search of the literature revealed just six reports that met the inclusion criteria. Of the six reports, (a) two included a systematic review but no meta-analysis (i.e., Smith et al. 2004; Vreeman and Carroll 2007), (b) two included a systematic review and a meta-analysis (i.e., Merrell et al. 2008; Farrington and Ttofi 2009; Ttofi and Farrington 2011; references referring to the same project), and (c) two were not based on systematic searches of the literature but included some level of meta-analytic assessment (i.e., Baldry and Farrington 2007; Ferguson et al. 2007; only the latter carried out a full meta-analysis calculating weighted mean effect sizes for bullying perpetration).

Consistent with previous literature (Farrington 2003, 2006; Petrosino 2003), it is clear from the review of Table 1 that there is a marked degree of variation in the criteria employed and, to some extent, the quality of the currently available research reviews. Four of the included reviews of bullying prevention programs were based on systematic searches of the literature, but the intensity of the searches varied considerably. For example, the studies ranged from (a) 1 to 35 journals searched, (b) 1 to 18 databases screened, (c) 2 to 14 keywords for the online searches, and (d) the screening of 321–622 relevant documents. Only the most recent review (Farrington and Ttofi 2009; Ttofi and Farrington 2011) coded all relevant manuscripts based on a "relevance scale" in line with the aims of the systematic review.

Within each review, the timeline for carrying out searches also varied. While some authors set the beginning of searches in the 1980s and after the first Olweus Bullying Prevention Program evaluation (i.e., Farrington and Ttofi 2009; Merrell et al. 2008; Ttofi and Farrington 2011), others set their timeline for beginning searches in the 1960s, perhaps because the authors included outcome measures other than bullying (e.g., "school violence" and "peer aggression" in the Vreeman and Carroll (2007) review). It is plausible that variations in searching strategies are also affected by the type of language restrictions that the reviewers set in advance. Of the four systematic reviews, two were not transparent on this issue (i.e., Smith et al. 2004; Vreeman and Carroll 2007), and one specified language restrictions in obtaining studies written in English (Merrell et al. 2008). Only the Ttofi and Farrington (2011) systematic review was unrestricted and included studies in other languages such as German, Spanish, and Italian.

What reviewers and meta-analysts defined as "systematic" varied greatly in line with the type of inclusion criteria set in advance – and, more importantly, the extent to which these criteria were carefully followed. It is disconcerting that two out of four meta-analytic reviews computed effect sizes from uncontrolled designs despite the fact that their inclusion criteria explicitly defined "either controlled studies or quasi-experimental studies only" (i.e., Baldry and Farrington 2007; Merrell et al. 2008). Another meta-analytic review (i.e., Ferguson et al. 2007) included only evaluations of bullying prevention programs that were implemented using a controlled design. However, since the actual evaluations included in the meta-analysis are not shown in the relevant publication, it is not possible to ensure that all studies met this criterion.

All meta-analytic reviews calculated effect sizes based on evaluations of age-cohort designs, consistent with the approach employed by Olweus (2005). However, only one of these reviews (Farrington and Ttofi 2009; Ttofi and Farrington 2011) presents not only a summary effect size across all studies irrespective of their methodological design but also a summary effect size relating to each of the four types of methodological designs (i.e., an overall summary effect size and also four separate summary effect sizes specific to randomized experiments, before-after experimental-control studies, other experimental-control studies, and age-cohort designs).

What is also apparent from this synthesis of existing evaluation research is that the results vary greatly depending on the *theoretical stance* of the authors. For example, three out of six reviews included "bullying and other related antisocial behaviors" as an outcome measure (Ferguson et al. 2007; Merrell et al. 2008; Vreeman

Bullying Prevention: Assessing Existing Meta-Evaluations, Table 1 Efficacy of bullying prevention programs: A synthesis of reviews

Publication	Smith et al. (2004)	Baldry and Farrington (2007)	Ferguson et al. (2007)	Vreeman and Carroll (2007)	Merrell et al. (2008)	Farrington and Ttofi (2009); Ttofi and Farrington (2011)
Inclusion criteria/ characteristics of the evaluation synthesis	Systematic review (no meta-analysis) including studies if: Evaluation of whole-school bullying prevention programs Reports with quantitative data Studies conducted in more than one classroom (see p. 549)	No systematic review “Meta-analytic” evaluation of programs (effect sizes for each study is given, i.e., percent change, but not a weighted effect size for each study or a weighted summary effect size) Evaluations with at least 200 students included Experimental or quasi-experimental or age-cohort designs Programs specific to school bullying Studies with quantitative data	No systematic review Meta-analytic evaluation of programs aiming to reduce either bullying or violence Only studies with random assignment to experimental and control group Controlled studies only School-based programs Only manuscripts published in journals (see pp. 406–407)	Systematic review (no meta-analysis) including studies if: Controlled studies with follow-up measures School-based programs aiming (i.e., specific)to prevent bullying (see p. 79) The reviewers “extracted data from the selected articles regarding direct outcome measures of bullying, including bullying . . . aggressive behavior, violence . . .” (ibid.)	Systematic review and meta-analysis including studies if (see p. 28): School-based intervention Targeting bullying or peer-related antisocial behavior that could be interpreted as bullying Controlled studies or quasi-experimental studies with some sort of control group Published in English only No restriction to the type of manuscript (e.g., books and theses included) Quantitative data presented	Systematic review and meta-analysis including studies if (see pp. 31–32 from journal paper): Evaluation of a program specifically targeting (kindergarten to secondary) school bullying Clearly stated definition of bullying shown in the publication Measurement of bullying via self-, peer, and teacher reports or observational or other data Evaluation including an experimental and control group with baseline and follow-up measures (including age-cohort designs analyzed separately) Published and unpublished reports of any type (including theses and government reports) Quantitative information that allowed calculation of an effect size
Keywords used (N)	3 (p. 549)	4 (p. 186)	12 (p. 406)	2 (p. 79)	5 (p. 28)	14 (see p. 33)

Note 1: Evaluations with other outcome measures in the Vreeman & Carroll (2007) synthesis include: Elliot & Faupel, 1997 (on children's solutions on hypothetical bullying scenarios); Englert, 1999 (on violence); Fast et al., 2003 (on peer aggression); Metzler et al., 2001 (on perceptions of safety, feelings of being target of harassment, discipline referrals and reports of receiving praise); Mitchell et al., 2000 (on school initiatives promoting health); Teglasi & Rothman, 2001 (on peer aggression); Twemlow et al., 2001 (on school violence); Warden et al., 1997 (on ability to respond to hypothetical dangerous situations, including hypothetical incidences of bullying). Exact references can be found in the Vreeman and Carroll (2007) paper.

Note 2: The authors (Merrell et al., 2008) argue that they have included 16 evaluations in their meta-analyses of various outcome measures (see table 4, p. 37). Effect sizes for each study are not presented and searches/screening of documents is not clearly specified, but the following should be noted: (a) four publications of the same evaluation (i.e. those related to the Flemish Anti-bullying Program by Stevens and colleagues) are presented as separate evaluations. On table 1, we have counted all four publications as one study; (b) the Leadbeater et al. (2003) publication includes relational and physical victimization as outcome measures; it is not specific to bullying victimization; and (c) one evaluation (i.e Newman, 1999) is presented alongside the age-cohort design evaluated in Norway by Olweus. However, the Newman (1999) evaluation was conducted in the States and the outcome measure targeted improving teachers' knowledge of appropriate bullying intervention skills that they should be utilizing; participants were school teachers and not students. Exact references can be found in the Merell et al. (2008) paper.

and Carroll 2007), whereas other reviews focused specifically on bullying (Smith et al. 2004; Baldry and Farrington 2007; Farrington and Ttofi 2009). The *methodological approach* of the reviewers can also affect their analytic strategies. For example, Vreeman and Carroll (2007, p. 79) "… did not exclude or discount studies based on … *retention rates* or program *intensity* because these characteristics are not associated definitely with the strength of treatment effects." In contrast, the authors of the latest systematic review (Farrington and Ttofi 2009; Ttofi and Farrington 2011) coded the *program intensity* and *duration* and correlated these features with the effect sizes in order to examine their association. Ttofi and Farrington (2011) also identified concerns about *retention rates* – and issues with possible *differential attrition* – which are related to the effect size measures; some of the effect sizes for specific evaluations included in their review were not based on the published reports but based on results obtained via e-mail communication with evaluators, in order to avoid biased findings resulting from issues related to differential attrition, multiple imputation methods, etc. (Farrington 2006; Farrington and Ttofi 2009).

As another example, the review by Ferguson et al. (2007), which was not based on systematic searches, primarily aimed at extending previous research by conducting publication bias analyses (see pp. 405–406), but they restricted their searches to journal articles only (see p. 407). In contrast, other reviews (e.g., Farrington and Ttofi 2009; Ttofi and Farrington 2011) did not set language or sample size restrictions, or limit the type of manuscripts to be included, because of concerns about publication bias. While there is some disagreement about this issue in the literature, it is common for researchers to extend searches beyond published reports in evaluation research of primary studies (Wilson 2009).

In conclusion, the existing reviews of the efficacy of bullying prevention programs varied greatly in methodology employed, including their inclusion criteria, depth of searches, and screening of relevant documents. Consequently, the resulting meta-analyses presented a summary effect size obtained from 13 (Merrell et al. 2008), 23 (Ferguson et al. 2007), and 44 (Farrington and Ttofi 2009; Ttofi and Farrington 2011) evaluations accordingly. These differences in methodology and number of studies included could explain the marked discrepancies in the summary effect obtained across reviews, as shown in Table 1. This could also explain why some previous reviews (e.g., Ferguson et al. 2007; Merrell et al. 2008) concluded that bullying prevention programs had little effect in reducing the level of bullying perpetration and victimization, while other reviews (Farrington and Ttofi 2009) were optimistic in their findings. Ideally, these reviews should critically assess and synthesize the existing evaluation research, with the final aim of minimizing bias. However, bias is not only the province of primary studies – it may also exist at the level of a review (Wilson 2009).

Open Questions and Future Research Directions

The rapid growth in the research on school bullying has undoubtedly advanced the scientific knowledge in this issue. However, considerable work is still needed for its successful translation into effective practice and policy (Swearer et al. 2010). For example, systematic reviews in social sciences offer a great promise. Unfortunately, reviews published in social science journals quite often lack a methodological rigor or transparency in the methods. This is evident in the current synthesis of previous meta-evaluation studies of bullying prevention programs. When conducting research trials of prevention programs, researchers in psychology and other social sciences should follow the methodological quality criteria of the Consolidated Standards of Reporting Trials (CONSORT) statement (Altman et al. 2001), or the procedures outlined by the Cochrane Collaboration for secondary research reviews, as is common in public health and medicine. There is a steady trend in the social sciences toward greater transparency in the research process, as illustrated by increased efforts to create an equivalent CONSORT statement for the social sciences (Perry and Johnson 2008) and the creation of the Campbell Collaboration's methodological criteria for secondary analyses (Farrington et al. 2011). These standards for evaluation research can also be used by scholars, policymakers, and the general public to assess the validity of conclusions about the effectiveness of interventions in reducing bullying at school (Ttofi and Farrington 2011). This entry has provided clear examples of how substantial differences in the procedures followed for secondary reviews can result in marked differences in the conclusions drawn across these reviews regarding the effectiveness of bullying prevention programs.

Another important guideline in future meta-evaluation research refers to the issue of conflict of interest. The importance of conducting conflict of interest (COI) analyses is well established in the fields of medicine and public health. Within the field of criminology, recent studies have also shown that the reported effect sizes of prevention and intervention trials are larger when program developers are involved in a study than when trials are conducted by independent researchers; these differences may be due to various different types of biases, including biases resulting from conflict of interest issues (Eisner 2009; Farrington 2006). COI analyses have not been conducted in previous meta-analytic studies of bullying prevention programs, and this is a promising new line of research. It is noteworthy, for example, that the effect sizes obtained from the independent evaluation of a specific bullying prevention program are substantially smaller than those obtained from trials conducted by the developer as evaluator (Eisner 2009), although other explanations are also possible. Eisner and Humphreys (2011) developed an instrument for assessing COI in evaluation research, and initial tests of the scale in the area of family interventions are very promising. Interested scholars in the area of school bullying could begin a new line of evaluation research by testing and perhaps refining the relevant scale.

Another highly neglected topic at the level of meta-analytic research is that of cost-benefit analyses (Farrington and Ttofi 2009). Cost-benefit analyses can be a big "selling point" to policymakers and potential funding agencies, especially given the scarce resources that schools are often faced with. Admittedly, this type of analyses can also be conducted at the level of primary research. It is interesting to indicate, however, that of the 53 different evaluations of bullying prevention programs, only the review by Bagley and Pritchard (1998) included a cost-benefit analysis.

In prevention and intervention research, a distinction is made between efficacy, effectiveness, and dissemination trials (Flay et al. 2005). The importance of this distinction has been highlighted in meta-analyses that have examined factors that affect the size of treatment effects, with larger effect sizes found in efficacy trials (Eisner et al. 2011), most likely due to the increased researcher-imposed support and structure during the implementation process. This distinction is absent in the current meta-analytic studies of bullying prevention programs despite the fact that it may be critical when it comes to translating research findings into policy recommendations. Most evaluations of bullying prevention programs would fall under the category of efficacy trials, with relatively few meeting criteria for effectiveness research (Flay et al. 2005); additional research is needed to examine whether dissemination trials would demonstrate significant effects of bullying prevention programs. Within the area of bullying prevention, there are very few examples of programs being rigorously tested when being brought to scale (e.g., Karna et al. 2011; Waasdorp et al. 2012). Future research should also try to establish factors related to sustainability of the treatment effect when going to scale as well as the issue of sustainability of the treatment effect at longer follow-ups. Notably, the majority of bullying trials have relatively short follow-up periods, which does not allow for the contextual changes, such as in the school climate or school culture, or leadership, which we theorized are important impacts of effective bullying prevention programs (Bradshaw and Waasdorp 2009). Many other recommendations for future research can be made, and for a more detailed discussion, interested readers should seek advice from a paper that is being prepared for a special issue of the *American Psychologist* journal (Bradshaw et al. submitted).

Conclusions

The mixed findings from the extant reviews of bullying prevention approaches have been particularly disconcerting to policymakers, researchers, and practitioners alike (Bradshaw and Waasdorp 2011), as several reviews have provided a rather pessimistic interpretation of the state of the science in bullying prevention programming (e.g., Ferguson et al. 2007; Merrell et al. 2008), whereas others have been more optimistic (e.g., Farrington and Ttofi 2009; Ttofi and Farrington 2011). As a result, many are unclear where the field stands in terms of the evidence base for bullying prevention programming. The current entry aimed to provide greater transparency across the extant reviews so that various constituents can have a better understanding of potential reasons for the discrepant findings. Given the current focus on contrasting the scientific approaches employed by the different reviews of bullying prevention studies and extracting a general conclusion regarding the efficacy of bullying prevention efforts, it is not possible to endorse any specific program or model. Rather, the current study aimed to provide some guidance for researchers, policymakers, and practitioners on the extent to which each of the reviews employed various research-based approaches, as these methodological issues likely impacted the conclusions drawn from the research. Given the significance of bullying prevention for policy and prevention science, we issue a call for more longitudinal randomized controlled trials of promising programs and programs in wide use (particularly in the USA), as well as more rigorous systematic and meta-analytic reviews, in order to strengthen the current evidence base for preventing bullying programming. Many challenges but also many promising avenues lie ahead for future research in the area of bullying prevention and intervention. The time is ripe for a new research agenda in unexplored scientific avenues such as conflict of interest analyses and cost-benefit analyses to mention a few.

Calibration of Simulation Models

Nick Malleson
School of Geography, University of Leeds,
Leeds, UK

Overview

Simulation models are becoming increasingly popular in criminology research. In order for researchers to have confidence in the results of simulation studies, it is essential to make sure that the models are properly evaluated. *Calibration* is a major element to this evaluation and refers to the estimation and adjustment of model parameters to improve the agreement between model output and a data set. This entry will discuss some different methods of model calibration as well as related quantitative methods of error assessment.

Introduction

Simulation models are becoming increasingly popular in criminology research, both as tools for exploring real-world crime patterns (explanatory models) and for experimenting with underlying theory (conceptual models). In order for researchers to have confidence in the results of simulation studies, it is essential to make sure that the models are properly evaluated. The process of evaluation is commonly divided into three activities, defined by Rykiel (1996) as follows:

- **Verification** is a demonstration that the modeling formalism is correct.
- **Calibration** is the estimation and adjustment of model parameters and constants to improve the agreement between model output and a data set.
- **Validatio**n is a demonstration that a model within its domain of applicability possesses a satisfactory range of accuracy consistent with the intended application of the model.

It is possible to calibrate a model quantitatively by assessing error using statistics or qualitatively by manually comparing model results and field data. Qualitative approaches are particularly well suited to spatial models where the researcher is able to compare maps. However, for complicated models with many parameters, a qualitative approach to calibration will probably be very time consuming and unlikely to reveal the optimal model configuration (which is the ultimate aim of calibration). Therefore, this article will focus on quantitative methods of error assessment (rather than relying on human objectivity) and automatic calibration routines that are able to explore a model's parameter space and estimate error without human intervention. Also, in the context of environmental criminology, it is much more important to accurately reflect field conditions when working with *explanatory models* – i.e., those that simulate real-world conditions – so the discussion will focus on these in particular. Conceptual models,

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

on the other hand, will not necessarily attempt to replicate real environmental conditions so automatic calibration methods are less relevant.

The article is organized as follows. Section outlines the main principles of calibration and Section follows with a more in-depth assessment of a number of methods for model calibration. Sections and complete the article by discussing the state of the art, literature controversies, and open questions.

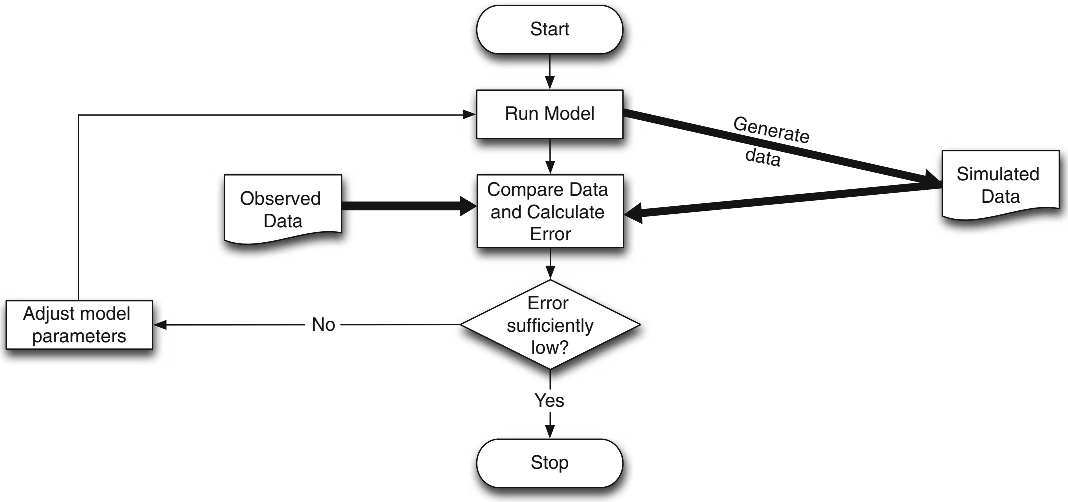
Background

Calibration refers to the process of configuring a model's parameters to match some observed historical data. This usually consists of searching for a combination of parameter values that cause the model to produce data which are similar to that collected from the real system under investigation. In many cases, a single "fitness" value is sought which succinctly summarizes the correspondence between simulated data and field observations.

Figure 1 illustrates the calibration process. The model is repeatedly reconfigured with the aim of reducing the error between the results and the field data. Once a predetermined error level has been reached, the process ends and the model can be considered calibrated, i.e., configured in such a way that it is apparently able to simulate the real system effectively. The level of error deemed acceptable is subjective and depends on the individual study. It is also worth noting that simply matching data is not necessarily a sufficient criteria for establishing model correctness, which is a point Section will address in more detail.

With simple models, the process of configuring parameters and calculating error is usually relatively simple. However, *simulation* models are often extremely complex and can contain a large number of configurable parameters. To confound the situation, model parameters often have nonlinear effects on the model's behavior which makes it difficult to predict how the model will behave under new parameter configurations. Hence, the process of manipulating a model's parameters to match some field conditions is often nontrivial.

To being with, the means of evaluating the degree of similarity between model results and expected data can be troublesome in itself. Once a quantitative measure of similarity has been developed, there are numerous methods that can be used to explore the parameter space of the model in search of the optimal configuration. These are also known as *optimization* methods. The following section will first discuss the



Calibration of Simulation Models, Fig. 1 An overview of the process of calibration different methods that can be used to calculate error and follow with a review of a number of automatic calibration/optimization routines.

Methods for Model Calibration

Assessing Goodness of Fit

In the context of calibration, goodness of fit (GoF) is an important measure. It refers to the error between the results of a model and the data that it is trying to replicate (hereafter referred to as "observed data"). Commonly, GoF statistics are applied to tabular data, such as the number (or rate) of crimes against different types of people, within different spatial areas or during a particular time period. Knudsen and Fotheringham (1986) experimented with a number of goodness-of-fit statistics and found the standardized root mean square error (SRMSE) to be the best performing. A drawback with SRMSE, however, is that the value itself is difficult to understand. For example, with the SRMSE it is not possible to state what percentage of the variation in observed data can be accounted for by a model. An alternative statistic, R^2 solves this problem because it represents the percentage of agreement between the model and the expected data. However, R^2 is insensitive to the overall amount of error, predicting a good fit in some circumstances where the SRMSE would not (Harland 2008).

The SRMSE can be defined as

$$SRMSE = \frac{\sqrt{\left(\Sigma\left(y_i' - y_i\right)^2/n\right)}}{\bar{y}} \tag{1}$$

where y_i' is the predicted value at matrix point i, y_i is the actual value at i, $\bar{y}$ is the mean value of the predicted values (y'), and n is the total number of values. The lower limit of the statistic is 0 which indicates no difference between the predicted values (y_i') and the observed values (y_i). The upper limit is usually 1 (Knudsen and Fotheringham 1986) but can be greater, particularly when matrices are sparse (Harland 2008).

Using the same notation, R^2 can be defined as

$$R^2 = 1 - \frac{\sum_i \left(y_i - y_i'\right)^2}{\sum_i \left(y_i - \bar{y}\right)^2} \tag{2}$$

and a value of 1 indicates identical data sets. The lower limit of the statistic is 0.

There are a variety of alternative GoF statistics that could be used to assess model error and the most appropriate will depend on the data and application area. For more information about the statistics discussed here, the interested reader can refer to the comprehensive assessment in Knudsen and Fotheringham (1986). Alternatively, there are a wide range of textbooks that define methods for both parametric and nonparametric data. In terms of calibration, the most important decision is to choose the GoF statistic that is appropriate to the study and the nature of the data so that a reliable assessment of error can be made. In addition, more than one statistic could be used simultaneously to provide a more comprehensive assessment of model error.

Goodness of Fit for Spatial Data

Many simulation models in environmental criminology explore the spatial distributions of crime (Liu et al. 2005; Groff 2007; Hayslett-McCall et al. 2008; Dray et al. 2008; Birks et al. 2012; Malleson et al. 2013). If the simulations work at an aggregate spatial scale (measuring crimes per area), then the procedure for assessing GoF is the same as that for nonspatial data. However, it is preferable for simulation models to use data on individual crime occurrences and, therefore, generate point pattern data. Common GoF measures cannot be used to compare point patterns directly as the data must be in the form of a table or matrix. One solution to this problem is to first aggregate the point data to commonly used areal boundaries such as the enumeration district or census tract. However, this process is far from ideal. Firstly, such aggregation will expose the results to the modifiable areal unit problem (MAUP: Openshaw 1984). Openshaw found that changing the size and shape of the boundaries themselves can have a dramatic effect on the resulting spatial patterns and subsequent results. Secondly, the process of aggregating is likely to hide important patterns that are present at finer geographies. Andresen and Malleson (2011), for example, showed that there was considerable spatial heterogeneity in crime rates at the street level which would be hidden at larger spatial scales. Hence aggregation will inevitably introduce error.

An alternative approach is to compare the point patterns directly *without aggregating*. Although no commonly accepted methods exist for this purpose, such as the SRMSE or R^2 there are a a number of useful spatial statistics that can describe the distributions of point patterns and can be used to make mathematical comparisons. These could replace, or compliment, traditional GoF statistics used to determine model error during calibration. Table 1 summarizes some of these statistics and illustrates the results of their application to three data sets: two similar point patterns produced by a simulation model ("Model1" and "Model2") and a point pattern produced by a random process ("Random").

The functions outlined in Table 1 provide information about the degree of clustering in

Calibration of Simulation Models, Table 1 A summary of spatial statistics that can be used to describe and compare the spatial structure of point patterns (Malleson 2010)

Statistic	Pros/cons	Usage with example data
Nearest Neighbour Index (NNI) – also known as the Clark and Evans *R* statistic (Clark and Evans 1954) – is the ratio of the minimum nearest-neighbour distance. The nearest-neighbour distance for a point *i* is the distance to the closest neighbouring point. ($d_{\min}$) to the expected minimum distance for a random point pattern ($\bar{\delta}$) $NNI = \frac{\bar{d}_{\min}}{\bar{\delta}} = \frac{\sum_{i=1}^{n} \frac{d_{ij}}{n}}{\frac{1}{2\sqrt{A/n}}}$ (3)	Gives a concise general picture of whether or not clustering is present (compared to random data) Usefil as a preliminary procedure (Bailey and Gatrell 1995) It is difficult to account for edge effects (there are some solutions to edge effect problems, such as circular or rectangular corrections (Levine 2006), but these are not ideal (Chainey and Ratcliffe 2005)) Too simplistic to be really useful	The NNI statistics suggests that all the data used in the following examples (Modell, Model2 and Random) are clustered which is to be expected (Malleson et al. 2010). Althought the statistic is not comprehensive enough to assess error in isolation, it could be useful as a preliminary measure of similarity as part of a larger error assessment during calibration
The *G* function, at a given distance, *d*, is the fraction of points, s_i, whose nearest neighbour is less than *d* away: $G = \frac{\#(d_{\min}(s_i)<d)}{n}$ (4) where # means "the number of" (as in Bailey and Gatrell 1995) **The *F* function** is similar to *G* but uses the distance from a randomly selected map location to the nearest point. As defined bu O'Sullivan and Unwin (2003): if $\{p_1 \ldots p_i \ldots p_m\}$ is a set of *m* randomly selected locations and *S* is the set of all points, then: $F = \frac{\#(d_{\min}(p_i,S)d)}{m}$ (5)	Describe clustering in more detail than the NNI index by providing a measure at different distances Can be used to differentiate between clustered and uniform data (see O'Sullivan and Unwin (2003) for a fuller discussion) Only consider a *single* nearest neighbour distance in their calculations so disregard a considerable amount of information	The following illustrates the *G* functions for the Model1, Model2 and Random data sets (graphs of *F* are similar). The graphs illustrate that, at shorter distances, the model data sets are more clustered than the Random one. Therefore a traditional GoF statistic could subsequently be used to estimate the differences between the *G* of *F* graphs for different data. This would provide a single statistical measure of similarity which could be used during calibration 
(*continued*)

Calibration of Simulation Models, Table 1 (continued)

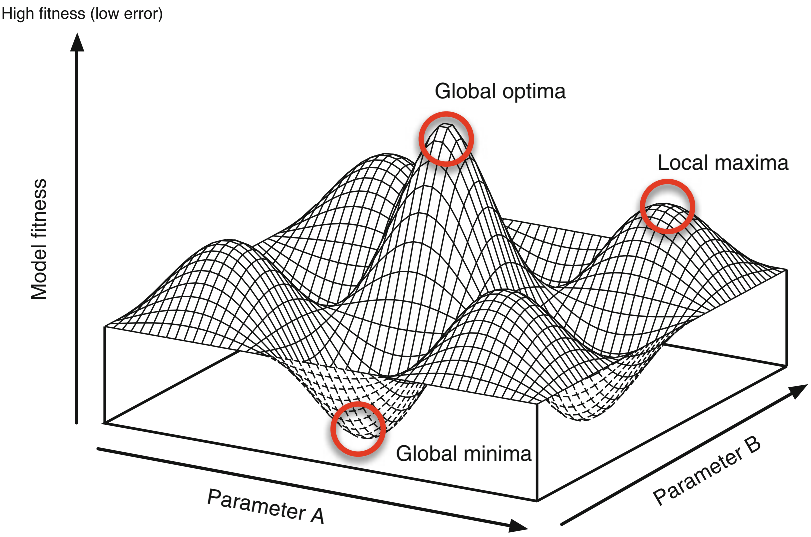
Statistic	Pros/cons	Usage with example data
The *L* **function** is a transformation of Ripley's *K* that provides evidence for whether or not clustering is more or less than would be expected under complete spatial randomness (CSR) (O'Sullivan and Unwin 2003): $L(d) = \sqrt{\frac{K(d)}{\pi}} - d \qquad (6)$ Values of $L(d) < 0$ suggest that there are fewer events in the space than would be expected under CSR and that the data are therefore less clustered. The reverse is true for $L(d) > 0$	Takes all the neighbours that are within a given distance into account so is a more descriptive statistic By comparing graphs of $L(d)$ it is possible to determine how similar the clustering of to point patterns is	The following graph illustrates that the Model1 and Model2 data are more clustered than the random dataset (which equates to approximately $L(d) = 0$ for low d values). Above $d \approx 3{,}000$ L begins to fall due to boundary effects (this is because many of the large circles produced by the underlying K function are nearly empty at large distances because they cover areas outside the simulation boundary with no points (O'Sullivan and Unwin 2003). As with the G and F functions, it would be possible to use a traditional GoF statistic to quantitatively compare the similarity of L functions for two point patterns (e.g., simulated data and calibration data) 
point pattern data. Although these statistics have the benefit that they are not susceptible to the modifiable areal unit problem, they could not be used during calibration, in isolation, because it is possible that two different point patterns nevertheless have the same clustering properties. However, these could be used in conjunction with other methods (such as aggregating the points to area boundaries and applying a GoF test) to provide a more comprehensive error assessment.

As well as comparing mathematical descriptions of clustering in point patterns, it is also possible to generate raster density maps from the point patterns and compare these mathematically. This approach is common in the field of spatial modeling for comparing simulated and real land use. For a review of recent approaches, the reader is directed to Kuhnert et al. (2005). Finally, it is also possible to aggregate the point patterns to a regular grid and then use traditional GoF statistics on the resulting matrix as discussed by Costanza (1989). This approach has the advantage of reducing the effects of the modifiable areal unit problem because numerous regular grids can be applied to the point patterns at the same resolution.

Exploring the Parameter Space

Having determined an effective means of estimating the goodness of fit between simulated and observed data, calibration itself can begin. The task of model calibration is effectively a search through the model parameter space, assessing the accuracy of the model under different combinations of parameters. For simulation models with large numbers of continuous parameters, this search space will be extensive. This is confounded by the fact that simulation models are often nonlinear, so the effects of changing parameter values are not easy to predict.

For example, Fig. 2 presents an example parameter space for a nonlinear model with two continuous parameters (A and B). Varying parameter combinations changes the accuracy of



Calibration of Simulation Models, Fig. 2 An example parameter space for a nonlinear model with two parameters

the model results; hence the aim of the calibration process is to find the optimal parameter configurations ("global optima"). However, even for a model with a low number of parameters, it becomes apparent that a manual search of the parameter space is unlikely to reveal global optima. Therefore calibration is often conducted by computer algorithms which are able to intelligently search the vast parameter space.

Parameter Sweeps

A parameter sweep is a simple process of systematically varying the model parameters in sequence so that many possible combinations are explored. Each parameter to be tested has a *start*, *end*, and *increment* value which determines the range of possible values that the parameter will take. Again using Fig. 2 as an example, a parameter sweep with $start = 1$, $end = 10$, and $increment = 1$ for both parameters A and B results in 100 possible parameter combinations.

Although the method is simple, it has a number of drawbacks, namely:

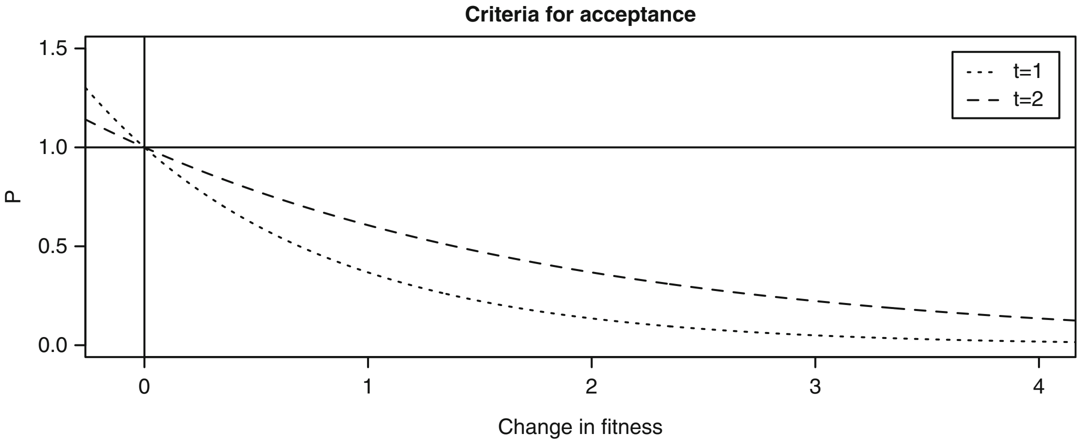
- The number of individual runs can be extensive because it increases exponentially with the number of parameters. For example, to conduct a parameter sweep on a model with five parameters, each of them integers between 1 and 10, a total of $10^5 = 100{,}000$ model runs will be required.
- The sweep explores the entire parameter space equally. More advanced approaches are able to expend greater effort fine tuning already successful configurations and ignore parts of the parameter space that are extremely unlikely to reveal global optima.

Hill Climbing

Hill climbing is a procedure that starts with an arbitrary model configuration and makes a small change to one of the parameters. If the change improves the performance of the model (reduces error), then it is retained. If the change increases error, then it is discarded. This process repeats until there are no possible parameter changes that improve the model. The main drawback with the approach is it is likely to get stuck on suboptimal configurations (e.g., the local maxima in Fig. 2), in which case it would be necessary to temporarily accept changes to the configuration that will actually *increase* the error between the model and the calibration data.

Simulated Annealing

Annealing is the process used in metallurgy in which a material is heated and then cooled in order to alter its properties (strength, brittleness, etc.). The amount of time spent at a high temperature and the rate of cooling influence the resulting properties of the material. The



Calibration of Simulation Models, Fig. 3 The effect of temperature on the probability of accepting a regressive move

simulated annealing optimization procedure takes its inspiration from an algorithm that simulates this annealing process (Metropolis et al. 1953). Originally formulated by Kirkpatrick et al. (1983), the procedure improves upon hill climbing algorithms by occasionally allowing choices that *lower* the fitness of the model. Whereas hill climbing will always choose the best move from those available, simulated annealing chooses a random move from the neighborhood. If the move improves the fitness, then it is always accepted, but if it does not, then there is still a *possibility* that it will be accepted. This helps the algorithm to climb out of local maxima.

The criteria for accepting a lower fitness is given by

$$P = e^{-c/t} > R(0,1) \tag{7}$$

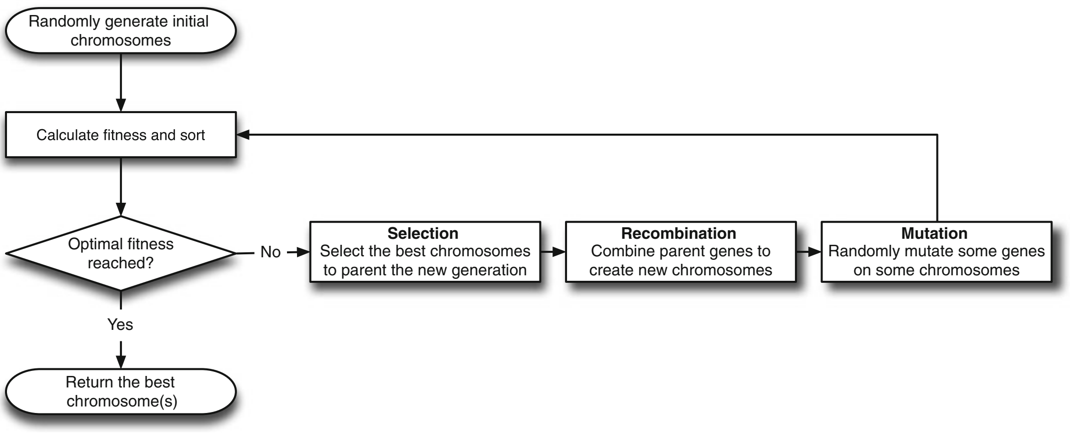
where c is the change in fitness (negative for an improvement, positive for deterioration), t is the temperature, and R(0,1) is a random number in the range 0–1. The temperature is used to reduce the chance of accepting poor moves over time so that the algorithm will converge. This is analogous to gradually reducing the temperature in the annealing process. If $t = 0$ then only improvements to the fitness will be accepted which causes the algorithm to behave like a hill climbing procedure. Figure 3 illustrates the change in P for a range of moves under two different temperatures. Note that if the change is positive ($x < 0$), then $P > 1$ so the move will always be accepted. As t decreases, so does the probability of accepting a move.

The rate at which t drops, as well as its initial and final values, will determine how successfully the algorithm will run. Unfortunately there are no standard rules for determining these values, although a number of methods for estimating suitable values have been proposed (Reeves 1995).

Genetic Algorithms

A Genetic Algorithm (GA) is a form of evolutionary algorithm, based on Darwin's theory of natural selection (Darwin 1859). The algorithm works on the premise that small variations in organisms can accumulate if they induce an increase in the overall fitness and this improves the individuals' ability to reproduce (Reeves and Rowe 2003). When describing GAs, the following concepts are important:

- A **gene** is a single model parameter.
- A **chromosome** is a combination of genes, i.e., a unique model configuration.
- The **population** is the current set of chromosomes that the algorithm is using to explore the parameter space.



Randomly generate initial chromosomes
Calculate fitness and sort
Optimal fitness reached?
No
Yes
Selection
Select the best chromosomes to parent the new generation
Recombination
Combine parent genes to create new chromosomes
Mutation
Randomly mutate some genes on some chromosomes
Return the best chromosome(s)

Calibration of Simulation Models, Fig. 4 The process of running a genetic algorithm

- **Selection** is the process of choosing the fittest chromosomes.
- **Recombination** is the process of combining the best chromosomes to initialize the new population.
- **Mutation** is a means of exploring a wider area in parameter space by randomly varying some genes in a new population.

The GA is an iterative process, as illustrated by Fig. 4. At each iteration, the algorithm finds the fittest chromosomes (the model configurations with lowest error) and uses these to create the population in the subsequent iteration. The algorithm runs for a set number of iterations or until an acceptable goodness-of-fit value has been found. Although the process of running a GA does not change substantially across implementations, the means of performing selection, recombination, and mutation can be adapted depending on the characteristics of the parameter space. See Reeves and Rowe (2003) for more information.

The main advantage of a GA over the other procedures is that it is able to "home in" on the space with the fittest parameter configurations without devoting effort to exploring suboptimal areas. This makes it much more efficient. Also, mutation allows the algorithm to explore a wider search space which can prevent it from becoming trapped in local maxima.

Calibration of Criminology Models

On the whole, very few simulation models in the field of criminology apply the techniques outlined here. This is partly because simulation modeling has been, until recently, relatively underused in criminology so there is only a limited literature base to begin with. Also, and perhaps more importantly, a large number of studies are *conceptual* rather than *predictive*. Conceptual models do not attempt to replicate real-world crime patterns and instead explore the dynamics of criminology theory in an abstract, artificial environment. Hence it is normally neither necessary nor possible to configure these models to simulate data from the real world. Predictive models, on the other hand, do attempt to replicate real-world patterns and therefore calibration should be an important part of the modeling process.

However, of the limited relevant published studies, very few have applied the formal methods outlined here. For example, Malleson et al. (2013) implement a simulation model of residential burglary and, although automatic calibration is noted as advantageous, the authors result to manual parameter configuration because the extensive run time of the model leads to in insurmountable computational requirements for automated calibration algorithms (Malleson et al. 2012). Similarly, Groff (2007) discusses the advantages of a "common sense" approach to model evaluation by examining factors such as the degree of clustering and the spatial dynamics of hotspots. Again, formal calibration methods such as those outlined here are not applied, although the authors stress that the field is "wide open" (Groff 2007, p. 99). There are numerous other predictive simulation models that would benefit from a rigorous approach to calibration but, for a number of reasons, calibration is not applied with the same rigor as with simulation models in other fields. Partly, this will be because the methods discussed here are not simple and require a degree of computer literacy. But, also, it is due to the novelty of the models to the field and, with time, it is extremely likely that calibration, as well as the other elements to model evaluation, will form a more substantial part of the modeling process.

Controversies and Open Questions

This entry has made reference to a number of calibration methods that can be used to calibrate simulation models. Other methods are available, including simply adjusting parameters manually. But those discussed here are the most suitable for models of complex systems which often have a large number of parameters, behave nonlinearly, and consume/produce large amounts of data. However, unless reliable observed data can be gathered and methods developed to compare the data to simulation results, the process of calibration will not be able to improve model performance (at least in the sense that the model is a good representation of the real world). The first problem is how to obtain reliable, real-world data on which to build a picture of the underlying system. Police recorded crime data is a common source but has a number of drawbacks:

- Discrepancies in police recording practices mean that some crimes, which are heavily underreported, will be misrepresented in police data – although this is somewhat mediated by the assertion that unreported crime clusters near reported crime (Chainey and Ratcliffe 2005).
- The temporal accuracy is often questionable because the actual time of the event is not always known.
- Spatial accuracy can be variable if a location is hard to code accurately (e.g., somewhere in a park) or if human error corrupts the recorded location.
- Offender data, which can be useful for the calibration of the spatial movements of offenders, by definition only provides information about people who have been in contact with the police and therefore misrepresents the actual population of offenders.

Assuming good-quality crime data are available, it is still not certain that those data are the most suitable for use in calibration. Firstly, many models might be able to recreate the observed crime patterns, but this does not guarantee that any of them correctly represent the internal dynamics of the system. This is known as the identifiability problem and one that is common to all modeling approaches – see, for example, the discussion in Windrum et al. (2007). To determine which, if any, are "correct," it might be necessary to simultaneously calibrate against various different data sources that capture elements of the system other than simply the crimes committed. Examples might include the use of social surveys to represent victim behavior, crowd-sourced data to explore "normal" day-to-day behavior patterns or transport data to estimate the routes that people use to navigate cities. The "correct" model will fit the patterns illustrated by these data *and* closely approximate the observed crime data.

Although there is huge scope for improving the calibration of criminology simulation models, relatively little has been done in practice. This is not, however, unexpected. The methods employed are still in their infancy, relative to their traditional mathematical counterparts at least, so it takes some considerable effort to develop a model in the first place. However, as the methods become more widely used and the tools to develop them become easier to manage, there is no reason that standard, widely adopted approaches to calibration cannot emerge.

Cambridge-Somerville youth study

Overview

The Cambridge-Somerville Youth Experiment was a longitudinal study of 650 boys that began in 1935 in Cambridge and Somerville, two neighboring towns in the Boston, Massachusetts, metropolitan area. It was the first documented criminology experiment of that scale (Farrington 2003). A treatment group of at-risk "difficult" boys and control group were created, each with 325 boys assigned based on 160 matching characteristics. The treatment group received social welfare services including family guidance, medical and academic assistance, coordination of community agencies, and recreational services, provided by a friendly counselor sustained for almost 10 years; the control group received no special services. The goal of the study was to examine if delinquency could be prevented and if counseling was an effective approach to preventing delinquency (Powers and Witmer 1951). However, results were mixed, with no crime prevention benefits observed (McCord and McCord 1959), and it has largely been described as both well-intentioned and a failure (Dodge 2001).

Fundamentals

Participants

Boys attending public and parochial schools in Cambridge, Massachusetts, and public schools in Somerville, Massachusetts, who were age six or seven at enrollment were eligible for participation in the study (Powers and Witmer 1951). At the time, Cambridge and Somerville were primarily working-class, factory towns (McCord and McCord 1959). "Difficult" boys were identified by schools and social service agencies in the two towns and referred to the study team (Powers 1949). The selection process was lengthy; it involved interviewing hundreds of boys that had been identified as difficult, conducting medical and psychological exams and home visits, and completing a camping trip in which detailed notes were taken about each boy (Cabot 1940; McCord and McCord 1959). This initial process happened without potential participants' knowledge, but upon being contacted, the majority were willing to participate (Powers 1949). Participants were solicited beginning in 1935, and participants were enrolled between 1937 and 1939 (Powers and Witmer 1951).

Study Design

The study was designed by Dr. Richard C. Cabot and funded by the Ella Lyman Cabot Foundation, which was created in honor of Dr. Cabot's wife. The study was originally designed to be implemented over the course of 10 years, although this plan was curtailed by World War II and lasted for just over 8 years (Powers 1949; Powers and Witmer 1951). Additionally, some boys dropped out sooner, and other boys were intentionally dropped from the sample after 2–3 years if they were definitively classified as nondelinquent (Powers 1949). The study design was a randomized matched study: the two boys closest to each other in terms of approximately 160 background characteristics were paired, and then one of them was assigned to the intervention group, and the other was assigned to the control group on the basis of a coin flip (Cabot 1940; McCord and McCord 1959). These pairs were categorized as likely to be delinquent, not likely to be delinquent, or future delinquency trajectory uncertain (Cabot 1940).

Intervention

The structure of the intervention was to pair each boy in the treatment group with a trained counselor, who would then determine what services were most appropriate for each boy's unique situation with an eye towards positive character development (Cabot 1940). The trained counselor used social welfare practices, including health, educational, family, and community assistance, guidance, and support; boys on average received five such years of counseling (McCord and McCord 1959).

However, the quality of the intervention varied in terms of frequency of contact between the counselor and student, length of time the boy participated in the program, the gender of the counselor, and counselor turnover (McCord and McCord 1959). The most intensive intervention was defined as weekly participation for at least

2 years, in which the counselor and boy had a close relationship that included discussing personal issues; however, only 12 of the boys met these criteria, and so potential analyses were limited but illustrative that this more intense level of treatment may be effective (McCord and McCord 1959). Most boys had done recreational activities with their counselors, approximately half received tutoring, and medical care and summer camps were also common among boys in the intervention group (McCord 2003). Some boys in the intervention group were sent to foster homes and/or private schools per counselors' recommendations (Powers 1949), although this was done after attempting more moderate services (McCord et al. 1960). In comparison, the control group received "the usual services of the community" (McCord and McCord 1959).

Outcomes of Interest

The primary outcome of interest was criminal behavior (as measured by criminal convictions) (McCord and McCord 1959), although additional outcomes were observed in follow-up studies. Other outcomes of interest included mental hospital visits, participation in alcoholic treatment, and vital statistics (e.g., marriage, death) (McCord 1978). Anecdotally, individuals and counselors credited the program with changing boys' developmental trajectories (Powers 1949).

Key Findings

Although boys who participated in the intervention qualitatively credited the program to helping them in their development, there were null and/or harmful effects of the intervention for a range of quantitative outcomes, including criminal and health outcomes (McCord 1978, 2003). For example, there were no statistically significant differences between the intervention and control groups in criminal convictions (both ever being convicted and number of convictions) in their matched analyses and after controlling for additional potential confounders that had been identified more recently (McCord and McCord 1959). After a series of subgroup analyses, though, they found that boys who had met with their adult counselor once a week on average and boys who were younger when they enrolled in the program had statistically significantly lower incidences of criminal convictions compared to their counterparts (McCord and McCord 1959). In later follow-up studies, boys who received the intervention were more likely to have been convicted of "serious street crimes," died at an earlier age, and been diagnosed with a mental illness, compared to the controls (McCord 2003).

Some of the programming characteristics that were later attributed to the study's failure include that the boys were publicly identified as at risk and were given resources without being held accountable, and the boys also participated in activities together (e.g., summer camps) (Dodge 2001). Others noted that adverse effects associated with the intervention were most apparent for boys who participated in the intervention for the longest amount of time, with the most frequent visits, and with family cooperation (McCord 2003).

Additional studies took advantage of the matched pairs to consider subgroups of boys. For example, the boys who were in the intervention group and placed in foster care were compared to their matched pairs, and harmful effects of foster care placement were observed (McCord et al. 1960).

Since the Cambridge-Somerville Youth Experiment, several other programs have been rigorously evaluated, and other delinquency prevention program evaluations have also observed less-than-positive impacts, indicating that more research must be done and published in the academic literature, regardless of positive or negative results (McCord 2003). The Cambridge-Somerville Youth Experiment has also inspired the development of new theories, like deviancy training, to explain what may have occurred then; these theories have since been applied to and tested in new contexts (Gottfredson 2010).

Conclusion

The Cambridge-Somerville Youth Experiment is considered the first major randomized experiment in criminology. It is commonly used to exemplify the importance of rigorous evaluation of well-intentioned programs, including use of evaluation to determine if the positive results desired are actually observed.

Campus Crime

John J. Sloan III[1] and Bonnie S. Fisher[2]

[2]School of Criminal Justice, University of Cincinnati, Cincinnati, OH, USA

Overview

During the past two decades, campus crime has captured the attention of both the public and researchers who sought to unpack the causes, correlates, and consequences of various types of violent and property crime committed on college and university campuses. Much research to date has focused on identifying how students' lifestyles and daily routines create opportunities for on-campus victimization. Other studies have examined college campuses as places and explored how their features create opportunities for crime. This entry examines both lines of research and synthesizes the extant literature to describe the dynamics of campus crime. The entry also presents some of the controversies within the study of campus crime, including measurement issues, overreliance upon case studies of single campuses, and the problem of underreporting of crimes occurring on college campuses. The entry concludes with a brief discussion of open questions in the study of campus crime, including the question of the extent of campus crime, how to better translate research into policies or programs aimed at reducing campus crime, and the ultimate utility of legislation at the federal and state level designed to reduce campus crime.

Introduction

America's colleges and universities present an apparent anomaly: physically attractive places fostering the intellectual development of young adults that may, in reality, be dangerous places beset by violence, vice, and victimization. More specifically, the seemingly safe appearance of college campuses has been coupled with a conventional view held by many campus administrators, students, and their parents that campus violence, vice, and victimization are merely "youthful indiscretions" resulting from students' newfound personal freedoms, including sexual promiscuity, alcohol consumption, and recreational use of illegal drugs.

These views, however, changed during the 1990s when four groups – a student advocacy group called Security On Campus, campus feminists, campus crime victims and their families, and public health researchers – made claims that crime on US college campuses was not only increasing but becoming more serious and deadly in its consequences. Collectively these groups convinced the public, Congress, and several state legislatures that the "dark side" of the ivory tower was a "dangerous place" rife with "heinous crimes" that not only undermined students' safety and well-being but also threatened the core educational mission of higher education. As a result, during the early 1990s, Congress and multiple states passed statutes designed to address campus crime. For example, Congress passed the *Student Right to Know and Campus Security Act of 1990* (20 USC 1092[f]) (now known as the *Jeanne Clery Disclosure of Campus Security Policy and Campus Crime Statistics* or the *Clery Act*) which mandates that all Title IV schools (those eligible to participate in federal financial aid) not only publicly report their crime statistics in an annual report but also to implement policies and programs designed to address campus crime, in particular sexual assault against college coeds (Sloan and Fisher 2011). Additionally, nearly one-third of the states passed campus crime-related legislation with wide-ranging requirements (Sloan and Shoemaker 2007).

Looking at 2009 campus crime statistics compiled by the United States Department of Education (2011a) in fulfillment of the *Clery Act*, there were over 47,000 violent and property crimes reported on college campuses in the United States. The total included 31 murders and non-negligent manslaughters; over 3,300 forcible and non-forcible sex offenses; more than 4,600 robberies; approximately 4,900 aggravated assaults; more than 26,000 burglaries; over 7,200 motor vehicle thefts; and more than 700 incidents of arson. While the magnitude of these numbers is alarming, to put them into perspective, in 2009, over 20 million students were enrolled at 6,883 Title IV designated post-secondary institutions that were required to file annual campus crime reports with the federal government (United States Department of Education 2011b).

As the public began perceiving campus crime as a "serious" problem, a number of researchers started exploring the patterns, correlates, and causes of campus crime. During the past 20 years, this body of research can be classified as having two different, yet complementary, foci: studies whose primary interest was describing and explaining patterns of victimization relating to *individuals* and studies whose interest was understanding how the *characteristics of college campuses* such as physical layout and geography explained victimization patterns. In the former instance, the studies examined students' victimization patterns by different types of personal and property crime, including recent analyses of cyber-based victimizations suffered by students. Identifying individual-level behavior that apparently increased the risk for victimization led researchers to examine how students' lifestyles and daily routines played a significant role in increasing (decreasing) their risk of victimization. In the latter instance, researchers adopted a perspective which emphasized the college campus as a specific place with distinctive physical and social characteristics that contributed to victimization. Social scientists – including sociologists, criminologists, and geographers – adopting this perspective argued that a *criminology of place* is not only possible, but is a valuable theoretical and practical lens through which researchers and crime prevention practitioners alike can examine and understand campus crime and, more importantly, take steps to prevent its occurrence (Eck and Weisburd 1995).

This entry discusses the interrelationship between the characteristics of colleges and universities and students' lifestyles and daily routines that provide ample opportunities for on-campus personal and property victimization. Campuses are unique places characterized by a distinctive, yet somewhat stereotypical, built environment that helps to structure the daily routines of places and ultimately influences students' daily lifestyles and ensuing crime patterns. As discussed in more detail below, the patterns of the campus environment-student lifestyle nexus enhance opportunities for different types of crimes to occur more frequently than others.

The entry begins by discussing the notion of the college campus as a "place." Relevant literature is then presented that addresses how the characteristics and daily routines of places either may facilitate or retard crimes occurring at or near them. Next, what is known about the relationship between the characteristics of college campuses and crime occurring there is presented. The entry concludes by exploring important controversies and questions that remain concerning campus crime, especially those arising from the perspective of the criminology of place.

Background: The College Campus as a Place

To draw a detailed portrait of offenses occurring on campuses, one must first understand that these events occur at a specific *place*. Further, one must understand that the characteristics and daily routines of places are not simply physical locations where illegal activities occur. Rather, one must appreciate that the characteristics and routines of a place provide important ingredients necessary to create opportunities for victimization.

Geiryn (2000, pp. 464–465) described a place – such as a college campus – as possessing several salient features. First, a place occupies geographic location (a "unique spot in the universe") the size of which can vary tremendously. Many land-grant public universities occupy a dozen or more square miles of space, while so-called virtual universities exist in a single building whose carbon footprint is several 1,000 sq ft. Places, such as college campuses, also possess material form "[a] compilation of things or objects" (Gieryn 2000, p. 465). When people describe a particular college campus to others, they may do so by commenting on the particular architectural features the campus possesses such as a large bell tower atop the student union or in terms of natural features such as being adjacent to mountains or having a stream running through it. Places like college campuses also have *physicality* to them, including geographic markers (e.g., logo signage; staffed entry gates; the hallmark student union) that uniquely characterize a place's physical space and functions, and signal to visitors that they have entered a place separate and distinct from the adjunct community.

The physicality of a college or university campus is important because ". . . social processes happen *through* the material forms" that comprise the place (Gieryn 2000, p. 465). On campuses, daily interactions occurring among students, faculty, staff, and visitors take place both inside and outside of offices, classroom buildings, residence and dining halls, stadia, libraries, pathways, streets, parking structures, and green spaces. These interactions are the result of lifestyles or daily routines that each of these campus community members takes on as part of their respective purpose or role while on campus. These interactions and lifestyles – which are structured by physical spaces and their layout – create opportunities for a variety of violent (e.g., rapes, assaults) and property (e.g., automobile thefts, burglaries) victimizations to occur.

Finally, a college campus is invested with meaning and value. When individuals walk by a set of buildings consisting of a large residence hall, a library, a classroom building, and green space where young adults are throwing Frisbees, reading books and connecting to the internet, lounging in the sun, or playing touch football, most would not think "oh, that is a prison." Some scholars have argued that the meanings created by and resulting from the material form of a place prompt humans to think of these places as *communities*: locations where people with similar interests purposely gather to interact with one another (e.g., Smith 2002). Annually, college campuses draw groups of individuals who share interests. Researchers are drawn to college campuses because they house needed facilities and resources. Faculty members are drawn to the campus as a place where they can teach young adults and not only help shape their minds, but train them to enter an increasingly complex and competitive workforce. Those seeking positions as support staff are drawn for the opportunities the campus presents to find meaningful employment. Ultimately, those drawn to the campus – despite disparate reasons for arriving there – interact with one another and create a community (Bromley 2007).

The Routines of Place and Their Patterns

Places also have identifiable routines or rhythms that vary by time of day, day of the week, and season of the year which are shaped by both the built environment – manmade structures and features – and the natural environment. The routines of place include not only the movement of people into or away from it at regular intervals during the day but also the myriad of interactions that are facilitated by the features of the place. In effect, places have *patterns* associated with them.

Brantingham et al. (1995) have suggested that the patterns or routines that characterize college campuses can be conceptualized as occurring at different levels of spatial analysis. At the *macro level*, campus routines include vehicular and pedestrian traffic coming onto or exiting the campus and students moving *en mass* across the campus as one set of classes end and another begins from early morning to late evening. At the *meso level*, a particular building – for example, the student union – has *its* own routines and patterns which vary by time of day, day of the week, and season of the year. For example, the student union may be overrun with students during meal times each day during an academic term, but relatively quiet at other times of day when students are studying in their residence halls or in the library. Students' presence at the union on weekends may be reduced when visitors come to enjoy concerts, movies, or lectures. On some weekends, especially during final exams or the summer, the union may be essentially vacant of both students and visitors.

Finally, at the *micro level* are the routines associated with a *single room* within a building such as "Dr. Jones' laboratory" or "Ms. Smith's dorm room." Again, variation in the activities occurring in or around the lab or dorm room takes place according to time of day, day of the week, or academic term. The lab might be very busy in the morning but empty at night while just the opposite might be true of the dorm room. At the beginning (or end) of a term, the lab and the dorm room would be a beehive of activity, while during various breaks in the academic year, each may be occupied by only a handful of students.

Conceptualizing the routines of place as occurring at different levels can be useful to understanding the crime patterns of a place, including college campuses. On a college campus, identifying macro level crime patterns helps to understand the "big picture" of crime at that particular place. What is the most commonly occurring offense on the campus? Are there particular areas of the campus where crime tends to be concentrated – so-called hot spots? If so, where are these located? At the meso level, crime patterns can also be identified for a much smaller part of the larger place. How many rapes or burglaries occurred in the undergraduate residence halls during the fall semester? Which parking garage had the most auto break-ins? Finally, at the micro level, one can again assess patterns that may be associated with a single residence hall room, laboratory, office, or classroom. For example, several years ago at UAB, a particular computer laboratory in one of the older buildings on campus was repeatedly broken into over the course of several months and most of the equipment was stolen. By analyzing evidence at the site of the break-ins, the campus police learned the thefts were generally confined to very early morning hours, that homeless people had been seen climbing through unlocked windows into the building, and that the security devices protecting the equipment had been disabled from the inside.

The patterns associated with the routines of place have both theoretical and practical importance for understanding crime and developing sound situational interventions to address it. Research has consistently shown, for example, that crime is *not* randomly distributed either spatially or temporally but rather tends to cluster by place and in time (Eck and Weisburd 1995). When crime clusters at certain locations, these are known as "hot spots" (Sherman 1995). The most basic hot spot is a place or area that has a greater than average number of crime or disorder events, or where targets have higher than average risk of victimization. Places include specific addresses, street corners, or other small locations that can be seen by a person, such as a house, convenience store, or drug dealing location. As a result of the groundbreaking "hot spots" work by Sherman and others over the past several decades, combined with developments in spatial and temporal analysis of crime, criminologists developed a new theoretical orientation that instead of focusing on individuals and their behaviors focuses on places – the "criminology of place" – to underscore that opportunities for crime are shaped by the characteristics of places, individuals' lifestyles and daily routines, and time of day. Further, places – like individual offenders – have "careers" associated with them including onset, continuance, specialization, and desistance (Sherman 1995). A particular hot spot was not always "hot." It develops over time based on how its features – both physical and symbolic – and routines draw prospective offenders and targets to it (onset). The place continues as a hot spot for some period (continuance), which may be years, and may disproportionately involve certain crimes such as armed robbery (specialization). Finally, because of direct police intervention, neighborhood changes, or other factors, the hot spot desists as a place disproportionately responsible for crime (desistance).

On a practical level, understanding the dynamics of place including how they are organized for crime to occur and how the routines of place at the macro, meso, and micro level bring together would-be offenders and potential targets can inform primary prevention measures to reduce the probability of crime occurring. Strategies such as target hardening, changing the physical design features of a place, having individuals change their daily routines (e.g., not carrying large amounts of cash on their person; insuring valued goods stored in a vehicle are not left in the open), or altering their lifestyles (e.g., not getting drunk, not consuming illegal substances) when frequenting certain types of places (e.g., residence halls) can help to change the routines of a place and patterns of behavior and therefore might reduce the opportunity for victimization.

College Campuses and Opportunities for Crime: Institutional, Demographic, and Lifestyle-Routine Characteristics

The institutional, demographic, and lifestyle characteristics of colleges and universities create untold opportunities for violent and property victimization for the nearly 20 million students and the millions of faculty and staff, and countless visitors to college campuses each year. Below, these characteristics and their contribution to crime on college campuses are examined.

Institutional and Demographic Characteristics

Although the more than 6,000 Title IV 2- and 4-year post-secondary institutions differ widely across their institutional characteristics, researchers have identified a set of characteristics strongly correlated with official crime rates – crimes known to and recorded by the campus police or security (Fernandez and Lizotte 1995; Bromley 1994; Sloan 1994). Schools with large enrollments, for example, have higher rates of on-campus rape, assault, robbery, burglary, and larceny than schools with smaller enrollments. Campuses with large student enrollments apparently provide more opportunities for victimization because they: (1) possess more targets for would-be offenders, and (2) allow for greater anonymity among potential offenders within the student body.

Research also shows that campuses with a large percentage of full-time students have higher official rates of assault, robbery, burglary, and motor vehicle theft. One explanation for this is that full-time students tend to spend more time on campus than part-time students which increases their exposure to potential offenders and provides a larger number of targets from which offenders may choose.

Residential campuses – schools that have a large number of students living in on-campus residence halls or apartments – have higher rates of rape and larceny whereas commuter schools have higher rates of motor vehicle theft and robbery. In contrast, rural campuses, on average, have lower rates of all forms of violent (rape, assault, and robbery) and property crime (burglary, motor vehicle theft, and larceny) than do urban campuses.

One of the strongest and most consistent predictor of official rates of campus crime is the cost associated with room and board per academic year. Campuses with higher room and board costs generally report higher rates of crime whose motivation is economic, for example, robbery, burglary, motor vehicle theft, and larceny. Students enrolled at "costly" schools might also have plenty of attractive, high-quality targets (e.g., electronic devices and their accessories; designer clothing) to steal with relatively little risk for the offender. Further, research shows that most students while on campus do *not* routinely engage in proven crime prevention behaviors that reduce their chances of victimization (Fisher et al. 1997).

Research further indicates there is a demonstrable relationship between students' demographic characteristics and campus crime rates (Fernandez and Lizotte 1995; Bromley 1994; Sloan 1994). Since the 1940s, the demographic composition of colleges and universities has changed dramatically, with total student enrolled increasing annually. In particular, the number of women and minorities enrolled at post-secondary degree-granting institutions has seen tremendous increases, especially over the past three decades. In 2009, approximately 55 % of the 20 million students enrolled at all post-secondary institutions were women (United States Department of Education 2011c) while some 32 % of students enrolled at degree-granting post-secondary schools in 2009 were racial and/or ethnic minorities (Rigg 2010).

Several studies find that the percentage of male students enrolled at a college or university consistently is linked with campus crime rates, such that the more males enrolled, the higher the overall crime rates (Fernandez and Lizotte 1995; Bromley 1994; Sloan 1994). Research also shows that colleges and universities with higher percentages of minority students also have higher rates of violence reported to officials. A similar relationship is found between the percentage of African-American students enrolled and rates of campus assault, robbery, and burglary.

Understanding the effects of institutional and students' demographic characteristics allows post-secondary administrators to determine whether campus crime rates at their school are typical for or similar to comparable campuses or due to other factors, perhaps students' lifestyles and routines. For example, some campuses with large student enrollments may have "naturally" high crime rates. A problem arises when campuses with *high* crime rates have institutional and demographic characteristics associated with *low* crime rates. This requires exploring how the physical design features of the campus as a place potentially interact with the lifestyle-routine activities of campus members to see how those interactions provide opportunities for victimization.

Campus Places

College campuses occupy finite geographical areas that vary in size. Campuses typically are divided into smaller parcels designated for various uses including housing, instruction, research, common areas, entertainment and leisure, etc. These spaces also are usually arranged in a way such that the space utilized for one function does not mix with space designated for another. Collegiate residence halls or apartments for married students, for example, would ordinarily not be located directly adjacent to a football stadium or research laboratories where exotic and potentially lethal viruses are being studied. Rather, residence halls tend to be located near one another and away from other space clusters designed for different uses.

Arranging common usage of space on the campus is conducive to creating daily interactions among faculty members, students, staff, and visitors. There may be several such segmented areas on a campus depending on its age and needs, or as new needs arise or priorities change to account for expansion of student and faculty needs. However, for reasons ranging from the utilitarian to the aesthetic, the general pattern is that similarly designated spaces tend to cluster together in space.

This segmentation of a campus into areas of designated usage has implications for understanding the spatial and temporal distribution of campus crime. A college or university with several thousand students living on campus will have many residence halls and student apartments to accommodate housing demand. These, in turn, will likely be clustered together and several such clusters will be located around campus. Buildings that primarily contain classrooms or research laboratories will likewise be clustered together, rather than randomly placed, and again may be found in several locations around campus. Parking lots and decks are typically located on the edges of the campus, especially if the campus is "pedestrian friendly" and vehicular access is restricted to the fringes of the campus.

Clusters of similarly utilized space provide differential opportunities for offenders. For example, a five-story parking deck is a far more likely candidate for automobile theft or automobile break-ins than is a building housing research laboratories where theft of property, such as laboratory equipment, would be likely more common. Offenders may perceive that a cluster of dormitories is a good target for burglary, but less so for crimes against the person such as robbery. A small, isolated parking lot on the fringe of campus may be perceived as a good target for robberies but not for automobile theft, due to the limited number of vehicles actually parked there. Ultimately, spatial distribution and space utilization of a campus has significant implications for target selections by prospective offenders.

Additionally, clusters of similarly utilized spaces have their own routines at various points during the day or evening which likely differs from the routines associated with other clusters. During a typical day, there will likely be specific times when clusters of buildings, parking lots and decks, residence halls, etc. are "busy" with students, faculty, or staff coming and going. There are specific times during the day or at night when such spaces are relatively quiet. These "down-periods" during the 24-h cycle of the day present opportunities to offenders since few people are present to serve as guardians for the places that prospective offenders may perceive as attractive targets. Large parking decks or lots while classes are in session likely mean few people would be present, which increases opportunities for vehicular thefts or break-ins. As a result, because of variation in the routines associated with clusters of differentially utilized spaces, prospective offenders are likely to perceive these clusters – and the individuals typically found there – as differently convenient targets. Thus, not only the spatial distribution of spaces and their usage but also the temporal patterns associated with those spaces matter in terms of understanding campus crime.

Campus Routines and Lifestyles

The routine, everyday activities of students, faculty, staff, and visitors have significant influences on their chances of becoming a victim of crime while on campus. Although its population is moderately transitory, college campuses also have constant and familiar activities and routines.

The lifestyle-routine activity approach to understanding crime victimization describes how one's daily activities and lifestyles converge in time and space with a would-be offender to create opportunities for criminal victimization (Cohen and Felson 1979). Four concepts are central to this approach for explaining how and why victimization can occur: attractiveness of the target; proximity of one or his/her property to a motivated offender; guardianship over a person or his/her property; and exposure of his/her property to a potential offender. Understanding how each of these concepts plays out on campus broadens one's understanding of the mechanisms underlying the occurrence of crime on college campuses.

Students and Victimization. Students' pursuit of education and recreation has them on campus at all hours of the day, every day of the week. They also experience a variety of violent and property victimizations while on campus. Fisher et al. (1998) found that nearly one-fourth of the students in a national sample had been victimized at least once while on campus during the current academic year. Campus victimizations occur in a wide array of situational contexts that are unique to on-campus locations, compared to those that are off campus. For example, Hart and Miethe (2011) have shown that the specific attributes of "minor assaults of male victims in daytime hours" were far more likely to occur in on-campus contexts than off campus.

Students who live on campus spend a considerable amount of time in their residence halls. These provide not only shelter and food, but they are also places where daily relationships and routines are established (and broken). Living in a residence hall, especially those that are high-density with little supervision as to who enters or exits, increases opportunities for victimization by increasing the number of suitable targets and exposure of them to motivated offenders, while reducing the level of guardianship over person and property. Fisher and her colleagues (1997) reported that of the student victims of crime who lived on campus in undergraduate or graduate housing, or in a fraternity or sorority, 86 % of them lived in an undergraduate residence hall. Identifying on-campus locations where incidents had occurred revealed that crimes of violence, vandalism, threats, and harassment occur most frequently in students' living quarters.

Students' lifestyles and routines also lend themselves to opportunities for victimization every day of the week around the clock. Each year students bring attractive, portable, lightweight targets to campus with them: portable computers, electronic pads and tablets, cell and smart phones, calculators, backpacks, books, roller blades, skateboards, and bicycles. Students carry many of these items with them while they attend classes or social events. Many students drive motor vehicles to campus daily or park vehicles on or near campus during the duration of the academic term. Concurrently, they are all too often inattentive guardians of their property (or their person) and leave residence hall, office, or vehicle doors unlocked or propped open; leave bicycles unlocked; or just walk away from their property at the library, student union, or classroom for "just a few minutes." As a result, dormitories, bicycle racks, libraries, student unions, or classrooms can all become "hot spots" of crime because students are typically poor guardians of their property. Moreover, students leave the campus *en mass* at the end of an academic term or for long periods during holiday breaks, which leaves the campus filled with many attractive targets without guardianship.

The college years are also notorious for an active social life for many students. They may attend weekly parties; drink habitually and heavily or experiment with drugs; and attend entertainment or cultural events. All of this activity occurs in places on campuses where students naturally congregate. Such lifestyles and routines have, in turn, been linked to increased probabilities for on-campus victimizations. The Harvard Alcohol Study found that students who had been the victims of crime on campus reported significantly more frequent drug and alcohol use than students who had not been victimized (Dowdall 2009). The number of nights spent on campus partying and the likelihood of regularly taking recreational drugs during the past year also have been reported to be significant predictors of students' on-campus violent victimization (Fisher et al. 1998). Given their 24–7 on-campus lifestyles, it is not surprising that a temporal pattern concerning on-campus student victimization shows that violent crimes were likely to have occurred in the early morning hours, in particular between 12:00 a.m. and 2:00 a.m. (Fisher et al. 1998).

Faculty, Staff, and Victimization. Faculty members, like students, also have routine activities on college campuses that increase their risk for victimization. Faculty members, especially untenured assistant professors, are frequently on campus during the week and on weekends, sometimes spending long hours into the night and early morning working on research, grading papers, or writing manuscripts. Many spend considerable amount of time in their offices or laboratories, or walking to and from classes, meetings, the library, or a seminar. Most faculty members work alone in their office even when support staff have gone home for the day. Many faculty members also teach night courses. Because of their routines, many faculty members are exposed to a large number of students every academic term. Some faculty members even socialize with students outside of class in the student union or other establishments on or near campus.

Faculty members also have valuable, attractive targets such as laptop computers, multimedia equipment, laser printers, laboratory equipment, secured data, books, motor vehicles, and other personal items. Faculty can also be poor guardians of their property. At times, they leave offices or laboratories unlocked or computers unsecured between classes or meetings, and may prop open doors to buildings, offices, or laboratories so as not to have to fetch keys or recall a lock combination. With the routine arrival of new faculty members each academic term, while others are on leave or sabbatical during the school year, access control to buildings and offices may be severely compromised on a daily basis.

Wooldredge, Cullen, and Latessa (1995), in a study of faculty members' victimization experiences at the University of Cincinnati West campus (all colleges except the medical and nursing colleges), reported 27 % of faculty members surveyed reported they had experienced at least one property victimization on campus (burglary, stolen property, or damage to property) during the academic year, while 5 % reported they had experienced at least one personal victimization (robbery, assault, sexual assault, or assault with a deadly weapon). Those whose offices are not within shouting distance of their colleagues; who do not teach in buildings where their office is located; and whose office is in a comparatively non-secure building on campus are more likely to experience an on-campus property crime. Faculty members who spend more time on campus after hours and on Saturdays, who walk alone on campus more frequently (other than going to class), and who socialize with students outside class are also more likely to experience personal victimization while on campus.

Staff members typically work 8-h shifts, primarily Monday–Friday and during daylight hours. Like faculty, they too possess attractive targets. To date, there are no published studies on the extent and nature of victimization among staff working on college campuses. Anecdotal evidence, however, suggests that their patterns of victimization may be similar to those of faculty.

Visitors to Campus and Victimization. The routine activities of visitors to campus are somewhat different from those of students, faculty members, and staff. Every term, prospective students and their parents frequently meander around the campus. Students from other campuses visit with friends; sports fans attend athletic events or hold tailgate gatherings; and cultural buffs frequent movies, concerts, art galleries, and plays. Delivery trucks filled to the brim with products and packages are daily sights on campus. Visitors bring plenty of property with them that is attractive to would-be offenders – cash, portable electronic equipment, expensive jewelry and watches, motor vehicles. Like staff, no studies of campus visitors have been published but it is likely that students who visit friends and enjoy activities where alcohol and drugs are plentiful and visitors who attend sporting events and enjoy pregame, during-the-game, and post-game celebrations might experience a pattern of victimization similar to students who actively engage in an active "party lifestyle."

Tracking the Spatial and Temporal Distribution of Campus Crime

Crime on campus, like crime in other locations, is not randomly distributed in space or time. Robinson and Roh (2007) illustrated this point in an analysis of crime on the campus of Appalachian State University (ASU) for the period 2004–2005 using calls-for-service data stored in campus police crime logs. Analyzing those data revealed that the four most commonly reported offenses on the ASU campus over the 2-year period of study included alcohol violations, theft of property, illegal drug possession, and vandalism (Robinson and Roh 2007, p. 239). More importantly, they determined that hot spots on the ASU campus included locations at or near: (1) student residence halls, (2) high-traffic areas between the main parts of the campus such as near classroom buildings and parking lots near pedestrian tunnels, and (3) specific locations for drug violations, alcohol violations, breaking and entering, and assaults/sexual assaults/forcible fondling. These "crime attractors" or "crime generators" remained relatively stable over the 2 years of study and possessed certain features. For example, one hot spot included two residence halls located within walking distance to the football stadium, its parking lots, and an open field which students use for recreational activities including consuming alcohol, playing sports, and hosting parties. Robinson and Roh also reported that residence halls that were "hot spots" for various crimes tended to be older residences located in the heart of the campus. Compared to these "older" residence halls, newer residence halls' distance from the center of the campus made them both more physically and socially isolated and apparently less vulnerable to opportunities for victimization.

In a similar study, Resler (n.d.) examined the spatial distribution of crime on the campus of the University of Texas at Austin using police calls-for-service data from 1998. Using geographic information system (GIS) crime mapping software and spatial analysis models, Resler (n.d.) found that ". . . concentrations of crime occur[ed] predominantly around the periphery of campus [and] the characteristics of these high crime areas, such as location and density, influence victimization." Resler concluded that use of GIS software to map crime distributions and concentrations was an effective tool, and its use opened new avenues for research.

Brower and Carol (2007) examined the temporal and spatial distribution of reported incidents of liquor law violations, assaults and batteries, vandalism, and noise complaints during 2003 on the campus of the University of Wisconsin-Madison and the City of Madison. They also used GIS crime mapping technology and tracked the movement of different crimes through the city of Madison by time of day, and investigated the relationship between these spatial and temporal movements of crime and the proximities of various student and nonstudent neighborhoods to each other and to high-density bar areas. They found different categories of crime presented different temporal and spatial patterns. For example, serious crimes such as assaults tended to peak between 2:00 a.m. and 3:00 a.m. which coincided with bar closing time. Less serious crimes, such as noise violations, peaked between 11:00 p.m. and 12:00 a.m. Vandalism tended to peak during the late morning and early afternoon. "Hot spots" for the different crimes moved throughout the downtown by time of day. Results of the study were then used by University of Wisconsin and City of Madison officials to implement changes to address high-risk drinking behavior.

Controversies

Because the study of crime on college and university campuses is, relatively speaking, still in its infancy, controversies over study results are bound to arise. Below, a few of the more important questions that have been raised with these studies are presented.

One significant controversy in the literature concerns wide-ranging estimates that have been produced concerning the extent college women experience various forms of sexual violence during their college tenure. Part of the explanation for disparate estimates of college women's victimization experiences has to do with how questions about rape, sexual assault, stalking, and other forms of violence are framed. Generally, the broader the question about sexual victimization asked of college women, the larger are the estimates of sexual violence. Fisher and her colleagues (2000) were among the first to document how specific, behaviorally based questions relating to sexual violence against college women significantly affected estimates for victimization. As a result of their work, studies now are more apt to use narrow, behaviorally based questions in surveys of college women to explore the extent of sexual victimization perpetrated against them.

A second controversy is the predominance of research using case studies of crime occurring on a single campus. Typically, one or more researchers will survey students (or faculty or staff) enrolled at a single school or use official data compiled by a single school to examine the causes, correlates, and consequences of crime occurring on campus. While many of these studies have contributed insight into the dynamics of campus crime, the problem is that results from such case studies cannot be generalized to colleges and universities more generally. The works of Fisher and her colleagues (1998, 2000) are notable exceptions; both projects involved national samples of college students.

A final major controversy revolves around the utility of officially compiled data collected by Title IV eligible post-secondary institutions in compliance with the mandates of legislation such as the federal *Clery Act*. Among other requirements, the legislation mandates that colleges and universities compile statistics on crimes reported to campus authorities for the following offenses: murder and non-negligent homicide; rape; robbery; assault; burglary; automobile theft; and arson. One weakness is that the *Clery Act* fails to include what is generally regarded (based on victimization surveys) as the most commonly occurring crime on campus, namely, theft or larceny. A second problem, again based on victimization surveys conducted on college students, is that large numbers of offenses occurring on campus go unreported to campus law enforcement or other authorities. As a result, those offenses are never included in the crime statistics published as part of *Clery Act* requirements, which means *Clery Act* statistics grossly underestimate the volume of crime occurring on the nation's college campuses (Fisher et al. 1998).

Unless and until these controversies are settled, contributions from studies of campus crime will likely not have the impact they might, were these issues to be addressed. In particular, campus administrators who may be relying upon extant literature to help them craft responses to crime occurring on *their* campuses may not develop as effective a response as they might were the controversies settled.

Open Questions

Given the above controversies, several questions remain open to exploration, comment, and debate. The first is rather basic: How much crime occurs on college campuses each year? Currently, the answer to that question depends on where one looks: case studies (from which national-level extrapolations might be developed); "official" data (such as those compiled in compliance with the *Clery Act* but which, as discussed above omit a major type of crime and suffer from underreporting); or national-level studies (some of which are more than 15 years old).

A second open question is how to better translate the results of academic research on campus crime into practical policies and programs to address the problem and then to evaluate their impact on both crime and fear of crime. Assuming study results used to develop specific programs or policies to reduce campus crime are sound, there is little evidence that programs based on these results are ever evaluated. Further, policies or programs aimed at reducing campus crime too often fail to use sound scientific designs that allow for such necessities as control groups, or designs which rule out rival hypotheses. Criminologists are increasingly advocating the need to use controlled experiments to examine the effectiveness of interventions designed to reduce crime; the same should be true of efforts occurring on college campuses.

Finally, but certainly of no less importance is the ultimate utility of legislation like the *Clery Act* that is designed to reduce/eliminate campus crime. There are actually several problems with campus crime reporting legislation. First, because reliable baseline statistics for the years prior to the passage of *Clery* do not exist, it is difficult to know if the legislation has had a positive, negative, or neutral impact on campus crime. Second, post-secondary institutional compliance with *Clery* has been less than total for a number of reasons, none the least is the amount and type of resources necessary to compile and report the data required by the law. Finally, there is enough evidence to indicate that the very consumers whom the law was passed to serve (particularly prospective college students and their parents) are either unaware of the law and the various reports that are to be generated by colleges and universities in compliance with the law's mandates, or if they are aware of these reports, few actually consult them (Gregory and Janosik 2007).

Conclusions

Campuses are neither hot beds of criminal victimization nor are they ivory towers immune from the grim reality of crime. They are *places* whose built and physical environments, institutional and demographic characteristics, space distributions, functional usage, temporal patterns, lifestyles and routines create opportunities for victimization. By developing an orientation that focuses on the criminology of place and on identifying campus characteristics and lifestyles/routines that facilitate opportunities for crime, researchers now better understand how and why campus crime happens. Through identification of crime patterns, researchers also have informed interventions (e.g., banning alcohol on campus or enhancing campus lighting) intended to disrupt the rhythms and routines associated with campus crime.

This work has clear implications for campus policing and campus security, because it is these agencies that will benefit the most from research focusing on the relationship between campus *places* and campus *crime* (Ratcliffe 2002). It is these agencies that routinely collect data that can then be used to identify hot spots and adapt personnel and tactics according to changing conditions. These agencies, through place-based analyses of campus crime, also can work with campus administrators to develop and better enforce policies relating to parking, consumption of alcohol, noise ordinance violations, and other problems.

There is reason for optimism that as research devoted to college campuses as places matures, nagging questions about campus crime will be answered. There is also reason to hope that the answers uncovered will, in turn, inspire the development and evaluation of evidence-based policies and programs to reduce or even eliminate campus crime.

Capture Recapture to Estimate Criminal Populations

Population size estimation

Overview

Methodology is presented that allows to estimate the size of population from a single register, such as a police register of offenders. A capture-recapture variable is constructed from Dutch police records and is a count of the police contacts for a violation. A population size estimate is derived assuming that each count is a realization of a Poisson distribution and that the Poisson parameters are related to covariates through the truncated Poisson regression model or variants of this model. As an example, estimates for perpetrators of domestic violence are presented. It is concluded that the methodology is useful, provided it is used with care.

Fundamentals of Capture Recapture

Introduction

For many policy reasons, it is important to know the size of specific delinquent populations. One reason is that it provides insight into the threat these populations may pose on society. Another reason is that it gives an estimate of the workload of the police.

However, estimating the size of a delinquent population may be problematic for various reasons. Counting the number of crimes from police records may lead to a dark number problem. It may be that the crime is registered but the offender is not known or, as is often the case with victimless crimes, the crime is not registered at all. In victim surveys, people report the number of times they have been the victim of a particular crime, like robbery or burglary. Based on that information, an estimate can be obtained of the total number of these crimes. However, victim surveys do not provide an estimate of the number of offenders, since they usually are unknown to the victim, nor do they provide insight into victimless offenses. Self-report studies can potentially estimate the size of a delinquent population since people are simply asked whether they are member of this type of population. Problems related to self-report studies are the difficulty of obtaining a representative sample, the risk of socially desirable answers, and the need for large samples if offenses are infrequent. For a more elaborate comparison and an overview of the literature on police registers, victim surveys, and self-report studies, the reader is referred to Wittebrood and Junger (2002).

The methodology presented here makes use of a single register. There is a large literature on capture recapture making use of two registers. Estimation based on a single register has two important advantages: first, it does not require the unverifiable assumption that the two sources are statistically independent, and, second, it does not require the elaborate process of linking databases that is often troubled by privacy regulations. Also, often there are technical problems in making correct linkages and in avoiding incorrect linkages. A single register that contains (re)captures circumvents these problems.

In this entry, a way to estimate the number of offenders from police data is discussed. The data are from the Dutch police register system. Offenses committed by a known offender are registered in this system. So for each specific offense, like, for example, illegally owning a gun, an offender-based data set can be constructed that shows the number of illegal gun owners apprehended once, twice, three times, and so on. Note that illegal gun owners who were not apprehended are not part of this offender-based data set. Yet, if their number could be estimated, this would yield an estimate of the total number of illegal gun owners (compare van der Heijden et al. 2003a).

The aim is to estimate the number of offenders never apprehended, using the data about offenders apprehended at least once. These estimates are derived under two assumptions. First, the number of apprehensions is a realization of a Poisson distribution. Second, the logarithm of the Poisson parameter for an offender is a linear function of his covariates. These assumptions are discussed in greater detail at the end of the introduction.

At this point, it is indicated how, using these assumptions, the size of the population never apprehended can be estimated. Consider an offender with a Poisson parameter that gives him a probability of.25 to be apprehended at least once. Suppose that this offender is indeed apprehended, then there are three other offenders with the same Poisson parameter who have not been apprehended. By performing this trick for every offender who is apprehended and adding up all individual estimates, an estimate is obtained of the number of offenders who are not apprehended, and this solves the problem.

The methods employed in this entry originate from the field of biology, where they are used to estimate animal abundance. In these applications, the data are collected at specific time points, and for each animal that is seen at least once, there is a capture history. For example, if there are five capture times, a history could be 01101 if the animal is seen at captures 2, 3, and 5 and not seen at captures 1 and 4. In the present methodology, however, the data are collected in continuous time, so only the total number that someone is captured is used.

Typically, in the biological application area, covariate information is not available or not used, leading to a basic model in which the Poisson parameters are assumed to be homogenous over the animals. For an overview of this area, the reader is referred to Seber (1982, Chap. 4), Chao (1988), and Zelterman (1988). In the statistical literature, this problem is also known as the estimation of the number of (unseen) species (Bunge and Fitzpatrick 1993).

In criminology, there are some early studies by Greene and Stollmack (1981) who use arrest data to estimate the number of adults committing felonies and misdemeanors in Washington D.C. in 1974/1975; Rossmo and Routledge (1990) who estimate migrating (or fleeing) fugitives in 1984 and prostitutes in 1986/1987, both in Vancouver; and Collins and Wilson (1990) who use arrest data to estimate the number of adult and juvenile car thiefs in the Australian capital territory in 1987. In the field of drug research, a one-source capture-recapture analysis has also been applied to estimate, for example, the size of the marijuana cultivation industry in Quebec (Bouchard 2007) and young drug users in Italy (Mascioli and Rossi 2008). These studies do not devote systematic attention to covariate information on the apprehended individuals.

The methodology reviewed here makes use of covariates that are available in police registers, such as age, gender, and so on. The methodology yields the following results: (1) the hidden number of offenders and a 95 % confidence interval for this hidden number, (2) a distribution of these hidden numbers over covariates, and (3) insight into which part of the hidden number is visible in the register and which part is missed, stratified by the levels of the covariates.

Covariate information is incorporated by using a regression model that makes use of truncated Poisson distributions, such as the truncated Poisson regression model and the truncated negative binomial regression model, that are well known in econometrics (e.g., Cameron and Trivedi 1998, Chap. 4). These models are elaborated so that a frequency can be estimated for the zero count as well as a confidence interval for this point estimate (see Van der Heijden et al. 2003a, 2003b; Cruyff and van der Heijden 2008; Böhning and van der Heijden 2009, that also show examples on undocumented immigrants, illegally owned firearms, and drunk driving). The methodology will be illustrated for perpetrators of domestic violence (van der Heijden et al. 2009).

Assumptions

As the methodology originates from the field of biology and it is used in the field of criminology, the assumptions of the methodology are discussed here in greater detail. Of course, assumptions that are realistic for animals will not always be realistic for human offenders.

The first assumption is that the number of times an individual is apprehended is a realization of a Poisson distribution (equations will be provided later). Johnson et al. (1993) discuss the genesis of the Poisson distribution and state that it was originally derived by Poisson as the limit of a binomial distribution with success probability p and N realizations, where N tends to infinity and p tends to zero, while Np remains finite and equal to λ. It turns out that even for $N = 3$, the Poisson distribution approximates the binomial distribution reasonably well if p is sufficiently small. Johnson et al. (1993) also note that the probability of success p does not have to be constant for the Poisson limit to hold. This implies that an individual's count still follows a Poisson distribution, even if this individual's Poisson parameter has changed during the period of observation. It follows for the type of applications being discussed that individuals do not need to have a constant probability to be apprehended, but it suffices if they can be apprehended a number of times (see van der Heijden et al. 2003a).

It is important to note that the Poisson assumption is only valid if a change in the individual Poisson parameter is unrelated to any prior apprehensions or non-apprehensions. This follows from the independence of subsequent trials in a binomial distribution. In the biostatistical literature, this problem is known as positive contagion (if the probability increases) or negative contagion (if the probability decreases).

Closely related to the contagion issue, there is the problem of an open or closed population. A population is closed if the number of offenders is constant over the period of data collection and is open if offenders may enter or leave the population during this period. Given what has been noted above, it is clear that the population may be open as long as entering or leaving it is not related to apprehension or non-apprehension. For example, detention following an apprehension removes the person from the population and excludes the possibility of any subsequent apprehensions and can therefore be seen as an extreme case of negative contagion.

So far the Poisson assumption pertaining to an individual count is discussed. The second assumption follows from using a regression model, in which the logarithm of the Poisson parameters is a linear function of covariates. In the regression model, the Poisson parameters are still assumed to be homogeneous for individuals with identical values on the covariates, but they are allowed to be heterogeneous for individuals with different values. Since here the differences in Poisson parameters are determined by the observed covariates, this is referred to as observed heterogeneity. If, in addition to observed heterogeneity, there are differences in the Poisson parameters that cannot be explained by the observed covariates, we speak of unobserved heterogeneity. If the Poisson regression model does not fit due to unobserved heterogeneity, this is referred to as overdispersion.

In conclusion, the most important violations of the Poisson assumptions in criminological applications are contagion and overdispersion. The contagion problem may be larger for some offenses than for others, and an indication of its importance can be obtained by studying the behavior of offenders as well as police officers (e.g., by doing qualitative research). If no additional information is available on their behavior, it seems best to interpret the results with caution. Overdispersion can be assessed in the data as a result of the analysis, and this will be discussed below.

Models

An informal definition of a Poisson distribution is as follows. The Poisson distribution is characterized by a Poisson parameter denoted by λ. This parameter λ expresses the probability of a given number of events (i.e., the count) under two assumptions, namely, that events occur:

1. With an average rate in a fixed interval of time
2. Independent of the time since the last event

The probability that the count Y generated by a Poisson distribution with Poisson parameter λ is equal to j is

$$p_j = P(Y = j) = \frac{e^{-\lambda}\lambda j}{j!}. \tag{1}$$

Three models for count data are discussed, namely, (1) the truncated Poisson regression model, (2) the truncated negative binomial regression model, and (3) the Zelterman regression model.

First consider Eq. 1. Two examples of a Poisson distribution are provided in Table 1. In the first example, an individual has a Poisson parameter $\lambda = .5$. Then his or her probability to be seen zero times is .607, the probability to be seen once is .303, twice is .076, and so on. These probabilities add up to 1. In the second example, it is assumed that there is an individual with Poisson parameter 1. His or her probability not

Capture Recapture to Estimate Criminal Populations, Table 1 Two examples of Poisson distributions (line 1 and 2) and their corresponding truncated Poisson distributions.

	0	1	2	3	4	5	6	Total
$\lambda = .5$	.607	.303	.076	.013	.002	.000	.000	1.000
$\lambda = 1$	.368	.368	.184	.061	.015	.003	.001	1.000
$\lambda = .5$	–	.771	.193	.032	.004	.000	.000	1.000
$\lambda = 1$	–	.582	.291	.097	.024	.005	.001	1.000

Notes: The columns show the number of times an individual is seen. The cells give the probabilities

to be seen is .368, the probability to be seen once is .368, twice is .184, and so on. Note that the individual with Poisson parameter $\lambda = 1$ has a larger probability to be observed at least once, namely, (1 − .368) = .632, whereas this probability for the individual Poisson parameter $\lambda = .5$ is only (1 − .607) = .393. It follows that the individual with Poisson parameter $\lambda = 1$ has a larger probability to be seen.

Model 1: The Truncated Poisson Regression Model

In single-register capture-recapture data the observed individuals each have a count larger than zero. Since for the observed individuals the count cannot be zero, these individuals have the so-called truncated Poisson distributions. For the data in the first and second row of Table 1, the truncated distributions for $y > 0$ are obtained by dividing the probabilities by $1 - \mathrm{P}(y = 0|\lambda)$, that is, for the first example we divide by 1 − .607 = .393 and for the second example we divide by 1 − .368 = .632; see rows three and four of Table 1.

As a first step towards developing the truncated Poisson regression model, assume that there are no covariates. This implies the homogeneity assumption, so that only a single Poisson parameter needs to estimated. This Poisson parameter is then used to obtain the probability of not being registered given that the Poisson parameter equals the value λ, as denoted $P(y = 0|\lambda)$. Using $P(y = 0|\lambda)$, the part of the population is estimated that we did not see. A small example will illustrate this. Assume that $n = 250$ individuals are observed with a Poisson parameter for which $P(y = 0|\lambda) = .667$. This would mean that $P(y > 0|\lambda) = .333$, that is, only one-third of the population is observed so our n refers to one-third of the population size. The missed part of the population size is (.667/.333) * 250 = 500. The estimated population size would then be equal to the observed part plus the missed part, that is, $N = 250 + 500 = 750$. In the statistical literature, this is known as the Horvitz-Thompson estimator of the population size (see Van der Heijden et al. 2003b).

Secondly, the Poisson parameter for individual i is related to the covariate values $x_{1i}, x_{2i}, \ldots$ of individual i by a log-linear model, that is,

$$Log\, \lambda_i = b_0 + b_1 x_{1i} + b_2 x_{2i} + \cdots \qquad (2)$$

This equation explains the term "regression" in the name "truncated Poisson *regression* model." Once the model is estimated and the parameters are known, the Horvitz-Thompson method can be applied on an individual level (see Van der Heijden et al. 2003b). Using the earlier example, for each of the 250 individuals in the data, there is an estimated λ_i-parameter. For each individual i separately, $P(y = 0|\lambda_i)/P(y > 0|\lambda_i)$ can be calculated, and this yields the number of missed individuals with covariate values identical to individual i. If these numbers of missed individuals over i are summed and 250 is added, the estimated population size is found derived under the truncated Poisson regression model.

Summarizing, the homogeneity assumption is exchanged for a heterogeneity assumption that allows individuals to be different with regard to their covariates. It is important to consider the case where heterogeneity is completely or partly ignored. Van der Heijden et al. (2003a) show that ignoring heterogeneity leads to an estimated population size that is too low. Ignoring heterogeneity may happen if important covariates are not used in Eq. 2.

It is possible to investigate whether there is ignored heterogeneity by using a test presented by Gurmu (1991). If this test is significant, then there is evidence for additional heterogeneity (i.e., additional with regard to the heterogeneity that is already taken into account by the covariates), and the estimated population size is to be interpreted as a lower bound for the true population size. Thus, the Gurmu test can be used to investigate the fit of the model. Another way of investigating the validity of the Poisson assumption is the ratio plot (Böhning and Del Rio Vilas 2008). According to the previous section, $r_j = (j + 1)p_{j+1}/p_j = \lambda$, a constant, if the p_j follows a Poisson distribution. Departure from this constant indicated unobserved heterogeneity.

Model 2: The Truncated Negative Binomial Regression Model

The distinction between the truncated negative binomial regression model and the truncated Poisson regression model is that the truncated negative binomial regression model allows for additional heterogeneity of Poisson parameters after the covariates have been taken into account. Equations for the negative binomial model are complicated; see Hilbe (2011) for details.

Cruyff and Van der Heijden (2008) discuss the application of the truncated negative binomial regression model for population size estimation. It turns out that this model is often difficult to fit numerically, in particular when Poisson parameters are small. For details, see Cruyff and Van der Heijden (2008) where this is shown using a simulation study. Unfortunately there are also numerical problems for the example discussed below. For an example of opiate users where fitting the truncated negative binomial regression truncated Poisson regression model did not lead to numerical problems, see Cruyff and Van der Heijden (2008).

Model 3: The Zelterman Regression Model

The Poisson distribution Eq. 1 has the property that, for any j, $P(j + 1|\lambda)/P(j|\lambda) = \lambda/(j + 1)$. This can be rewritten as $\lambda = (j + 1)\ P(j + 1|\lambda)/P(j|\lambda)$. Zelterman (1988) uses this property to propose local estimators of the Poisson parameter by plugging in observed frequencies f_j of count j for $P(j|\lambda)$ and $P(j + 1|\lambda)$. In particular, if the frequencies f_1 and f_2 are plugged in, an estimate of the Poisson parameter

$$\hat{\lambda} = \frac{2f_2}{f_1}$$

is found, and this estimate of λ can then be used to estimate $P(0) = 1 - \exp(\lambda)$ and hence the Zelterman population size estimator $N_Z = n/(1 - \exp(\lambda))$. This estimator is closely related to Chao's estimator $N_C = n + f_1{}^2/2f_2$, that is used for similar purposes (Böhning 2010).

Zelterman's proposal has the advantage that it is robust against violations of the Poisson assumption such as unobserved heterogeneity. Also, when interest goes out to the frequency of the missed count f_0, then it makes sense to use the information that is the most close to f_0, that is, f_1 and f_2, because individuals that make up f_1 and f_2 will be most similar to the individuals that make up f_0. Probably for this reason and because the estimator is easy to understand, Zelterman's estimator is quite popular in estimates of drug using populations (see, Van Hest et al. 2007).

Recently Böhning and Van der Heijden (2009) generalized the Zelterman estimator so that it can take covariates into account as in Eq. 2. As the Zelterman estimator is a useful competitor of the Poisson estimator if there is heterogeneity of the Poisson parameters, the Zelterman regression model is a useful competitor of the truncated Poisson regression model when the homogeneity assumption of the Poisson parameters (conditional on the covariates) is violated. This follows from the robustness property of the Zelterman estimator.

Model Choice

In the truncated Poisson regression model, the presence of unobserved heterogeneity in the data can be investigated with a test proposed by Gurmu (1991) and ratio plots (Böhning and Del Rio Vilas 2008). If unobserved heterogeneity can be ignored, the truncated Poisson regression model is the model of choice. If unobserved heterogeneity cannot be ignored, the population size estimate given by the truncated Poisson regression model is to be interpreted as a lower bound for the true population size. In this situation, the truncated negative binomial regression model can be tried. However, regularly numerical problems are encountered in the estimation of the model. If there is doubt about

Capture Recapture to Estimate Criminal Populations, Table 2 Observed and fitted frequencies of counts 0, 1, 2, . . . for domestic violence data under truncated Poisson regression model

	0	1	2	3	4	5	>5	Total
Observed	–	15,169	1,957	393	99	28	16	17,662
Estimated	51,629	14,814	2,494	317	33	3	0	69,290[a]

[a] 95 % confidence interval is 66,242–72,338

the Poisson assumption for individuals having counts higher than 2, then the Zelterman regression model provides a robust estimate.

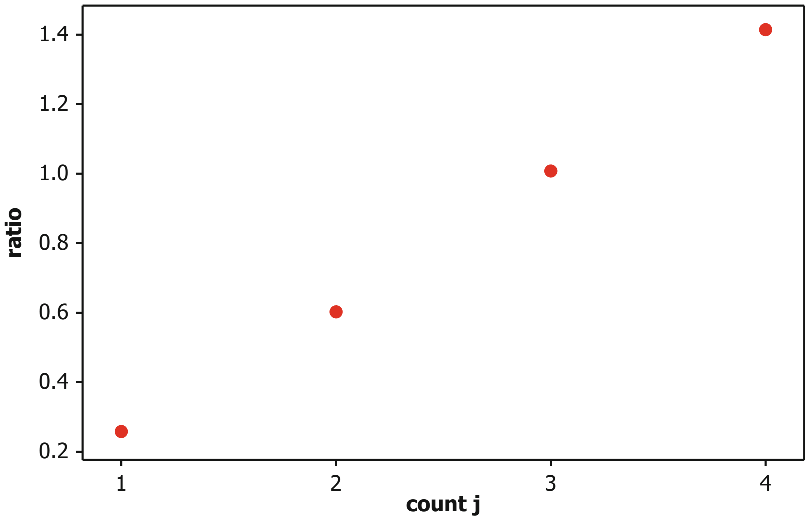
Example

In the context of domestic violence policy, it is important to have reliable estimates of the scale of the phenomenon. In 2009, a study was conducted to supplement a victim study and perpetrator study (van der Heijden et al. 2009). Here the perpetrator study is reported. cthe prevalence of domestic violence, particularly because so few victims are willing to file charges, which leads to underreporting, that is, the dark number in registers. The aim of the capture-recapture methods used in this study is to estimate the size of the underreporting. Adding up the reporting and underreporting then yields an estimate of the total population of offenders. The estimates have been made using data from incidents that were reported and where charges were filed. The data represent the Netherlands except the police region for The Hague.

The estimates presented have been calculated using the Poisson regression model and the Zelterman regression model. The negative binomial regression model had numerical estimation problems. The estimates are presented for a year ranging from mid-2006 to mid-2007. Distinctions were also drawn as regards specific features of the estimated populations, that is, the sex and age of the individual suspect, the type of violence used, the type of victim of domestic violence, and the ethnic background of the suspect.

The first line of Table 2 shows the observed distribution of the counts. A total of 17,662 perpetrators are observed in the year ranging from mid-2006 to mid-2007, of whom 15,169 were observed once, 1,957 twice, and so on. The second line of Table 2 shows the fitted values under the truncated Poisson regression model. The estimated population size is 69,290 (confidence interval is 66,242–72,338) of whom 51,629 perpetrators are not found in the police register. The fit of the model is not good, as is revealed by comparing the observed frequency of the counts and the estimated frequency of the counts: The Gurmu test on overdispersion gives a chi-squared distributed test value of 30.04 for 1 ° of freedom ($p < .0001$), showing that the departure from the truncated Poisson regression model is significant. Similarly, Fig. 1 shows a ratio plot (Böhning and Del Rio Vilas 2008) where these ratios are monotonically increasing, indicating strong unobserved heterogeneity. For this reason, further results for the truncated Poisson regression model are not presented, but the focus will be on the Zelterman regression model.

The Zelterman regression model yields a population size estimate of 84,862 (confidence interval is 80,293–89,431). Columns 1–3 of Table 3 provide parameter estimates, standard errors, and p-values for a Wald test. Gender is significant, and the fitted conditional Poisson parameter for males is exp (.49) = 1.63 times as large as the fitted conditional Poisson parameter for females. For type of domestic violence, sexual and physical assaults have a lower fitted Poisson parameter than threat. In comparison to an (ex-) partner, a family friend and "other" have lower fitted Poisson parameters. Ethnic background (first or second generation) is not significant, except for "not registered" in the official register, which are undocumented foreigners, who have a lower fitted Poisson parameter than the native Dutch population.



Capture Recapture to Estimate Criminal Populations,
Fig. 1 Ratio plot for the observed frequencies in Table 2

Columns 4 and 5 of Table 3 provide observed univariate frequencies and fitted frequencies. For example, 14,827 males are found in the police register, and the estimate of the number of males is 68,048; thus, it can be concluded that 14,827/68,048 * 100 = 22 % of the male perpetrators is observed. For females, this percentage is 2,653/16,813 * 100 = 16 %. The other percentage can be derived in an identical way.

Future Directions

It is shown how police records can be used to estimate the size of criminal populations. These estimates can be used to evaluate the effectiveness of the police forces and grant insight into differential arrest rates (Collins and Wilson, 1990) for different groups. Even though the definition of the data is straightforward, however, the data are sometimes contaminated with errors. The reason is that the police does not collect these data for the purpose of conducting statistical analyses, they do so to facilitate the process of apprehending offenders. Therefore, the register is not always as careful as it should be. For example, data cleaning was required to minimize the likelihood of incorrect double counts (i.e., the same apprehension appears twice in the system). Clearly, an incorrect double count incorrectly decreases f_k by 1 and increases f_{k+1} by 1, so that there appear to be more recaptures than there actually are. The result is that the estimated zero count is too low. Although careful attention has been devoted to the appearance of incorrect double counts, it is possible that there are still a few in the data.

Conversely, suppose that an individual has been apprehended several times, but this has not been recognized so that this individual has been entered several times as several single persons. This will lead to the result that f_1 is too large whereas f_j with $j > 1$ is too small, leading to an overestimation.

Apart from problems in the correctness of the data, it may also be that data do not follow the assumptions of the model. This will lead to biased estimates. Above we discussed the problem of positive contagion (leading to estimates that are too low) and negative contagion (leading to estimates that are too high). Another problem discussed above is unobserved heterogeneity, leading to estimates that are too low. It may very well be that unobserved heterogeneity always plays a role when the data are derived from a police registration.

As regards the meaning of our population size estimate, one might wonder what it stands for?

Western (1)	.02	.17	92	593	2,807
Not registered	−.54	.11	.00	1,268	9,325

Basically, the apprehended individuals can only be generalized to similar individuals who are not apprehended (but who are in principle apprehensible and where charges could be filed). Thus, the population size estimate does not stand for the total number of perpetrators of domestic violence; it stands for the apprehensible ones. The population estimate is still useful, since it represents the number of individuals who pose a threat to society and is thus an indication for the police potential workload.

Career Criminals and Criminological Theory

Raymond Paternoster
Department of Criminology and
Criminal Justice, University of Maryland,
College Park, MD, USA

Synonyms

Chronic offenders; Persistent offenders

Overview

In 1986, the National Academies Press published a two-volume compendium entitled "Criminal Careers and 'Career Criminals'"

(Blumstein et al. 1986) that gave expression to the growing interest in both the field of criminology and among policy makers in the career criminal. Although there is no exact agreement on what a career criminal is, in the literature it has generally referred to persons who commit many crimes beginning at an early age and who persist in offending over the life course. Among other things, then, the career criminal is a habitual, persistent, or "chronic" criminal offender, committing criminal acts at every stage of the life course. Blumstein and colleagues' report was not, however, the first instance of academic interest in the career criminal. From the 1930s to 1950s, Sheldon and Eleanor Glueck assembled several large longitudinal data sets that tracked offending from a young age to adulthood. Most notably, the Unraveling Delinquency Study (Glueck and Glueck 1950) which included 500 boys selected from two youth correctional centers in Massachusetts – the Lyman School for Boys and the Industrial School for Boys. Initial data were collected when the average age of the boys was 14, and they were followed up at age 25 and again at age 32. The presence of a persistent or career offender could be deduced from the fact that 55 % of these seriously delinquent boys experienced an arrest at some time between the ages 32 and 45 (Sampson and Laub 1993: 30).

Additional interest in the notion of career criminals was sparked by Wolfgang and colleagues' Philadelphia cohort studies. In the 1945 cohort, they classified youth with five or more police contacts as chronic or habitual offenders (Wolfgang et al. 1972). While these chronic offenders comprised only 6 % of the total birth cohort of nearly 10,000, they had 52 % of all police contacts and committed 63 % of all recorded index crimes, 71 % of all homicides, 73 % of all the rapes, and 82 % of the robberies. In a subsequent work, they followed a sample of this cohort up to age 30 and identified what they called "persistent" offenders as those who committed offenses both as juveniles and adults. Of the 975 boys who were followed up, 459 had at least one official arrest, and nearly 39 % of these were persistent offenders who had an arrest as juveniles and adults. Further, these persistent offenders committed both more frequent and more serious offenses than those who committed crimes only as juveniles or only as adults (Wolfgang et al. 1987: 24).

Key Issues and Themes

Interest in the career criminal persists today among scholars and policy makers. With respect to the former, Laub and Sampson (2003) have obtained arrest histories for the Glueck boys up to age 70 and identified a small group (less than 5 % of the total) of chronic offenders who were experiencing arrests into their 60s. In a Dutch sample, Blokland (2005; Blokland and Nieuwbeerta 2005; Blokland et al. 2005) identified a small group of offenders (also less than 5 % of the total) who experienced criminal convictions from their teens to their 60s. Finally, Sohoni et al. (2013) found a group of offenders (about 4 % of the total) in the South London data of Farrington and West who experienced convictions from their teens to age 50. With respect to public policy interests, most states have habitual offender statutes that provide for enhanced penalties for offenders with several prior convictions as well as "three-strike" laws that provide for life imprisonment for those repeatedly convicted of serious felonies.

Given the very strong interest in *identifying* the career criminal, it might perhaps be surprising that an equivalent amount of effort and attention has not been devoted to understanding the cause of persistent offending. The Glueck's, for example, were loath to provide a comprehensive theoretical account either of delinquents in general or those who persisted in crime throughout their lives arguing that it was "premature and misleading to give exclusive or even primary significance to any one of the avenues of interpretation" (Glueck and Glueck 1950: 281). Instead, they put forward an atheoretical multifactored explanation that simply consisted of a list of the risk factors they empirically found to be related to crime. Wolfgang and his colleagues were silent with respect to how the small group of chronic and habitual offenders they identified could be explained. It was really not until the mid-1980s rebirth of empirical interest in the career criminal that some attention was beginning to be devoted to understanding and explaining the high-rate offender who persists over time. In fact, the empirical work of career criminal researchers was in part responsible for the emergence of developmental and life-course theories of offending, theories that among other things were devised to explain why it is that offending takes place throughout the life course.

Theoretical Explanations for the Career Criminal

There really is no theory of the career criminal in the sense of a separate theory of crime to explain this phenomenon. Rather, there are theories of persistent offending, without speaking to the career criminal, and there are general theories of offending that can be adapted to explain the habitual or persistent offender whose long-term pattern of offending can be described as a career in crime.

Terrie Moffitt (1993) has presented a typological theory of criminal offending that provides some theoretical light on the career criminal. She argues for a distinction between two qualitatively distinct types of offenders: the adolescent-limited and the life-course-persistent offender. The life-course-persistent offender would qualify as a career criminal since they are described as committing crimes at a high rate over a protracted period of time: as children, adolescents, and adults. They are a small group, comprising approximately of 5 % of any sample of youth, consistent with the Glueck's high-rate offender and the chronic and habitual offender of Wolfgang et al.

In accounting for the life-course-persistent offender, Moffitt appeals to an integration of constitutional and environmental factors. The life-course-persistent offender suffers initially from neuropsychological deficits that are either prenatal or neonatal in origin and are manifested in profound cognitive and executive function difficulties (impulsivity and poor verbal skills are particularly important). Since infants with these kinds of neuropsychological deficits are frequently born in disadvantaged and criminogenic environments, these deficits frequently go uncorrected and are more often made worse. In a nutshell, a difficult child often overwhelms distressed and poorly resourced parents unable to cope with the challenge who frequently respond with erratic and harsh discipline. Such responses by caregivers only exacerbate the child's initial difficulties, and as a result of this destructive interaction, the child fails to develop behavioral restraints – they are undersocialized. This negative interaction continues with development, and the poorly controlled toddler becomes the poorly controlled child who becomes the poorly controlled adolescent on into adulthood. As described by Moffitt (1993: 12) the life-course-persistent child becomes ensnared in an ongoing sequence of failed development: "personal characteristics such as poor self-control, impulsivity, and inability to delay gratification increase the risk that antisocial youngsters will make irrevocable decisions that close the doors of opportunity."

A related theory of the persistent offender, related because it appeals to the same set of empirical facts and develops a similar theoretical argument, was presented by Patterson and colleagues (1990). Like Moffitt, Patterson et al. define two etiologically distinct trajectories of offending. One starts early (the early-onset offender) and persists over the life course into adulthood in a way that would be harmonious with the idea of a career criminal. The behavioral trajectory of the early-starting offender is similar to Moffitt's life-course-persistent offender. The second starts offending in mid- to late adolescence and ceases offending as they enter adulthood. The behavioral trajectory of the late-starting offender is similar to Moffitt's adolescent-limited offender.

In Patterson's typology, the cause of the early-starting and late-persisting offender is a combination of disruptive family practices (harsh discipline, emotional coldness and little intimacy, little parental involvement with the child, and poor monitoring and supervision). The immediate result of these inept child-rearing practices is that the child learns to be coercive and aggressive both directly from parents (modeling their physical violence) or indirectly (parents tolerate or support the child's violence) which over time culminates in an aggressive poorly controlled child. Although perhaps adaptive in the short term in the home, such verbally and physically aggressive behavior results in both academic and social failure in the school as well as rejection by normal peers and acceptance by equally disruptive peers. Finally, in a process that is reminiscent of Moffitt's "ensnarement," these aggressive adolescents are at a great risk for committing serious delinquent offenses as adolescents and criminal offenses as adults.

There is an important common causal thread that runs through the theories of the persistent or career criminal in both Moffitt and Patterson's work. While Moffitt's theory admittedly has a neuropsychological component that is lacking in Patterson, both appeal to a disruption in family processes, particularly inadequate training or socialization by parents or caregivers. Caregivers who for various reasons are emotionally uninvolved with their children and therefore inadequately monitor and supervise their conduct create children who are impulsive, poorly controlled, and act in ways that may be in their immediate interest (ex: snatching a toy away from another child, stealing another child's bike) but is destructive in the long term. Such poorly socialized children are not easily able to make up for past deficits and in fact misplay prosocial opportunities and experiences they confront. In other words, they never catch up and in fact fall further behind developmentally in diverse areas, with the ultimate outcome that they are at high risk for frequent adult criminal offending and other self-destructive behaviors such as drug use, alcohol abuse, long bouts of unemployment, and unhealthy social relationships.

The preceding paragraphs may be very familiar to many criminologists since it describes a causal explanation for repeated offending that is not tied directly to the career criminal paradigm, in fact one that has been hostile to that paradigm – Gottfredson and Hirschi's (1990) general theory of crime. There are in fact several general theories of crime that provide an adequate theoretical explanation for the persistent offending that characterizes a criminal career.

In 1990, Michael Gottfredson and Travis Hirschi (1990: 117) published what was to be a highly influential book titled *A General Theory of Crime* in which they presented a theory which could explain "all crime, at all times" and that could also explain behaviors that are as self-destructive in the long term as crime. The key theoretical construct they premised their theory on was the notion of low self-control which, while its precise meaning has changed somewhat over time, is manifested in a person's inability to consider both the short- and long-term negative consequences of their actions. The person low in self-control, then, is attracted to behaviors which while they may provide gratification in the short term, such as crime and drug and alcohol abuse, have detrimental long-term consequences, and since the costs of actions are generally delayed relative to their benefits, they play a much less consequential role. Very similar to Moffitt's and Patterson's theories, Gottfredson and Hirschi trace the origins of low self-control to family disruption. In fact, there is a very close correspondence in the causal mechanisms underlying the person with low self-control and the life-course-persistent and early-starting offender. In each theory, an emotional connection or relationship between caregiver and child is absent, and this affective distance results in inept socialization. Caregivers who are not emotionally attached to the child are unlikely to monitor or supervise the child's conduct properly and unlikely to correct inappropriate and reward appropriate behavior.

Another important piece of common ground among the theories is that the initial failure to socialize has reverberations down the life course. Moffitt (1993), for instance, speaks about poorly socialized youth becoming "ensnared in a deviant life style by crime's consequences" because they "will make irrevocable decisions that close the doors of opportunity." She links poor childhood socialization to teenage pregnancy, school dropout, drug addiction, unemployment, and incarceration such that "the behavior of life-course-persistent antisocial persons is increasingly maintained and supported by narrowing options for conventional behavior." Patterson (1990: 266) in a process that parallels the notion of "ensnarement" argues that the child who is poorly socialized becomes aggressive and predatory at an early age and that such behavior leads to a lack of success in school and ostracism from normal peers in a causal spiral that over time leads to "school dropout, uneven employment histories, substance abuse, marital difficulties, multiple offenses, incarceration and institutionalization." Similar to both of these, Gottfredson and Hirschi (1990: 96) account for the persistent offender by noting that because they are relatively unaffected by the negative consequences of their actions, the poorly socialized person with low self-control fails to take advantage of opportunities to change throughout life, and they too become ensnared in a cycle of repeated failure and persistent criminality: "The traits composing low self-control are also not conducive to the achievement of long-term individual goals. On the contrary, they impede educational and occupational achievement, destroy interpersonal relations, and undermine physical health and economic well-being."

There are, however, some important distinctions among the three theories. First, the theory of self-control argues that low self-control and therefore the propensity to become a habitual or career offender lies on a continuum rather than being a typology. They argued (1990: 95) that "though there will be little variability among people in their ability to see the pleasures of crime, there will be *considerable variability* in their ability to calculate potential pains" (emphasis added). Second, unlike Moffitt's theory that relies on antecedent neuropsychological mechanisms or Patterson's that relies on the mediating causal effect of deviant peers, Gottfredson and Hirschi locate the source of poor self-control solely in the family, and involvement with deviant peers has no causal effect on persistent offending but is simply another manifestation of low self-control.

Another general theory of crime that can offer us an explanatory account of the persistent offender is Sampson and Laub's (1993, 2003) age-graded informal theory of social control. In discussing this theory, one cannot help but be struck with the substantial common ingredients in all of these theories of the persistent offender in spite of their supposed, much ballyhooed differences. Acknowledging the existence of a persistent criminal offender whose numbers may be small but whose maladaptive behavior is quite broad to cover marital problems, unemployment, drug and alcohol addiction, and the corporal punishment of children (heterotypic continuity), Sampson and Laub (1993: 123–138) appeal to a causal process that should by now be familiar to the reader. Children who are poorly socialized and antisocial are maintained or ensnared in their behavior through two causal mechanisms. First, antisocial behavior in children calls forth destructive and maladaptive responses by caregivers and others in their social environment, and such responses fuel further antisocial behavior by children, a process termed "interactional continuity" (Sampson and Laub 1993: 124). Second, the antisocial behavior of young children and the delinquent acts of adolescents have "negative structural consequences" for subsequent life chances that "may lead to the 'closing of doors' as far as opportunities go (for example, school failure, unemployment)," in a process termed "cumulative continuity."

In their 2003 book, *Shared Beginnings*, Laub and Sampson (2003: 150–195) discuss the persistent or habitual offender at some length and make a concerted effort to draw a distinction between their theoretical account and Moffitt's. Their view of Moffitt's theory is that it places great weight on early childhood factors (perhaps ignoring Moffit's explanation of being ensnared in a life of crime over time), and they find little evidence either in the 2003 or earlier 1993 book that childhood risk factors have an effect on adult criminality. Instead, Sampson and Laub put the majority of their eggs in the "adult life events" basket, arguing that persistence in adult crime is due to a weakness in adult social bonds. In point of fact, however, in further differentiating their position from so-called propensity theorists like Moffitt, Sampson and Laub also place great weight on a labeling process to account for the persistent or career offender. In *Crime in the Making* (1993: 137), they refer to a "structural version of labeling theory and state dependence" in which early arrest and incarceration experiences cut persons off from conventional opportunities: "the connection between official childhood misbehavior and adult outcomes may be accounted for in part by the structural disadvantages and diminished life chances accorded institutionalized and stigmatized youth." In fact, in an earlier paper, Sampson and Laub (1997) described the criminal career as a "stable pattern of deviant behavior that is sustained by the labeling process." In other words, contact with both the juvenile and adult criminal justice system creates problems of adjustment (Lemert 1967: 63) for people because it "denies them the ordinary means of carrying on the routines of everyday life open to most people" (Becker 1963: 35). In a reversal of the desistance process they describe, those with histories of imprisonment are "knifed off" from normal lives because of weakening social bonds. Sampson and Laub (2005: 171) in fact subsequently concede that "explanations of desistance from crime and persistent offending are two sides of the same coin." Just as a strengthening of adult social bonds may knife off a criminal offender from a previous life of crime and criminal associates, so may criminal justice intervention knife them off from a conventional.

It is important at this time to reiterate the similarities among all these theories of the persistent offender. In Moffitt's, Patterson's, Gottfredson and Hirschi's, and Sampson and Laub's theory, some childhood deviants grow up to be persistent adult offenders because they are all too frequently cut off from many conventional opportunities and fail at virtually every opportunity they are afforded to do good. In addition, events that occur in childhood are important in initiating that causal process. As such, all of the theories we have discussed thus far reflect Hagan's (1993) notion of the consequences of "criminal embeddedness." Hagan (1993: 487) argues that youth crime and contacts with the justice system cut adolescents off from sources of social capital and other social networks that connect to conventional lives. He further asserts that youths in trouble instead acquire "criminal capital," that is, they have social networks that connect them to illegal labor opportunities such as theft and drug dealing which embed them in a criminal lifestyle: "criminal youths are embedded in contexts that isolate them from the likelihood of legitimate adult employment."

Other general theories of crime offer their own theoretical account of the persistent, career criminal that are variations of the ones just discussed (with, of course, their own nuances). Farrington (2005) presented what he called an Integrated Cognitive Antisocial Potential (ICAP) theory that is a very eclectic account of criminal offending over the life course, including both desistance from and persistence in crime. According to ICAP, initiation into offending is due to a mixture of short-term and long-term antisocial potential (AP, which is defined simply as the potential to commit criminal acts) interacting with a person's social environment, while persistence in criminal offending is due to the fact that an initial distribution of long-term AP is relatively stable over time. Reminiscent of Gottfredson and Hirschi, then, persistence in offending in Farrington's theory is brought about because of the relative stability of an initial distribution of a time-stable individual trait, long-term AP, which consists of impulsiveness, the experience of strain, criminal modeling, socialization, and criminogenic life events.

Thornberry (Thornberry and Krohn 2005) applies his general Interactional Theory of crime to account for the persistent, career offender. In this theory, long-term persistence in crime is accounted for by two developmental processes: (1) the causal factors that produce an introduction into crime are themselves stable over time, and (2) there is a constancy in "negative temperamental traits" that are stable from childhood to adulthood. In a quasi-typological approach, Thornberry and Krohn (2005) suggest that for those who commit their first offense at an early age, the developmental deficits (poor parental supervision and monitoring, weak parental attachments, poor school performance and adjustment) are more extreme than for those whose onset into crime comes later, and since they are more extreme, they are also more stable over time. In addition to this, they describe a state-dependence-like process whereby early offending triggers hostile and maladaptive responses from the environment such as caregivers, teachers, and conventional peers. Essentially, early conduct problems ensnare youths by limiting conventional opportunities and social networks (i.e., they become embedded in a criminal lifestyle), restricting the development of social, personal, and human capital. In their own words, but words that seem to just as easily could have come from Moffitt, Patterson, Hagan, or Sampson and Laub, Thornberry and Krohn (2005: 198) posit that: "individuals who initiate antisocial behavior at very young ages are more likely than average to persist because the causal factors are likely to remain in place (both environmental and personality/trait factors) and because early involvement in antisocial behavior generates cumulative and cascading consequences in the person's life course. All of this reduces the formation of social bonds and social capital and increases embeddedness in deviant networks and belief systems, foreclosing conventional lifestyles and entrapping the individual in deviant lifestyles."

This account for persistence in offending for those who onset early is not, however, likely to hold for those whose initiation into offending is more "on time" and occurs during adolescence. Nevertheless, some of these on-time onsetters can also persist in offending in their adult years, and they do so primarily because their involvement with crime puts them at higher risk for school failure, unstable and unsatisfying social relationships, and problems at home and in the workplace and disrupts their successful transition into adult roles. Thornberry and Krohn (2005: 200) place great emphasis (as does Moffitt and Patterson for the adolescent-limited and late-onset offender) on the detrimental consequences of becoming embedded in deviant social networks for the youth who commits his first crime later rather than earlier.

Bouffard and Piquero (2010) recently offered a theory of the career criminal offending that appeals to Sherman's (1993) notion of defiance as an emotional reaction to labeling. Sherman had argued that when a poorly bonded person responds to the imposition of what they perceive to be an unfair sanction with anger rather than shame and an acknowledgement of harm, they become defiant and resentful and as a result are likely to commit further acts of crime rather than be deterred. Bouffard and Piquero (2010: 233) take this general theory of crime and apply it to the study of desistance and persistence arguing with respect to the latter that persistent offending is a "defiant response of a poorly bonded offender who defines their sanction as unfair and stigmatizing and refuses to acknowledge the shame they feel. These individuals may continue or escalate their offending." What happens when a poorly bonded person gets labeled, then, is that they react in such a way (with defiance, resentment, and rejection) that their already weak bonds become even weaker in a process that by now should be very familiar. The ingredient that Bouffard and Piquero add to this mix is the role of emotions, a welcome addition since emotions are a neglected factor in criminological research.

Wikström and Treiber (2009) presented a theory of the persistent or career offender that is a derivative of Wikström's (2005) Situational Action Theory (SAT). According to SAT, all criminal offending is moral rule breaking with the explicit implication that a key explanatory variable is an individual's moral values as well as the interaction between an individual's personal characteristics (such as their moral values) and environmental factors. An individual with a strong moral position against committing a criminal act will not view crime as a viable course of action and will not, therefore, be affected by contingencies in the environment, such as opportunities or the perceived costs and benefits of offending. It is also reasonable to conclude that such individual factors as an individual's propensity to commit crimes as manifested in their self-control are activated only when crime is perceived to be a morally available course of action. In SAT, then, the interaction between a person's moral values and their propensity to rule breaking will strongly influence what courses of action are available in a given situation and, therefore, what choices are available to be selected.

With respect to the career criminal, Wikström and Treiber (2009: 411) make a distinction between perception, choice, and action in a given setting that is "either *habitual* or *deliberate*, depending on the actor's familiarity with the setting" (emphasis is original). The more familiar an actor is to a given setting, the more their perceptions and behavior are likely to be guided by habit rather than deliberation. Actors who repeatedly find themselves in particular environments, such as one of extreme deprivation or abundant criminal opportunities with low moral restraints and little risk, will respond habitually to such contexts, and their behavior will tend to be highly stable and persistent over time. This constancy of the person-environment interaction and resultant habituation led Wikström and Treiber (2009: 411) to conclude that "there may be strong habitual elements in what drives much of persistent offenders' criminality."

Finally, it must be noted that there is more than one biologically based theory of the persistent, career criminal, though the common ground seems to be that they all link habitual offending to an early onset of offending and the interaction between biological and environmental factors (see Savage 2009). One such example is Tibbetts (2009: 183) whose initial premise is that "early onset is the most important factor in predicting which individuals are most likely to become chronic, habitual offenders." The secret to unlocking the origins of the career criminal, therefore, is to understand who onsets their offending early. In explaining the early-onsetting offender, Tibbetts' account relies on the interaction between a cluster of biological risk factors such as pre- or perinatal brain trauma, lower heart rate, arousal, slower brain wave patterns, deficits in pre- and perinatal nutrition, personality attributes (impulsivity), and a cluster of environmental deficits such as poverty, single-parent families, family size, and a criminogenic neighborhood. Whatever their particular composition, Tibbetts' and other biologically inclined theories of persistent offending are clear in stating that it is not biological factors nor environmental factors that are themselves responsible for the persistent offending of the career criminal but the interaction between the two.

Career criminals, offenders with both a high frequency and long duration of offending, have been the topic of theoretical discussion in criminology for over 20 years. One might get the impression from that fact that there is a great diversity of opinion with respect to the causes of career criminal offending. If so, one is in for a disappointment, for while there are numerous attempts to explain the persistent or habitual offender, for the most part the explanatory schemes are surprisingly similar, despite the many disciplines that have participated. While some theorists do place more of their eggs in an initial biological/psychological basket – those who eventually become persistent offenders have various constitutional, neuropsychological, or personality deficits – and others less, the natural progression to persistent offending is oddly very similar across many theories. The explanatory schemes involve notions of a state-dependent or dynamic process whereby initial developmental failures (hostile relationships with inept caregivers, failure at school, social rejection by normal peers) have reverberations that are felt down throughout the life course. It is not an oversimplification to say that toddlers who get into trouble with parents turn into adolescents who get into trouble with teachers and "good peers" who get into trouble with employers and spouses/partners who then get into trouble with the criminal justice system. In many if not all of these theories, there is a strong labeling component whereby initial antisocial behavior that is responded to informally leads to formal criminal justice system intervention which then leads to a “knifing off” of legitimate and conventional routines of life. The repeat adolescent offender finds it hard in Lofland’s (1969) terms to have access to normal places, others, and hardware; as a result of which, they are only able to secure “criminal capital” and become more and more embedded in a criminal lifestyle (Hagan 1993).

While one may lament the absence of theoretical variety in theories of the persistent offender (many in fact argue that persistence is simply the flip side of desistance), the brute fact is we know very little about how adequate these explanations really are. The extensive empirical work to determine what factors best explain persistent offending or the career criminal has hardly begun. While we know something about the process by which offenders drop out of crime, we know far less about the causal mechanisms behind repeated, habitual criminal offending.

Careers in Organized Crime

Edward R. Kleemans and Vere M. van Koppen
VU University Amsterdam, Amsterdam,
The Netherlands

Overview

This entry elaborates upon theoretical and empirical insights into criminal careers in organized crime. The first section provides an overview of life-course criminology, older offenders, and adult onset. The second section briefly reviews literature on criminal careers in white-collar crime and concludes that situational context is a key concept in explaining a large proportion of involvement in white-collar crime. The third section explores involvement mechanisms in organized crime: recruitment, social ties, work ties, leisure activities and sidelines, and life events (including financial setbacks). The fourth section reviews major studies on criminal careers in organized crime and describes how the findings of these studies differ from the main findings of developmental and life-course criminology. The last section comprises the main conclusions and suggestions for further research.

Traditional research on criminal careers has mainly focused on juveniles, adolescents, and high-volume crime. Although much empirical progress has been made in developmental and life-course criminology (e.g., Farrington 2005), this research tradition tends to ignore certain kinds of offenders, particularly adult offenders, and certain types of crime, particularly organized crime, white-collar crime, and terrorism (Weisburd and Waring 2001; Leeper Piquero and Benson 2004; Steffensmeier and Ulmer 2005). Mainstream research focuses on property crimes and violent crimes, crimes for which opportunities are ubiquitous and open to anyone. Furthermore, many empirical longitudinal studies focus on a relatively early and short lifespan (Piquero 2008). These studies are therefore unable, almost by definition, to identify offenders who become engaged in crime only later on in life.

There are several reasons why criminal careers in organized crime may be different from high-volume crime. Anybody is able to steal something or commit a violent act, but things are somewhat more complex in organized crime and particularly in cases of cross-border crime or “transit crime.” Nowadays, many activities of organized crime groups boil down to international smuggling activities such as drug trafficking, smuggling illegal immigrants, human trafficking for sexual exploitation, arms trafficking, trafficking in stolen vehicles, and other transnational illegal activities, such as money laundering and evasion of taxes (e.g., cigarette smuggling, value-added tax fraud, and

European Community fraud) (Kleemans 2007). Such activities pose different requirements than traditional high-volume crime (Kleemans and De Poot 2008).

The first distinct feature is the greater importance of social relations in organized crime. It is simply impossible to get started without access to suppliers, clients, co-offenders, and profitable criminal opportunities. Trust is also important, as the financial stakes are high and the rules and mechanisms that make transactions in the legal world so much easier are absent: entering into contracts, paying via the official banking system, and – in case of disagreement – the availability of mediation or the judiciary (Reuter 1983). For this reason, existing social ties are used or illegal business relationships have to be built up. Not everyone has suitable ties that provide access to these profitable illegal opportunities, whereas building up such relationships takes time and energy.

The second distinct feature of organized crime is the transnational character of many of these criminal activities. Many types of organized crime are based on international smuggling activities. Yet many people lack international contacts that may connect them to these illegal opportunities, as social networks are typically constrained by laws of geographical and social distance (e.g., Feld 1981). Thus, not all offenders have access to these transnational contacts and some only later on in life.

A third common feature is that the activities are logistically considerably more complex and call for more co-offenders and specific expertise (e.g., Cornish and Clarke 2002). As more co-offenders are generally required for the successful commission of these crimes, seeking and finding suitable co-offenders is important (see, e.g., Tremblay 1993). Reliance on co-offenders from within one's own social circle is not always sufficient, as they may not possess the necessary capabilities. Contacts with the legal world are also salient for transport, money transactions, and shielding activities from the authorities. Many people lack these contacts and expertise, and some acquire them only later on in life, e.g., through their professional activities and contacts.

This entry elaborates upon theoretical and empirical insights into criminal careers in organized crime. The first section provides an overview of life-course criminology, older offenders, and adult onset. The second section briefly reviews literature on criminal careers in white-collar crime and concludes that situational context is a key concept in explaining a large proportion of involvement in white-collar crime. The third section explores involvement mechanisms in organized crime: recruitment, social ties, work ties, leisure activities and sidelines, and life events (including financial setbacks). The fourth section reviews major studies on criminal careers in organized crime and describes how the findings of these studies differ from the main findings of developmental and life-course criminology. The last section comprises the main conclusions and suggestions for further research.

Life-Course Criminology, Older Offenders, and Adult Onset

Developmental and life-course criminology place a strong emphasis on individual characteristics and long-term risk factors when explaining differences in criminal careers (see, e.g., Moffitt 1993). For example, Moffitt's well-known "dual taxonomy" distinguishes between a large group of people who engage in crime and antisocial behavior mostly during adolescence ("adolescence-limited" offenders) and a small group of people who are antisocial from an early age, engage in crime in adolescence, and remain active in crime and other forms of antisocial behavior throughout their lives ("life-course persistent"). The explanation for "life-course-persistent" criminal behavior is generally sought in fairly stable biological or psychological characteristics – often deficiencies – such as low intelligence, high impulsivity, or low self-control. Moffitt argues that early problem behavior is an indicator that a person belongs to the life-course-persistent group and that antisocial and criminal behavior is likely to continue into later life.

Gottfredson and Hirschi (1990) follow a similar route in their "general theory of crime." Although they deny the very existence of different "types" of offenders, their basic approach is quite comparable: people develop self-control early in life, and those who lack sufficient self-control engage in criminal acts and similar behavior – with short-term benefits and long-term costs such as drinking, smoking, and adultery – at higher rates than others throughout their lives. Many developmental and life-course theories of offending, though often more nuanced and empirically grounded, share this strong emphasis on individual characteristics and long-term risk factors and treat antisocial behavior in children as essentially similar to offending in adults (Farrington 2005).

In this light, many theories assume that onset occurs early in life and that adult offending requires childhood antisocial behavior (see, e.g., Robins 1978). From this perspective, adult-onset offending is a rare phenomenon that needs no serious research effort (e.g., Gottfredson and Hirschi 1990). As a result, adult onset is an anomaly in developmental and life-course criminology and is treated in the same way as anomalies are generally treated in "normal science" (e.g., Kuhn 1962). Anomalies are discovered now and then but are often brushed aside empirically or theoretically (for an overview on adult onset, see Van Koppen et al. 2010).

The general neglect of adult-onset offending can be attributed to two major factors. First, almost all research on criminal careers is concerned with high-volume crime, in which adult-onset offending seems relatively scarce. Second, the majority of trajectory research focuses on a relatively small (and mostly young) age frame and is therefore unable to identify adult-onset offenders by definition. Piquero (2008) provides an overview of all research using trajectory methodology in studying criminal activity over the life course between 1993 and 2006. These 90 studies reflect about 50 different samples. Only half of the samples include individuals after age 18, and only a fifth have data available after age 30. Birth cohort studies that do follow individuals long enough into adulthood systematically identity a significant share of adult-onset offenders. A quarter up to half of the criminal samples of cohorts drawn in Racine, Stockholm, and Philadelphia turn out to start offending in adulthood (e.g., Eggleston and Laub 2002).

Hence, the dominant way in which criminal careers are studied – longitudinally, over a short (adolescent) life-span, using self-reports with limited follow-ups, and mainly focused on high-volume crime and (re)traceable young offenders – reinforces received wisdoms that might be challenged by other types of research, focusing on other types of crime, such as white-collar crime and organized crime.

Criminal Careers in White-Collar Crime

Over the past years, a number of studies have examined criminal careers in white-collar crime. Although there is a difference between white-collar crime and organized crime, both concern more uncommon types of crime, and both may reveal different patterns than the ones discovered in more traditional research. Until 1980, most of what was known concerning white-collar offenders and their crimes was extracted from case studies. From 1980 on, datasets were constructed containing white-collar crimes committed in the United States (Leeper Piquero and Benson 2004; Weisburd and Waring 2001). These new efforts immediately refuted a common belief about white-collar offenders. They are not all one-time offenders, as had been stated before (see, e.g., Edelhertz and Overcast 1982). Almost half of the white-collar offenders have had at least one other official contact with the criminal justice system (Benson and Moore 1992). Furthermore, these criminal careers turn out to differ substantially from careers of high-volume crime offenders on several aspects. Or as noted by Leeper Piquero and Benson (2004), "the typical white-collar offender greatly differs from the typical street offender and does not appear to fit into the proposed explanations of life-course-offending patterns."

Based on their findings on white-collar criminals, Leeper Piquero and Benson (2004) propose a theory on career patterns in white-collar crime called *punctuated situationally dependent offending*. It assumes that white-collar criminals are criminally active during adolescence (just like high-volume crime offenders), then desist for a while, and begin to offend again when they reach their 30s or 40s. External factors are used to explain this revival later in life. One explanation involves a personal or occupational crisis the offender is going through. A second explanation relates to opportunities presented when a certain occupational status has been reached. Situational context is a key concept in explaining a large proportion of involvement in white-collar crime (see for a review, e.g., Benson and Simpson 2009). Results of a study by Weisburd and Waring (2001) corroborate this idea: the white-collar offenders studied differ on various career aspects from offenders of high-volume crime, the age of onset was relatively late, and they were criminally active for a substantially longer period and were arrested for fewer offenses throughout their criminal career. These lines of research show the importance of incorporating new groups of offenders.

Organized Crime: Involvement Mechanisms

Before contemporary research on criminal careers in organized crime will be discussed further below, several involvement mechanisms are presented, explaining processes and situations that provide opportunities for organized crime. How do people get involved in organized crime?

Recruitment

According to the standard idea of recruitment, criminal "organizations" recruit outsiders who may move up in the hierarchy by proving their suitability. They start by doing dirty jobs and are ultimately rewarded. Behind this idea lies the assumption of a more or less static criminal organization (cf., e.g., Cressey 1969), while research shows that, much more often, the world of organized crime consists of criminal networks in which offenders may cooperate with one another in changing constellations (for a review, see, e.g., Morselli 2009). Within these criminal networks, there often are nodal actors, on whom many other offenders depend because of their money, knowledge, and contacts. These nodal actors resurface time and again, in different criminal investigations and different criminal collaborations. Still, other offenders may gradually become less dependent on these nodal actors because they accumulate money, knowledge, and contacts for themselves and subsequently develop increasingly more criminal activities of their own.

Social Ties and the Social Snowball Effect

Social ties are very important in organized crime. Opposite to the standard view of recruitment, social ties create a "social snowball effect": people get involved in organized crime through their family, friends, and acquaintances; as they go along, their dependency on the resources of other people (such as money, knowledge, and contacts) gradually declines; and they generate new criminal collaborations. They involve people from their own environment in their activities, keeping the snowball in motion (Kleemans and Van de Bunt 1999: 29–34). Examples comprise partners, girlfriends, spouses, sons, daughters, brothers, sisters, and half-brothers, who get involved in criminal activities; a father who starts helping his son in drug trafficking; or a smuggled Iranian who ultimately becomes responsible for human smuggling operations himself. Hence, the choices people make are prestructured, and the opportunities that present themselves are not presented to anyone.

Similar prestructured choices relate to three other involvement mechanisms, which are encountered when analyzing starters in organized crime. Within the context of the Dutch Organized Crime Monitor, 120 major investigations into organized crime groups have been analyzed systematically (see for more information: Kleemans 2007). In 2008, the criminal careers of 92 "starters" were analyzed, suspects that did not have any other judicial contacts before and who had not "progressed" from high-volume crime into organized crime (Kleemans and De Poot 2008). Next to deliberate recruitment, emphasis was placed upon social ties and the social snowball effect, work ties, leisure activities and sidelines, and life events (including financial setbacks).

Work Ties

Generally, people associate occupations with white-collar crime, yet organized crime is equally dependent on contacts with the licit world. Therefore, occupations are also important in explaining involvement in organized crime. Just like social ties cross boundaries between legality and illegality, so do some work settings in which people spend a considerable share of their daily life. Several occupational characteristics may help in providing opportunities for organized crime (Kleemans and Van de Bunt 2008). First, the social nature of work activities may create opportunities; individuals who often interact with others can meet with potential co-offenders. Second, international contacts and travel movements may create such opportunities. Contacts with other countries and other social groups enable someone to discover and effectuate certain possibilities to commit (transnational) criminal activities. Examples are occupations involving mobility, transport, and logistics. It is the story of the fruit trader who also uses his contacts and knowledge for the import and export of drugs; airline personnel who travel on a regular basis, and who know how to evade baggage checks in airports; and an international trader in clothes who also engages in human trafficking and underground banking. Third, the individual freedom of action of particular occupations is important, or in other words: autonomy. This explains the involvement of directors of (usually) small businesses, independent professionals, and relatively autonomous persons employed by larger organizations, such as corporations and banks. It also explains the relative absence of professionals in the salaried employment of the government or large organizations. Similar findings on occupations that emphasize the assets of international social contacts and autonomy follow from interviews with incarcerated offenders, most notably highlighting the salience of people working in logistically important sectors such as boating, fishing, import and export, transport, and the airline sector (e.g., Dorn et al. 2005).

Leisure Activities and Sidelines

The chances of getting into contact with organized crime differ from person to person and from occupation to occupation. Yet people from different social worlds, involved in disconnected networks, may also run into each other through leisure activities and sidelines. Local bars, nightlife, parties, after parties, drug joints, brothels, shooting clubs, or motor clubs, these are all places where all sorts and conditions of people can meet. These meeting places are especially important for forging contact between representatives of the “underworld” and the “licit world,” who would not meet each other so easily in everyday life. This is why these places also play a vital role in the coming about of involvement in organized crime.

Life Events and Financial Setbacks

A final involvement mechanism relates to life events. In developmental and life-course criminology, the emphasis is on the positive effects of life events such as getting a permanent job, a stable relationship, or having children (Laub and Sampson 2003). These positive life events make problems like crime disappear like snow in summer. Involvement in organized crime, however, results from the negative sides of life events, particularly among men in middle age: divorce, illness, disability, unemployment, and bankruptcies; these are all moments when people are suddenly confronted with setbacks, socially and financially. They are down and out, bankrupt or deeply in debt, and subsequently some of them weigh pros and cons differently when generous financial investors appear on the scene or lucrative illegal opportunities present themselves.

What these five involvement mechanisms have in common is that the opportunities presenting themselves to people are prestructured in a way which those people do not necessarily have to realize. Options differ from person to person and are different at the beginning of one’s life course compared to later on in life.

This is also one of the reasons why criminal careers in organized crime may evolve differently than traditional high-volume crime careers, as the options are not open to anyone and generally only provide themselves later on in life for a selected group of criminals and non-criminals.

Criminal Careers in Organized Crime

Empirical research into criminal careers in organized crime is scarce, yet recent studies have challenged several basic facts and received wisdoms of developmental and life-course criminology. For one, the age-crime curve describing that in general the prevalence of offending rises steeply in the early teenage years and reaches a peak between the ages of 15 and 17, followed by a decline over the rest of the life course. For another, the dominance of individual differences (risk factors) explaining persistence in offending for a very small group of offenders ("life course persistent offenders") as opposed to the majority of "adolescence-limited offenders" (e.g., Moffitt 1993).

First, juveniles are almost absent in organized crime, and most offenders are quite old, in their 30s, 40s, 50s, or even older. Second, a large share of organized crime offenders get involved in crime only at a later age. Late starters are not exceptional, as in traditional research on criminal careers, yet comprise a substantial group of offenders (Kleemans and De Poot 2008). This finding of a substantial presence of "late-onset" offenders is robust across several different criminal activities (drugs, fraud, and other activities) and different roles in criminal groups (leaders, coordinators, and lower-level suspects) (Van Koppen et al. 2010). These findings contradict the general idea that crimes at a later age should be preceded by crimes in adolescence and that individual characteristics and long-term risk factors are the major explanation for a life in crime, let alone a life in serious and organized crime.

The scarce literature on organized crime offenders often resonates the preoccupation with special characteristics of offenders. For instance, Bovenkerk (2000) states that certain characteristics that are conducive to a career in business (based on the "Big Five" from test psychology) are also conducive to a career in organized crime. Basically, the personality traits of successful legal entrepreneurs would be mirrored in the personality traits of illegal entrepreneurs: *extraversion, controlled impulsiveness, a sense of adventure, megalomania, and narcissistic personality disorder*. This line of reasoning is based upon ideas of "the survival of the fittest" in which only offenders with certain characteristics end up in organized crime or in certain leadership positions.

However, there are important lines of research that raise objections against this traditional focus on individual characteristics. Some offenders of organized crime are quite normal and well adapted in many respects, even though they are involved in serious forms of crime. A significant amount of offenders have legitimate jobs and sources of income. Moreover, not all crimes are the same nor just symptoms of latent characteristics such as low self-control and a variety of people can become involved in organized crime (e.g., Steffensmeier and Ulmer 2005). Next to individual personality differences, these studies draw attention to situational factors that may be important to explain involvement in organized crime.

Most of what is known on organized crime offenders, comes from (auto)biographies and case studies of mafia groups (e.g., Paoli 2003; Steffensmeier and Ulmer 2005). These studies, based on memoirs and testimonies, illustrate the complexity of a criminal life course, including contacts, situational context, and processes such as persistence and desistance. Morselli (2005) describes in detail the careers of Howard Marks and "Sammy The Bull" Gravano. Based upon Burt's work on brokerage (Burt 2005), he has put forward the idea that "brokers do better" and that advancements in criminal careers can be explained by deliberate choices people make in investing in certain relationships. Based upon Marks' autobiography, Morselli focuses on the personal network that explains why Marks was able to be successful in the cannabis trade. Central issues are brokerage (linking disconnected networks), the number of (non-redundant) contacts, and social network dynamics.

One of the main problems of case studies is that one may wonder whether these case studies reflect the average or exceptional offender in organized crime and whether these case studies are able to capture the full range of different pathways in organized crime. Case studies may be biased toward more interesting, more talkative or defective, atypical offenders. Moreover, autobiographies often focus on people with long criminal careers instead of "late-onset" offenders. Two studies, however, comprise a broader, comparative view on several criminal careers in organized crime.

The first study is based upon quantitative and qualitative information about the criminal careers of 979 suspects who were involved in 79 different organized crime cases that have been analyzed in the context of the Dutch Organized Crime Monitor (Kleemans and De Poot 2008). First, key figures of these criminal careers are compared to careers of the total offender population. Offenders in the studied organized crime cases are mostly men between 30 and 50 years old. They are generally older than the total offender population, and the studied group of suspects includes no juveniles at all. The age distribution seems to reflect the fact that it is a highly specific group that does not come within the focus of traditional research into criminal careers. Kleemans and De Poot also analyzed criminal careers of 92 "starters," suspects who did not have any other judicial contacts before and who had not "progressed" from high-volume crime into organized crime. Five involvement mechanisms were described in more detail: deliberate recruitment by criminal groups, social ties and the social snowball effect, work ties, leisure activities and sidelines, and life events (including financial setbacks) (see above). Finally, they analyzed the careers of 66 (ring) leaders and "nodal" offenders in more detail to find out how their criminal careers had developed. Some (ring) leaders had a long criminal career: the versatile but regionally constrained "local hero" (versatility as a result of both opportunities and constraints of the local context); progression through an increase in scale (specialization, particularly in international drug trafficking); progression through capital accumulation (investing in drug transports (while refraining from hands-on activities) and becoming a "background operator"; and expertise, contacts, and network formation (people getting a central position in criminal networks because many offenders and criminal groups need their contacts and expertise). Surprisingly, a significant share of (ring) leaders could be typified as "late-onset" offenders, who had made a switch from a legal occupational background to organized crime. Among these 32 offenders, a distinction could be made between a group of 19 with a background in legal trade (including import and export) and a group of 13 with other types of occupation – people from the business sector, the construction industry, assembly, hotels and catering, financial services, or government. Three different types of "late onset" were described: criminal activities extending from legal activities (opportunities that arise during day-to-day work, particularly in fraud cases); people who obviously switch careers, from legal to illegal commodities, motivated by the big profits that can be obtained in the trade in prohibited commodities such as narcotics; and finally, people seizing upon criminal opportunities only later on in life after specific, significant life events (including financial setbacks and problematic debt situations).

Both the research on "starters" and on "late-onset (ring) leaders" illuminate the mechanisms behind the "anomaly" of "adult onset." In essence, the story is that explaining involvement and success in organized crime requires more than a focus on individual differences and long-term risk factors. Kleemans and De Poot (2008) explain their findings by *social opportunity structure* – social ties providing access to profitable criminal opportunities. Social opportunity structure is unequally distributed across the population and across age. Certain kinds of people have social ties that give them direct access to illegal opportunities. Major examples are migrants, who connect source countries of narcotics to Western consumer markets, and people with occupations that are connected to mobility, transport, and logistics. Furthermore, social opportunity structure is unequally distributed across age. Some offenders lack necessary social ties at a younger age, which explains why some offenders become involved in organized crime only at a later age. It also explains the interesting phenomenon of "late starters" – people without any appreciable criminal history – and legally employed people switching careers.

The second study that takes a comparative view on careers in organized crime was a follow-up study by Van Koppen et al. (2010). They elaborated upon this research and investigated criminal trajectories of 854 suspects, based upon quantitative and qualitative data from the Dutch Organized Crime Monitor. A semiparametric group-model was used to cluster 854 individuals into groups with similar developmental trajectories. The most important finding of this study relates to the substantial group of adult-onset offenders (40 %) and a group without any previous criminal records (19 %), next to a group of early starters (11 %) and a group of persisters (30 %). Up till then, no trajectory study had ever discovered such a vast share of adult-onset offenders. Furthermore, the findings turn out to be quite robust across different kinds of criminal activities (drugs, fraud, and other criminal activities) and different roles in criminal groups (leaders, coordinators, and lower-level suspects). Adult-onset offenders emerge in several kinds of criminal activities and in several kinds of roles in criminal groups. Hence, it is not true that the amount of fraud cases in the sample would explain the substantial share of late-onset offenders; late onset is equally important in other types of criminal activities such as drug trafficking. Neither could roles in criminal groups explain "late onset": late onset seems to be equally present in lower-level suspects as in coordinators and (ring) leaders. The mechanisms described in the study by Kleemans and De Poot (2008) may explain these robust findings, as these mechanisms may equally apply to different kinds of criminal activities and to people with different types of roles in criminal groups.

Conclusion and Challenges for Future Research

Differences between organized crime and high-volume crime may explain several interesting findings that challenge basic findings from developmental and life-course criminology. First, juveniles are almost absent in organized crime, and most offenders are quite old, in their 30s, 40s, 50s, or even older. Second, a large share of offenders get involved in organized crime only at a later age. Late starters are not exceptional, as in traditional research on criminal careers, yet comprise a substantial group of offenders. This finding of a substantial presence of "late-onset" offenders is robust across several different criminal activities (drugs, fraud, and other activities) and different roles in criminal groups (leaders, coordinators, and lower-level suspects). These findings contradict the general idea that crimes at a later age should be preceded by crimes in adolescence and that individual characteristics and long-term risk factors are the major explanation for a life in crime, let alone a life in serious and organized crime. The findings can also be explained by different involvement mechanisms that play a role in organized crime. Next to deliberate recruitment, four other involvement mechanisms play a key role: social ties and the social snowball effect, work ties, leisure activities and sidelines, and life events (including financial setbacks). What these involvement mechanisms have in common is that the opportunities presenting themselves to people are prestructured. Options differ from person to person and are different at the beginning of one's life course compared to later on in life. This is also one of the reasons why criminal careers in organized crime may evolve differently than traditional high-volume crime careers, as the options are not open to anyone and generally only provide themselves later on in life for a selected group of criminals and non-criminals.

Kleemans and De Poot (2008) use the theoretical concept of *social opportunity structure* – social ties providing access to profitable criminal opportunities. Social opportunity structure is unequally distributed across the population and across age. Certain kinds of people have social ties that give them direct access to illegal opportunities. Major examples are migrants, who connect source countries of narcotics to Western consumer markets, and people with occupations that are connected to mobility, transport, and logistics. Furthermore, social opportunity structure is unequally distributed across age. Some offenders lack necessary social ties at a younger age, which explains why some offenders become involved in organized crime only at a later age. It also explains the interesting phenomenon of "late starters" – people without any appreciable criminal history – and legally employed people switching careers.

An important new insight from the literature is that occupations do not only play a major role in white-collar and corporate crime but in organized crime as well. Many studies on organized crime tend to draw a sharp distinction between licit activities and illicit activities and between the licit world and the underworld. Some studies focus on the infiltration or extortion of licit economic sectors by organized crime, while other studies tend to emphasize symbiosis and "interfaces" between legal and illegal actors. Empirical research, however, indicates that both worlds may converge. Occupations, work relations, and work settings may provide the breeding ground for organized crime activities, particularly transit crime. Furthermore, occupations offer work relations and work settings that are directly relevant for providing opportunities to search for suitable co-offenders, to gain trust, and to exercise control. Social ties cross boundaries between legality and illegality, as do some work settings in which people spend a considerable share of their daily life. Empirical research highlights the salience of social relations, work relations, and work settings for criminal activities, also in cases of organized crime. From a theoretical point of view, these findings are important in bridging ideas from social network theory and opportunity theory. Social relations are influenced by "foci of interaction" (Feld 1981). Social relations do not happen at random but often obey the laws of social and geographical distance, producing a certain kind of clustering based on geographical distance, ethnicity, education, age, etc. (e.g., Burt 2005). For many people, work is also an important focus of interaction. Second, social relations and work relations often coincide, either because people find a job through social relations or because working relationships develop into more or less close social relations. Third, the blending of work relations and social relations may also contribute to the effective concealment of illegal activities. For a variety of reasons, potential witnesses may remain silent, look the other way, or feel reluctant to blow the whistle. Effective concealment does not require secret societies. "Walls of silence" may also emerge in licit worlds that are mobile, dynamic, and social (Van de Bunt 2010).

Studies on criminal careers in organized crime pose several challenges for criminal career research. First, these studies might refocus attention to social context and co-offenders promoting certain pathways in crime. Co-offending is still an understudied aspect in criminal career research. Second, these findings challenge the traditional boundaries between legality and illegality. Social ties cross boundaries between legality and illegality, as do some people's activities at particular times in their lives. Third, the studies on organized crime careers suggest that criminal career research should focus not only on adolescence but also on later stages in life, as important changes in criminal careers occur with age. Fourth, studying these stages in life should go beyond a preoccupation with desistance. Steffensmeier and Ulmer (2005) state that desistance cannot be explained by stakes in conformity alone; another important factor is a lack of profitable criminal opportunities or the reverse. One could argue that this is particularly salient during stages in life when making money is more important than in adolescence. It could also provide an answer to the question why successful offenders in organized crime never seem to "retire" and continue along the path of crime. Finally, some people seize upon illegal opportunities, while others do not. Clearly, there is both "agency" and "opportunity" (Laub and Sampson 2003). The question why, when confronted with opportunities, some people turn to crime and others do not, and under which conditions, is still unresolved and needs further exploration.

Causes of Police Legitimacy

Overview

Police legitimacy plays a crucial role in promoting a variety of crucial, pro-social outcomes. Research demonstrates the capacity of police legitimacy to promote law-abiding behaviors, cooperation with police, reporting crime and suspicious behaviors, support for police, and public collaboration with police (Fagan and Tyler 2004; Fagan and Tyler 2005; Gau 2011; Kochel et al. 2011; Reisig et al. 2007; Sunshine and Tyler 2003; Tankebe 2009; Tyler 1990; Tyler 2006; Tyler and Fagan 2008). These outcomes are particularly important to the efficiency and effectiveness of police within democratic contexts. Police rely on public support for resources and authorization, and even more importantly, police are expected to generate *voluntary* compliance to the law and to police directives by a majority of citizens, rather than using force and fear to coerce cooperation (Tyler 2004). Jackson and colleagues (2012) suggest that normative-based compliance (such as that motivated by perceptions of police legitimacy) is more stable than instrumentally motivated compliance. Police cannot be at all places at all times, thus minimizing the potential effectiveness of a deterrence-approach for securing order. Instead, police in democratic contexts rely on a social culture supportive of law-abiding behavior and order. Police legitimacy serves as a basis for this social culture (see "▶ Procedural Justice, Legitimacy, and Policing" and "▶ Police Legitimacy and Police Encounters" in this volume to learn about the consequences of police legitimacy). Views about police legitimacy and other judgments about police tend to be fairly stable in the United States and elsewhere, but scholars have reported declines in police legitimacy in recent decades LaFree 1998; Tyler et al. (1997).

Thus, understanding the causes of or contributors to police legitimacy and whether patterns of police legitimacy and the factors that promote it vary under different contexts or across different characteristics of people has important practical implications for police, the public, and democracies in general. Tyler (1990) suggests that policing style and the process of policing may influence individuals' judgments about police legitimacy. This encyclopedia entry describes, based on past theoretical and empirical research, three factors that may contribute to police legitimacy – procedural justice, crime control effectiveness, and distributive justice. The entry describes the three models, their relative impacts, and whether these effects vary under different conditions.

Background: Defining Legitimacy

Police legitimacy is a normative perspective that police authority is valid and ought to be obeyed and respected. Police have legitimacy when members of the public believe police have a right to their authority and thus that citizens have a moral obligation and civic duty to honor, accept, and adhere to that authority (Tyler and Huo 2002). The concept of institutional legitimacy originates with Max Weber (1947). He first explained that citizens who view an authority as legitimate feel a personal sense of responsibility to act consistently with that authority's expectations, even in the absence of that authority and even when the compliant behavior contradicts self-interests.

Although this definition of legitimacy is widely acknowledged, research examining the correlates and consequences of police legitimacy has suffered from construct validity problems (Gau 2011; Reisig et al. 2007). Scholars have sometimes operationalized legitimacy to include the anticipated consequences of police legitimacy, such as compliance with the law or cooperation with police, and at other times, legitimacy measures incorporate theorized antecedents, especially elements of procedural justice. Additionally, while most studies of police legitimacy incorporate into the measure a perceived obligation to obey, some of Tom Tyler's studies (the present day scholar who refocused the criminologists and criminal justice practitioners on this issue with a series of survey studies) and other studies incorporate moral trust or institutional trustworthiness as a component to legitimacy. This component is not part of Weber's initial construct, and recent psychometric studies have suggested that trust does not combine with views about the obligation to obey to form a legitimacy measure (Gau 2011; Reisig, et al. 2007). Thus, this entry aims to provide the status of current research on police legitimacy conceptualized as the perceived moral obligation to voluntarily obey police, while avoiding some of the construct validity pitfalls experienced by it.

Key Issues

One way individuals form opinions about whether and the degree to which police authority is legitimate is based on personal or vicarious experiences with police. While Tyler (1990) found that only about four percent of the variance of legitimacy in a Chicago sample was explained by individual personal experiences with police, Tyler and Huo (2002) and Tyler (2001) saw a much stronger impact of personal experience on legitimacy judgments, explaining up to 34 % of the variation in legitimacy. Other sources include stories and media coverage about police behaviors and accomplishments, peer assessments of police, generalized understandings about the institution of police, and demographic and cultural characteristics of the individual and context that may color individuals' perceptions. Past scholarship has focused on how three aspects of these experiences and attitudes may contribute to police legitimacy. Procedural justice, distributive justice, and police effectiveness are the three antecedents expected to promote police legitimacy.

The Process-Based Model/Procedural Justice Model

Procedural justice refers to an impartial process that is not affected by race, gender, age, or other demographic characteristics: one in which people have a voice, one where different people in similar situations are treated consistently, a process whereby decisions are based on facts, one in which people are treated with dignity and respect, and a process protected by accountability to higher authorities (Leventhal 1976). The process-based model or procedural justice model purports that when members of the public perceive that police behave fairly and respectfully toward citizens, this generates a perception that the police and the public share similar values and beliefs. Lipset (1959), writing about the time of Weber, suggests that social institutions acquire legitimacy based on whether the institution's values align with its constituents.

Gau (2011) explains that being treated well by police may indicate to people that they are a valued member of society, affirming the individual's status as a member of the group, which includes police. This belief in a common moral perspective with police or common group membership encourages acceptance of a moral obligation to obey police authority and promotes a cultural value supportive of lawfulness (Tyler and Huo 2002). Tyler (1997) links this process back to social identity theory, whereby individuals gain information about their identity and status by how authorities treat them. When individuals feel that they have been treated respectfully by an authority, this action signifies their accepted group status and they respond with deference.

Of course, not all members of the public experience personal contact with the police from which to assess procedural justice. Tyler and others assert that residents can draw on their general perceptions about the character of police to form opinions about procedural justice and thus legitimacy. Additionally, the process-based model does not require an objective assessment of the fairness of police procedures. Rather, what matters are individuals' subjective opinions about police fairness, which derive from a variety of perspectives and experiences.

The types of measures that are typically used to operationalize procedural justice include items asking whether police treat people fairly or with dignity and respect, make decisions based upon facts, explain their actions, listen to people before making decisions, respect people's rights, try to help people solve problems, or have the best interest of a group or area at heart. Some studies also include whether police fairly decide whom to stop and question or arrest or whether police apply too much force under certain circumstances.

The Instrumental/Performance-Based Model

Lipset (1959), who advocated the importance of the process-based model, also contends that social institutions gain legitimacy when they can demonstrate prolonged effectiveness. Lipset suggests that both shared values *and* effectiveness can provide the source of legitimacy, but prolonged effectiveness in the absence of shared values offers only an unstable form of legitimacy for a social institution.

The instrumental or performance-based model of legitimacy suggests that residents accept and conform to police authority when they perceive that doing so will produce beneficial outcomes or avoid negative ones. To gain benefits, residents must see police as a useful resource. Residents who perceive that police are competent and capable of reducing crime, bringing offenders to justice, creating and maintaining order, reducing fear of victimization, and improving neighborhood conditions will grant them legitimacy and subsequently provide their cooperation and adherence to police authority because they believe that doing so will achieve anticipated goals of better safety and less crime. In other words, they see police as an authority with the capacity to secure compliance and thus grant them legitimacy. Thus, when members of the public experience positive interactions with police or perceive these favorable outcomes are being and can be obtained, the performance-based model expects higher police legitimacy. However, when residents doubt the capacity of police to produce order, control crime, and hold criminals accountable, an instrumental model predicts that residents will be less inclined to acknowledge or feel obligated to conform to police authority, because they have little to gain.

The types of questions that are typically used to measure police performance address assessments about response time, the effectiveness of police at addressing social disorder, crime, or citizen fear, as well as general assessments about the safety of a neighborhood and other neighborhood conditions.

The Distributive Justice Model

The distributive justice model suggests that residents are more apt to view police as legitimate when they perceive that police services are equitably distributed and not motivated by characteristics about people or places (e.g., wealth, social class, race/ethnicity, political affiliation, geographic location) that are unrelated to the police mission. This is not to suggest that police attention would have to be evenly or equally allocated, rather that the allocation of resources is perceived as appropriate. The distributive justice model suggests that police will have greater legitimacy when residents perceive everyone is getting suitable attention and services from the police. Judgments about what is equitable are subjective and, like the other models, do not require personal interactions with police in order to form them.

The types of questions that are typically used to measure distributive justice generally ask whether groups are treated equally based on social characteristics such as race or wealth, or whether a certain group is treated better by police or receives better quality outcomes from police.

Weight of the Evidence

Much of the evidence about the antecedents of police legitimacy is based on citizen surveys across cities in the United States. Tom Tyler conducted a series of these studies in Oakland, California, Los Angeles, New York City, and Chicago (Sunshine and Tyler 2003; Tyler 1990; Tyler 2001; Tyler and Huo 2002; Tyler and Fagan 2008). Since this initial contribution, other scholars have also contributed, examining the antecedents of legitimacy in other US cities (Gau 2011) and in other developed and developing countries such as Australia (Hinds 2007; Hinds and Murphy 2007; Murphy et al. 2008), England (Hough et al. 2010; Jackson et al. 2012), Ghana (Tankebe 2008), Israel (Jonathan-Zamir and Weisburd 2011), Jamaica (Reisig and Lloyd 2009), and Trinidad and Tobago (Kochel 2012; Kochel et al. 2011).

Past research has shown some support for each of the three antecedents of legitimacy, suggesting that the pathway to legitimacy is not one dimensional. For example, Papachristos and colleagues (2009) show that a measure combining elements of police performance, procedural justice, and distributive justice was a strong positive predictor of legitimacy. Hinds and Murphy (2007) as well as Murphy et al. (2008) found a positive association among Australians between legitimacy and each of procedural justice, police performance, and distributive fairness. Tyler's (2002) New York sample showed the same result. Generally, however, these predictors do not have *equal* influence.

Past research strongly supports procedural justice as the most consistent and influential antecedent: the primary mechanism for promoting police legitimacy. Studies conducted by Sunshine and Tyler (2003); Fagan and Tyler (2004); Tyler et al. (2010), as well as Van der Toorn et al. (2011) in New York, Tyler (1990) in Chicago, Tyler and Huo (2002) in Los Angeles and Oakland, by Hinds (2007), Hinds and Murphy (2007), and Murphy et al. (2008) in Australia, by Hough and colleagues (2010) as well as Jackson and colleagues (2012) in England and Wales, Kochel (2012) and Kochel et al. (2011) in Trinidad and Tobago, and by Reisig and Lloyd (2009) in Jamaica have all found support that when individuals perceive the police as being more procedurally just, they also view them with higher levels of legitimacy and that procedural justice is a stronger predictor than distributive justice or perceived effectiveness. Kochel (2012) further demonstrates that these relationships carry through to the neighborhood level. In Trinidad and Tobago neighborhoods, when residents perceived higher levels of procedural injustice, a smaller portion of residents reported normative obligations to accept police decisions. Other studies demonstrating the important positive influence of procedural justice on legitimacy, but without accounting for either distributive justice or performance include Fagan and Tyler (2005), Tyler and Fagan (2008), and Gau (2011).

Limited past research also indicates a positive relationship between distributive justice judgments and perceptions about police legitimacy; however, the evidence is not nearly as clear or consistent as that for procedural justice. Tyler and Fagan (2008), Tyler and Huo (2002), Murphy and colleagues (2008), and Hinds and Murphy (2007) show a positive association between distributive justice and police legitimacy. However, Reisig and Lloyd (2009) and Tyler et al. (2007) found no significant effect. No studies of police legitimacy have reported a significant negative effect of distributive justice.

Similarly, past research shows mixed findings for the instrumental model; the influence of performance effectiveness in fighting crime, improving neighborhood conditions, and reducing fear of victimization on police legitimacy is not clear. However, Sunshine and Tyler (2003) (see the pre-crisis sample) and Van der Toorn and colleagues (2011) suggest that while performance effectiveness is less important than procedural justice, it can play a substantive role in forming legitimacy judgments. In particular, Van der Toorn and colleagues (2011) show that perceptions about police performance are nearly as important to their sample as procedural fairness in predicting police legitimacy. (Although Hinds and Murphy (2007) and Murphy and colleagues (2008) also support this association and suggest that in their study in Australia, police performance is nearly as influential as procedural justice on perceptions of police legitimacy, their measure of legitimacy is not well aligned with how it is defined in this encyclopedia entry as it includes components of satisfaction and performance and confidence in police.) Fagan and Tyler (2004), Tyler and Fagan (2008), and Tyler and colleagues (2010) did not show a significant effect of police performance on legitimacy judgments in New York among residents overall, or Muslim-Americans specifically. Hough and colleagues (2010) and Jackson and colleagues (2012) did not find a significant influence of effectiveness on legitimacy in a survey of British residents. No studies of police legitimacy have reported a significant negative effect of performance effectiveness.

Panel studies that have examined views about legitimacy over time suggest that individuals have fairly stable opinions about police legitimacy – their views about police legitimacy at the earlier timeframe are the best predictor of the present views about legitimacy. Often, more recent assessments about the fairness of police procedures also matter (Murphy et al. 2008; Tyler 1990; Tyler and Fagan 2008). In a few of these studies, some of the other models are also supported. Tyler and Fagan (2008) and Murphy and colleagues (2008) show support for performance effectiveness, while Murphy and colleagues also support the role of recent distributive justice assessments. Tyler and Fagan (2008), who conducted a panel study in New York City, reported that legitimacy judgments at time two were influenced by their initial views of police legitimacy at time one, as well as both procedural justice components and distributive justice opinions at time two, but not by police performance. Hinds (2007) conducted a study among Australian youth and found that procedural justice considerations outweighed the other significant predictors including police performance, youth-police relationships, expectations of police, negative contact with police, and fear of property crime.

Among the three models purported to influence police legitimacy, the process-based model is the clear champion. More research is needed to better understand the nature of the relationship between legitimacy and both distributive justice and police performance. In addition to these factors, favorable outcomes and prior positive interactions with police also have positive relationships with legal institution legitimacy (Tyler 1990; Tyler and Huo 2002; Sunshine and Tyler 2003).

Demographic Characteristics and Police Legitimacy

Individuals with different cultural, demographic, and experiential backgrounds often differ in their views about police legitimacy. For example, recent studies by Hough and colleagues (2010) and by Jackson and colleagues (2012) found a significant relationship between London residents’ moral values (a cultural measure of the degree to which the individual viewed certain behaviors as morally wrong) and their sense of duty to obey police. Independent of perceptions of procedural justice or police effectiveness, individuals with a stronger sense of personal morality had a greater sense of obligation to obey police. Other personal characteristics, discussed below, have shown similar independent effects.

Cherney and Murphy (2011) caution, however, that background characteristics may not only be associated with different levels of legitimacy, but in forming legitimacy judgments differently. They assert that when individuals have diminished legitimacy about the law, procedural justice qualities of police may not promote police legitimacy and in fact may have a backfire effect (They base this on their study, reported in Murphy et al. (2009), that found that among ethnic minorities who have reduced legitimacy for the law, procedural justice had a negative relationship on willingness to cooperate with police – an anticipated outcome of legitimacy and often used proxy for legitimacy).

Conversely, Tyler and Huo (2002) have suggested that people form opinions about legitimacy in the same way across different background characteristics. They theorize that even if people vary in the level of legitimacy that they ascribe to police, they tend to follow the same psychological process in coming to that conclusion.

Several studies have found relationships between views about police legitimacy and demographic characteristics. For example, a series of studies have shown a positive link between being Caucasian and higher levels of police legitimacy. Sunshine and Tyler (2003) found that white residents viewed police with more legitimacy than African-American and Hispanic residents in New York. Kirk and Papachristos (2011) found similar results in Chicago. Gau (2011) found that White residents feel a stronger obligation to obey police than Asian individuals. In spite of these differences, Tyler (2001), Tyler and Huo (2002), and Sunshine and Tyler (2003) found evidence that residents of different racial and ethnic backgrounds all rely primarily on procedural justice judgments to inform their legitimacy assessments. In these studies, different ethnic groups relied on similar psychological processes to form legitimacy judgments.

Additionally, older individuals tend to perceive the police with more legitimacy than younger people (Murphy et al. 2008; Papachristos et al. 2009; Tyler 1990; Tyler and Fagan 2008). Yet, Fagan and Tyler (2005) report that the adolescents they sampled relied on procedural justice to form views about legitimacy, as did adults in the many surveys conducted by Tyler across cities in the United States. Individuals of different ages rely on a similar process, even if they grant police different levels of legitimacy.

Past research by Tyler (1988) found that residents in Chicago who had recent experiences with police but with different demographic backgrounds (age, gender, race, income, education, and political ideology) used the same criteria when they assessed the fairness of their experience with police. Also in the New York sample, residents who had citizen-initiated contact with police and residents who had police-initiated contact, both reported that the quality of the treatment they received had a significant influence on their perceptions of police legitimacy, when accounting for other demographic characteristics (Tyler and Fagan 2008). Furthermore, a sample of Muslim-Americans relied on procedural justice judgments when forming opinions about legitimacy, just as has been found in samples that do not distinguish religious affiliation (Tyler et al. 2010). Finally, a sample of law enforcement officers and a sample of soldiers each also relied on the procedural justice model to form their views about legitimacy (Tyler et al. 2007). Thus, based on available research, preliminary indications favor Tyler and Huo (2002), suggesting that while some demographic groups have significantly higher or lower opinions about police legitimacy, different groups form their opinions relying primarily on procedural justice judgments.

Context and Police Legitimacy

Under certain contextual conditions, the strength of the factors predicting legitimacy or what is most important may vary. Prior research addressing a variety of individuals' attitudes toward police (e.g., satisfaction with police, support for police, confidence in police, views about fairness and effectiveness) suggests that neighborhood characteristics such as concentrated disadvantage, community disorder, collective efficacy, and the violent crime rate are important factors affecting individuals' opinions (Bradford and Jackson 2010a; Cao et al. 1996; Dunham and Alpert 1988; and Kirk and Papachristos 2011; Kochel 2012; Reisig and Parks 2000; Sampson and Bartusch 1998; Sun et al. 2004). So, it may be reasonable to expect that perceptions about legitimacy will also be impacted by these contextual factors and the realities and feelings that they generate, and that different antecedents to legitimacy may matter more in one context than another (Hough et al. 2010).

Dunham and Alpert (1988) found that generally, attitudes about police practices were more similar within neighborhoods than across neighborhoods. Kochel and Tankebe (forthcoming) find support that this holds true for police legitimacy. A variety of neighborhood qualities may explain this, including shared experiences with poverty, victimization risk, police contact, and sanctions, which may affect residents' fears about safety, feelings of marginalization or acceptance, desires for police assistance, and other attitudes that may be important in forming legitimacy opinions. Supporting this notion, Kochel (2012) found that neighborhoods with a higher proportion of victims, fewer negative police contacts, as well as fewer extremely wealthy residents had more residents who viewed police with legitimacy. Sun, et al. (2004) reported that police legitimacy is lower in areas of concentrated disadvantage.

Other scholars have looked at the related measure of legal cynicism within a neighborhood context. Sampson and Bartusch (1998) and Kirk and Papachristos (2011) found that people living in neighborhoods with concentrated disadvantage were significantly more likely to express legal cynicism. In Chicago, Kirk and Papachristos (2011) also identified high proportions of youth and residential stability as predictors of legal cynicism.

However, none of these studies examined whether residents of different kinds of neighborhoods or other varied contexts not only hold different views, but also rely on different processes in making legitimacy judgments. Two past studies offer the only indications about this issue. Both studies attempt to determine whether different legitimation processes are used when security is threatened.

Sunshine and Tyler (2003) conducted a survey of New York City residents immediately prior to the terrorist crisis on September 11, 2001, and then shortly after the attacks. They found that under the different security threat circumstances, the relative importance of the three models differed somewhat. The first survey revealed that procedural fairness and to a lesser degree performance effectiveness were the antecedents to police legitimacy. In this survey, the effect of procedural justice was nearly five times stronger than performance. Subsequently, residents who viewed police with more legitimacy also were willing to empower police to undertake a variety of actions, including actions that limit the freedoms of citizens. Shortly after the terrorist attack, a second survey found that the influence of distributive justice on legitimacy was statistically significant and was about half as important as procedural fairness to predict perceptions of legitimacy. Performance effectiveness during this time of crisis was not a significant antecedent of legitimacy; instead, it was directly related to residents' willingness to empower police to perform a variety of actions, some intrusive, including stopping and questioning people on the street and searching homes without permission from a judge. Empowerment was also still predicted by legitimacy, but in this context, performance drove empowerment to action, not perceptions of legitimacy (Similar results are reported in Ghana by Tankebe 2009).

Jonathan-Zamir and Weisburd (2011) studied a community in Israel that was located in close proximity to the Gaza Strip and subject to severe threat for missile attacks compared to other communities in Israel, who lacked similar threats. In both communities, police legitimacy (actually a measure of trust in the police) was positively predicted first by procedural justice and second by performance. The difference was that within non-threatened communities, but not in the community undergoing crisis, negative encounters with police and offenders' risk of getting caught also impacted their legitimacy measure.

Thus, early indications are that the process of forming legitimacy assessments may not drastically vary across social contexts. Procedural justice judgments are extremely important under a variety of situations and appear to be the primary influence on legitimacy. However, more research is needed on the process of forming legitimacy judgments within different contexts.

Conclusions

The important outcomes of police legitimacy substantiate careful consideration of the factors that promote it. Three models dominate theory: the process-based model, the instrumental model, and the distributive justice model. Available research strongly supports the consistent and strong influence of fair procedures in forming positive views about police legitimacy. This model is supported across individuals with a variety of different background characteristics as well as across social contexts, including in developed and developing countries, across a variety of cities in the United States and in places of severe security threats and those lacking such threats. Mixed evidence on the role of police performance effectiveness and distributive justice on legitimacy assessments speak to the need for further research in those areas.

Causes of Wrongful Convictions

Shawn Armbrust and Susan Friedman
Mid-Atlantic Innocence Project, American University, Washington, DC, USA

Overview

In any system of justice, there is a risk of convicting innocent people. The United States is no exception, and innocent people have been convicted throughout American history, a phenomenon that was first documented in 1923 (Borchard 1923). In the past two decades, however, more attention has been paid to this problem because, for the first time, post-conviction DNA testing has allowed us to determine with scientific certainty that innocent people have been convicted and often can point to the real perpetrator. The first such exoneration occurred in 1989, and as of 2012, the Innocence Project reports the exoneration of 297 individuals by post-conviction DNA testing. The National Registry of Exonerations identified hundreds more who have been exonerated using nonbiological evidence of innocence. As more of these exonerations occurred, they sparked interest in what can go wrong during an investigation and trial that can lead to such troubling systemic failures. Thus, advocates, academics, and policymakers have invested significant time and resources into identifying isolating the causes of wrongful convictions.

In 2008, in the most thorough study to date, University of Virginia law professor Brandon Garrett exhaustively studied the first 200 DNA exonerations, examining how they were handled from investigation through the trial, appellate, and post-conviction process. Garrett and others have demonstrated that there are six major causes of wrongful convictions: eyewitness testimony, unreliable forensic science evidence, false confessions, incentivized witnesses, government misconduct, and inadequate defense counsel. This entry will summarize how each of these problems can cause wrongful convictions and what can be done to ensure that these problems are addressed so that they do not lead to wrongful convictions in the future.

Eyewitness Identification

To date, eyewitness error is the number one cause of documented wrongful convictions in DNA cases and also is quite prevalent in non-DNA exoneration cases (Garrett 2008; Gross 2005). Professor Garrett found that in 158 of the first 200 DNA exonerations – 79 % – eyewitness error led to the wrongful conviction, and Professor Gross found that 219 of the 340 DNA and non-DNA wrongful convictions between 1989 and 2003 involved eyewitness error. Thus, it is clear that eyewitness fallibility is a significant problem.

The simple reason for this is that human memory for faces is far less accurate than most people – particularly participants in the criminal justice system – have long believed. In addition to being inaccurate, both human memory and confidence about the accuracy of one's memory are quite malleable (Wells et al. 1998). Moreover, even when problems with an eyewitness's memory can be exposed in the courtroom by pointing out discrepancies in the witness's description or problems with their ability to clearly see the perpetrator of a crime, research has shown that if an eyewitness is confident, that is the number one factor considered by jurors and courts in determining the accuracy of an eyewitness (Wells et al. 1998). This is true even though confidence at trial does not have a correlation with accuracy (although confidence at the time of the initial identification has a slightly higher correlation with accuracy) (Wells et al. 1998).

Unfortunately, unintended manipulation of human memory and confidence through the traditional identification process – in which an investigator on the case in question shows the witness several photos or individuals at the same time – exacerbates these problems (Wells et al. 1998). Social psychologists have been studying this issue for decades and have identified several key problems in traditional eyewitness identification procedures that exacerbate the fallibility and malleability of human memory. Those problems include:

- Feedback (often unintentional) to witnesses by law enforcement officers who are implementing a lineup procedure, which can improve a witness's confidence in the accuracy of the identification
- The use of "relative judgment," in which a witness looking at a group of photos or individuals at the same time chooses the individual who looks *most like* the perpetrator, even when the actual perpetrator is not in the lineup
- Repeated identification procedures (photo array, live lineup, preliminary hearing, etc.) that can increase a witness's confidence in the accuracy of an identification (Wells et al. 1998)

The same social scientists have recommended a series of reforms that have been shown to make eyewitness identifications more accurate and capture the confidence of a witness's identification at the time it was made, instead of relying on inflated confidence estimates at the time of trial. Those reforms include:

- Double-blind administration, a procedure in which neither the witness nor the officer administering the photo array or lineup knows who the suspect is
- Confidence statements that would require the witness to immediately make a statement about his or her confidence after making an identification

- Sequential lineups in which photos or individuals are shown to a witness one at a time, requiring the witness to use absolute judgment instead of relative judgment, comparing her memory to one individual in a lineup or one photo at a time
- Videotaping the identification procedures, which will allow defense counsel to identify any potential issues with the identification procedures (Wells et al. 1998)

According to a recent review of reforms that have been implemented (Norris et al. 2010), ten states have taken steps to improve eyewitness identification procedures by either recommending or requiring some or all of these recommendations. Those states are Georgia, Maryland, New Jersey, North Carolina, Ohio, Rhode Island, Vermont, Virginia, West Virginia, and Wisconsin.

Unreliable Forensic Science Evidence

With its purported ability to scientifically link a defendant to a crime scene, forensic science plays a critically important role in criminal trials. For decades, forensic science and forensic scientists were seen as infallible. With the development of DNA testing, however, flaws in many types of forensic science have been exposed. In fact, forensic science evidence is the second most common type of evidence used to secure a wrongful conviction. One hundred thirteen of the first 200 DNA exonerations involved cases in which some kind of forensic science evidence either linked the defendant to the crime scene or placed the defendant within the population of individuals who might have committed the crime (Garrett 2008). In those cases where analysts said that forensic science linked the defendant to the crime, DNA testing proved that this testimony and those sciences were wrong. The most common forensic evidence involved serology (conventional blood typing), followed by hair evidence, soil comparison, DNA tests, bite-mark comparisons, fingerprint evidence, dog scent identification, spectrographic voice evidence, shoe prints, and fiber comparison.

Most forensic science used in courtrooms – both before and after the advent of DNA testing – involves the attempt to determine whether a suspect can be tied to a crime scene. This can happen in several ways, including the following: (1) because a suspect leaves part of himself, such as hair, semen, saliva, sweat, or blood, at a crime scene; (2) because a suspect leaves something else, such as fibers, soil, or footprints, at a crime scene; or (3) because the weapon used to injure the victim has markings that can be compared to an item (usually a gun or knife) owned by the suspect. Oftentimes, forensic scientists testified that a suspect or items in possession of the suspect "matched" evidence found at a crime scene and that this match was conclusive proof that the defendant had, in fact, been at the crime scene. This testimony often went unchallenged by defense lawyers in the era before DNA testing.

However, the explosion of DNA exonerations in cases where at trial other forensic sciences conclusively linked a defendant to a piece of evidence at a crime scene proved that in many cases, what people believed to be infallible science was actually quite fallible and possibly not even science. Thus, in 2009, a committee of the National Academy of Sciences ("NAS") issued a report commissioned by Congress that was designed to evaluate the reliability of forensic science techniques. The report identified several flaws with the way that forensic science has been developed, regulated, and practiced. It expressed particular concern with microscopic hair comparison, fingerprint comparison, gunshot residue analysis, firearm and toolmark analysis, shoe prints, and soil and fiber comparisons. In each of those sciences, the report found that the conclusions reached by experts (that samples from crime scenes could be matched to defendants or items in the possession of defendants) were not grounded in any scientific research and were not validated by any empirical data. In addition, the lack of accreditation and certification among crime laboratories means that there frequently are no standards to determine what constitutes a match – examiners are allowed to determine for themselves, based on their experience, whether items match. Finally, even where there are standards, the lack of proficiency testing means that unqualified examiners are allowed to continue working and testifying without sufficient oversight.

In recent years, states have made some effort to reform crime laboratories and the use of forensic evidence in criminal trials. By statute, 13 states enacted some type of forensic oversight, and in two states, the state's attorney general established oversight entities. In addition to ensuring that crime laboratories are accredited and follow best practices, some oversight commissions are also charged with investigating forensic misconduct. In 2004, Congress passed the Justice for All Act, which included a provision that links the receipt of grants by state crime laboratories under the Paul Coverdell Forensic Science Improvement Grants Program to the establishment of guidelines for handling allegations of negligence or misconduct. In the wake of the NAS report, various advocates also are working to create an entity within the federal government that would foster real scientific research into various areas of forensic science, as well as set standards and licensing requirements that would help create some uniformity within the various forensic science disciplines.

False Confessions

Prior to the advent of DNA testing, it was difficult for most actors in the criminal justice system – including defense lawyers – to believe that an innocent person would confess to a crime that he or she did not commit. Although it was easy to imagine that such confessions would occur in an environment with physical coercion, most American police departments long ago abandoned those tactics and focus instead on persuasive psychological tactics. However, in Professor Garrett's study of the first 200 DNA exonerations, he found that 31 cases involved false confessions. Professors Steve Drizin and Richard Leo documented in a 2004 study published in the University of North Carolina Law Review 125 recent provable false confessions in the United States.

False confessions are particularly problematic because the phenomenon is so hard for most people to understand. Once an individual confesses to a crime, a conviction is almost assured. The police stop investigating, prosecutors ask fewer questions, defense lawyers are more likely to encourage a guilty plea, and juries are unlikely to believe protestations of innocence. This is true regardless of how reliable the confession appears. In many exoneration cases, the confessors were wrong about basic facts like the race of the victim, the location of the crime, and the weapon used, but they were convicted nonetheless. Quite simply, very few people believe that anyone could confess to something they did not do.

Because these false confessions are such a perplexing problem, they have been the subject of significant research by both psychologists and legal scholars who have sought to examine what factors – both individual and systemic – might lead someone to falsely confess to a crime. That research has determined that individuals who are "unusually suggestible and compliant" – such as juveniles and the mentally retarded – are more likely to provide authorities with a false confession (Drizin and Leo 2004). Of the 31 false confessions documented by Professor Garrett, 11 involved mentally retarded defendants, and 12 involved juvenile defendants. Juveniles are likely to falsely confess because they are more likely to make impulsive decisions, engage in risky behavior, and be more susceptible to suggestions. Individuals with mental retardation may be more susceptible to suggestions because they want to please authorities, want others to believe they are competent, often cannot control their impulses, and are willing to accept blame.

The idea that inherently suggestible individuals are more likely to falsely confess to crimes is not terribly surprising; it is far more surprising that a significant number of the false confessions documented by Professor Garrett and by Professors Drizin and Leo involved individuals who are not inherently suggestible. Thus, despite that lack of inherent suggestibility, these individuals made the choice to confess to a crime that they did not commit. Legal scholars and social scientists examining the reasons for this have determined that modern interrogations involve multiple tactics that – particularly when combined – can help cause false confessions. First, the purpose of interrogations is to elicit confessions and to ignore protestations of innocence (Drizin and Leo 2004) ("police are trained to interrogate only those suspects whose guilt they presume or believe they have already established"). Second, recognizing the inherent difficulty of getting anyone – guilty or innocent – to confess to a crime, interrogations are designed to convince the suspect that confessing is the logical choice. To do this, investigators rely upon a technique known as "minimization and maximization" (Drizin and Leo 2004), in which investigators maximize the extent of the evidence against the defendant to intimidate them but then offer them the opportunity to minimize their involvement (e.g., by claiming self-defense in a murder or consent in a rape) and thus avoid harsher criminal penalties. Third, the police are allowed to lie to suspects about the evidence against them (Drizin and Leo 2004). Fourth, during the course of an interrogation, police may – often inadvertently – provide the suspect with information about the crime that can be used to validate a false confession later. And fifth, interrogations often are quite long, which has been shown to increase an individual's likelihood of falsely confessing (Kassin 2010). One study found that in cases where a false confession was made, the interrogation lasted an average of 16.3 h (Kassin 2010). The same study also found that 34 % of interrogations lasted 6–12 h, and 39 % lasted 12–24 h (Kassin 2010).

Solving the problem of false confessions is achievable through reforms that often are beneficial to both law enforcement and to innocent defendants. The most common reform recommended to combat false confessions is the videotaping of all interrogations, from start to finish. Although this cannot prevent false confessions, it can increase the likelihood that false confessions are caught before they lead to conviction. More than 500 jurisdictions now do just that. In addition, some have recommended a reformation of interrogation practices, advocating for investigative interviews of suspects instead of interrogations that are designed only to elicit confessions (Drizin and Leo 2004). Thus, while false confessions are one of the most perplexing causes of wrongful convictions, they also are one of the easiest problems to solve.

Government Informants: Snitches

Investigating crime is difficult for many reasons, and one of those reasons is that relevant witnesses often do not want to cooperate with the police, often because of fear or bias against law enforcement or because it is against their interest. Thus, the government is permitted to incentivize testimony by offering reduced sentences, reduced charges, favorable treatment in prison, or – in some cases – reward money. Such deals can be offered to codefendants, reluctant witnesses, or – in the most dangerous form – jailhouse informants who allegedly heard the defendant confess to the crime in a jail cell. While such deals are a necessary evil, the potential for abuse is obvious.

Wrongful conviction cases prove this point again and again. In 35 of the first 200 DNA exonerations, Professor Garrett found that some type of incentivized testimony was used from an informant, a jailhouse informant, or an alleged co-perpetrator. In 2005, the Center on Wrongful Convictions released a study on the 111 death row exonerations since the death penalty was reinstated in this country in the 1970s. The study found that of those exonerations, 51 individuals were wrongfully convicted based on informant testimony, making incentivized testifying the leading cause of wrongful convictions in capital cases.

The reason for this is that the incentives, combined with the ease of making up seemingly credible information, create a world in which informants are able and willing to lie in ways that are difficult to detect. In the most problematic cases, informants make statements that the defendant has confessed to the informant – either out on the street or in a jail cell. Those statements often contain details that seemingly would be difficult to obtain from anyone other than the true perpetrator of a crime. However, when an informant has access to the Internet, media, friends, and – in some cases – the court file that the defendant has left in his jail cell, he or she can obtain information about the case that is used to create a plausible story that is difficult to either verify or disprove. Indeed, in a 60-min segment, Leslie Vernon White, who admitted to lying on many occasions as a jailhouse informant, demonstrated the ease with which he could obtain information about a crime and make up a confession.

These problems are exacerbated when either the deals provided to an informant or an informant's full history of cooperating with the government is not fully disclosed to the defense. If a jury knows that an informant has received some benefit for his testimony or that he has testified as an informant on multiple occasions, the jury at the very least has the benefit of more balanced information about the informant. In many cases, however, that information is not disclosed, which takes testimony that is inherently suspect and inappropriately bolsters it in the minds of the jury.

Despite its inherent flaws, banning informant testimony is not a tenable solution. Without the ability to incentivize witnesses, the government would have a difficult time convincing witnesses to talk. Thus, any solution to the problem of informants involves both appropriately verifying facts in the informant's testimony and properly disclosing an informant's history and benefits he has received in exchange for his testimony. Recommendations on how to handle incentivized testimony include having informants wear wires, recording informant conversations with authorities and providing the recording to defense counsel, disclosing the benefit that the informant will receive in exchange for testifying, and keeping a database of informants so that law enforcement and the defense know who may be manipulating the system to repeatedly receive benefits from the government. In Illinois, the state legislature requires significant disclosures, pretrial reliability hearings, corroboration, and cautionary jury instructions in any capital case involving a jailhouse informant.

Government Misconduct

In many cases, wrongful convictions are caused by an unfortunate series of honest mistakes – eyewitnesses who have erred, scientific testimony that was unintentionally overstated, and confessions that, while false, were obtained using what police believed to be appropriate tactics. In other cases, however, police and prosecutors who are under pressure to get convictions sometimes lose sight of their obligation to do justice and – whether intentionally or not – commit misconduct by, among other things, failing to turn over exculpatory evidence, improperly characterizing evidence at trial, engaging in improper interrogation tactics, or inappropriately attempting to influence an eyewitness. Such misconduct is far more widespread than anyone might have believed before the advent of DNA testing.

Although it is impossible to quantify exactly how many exonerations involved such misconduct because it is so difficult to uncover, it clearly has been a significant factor in many wrongful conviction cases (Garrett 2008). In 2003, the Center for Public Integrity found that since 1970 prosecutorial misconduct was a factor in dismissed charges, reversed convictions, or reduced sentences in at least 2,012 cases of the 11,452 cases in which claims of prosecutorial misconduct were reviewed by courts (The Justice Project 2009). Unfortunately, studies also have shown that there are few incentives for prosecutors, in particular, to avoid committing misconduct (Ridolfi and Possley 2010). Thus, this is an area that is ripe for reform.

The reforms suggested in the sections on eyewitness error and false confessions also would address government misconduct in these areas, but they would not address the problem of failing to turn over exculpatory evidence. In civil cases, both sides are required to liberally exchange information in lengthy and complicated discovery procedures. In criminal cases, however, discovery is much more limited. The Supreme Court found in *Brady v. Maryland* that the Constitution requires the government to disclose exculpatory and impeachment information to the defense, but the

Constitution requires nothing else. Some states, such as North Carolina, require the government to provide open-file discovery, but that is not the norm. In the federal system and the District of Columbia, for example, criminal defendants are entitled to only what is constitutionally required, their own statements, and expert notice. Unless a defendant has a good investigator, he may not even know who the witnesses against him are until those witnesses testify at trial.

Because so many states have such limited discovery, the onus usually is on the prosecutor to determine what information needs to be disclosed. Prosecutors are trusted to do this because they have two roles in the criminal justice system – to zealously prosecute crimes and to do justice. Unfortunately, the DNA exonerations and other exonerations have shown that prosecutors often fail to disclose information that could have been helpful to the defense. Sometimes, this is deliberate. In other cases, however, prosecutors who are working to zealously prosecute a defendant simply do not see certain information as exculpatory and therefore do not turn it over to the defense.

Various entities looking at this problem have proposed various solutions. Those solutions include open-file discovery and more meaningful sanctions for prosecutors who do break the rules. In addition, the Innocence Project has proposed criminal justice reform commissions that can bring all parties – including police and prosecutors – to the table to come to a consensus on how to handle the actors in the criminal justice system who do not follow the rules.

Inadequate Defense Counsel

The Sixth Amendment of the United States Constitution guarantees criminal defendants the right to counsel, and the Supreme Court in *Gideon v. Wainwright* found that this requires the state to provide indigent defendants with a lawyer who is financed by the state. While *Gideon* was a tremendous milestone for indigent defendants, it did not specify how states were required to make attorneys available to indigent defendants. Thus, states responded to *Gideon* in a variety of ways, including statewide public defender systems, contract systems in which independent agencies bid for court appointments and are awarded contracts based on a variety of factors, contract systems in which contracts go to the lowest bidder, and ad hoc court appointments in which judges appoint lawyers on a case-by-case basis. Predictably, this has resulted in a huge disparity between jurisdictions, with some committing to the provision of high-quality indigent defense lawyers despite the unpopularity of doing so and others providing defendants with inexperienced, poorly paid attorneys who are overburdened with extraordinary caseloads and denied access to investigators and necessary experts.

There is little incentive for states to provide anything other than the bare minimum. Although the Supreme Court found in *Strickland v. Washington* that defendants have a right to effective counsel, a defendant challenging his conviction based upon ineffective assistance of counsel must prove that his attorney was defective and that if his attorney had acted properly, the result of the proceeding would have been different. In any event, challenging a conviction based on ineffective assistance of counsel requires competent counsel, something many defendants simply do not have, particularly after they have been convicted and through the appellate process, when the right to counsel ends.

Unsurprisingly, the lack of quality defense lawyers leads to wrongful convictions. When an innocent defendant lacks an advocate who can investigate and meaningfully challenge the government's case, it is to be expected that a wrongful conviction might occur. According to the Innocence Project, many wrongful convictions in DNA cases involved lawyers who were incompetent, ineffective, overworked, or all three. Among the errors noted in these cases are lawyers who slept in the courtroom during trial, failed to investigate alibis, failed to consult experts or adequately challenge forensic evidence, and failed to show up for hearings.

This problem is difficult to solve largely because it requires the investment of scarce government resources in something that is considered to be unpopular, the representation of accused criminals. However, a commitment of sufficient resources to indigent defense systems would solve most, if not all of the problems that cause wrongful convictions. While it would not directly solve the problem of unethical or lazy attorneys, the proper investment of resources would help decrease caseloads, allow for sufficient investigative funds, provide funding for experts, provide training that is sorely lacking, and help reduce the disparity of resources between indigent defense systems and prosecutors. While such funding might not be popular, most prosecutors and other actors in the criminal justice system recognize that a well-funded indigent defense system helps make the system function properly and can help prevent the conviction of innocent people.

Conclusion

Every wrongful conviction is a tragic example of how the criminal justice system can fail at its most critical function: the reliable conviction of the guilty and exoneration of the innocent. While these cases are tragic, they also provide us with an unprecedented opportunity to learn where our criminal justice system is fallible and how it can be improved. It is known that wrongful convictions have exposed problems with eyewitness testimony, forensic science evidence, false confessions, government informants, government misconduct, and ineffective assistance of counsel. It is important to continue to study wrongful convictions so that best practices can be determined for how to handle these issues. With continued study and reform, steps can be taken to correct problems with these factors in order to prevent the conviction of the innocent in the future.

Overview

Western countries are experiencing a substantial increase in the use of closed-circuit television (CCTV) surveillance cameras to prevent crime in public places. Amid this expansion and the associated public expenditure, as well as concerns about their effectiveness and social costs, there is an increasing need for an evidence-based approach to inform CCTV policy and practice. This entry reports on an updated Campbell Collaboration systematic review and meta-analysis of the effects of CCTV on crime in public places. The results suggest that CCTV has a modest but significant effect on reducing crime. This overall result was largely driven by the effectiveness of CCTV schemes in car parks, which were targeted at vehicle crimes and included other interventions such as improved lighting, fencing, and security guards. Nonsignificant effects on crime were observed in the other public settings in which CCTV schemes were evaluated: city and town centers, public housing communities, and public transportation facilities.

CCTV has become a widely popular and commonplace technology that is being deployed to help make public (and private) places safer from crime. Across many cities and towns, it is touted as a panacea to crime. But it is not without its controversies, and many questions remain about its ability to reduce crime. This entry reports on the results of a systematic review – incorporating meta-analytic techniques – to assess the scientific evidence on the effectiveness of CCTV to prevent crime in public places.

In recent years, there has been a marked and sustained growth in the use of CCTV surveillance cameras to prevent crime in public places in many Western nations. The United Kingdom in particular is on the cusp of becoming, in the words of some, a "surveillance society," with upward of a million or more cameras in public places (Norris 2007).

There are no national estimates as yet on the number of CCTV cameras in the United States, but local accounts indicate that they are being installed at an unprecedented rate and their popularity is not limited to large urban centers. Some of this increased use in the United States has come about in an effort to aid the police in the detection and prevention of terrorist activities, especially in New York City and other metropolises. However, the prevention of crime remains an important aim of these CCTV systems. Similar claims about the purpose of public CCTV have been made in the United Kingdom. There are also signs that other countries are increasingly experimenting with CCTV to prevent crime in public places. Evaluation studies of public CCTV schemes have been carried out recently in a number of European countries, including Germany, Norway, and Sweden, as well as in Australia, Canada, and Japan. Many of these countries have not previously used CCTV in public places, let alone evaluated its effects on crime.

The growth in CCTV has come with a huge price tag. In the United Kingdom, CCTV has been and continues to be the single most heavily funded crime prevention measure operating outside of the criminal justice system. In the United States, estimates suggest that public expenditure on CCTV may be as much as $100 million each year (Savage 2007).

There has been much debate about the effectiveness of CCTV in preventing crime and hence on the wisdom of spending such large sums of money. A key issue is to what extent funding for CCTV, especially in the United Kingdom and the United States, has been based on high quality scientific evidence demonstrating its effectiveness in preventing crime (Welsh and Farrington 2009a, b).

Methods

The methodology employed in our systematic review follows the conventions set out by the Campbell Collaboration. Evaluations were included in the systematic review if they met a number of criteria, including if CCTV was the main intervention, if there was an outcome measure of crime, and if the evaluation design was of high methodological quality. At a minimum, high quality evaluation designs involve before and after measures of crime in experimental and comparable control areas. Control areas are needed to assess what would have happened in the absence of CCTV and to counter threats to internal validity.

Extensive search strategies were employed to locate studies meeting the criteria for inclusion, including searches of electronic bibliographic databases, searches of literature reviews on the effectiveness of CCTV on crime, and contacts with leading researchers. Altogether, 44 studies were found that met our inclusion criteria.

In order to carry out a meta-analysis, a comparable measure of effect size and an estimate of its variance are needed in each program evaluation (Lipsey and Wilson 2001). In the case of CCTV evaluations, the measure of effect size had to be based on the number of crimes in the experimental and control areas before and after the intervention. This is because this is the only information that was regularly provided in these evaluations.

The "relative effect size" or RES is used to measure effect size. The RES is intuitively meaningful because it indicates the relative change in crimes in the control area compared with the experimental area. For example, RES = 2 indicates that the change in the control areas is twice as large as the experimental areas. This value could be obtained, for example, if crimes doubled in the control area and stayed constant in the experimental area, or if crimes decreased by half in the experimental area and stayed constant in the control area, or in numerous other ways. The RES is computed from the pre- and post-CCTV crime counts in the control and experimental areas. The equation is as follows:

$$\mathrm{RES} = (\mathrm{a} * \mathrm{d})/(\mathrm{b} * \mathrm{c})$$

where a and b are the pre- and post-CCTV crime counts for the experimental areas, respectively, and c and d are the pre- and post-CCTV crime counts for the control areas, respectively.

The meta-analysis was performed on the logged values of RES with the final results converted back into the original scale by taking the antilog. In order to perform the meta-analysis, the variance of each logged RES is needed. If we assume that the crime counts are Poisson distributed, then the variance is 1/a + 1/b + 1/c + 1/d. This assumption is plausible because 30 years of mathematical models of criminal careers have been dominated by the assumption that crimes can be accurately modeled by a Poisson process (Piquero et al. 2007). In a Poisson process, the variance of the number of crimes is the same as the number of crimes (i.e., v = n). However, the large number of changing extraneous factors that influence the number of crimes may cause overdispersion; that is, where the variance of the number of crimes exceeds the number of crimes. Farrington et al. (2007) estimated the overdispersion (D) in crime counts as follows:

$$\mathrm{D} = 0.0008 * \mathrm{N} + 1.2$$

D increased linearly with N and was correlated 0.77 with N. The mean number of crimes in an area in the CCTV studies was about 760, suggesting that the mean value of D was about 2. However, this is an overestimate because the monthly variance is inflated by seasonal variations, which do not apply to N and VAR. Nevertheless, in order to obtain a conservative estimate, V(LRES), which is the variance of LRES (and is distinguished from Va, which is the variance of a), calculated from the usual formula above was multiplied by D (estimated from the above equation) in all cases. Specifically,

$$\mathrm{V(LRES)} = \mathrm{Va}/\mathrm{a}^2 + \mathrm{Vb}/\mathrm{b}^2 + \mathrm{Vc}/\mathrm{c}^2 + \mathrm{Vd}/\mathrm{d}^2$$

where Va/a = 0.0008 * a + 1.2

This is our best available estimate of the degree of overdispersion in area-based crime prevention studies.

Forty-one of the 44 studies could be used in the meta-analysis. RES effect sizes could not be calculated for three studies because numbers of crimes were not reported in the city and town center schemes in Ilford or (for the control area) Sutton or for the public housing scheme in Brooklyn. (Throughout this entry, the included studies are identified by the name of the city or town where they were implemented. Full references can be obtained from the authors' Campbell Collaboration systematic review, which is available at: http://www.campbellcollaboration.org/crime_and_justice/index.php.)

Findings

Setting

City and town centers. Twenty-two evaluations were carried out in city and town centers. Seventeen of these were carried out in the United Kingdom, three in the United States, one in Sweden, and one in Norway. Only some of the studies reported the coverage of the CCTV cameras. For example, in the Newcastle-upon-Tyne and Malmö studies, the camera coverage of the target or experimental area was 100 %. Many more studies reported the number of cameras used and their features (e.g., pan, tilt, zoom). Information on camera coverage is important because if a large enough section of the target area or even high crime locations in the target area are not under surveillance, the impact of CCTV may be reduced.

Most of the evaluations that reported information on the monitoring of the cameras used active monitoring, which means that an operator watched monitors linked to the cameras in real time. Passive monitoring involves watching tape recordings of camera footage at a later time. In some of the schemes, such as Newcastle and Birmingham, police carried out active monitoring. But more often it was carried out by security personnel who had some form of communication link with police (e.g., by a one-way radio or direct line telephone).

On average, the follow-up period in the 22 evaluations was 15 months, ranging from a low of 3 months to a high of 60 months. Six programs included other interventions in addition to the main intervention of CCTV. For example, in the Doncaster program, 47 "help-points" were established within the target area to aid the public in contacting the main CCTV control room. Four other studies used notices of CCTV to inform the public that they were under surveillance, but CCTV notices do not necessarily constitute a secondary intervention. A couple of the evaluations used multiple experimental areas (e.g., police beats), meaning that the CCTV intervention was quite extensive in the city or town center. Multiple control areas (e.g., adjacent police beats, the remainder of the city) were used in many more of the evaluations. The most comparable control areas were chosen for analysis. Where control and adjacent areas were used, control areas were analyzed.

The city and town center CCTV evaluations showed mixed results in their effectiveness in reducing crime. Ten of the 22 evaluations were considered to have a desirable effect on crime, 5 were considered to have an undesirable effect, and 1, the multisite British evaluation by Sivarajasingam et al. (2003), was considered to have both (desirable effects according to emergency department admissions and undesirable effects according to police records). The remaining six evaluations were considered to have a null ($n = 5$) or uncertain ($n = 1$) effect on crime. Schemes usually showed evidence of no crime displacement rather than displacement or diffusion of benefits.

As an example, in the program evaluated by Armitage et al. (1999), an unknown number of cameras were installed in the town center of Burnley, England. The experimental area consisted of police beats in the town center with CCTV coverage. Two control areas were used. The first comprised those police beats that shared a common boundary with the beats covered by CCTV. The second control area consisted of other police beats in the police division. The first control area was more comparable to the experimental area and was the one used in our analysis. After 12 months, the experimental area, compared with the two control areas, showed substantial reductions in violent crime, burglary, vehicle crime, and total crime. For example, total incidents of crime fell by 28 % in the experimental area compared with a slight decline of 1 % in the first control area and an increase of 10 % in the second control area. The authors found evidence of diffusion of benefits for the categories of total crime, violent crime, and vehicle crime, and evidence of territorial displacement for burglary.

In pooling the data from the 20 studies for which effect sizes could be calculated, there was evidence that CCTV led to a small but nonsignificant reduction in crime in city and town centers. The weighted mean effect size was a RES of 1.08 (CI 0.97–1.20), which corresponds to a 7 % reduction in crimes in experimental areas compared with control areas. However, when these 20 studies were disaggregated by country, the 15 British studies showed a slightly larger effect on crime (a 10 % decrease; RES = 1.11, CI 0.98–1.27, ns), while the five others showed no effect on crime.

An analysis of heterogeneity showed that the 20 effect sizes were significantly heterogeneous ($Q = 143.9$, $df = 19$, $p < 0.0001$). This means that the differences were not simply a matter of sampling error. The 15 UK studies were also significantly heterogeneous ($Q = 118.6$, $df = 14$, $p < 0.0001$), as were the five other studies ($Q = 14.02$, $df = 4$, $p = 0.007$). Therefore, random effects models that assume study-level variability were used in calculating weighted mean effect sizes.

Public housing. Nine evaluations were carried out in public housing. Seven were carried out in the United Kingdom and two in the United States. Camera coverage ranged from a low of 9 % (in Dual Estate) to a high of 87 % (in Northern Estate) in the six evaluations that reported this information. Active monitoring was used in all of the schemes, with monitoring in the Brooklyn evaluation conducted by police. In the six British schemes evaluated by Gill and Spriggs (2005), security personnel who monitored the cameras had some form of communication link with police (e.g., a one-way or two-way radio). On average, the follow-up period in the nine evaluations was 12 months, ranging from a low of 3 months to a high of 18 months. Only three schemes included other interventions in addition to the main intervention of CCTV. These involved improved lighting and youth inclusion projects.

The public housing CCTV evaluations showed mixed results in their effectiveness in reducing crime. Three of the nine evaluations were considered to have a desirable effect on crime, two had an undesirable effect, three had an uncertain effect, and one had a null effect. Only five schemes measured diffusion of benefits or crime displacement, and in each case it was reported that displacement and diffusion did not occur.

In pooling the data from the eight studies for which effect sizes could be calculated, there was evidence that CCTV led to a small but nonsignificant reduction in crime in public housing. The weighted mean effect size was a RES of 1.07 (CI 0.83–1.39), which corresponds to a 7 % reduction in crimes in experimental areas compared with control areas. The eight effect sizes were significantly heterogeneous ($Q = 47.94$, $df = 7$, $p < 0.0001$).

The evaluation by Williamson and McLafferty (2000) in Brooklyn, New York, the only one that could not be included in the meta-analysis, is somewhat representative of CCTV's rather negligible effect on crime in public housing. The housing community that received the intervention (Albany project) did not show any change in the total number of police-recorded crimes, either inside the project or inside a 0.1 mile buffer zone (established to measure crime displacement or diffusion of benefits), while total crime in the control community (Roosevelt project) dropped by 5 % inside the project and 4 % inside the 0.1 mile buffer zone. When total crime was disaggregated, a desirable program effect was observed for major felonies in both experimental and control projects. However, the authors note that, "the substantial decrease in major felonies around both public housing projects seems to be part of a larger downward trend that was occurring not only in Brooklyn but across New York City in the late 1990s" (Williamson and McLafferty 2000, p. 7). Furthermore, the authors' investigation of the occurrence of crime displacement or diffusion of benefits concluded that there was "no clear evidence" of either, "as the change in crime around the two housing projects does not vary predictably with distance" (p. 7).

Public transport. Four evaluations were carried out in public transportation systems. All of them were conducted in underground railway systems: three in the London Underground and one in the Montreal Metro. None of the studies reported on the percentage of the target areas covered by the cameras, but most did provide information on the number of cameras used. For example, in the Montreal program a total of 130 cameras (approximately 10 per station) were installed in the experimental stations. Each of the schemes involved active monitoring on the part of police; in the London Underground, this meant the British Transport Police.

With the exception of the Montreal program, each evaluation included other interventions in addition to CCTV. In the first Underground scheme, special police patrols were in operation prior to the installation of CCTV. For the two other Underground schemes, some of the other interventions included passenger alarms, kiosks to monitor CCTV, and mirrors. For each of these three Underground schemes, CCTV was, however, the main intervention. The follow-up periods ranged from a low of 12 months to a high of 32 months.

Overall, CCTV programs in public transportation systems present conflicting evidence of effectiveness: two had a desirable effect, one had no effect, and one had an undesirable effect on crime. However, for the two effective programs in the London Underground (southern sector and northern line), the use of other interventions makes it difficult to say with certainty that it was CCTV that caused the observed crime reductions, although in the first of these programs CCTV was more than likely the cause. Only two of the studies measured diffusion of benefits or crime displacement, with one showing evidence of diffusion and the other showing evidence of displacement.

In pooling the data from the four studies, there was evidence that CCTV led to a sizable but nonsignificant reduction in crime in public transport. The weighted mean effect size was a RES of 1.30 (CI 0.87–1.94), which corresponds to a 23 % reduction in crimes in experimental areas compared with control areas. The substantial reduction in robberies and thefts in the first Underground evaluation (an overall 61 % decrease) was the main reason for this large average effect size over all four studies. The four effect sizes were significantly heterogeneous ($Q = 30.94$, $df = 3$, $p < 0.0001$).

Car parks. Six CCTV evaluations met the criteria for inclusion and were conducted in car parks (parking lots). All of the programs were implemented in the United Kingdom between the early 1980s and early 2000s. Camera coverage was near 100 % in the two schemes that reported on it. All of the schemes, with the exception of one that did not provide data, involved active monitoring on the part of security staff. The large-scale, multisite Hawkeye scheme evaluated by Gill and Spriggs (2005) also included a radio link with the British Transport Police.

Each of the programs supplemented CCTV with other interventions, such as improved lighting, painting, fencing, payment schemes, and security personnel. In Coventry, for example, improved lighting, painting, and fencing were part of the package of measures implemented to reduce vehicle crimes. In each program, however, CCTV was the main intervention. The follow-up periods ranged from a low of 10 months to a high of 24 months.

Five of the car park programs had a desirable effect and one had an undesirable effect on crime, with vehicle crimes being the exclusive focus of five of these evaluations. For example, Tilley (1993) evaluated three CCTV programs in car parks in the following UK cities: Hartlepool, Bradford, and Coventry. Each scheme was part of the British Government's Safer Cities Programme, a large-scale crime prevention initiative that operated from the late 1980s to mid-1990s. In Hartlepool, CCTV cameras were installed in a number of covered car parks and the control area included a number of non-CCTV-covered car parks. Security personnel, notices of CCTV, and payment schemes were also part of the package of measures employed to reduce vehicle crimes. Twenty-four months after the program began thefts of and from vehicles had been substantially reduced in the experimental car parks compared with the control car parks. A 59 % reduction in thefts of vehicles was observed in the experimental car parks compared with a 16 % reduction in the control car parks. Tilley (1993, p. 9) concluded that, “The marked relative advantage of CCTV covered parks in relation to theft of cars clearly declines over time and there are signs that the underlying local trends [an increase in car thefts] begin to be resumed.” The author suggested that the displacement of vehicle thefts from covered to non-covered car parks occurred. Most studies did not measure either diffusion of benefits or crime displacement.

The RESs showed a significant and desirable effect of CCTV for five of the schemes. In the other scheme (Guildford), the effect was undesirable, but the small number of crimes measured in the before and after periods meant that the RES was not significant. When all six effect sizes were combined, the overall RES was 2.03 (CI 1.39–2.96, $p = 0.0003$), meaning that crime decreased by half (51 %) in experimental areas compared with control areas. This indicates a very large and highly significant desirable effect of CCTV on vehicle crimes in car parks. The six effect sizes were significantly heterogeneous ($Q = 31.93$, $df = 5$, $p < 0.0001$).

Other settings. Three of the 44 evaluations took place in other public settings: two in residential areas and one in a hospital. It was considered necessary to categorize these three schemes separately from the others because of the differences in the settings in which these three schemes were implemented as well as their small numbers.

There were some notable differences between the two residential schemes. The City Outskirts scheme was implemented in an economically depressed area on the outskirts of a Midlands city, while the Borough scheme was implemented throughout a southern borough of mixed affluence. Camera coverage was quite good in City Outskirts (68 %), but in Borough it was considered low. Gill and Spriggs (2005) noted that this was due in large measure to the use of redeployable cameras in Borough, while fixed cameras were used in City Outskirts. Other interventions were used in City Outskirts, but not in Borough. Evaluations of the two schemes also found contrasting effects on crime: a significant desirable effect in City Outskirts (a 25 % decrease) and a nearly significant undesirable effect in Borough (a 25 % increase).

The one evaluation of CCTV implemented in a city hospital showed that it produced a desirable but nonsignificant effect on crime (RES = 1.38, CI 0.80–2.40), corresponding to a 28 % decrease in crime in the experimental area compared with the control area. Among some of the scheme’s distinguishing features, camera coverage was high (76 %), active monitoring was used, there was a direct line between the camera operators and police, and other interventions were implemented, including improved lighting and police operations.

Crime Type

The major crime types that were reported were violence (including robbery) and vehicle crimes (including thefts of and from vehicles). Violence was reported in 23 evaluations, but CCTV had a desirable effect in reducing violence in only three cases (Airdrie, Malmö, and Shire Town). Overall, there was no effect of CCTV on violence (RES = 1.03, CI 0.96–1.10, ns). The 23 effect sizes were not significantly heterogeneous ($Q = 30.87$, $df = 22$, n.s.).

Vehicle crimes were reported in 22 evaluations, and CCTV had a desirable effect in reducing them in ten cases: in five of the six car park evaluations (all except Guildford), in three city or town center evaluations (Burnley, Gillingham, and South City), and in City Outskirts and City Hospital. Over all 22 evaluations, CCTV reduced vehicle crimes by 26 % (RES = 1.35, CI 1.10–1.66, $p = 0.004$). The 22 effect sizes were significantly heterogeneous ($Q = 115.1$, $df = 21$, $p < 0.0001$). The greatest effect was in the large-scale, multisite Hawkeye study, but there was a significant effect even if this study was excluded (RES = 1.28, corresponding to a 22 % decrease in crimes).

Country Comparison

Of the 41 evaluations that were included in the meta-analysis, the overwhelming majority of them were carried out in the United Kingdom ($n = 34$). Four were from the United States and one each from Canada, Norway, and Sweden. When the pooled meta-analysis results were disaggregated by country, there was evidence that the use of CCTV to prevent crime was more effective in the United Kingdom than in other countries. In the British studies, CCTV had a significant desirable effect, with an overall 19 % reduction in crime (RES $=$ 1.24, CI 1.10–1.39, $p = 0.0005$). The British studies were significantly heterogeneous ($Q = 350.5$, $df = 33$, $p < 0.0001$). In the other studies, CCTV showed no desirable effect on crime (RES = 0.97, CI 0.86–1.09, ns). The other studies were also significantly heterogeneous ($Q = 14.51$, $df = 6$, $p = 0.024$). Importantly, the significant results for the British studies were largely driven by the effective programs in car parks.

Key Issues/Controversies

Von Hirsch (2000) argues that there are two major issues that confront the "proper uses and limits" of surveillance for crime prevention in public places. The first issue pertains to privacy concerns. This can be expanded to include other social costs that may infringe on public interests or violate legal or constitutional protections. The second issue concerns the matter of the "legitimising role of crime prevention," or as von Hirsch (2000, p. 61) posits, "To what extent does crime prevention legitimise impinging on any interests of privacy or anonymity in public space?"

In car parks, there may be little resistance to the installation of CCTV cameras. In part, this is because the public space is utilized for one rather inconsequential purpose – parking vehicles. It is also the case that a car park is a well-defined and clearly marked physical space, meaning that individuals know that it is a car park and can choose to park their vehicle there or not (providing there are other alternatives). These points stand in sharp contrast to how individuals come into contact with CCTV in other public settings.

CCTV in other public settings such as city and town centers, public housing communities, and transportation facilities evokes more resistance on the basis of threats to privacy and other civil liberties, and is associated with a larger number of social harms, including the reinforcement of the notion of a fortress society and the social exclusion of marginalized populations (Clarke 2000). Indeed, it is often these settings that are at the center of the debate over how best to strike a balance between the potential crime reduction benefits and social costs associated with CCTV.

In these other public settings, CCTV may also result in the social exclusion of vulnerable or marginalized populations such as unemployed youths and the homeless. The fear is that, instead of providing assistance for these groups to get off the street so to speak, CCTV, among other interventions like police and security guards, may push them further away from available services and cause increased harm in the form of crime, victimization, or both. Efforts to reduce any social exclusion effect associated with CCTV in these settings would need to involve other services.

Future Directions

Advancing knowledge about the crime prevention benefits of CCTV schemes should begin with attention to the methodological rigor of the evaluation designs. The use of a reasonably comparable control group by all of the 44 included evaluations went some way toward ruling out some of the major threats to internal validity, such as selection, maturation, history, and instrumentation. The effect of CCTV on crime can also be investigated after controlling (e.g., in a regression equation) not only for prior crime but also for other community-level factors that influence crime, such as neighborhood poverty and poor housing. Another possible research design is to match two areas and then to choose one at random to be the experimental area. Of course, several pairs of areas would be better than only one pair.

Also important is attention to methodological problems or to changes in programs that take place during and after implementation. Some of these implementation issues include: statistical conclusion validity (adequacy of statistical analyses); construct validity (fidelity); and statistical power (to detect change). For some of the included evaluations, small numbers of crimes made it difficult to determine whether or not the program had an effect on crime. It is essential to carry out statistical power analyses before embarking on evaluation studies. Few studies attempted to control for regression to the mean, which happens if an intervention is implemented just after an unusually high crime rate period. A long time series of observations is needed to investigate this. The contamination of control areas (i.e., by the CCTV intervention) was another, albeit less common, problem that faced the evaluations.

There is also the need for longer follow-up periods to see how far the effects persist. Of the 44 included schemes, many were in operation for 12 months or less prior to being evaluated. This is a very short time to assess a program's impact on crime or any other outcome measure, and for these programs the question can be asked: Was the intervention in place long enough to provide an accurate estimate of its observed effects on crime? Ideally, time series designs are needed with a long series of crime rates in experimental and control conditions before and after the introduction of CCTV. In the situational crime prevention literature, brief follow-up periods are the norm, but "it is now recognized that more information is needed about the longer-term effects of situational prevention" (Clarke 2001, p. 29). Ideally, the same time periods should be used in before and after measures of crime.

Research is also needed to help identify the active ingredients of effective CCTV programs and the causal mechanisms linking CCTV to reductions in crime. Forty-three percent (19 out of 44) of the included programs involved interventions in addition to CCTV, and this makes it difficult to isolate the independent effects of the different components, including the unique effect of CCTV, and the interaction effects of CCTV in combination with other measures. Future experiments are needed that attempt to disentangle elements of effective programs. Also, future experiments need to measure the intensity of the CCTV dose and the dose-response relationship, and need to include alternative methods of measuring crime (surveys as well as police records).

In order to investigate displacement of crime and diffusion of crime prevention benefits, the minimum design should involve one experimental area, one adjacent area, and one nonadjacent comparable control area. If crime decreased in the experimental area, increased in the adjacent area, and stayed constant in the control area, this might be evidence of displacement. If crime decreased in the experimental and adjacent areas and stayed constant or increased in the control area, this might be evidence of diffusion of benefits. Unfortunately, few CCTV studies used this minimum design. Instead, most had an adjacent control area and the remainder of the city as another (noncomparable) control area. Because of this, any conclusions about displacement or diffusion effects of CCTV seem premature at this point in time.

This systematic review focused on CCTV's effects on crime, but it would also be desirable to investigate effects on detection, prosecution, and conviction. Exactly what the optimal circumstances are for effective use of CCTV schemes is not entirely clear at present, and this needs to be established by future evaluation research. But it is important to note that the success of the CCTV schemes in car parks was mostly limited to a reduction in vehicle crimes (the only crime type measured in five of the six schemes) and camera coverage was high for those evaluations that reported on it. In the national British evaluation of the effectiveness of CCTV, Farrington et al. (2007) found that effectiveness was significantly correlated with the degree of coverage of the CCTV cameras, which was greatest in car parks. Furthermore, all six car park schemes included other interventions, such as improved lighting and security guards. It is plausible to suggest that CCTV schemes with high coverage and other interventions and targeted on vehicle crimes are effective. Conversely, the evaluations of CCTV schemes in city and town centers and public housing measured a much larger range of crime types and only a small number of studies involved other interventions. These CCTV schemes, as well as those focused on public transport, did not have a significant effect on crime.

Crime policy is rarely formulated on the basis of hard evidence, and the use of CCTV is no exception. Campbell Collaboration systematic reviews, like the one presented here, provide the most rigorous source for scientific evidence on the leading criminological interventions. It is high time that the evidence is put at center stage in political and policy decisions about preventing crime.

Acknowledgments We wish to thank David Wilson for helpful comments on an earlier draft of this entry.

Certainty, Severity, and Their Deterrent Effects

Horst Entorf
Department of Economics and Business Administration, Goethe University Frankfurt, Frankfurt, Germany

Overview

Severity of punishment without the credible threat of being detected and convicted "… *is the sound of one hand clapping*" (original quote: "Mediation without the credible threat of judicial determination is the sound of one hand clapping," Genn 2010, p. 125). Theoretical and empirical analyses of general deterrence need to consider both certainty *and* severity of sanctions, that is, the intertwining activities of police, public prosecution, courts, and prison conditions. Many studies only rely on the probability of detection, that is, on police activity or efficiency, when discussing the role of *expected* sanctions. Other studies, in particular articles dealing with US data and thus motivated by the highly persistent upward trend in prisoner population, focus on the imprisonment rate and the severity of sanctions as crucial factors of deterrence (see the survey by Donohue 2009). The (brief) survey at hand summarizes the classical rational-choice fundamentals of modern deterrence theory and covers major theoretical and empirical findings on the interplay of certainty and severity of punishment as well as important underlying methodological problems since the early 1970s of the last century.

Any survey of the economics of crime would be incomplete without reminiscence of recent developments in behavioral economics of crime. The last few years seem to have witnessed a change in mainstream economics of crime. Rational-choice models are often criticized because they ignore that cognitive restrictions and emotional factors such as time pressure, peer group influence, or anger restrict the long-run *optimality* of individual decisions. Simon (1957) was the first to point out that the complexity of situations and limitations of both available information and cognitive capacity would lead to decisions under *bounded rationality*. Several recent papers focus on shortcomings and necessary extensions of the classical notion of certainty and severity of sanctions. This contribution discusses significant insights stemming from behavioral economics such as impulsiveness (myopia), prospect theory, and anger. Moreover, stigma effects (dynamic deterrence) and the distinction between objective and perceived threats of potential punishment will be addressed.

This survey contains the following subchapters: fundamentals of general deterrence theory, theoretical and empirical results concerning (a) the certainty of punishment and (b) the severity of sentences, limitations and extensions of the classical deterrence model, and, finally, the threat of punishment when trust in criminal law is absent. The entry concludes with remarks on future directions of research in deterrence.

Fundamentals of General Deterrence Theory

General deterrence is the avoidance of crime by (deterrable) potential offenders through the credible threat of punishment. This definition entails (a) there is a threat in terms of a judicial system of appropriate sanctions and (b) this threat is credible, that is, there is a legal enforcement system of police, prosecutors, and judges which has the capability to realize a perceptibly high (strictly positive) probability of detection and conviction. The definition also requires that there is a nonempty group of compliers, that is, a deterrable subgroup of the population which can be correctly described as *potential offenders* because otherwise the theory of deterrence would be futile. The identification of *deterrable* and *non-deterrable* subpopulations is important but a rather neglected field in criminology.

The theoretical foundations of general deterrence are usually ascribed to Gary Becker's (1968) seminal article, although the philosophical foundation of deterrence dates back to eighteenth century (Bentham (1781)). In a broader sense, the idea of general deterrence is related to rational-choice theory, which assumes that all individuals, irrespective of being criminal or not, respond to incentives, or as Becker puts it, "*Some people become 'criminals' not because their basic motivation differs from that of other persons, but because their benefits and costs differ*" (Becker 1968, p. 176). Though often disputed and criticized (see, among many others, McAdams and Ulen 2009), the importance of rational choice and general deterrence has also been acknowledged by criminologists and sociologists (as discussed in Rupp 2008, p. 6).

Becker's theory on the supply of offenses is based on the comparison of (uncertain) expected utility from criminal activities to the (relatively certain) utility from not committing crimes. Thus, increasing the individual *costs* of crime by increasing the expected sentence would lead to a reduction of criminal behavior for rational offenders. Assuming additivity, the theory predicts that if the expected utility from committing a crime,

$$E_C = (1 - p)U_C + p(U_C - C_C), \qquad (1)$$

exceeds the expected utility from obeying the societal legal norms, E_{NC}, a crime will be committed; otherwise individuals refrain from wrongdoing. Here p denotes the probability that the illegal act will be detected and punished, $(1 - p)$ is the probability of getting away with it, U_C represents utility from crime, E_{NC} is utility from noncrime, and C_C captures disutility (cost) from being punished. Obviously, to make punishment effective, C_C needs to be higher than U_C. This condition fits Bentham's (1781) "Principles of Morals and Legislation": According to Rule 1 of "Of the Proportion Between Punishments and Offences," "*The value of the punishment must not be less in any case than what is sufficient to outweigh that of the profit of the offence*" (Bentham 1781, p. 141).

Equation 1 can be expressed as the difference between the benefit from committing a crime and the expected sentence in case of detection, that is,

$$E_C = U_C - pC_C. \qquad (2)$$

Equation 2 can be considered as the most parsimonious representation of severity and certainty of conviction. It is obvious that credibility of the threat of sanctions requires the expected sentence, that is, product pC_C, to be positive. As an example of the deterrence rationale, consider the choice between paying a certain amount of money, say, 3 Euros, for a short-term city parking space and not paying the amount and taking the risk of a fine of, say, 20 Euros. If on average every 10th *free parking* is detected, that is, $p = 0.1$, then the utility from the illegal action, U_C, would be 3 Euros, whereas the expected fine was 2 Euros. Hence the risk-neutral rational "*offender*" would decide against putting a coin into the parking meter and in favor of the illegal alternative. Of course, such reasoning may be ambiguous in case of risk preference, and as mentioned above, it requires that a nonempty subgroup is complying according to rational-choice rules, that is, a significant number of people belong neither to the group of always strictly norm-abiding citizens nor to the group of never law-abiding individuals. Thus, summarizing the standard rational-choice reasoning covered in Eq. 2, deterrence would not work either when the certainty of a sanction is zero or when sanctions lack severity. In both cases, the product pC_C would be zero, that is, there would be no credible threat from expected sanctions for wrong doing.

Equation 2 also represents the basic foundation of Becker's so-called supply of offenses, which is grounded on first-order conditions of the difference between illegal and legal sources of expected utility, $E_C - E_{NC}$. Taking derivatives with respect to the crucial impacting factors p, C_C and E_{NC} yield the behavioral equation

$$C = C(\underset{(-)}{p}, \underset{(-)}{C_C}, \underset{(-)}{E_{NC}}, X). \qquad (3)$$

Thus, under standard neoclassical assumptions (see Becker 1968 for details), crime (C) would fall when the probability of detection and punishment increases or when potential offenders face the risk of higher costs from committing crimes. These disincentives to crime change in response to longer or tougher prison sentences, for example, in terms of tough-on-crime policies such as the Californian *three-strikes* law or the application of adult criminal law instead of juvenile criminal law (as discussed in Entorf 2012). Crime would also decrease when utility from noncriminal activities, E_{NC}, increases, for instance, because of lower unemployment risk, or improving current and future legal income opportunities, which include the broad and lasting impact of education on crime. Of course, empirical models on crime would fail if only p, C_C, and E_{NC} were included as explanatory factors of crime. Thus, X represents further factors of which age, gender, alcohol and drug addiction, migration background, race, peer influence, and family background belong to the (incomplete) list of variables often (but not regularly) found in crime studies. An indeterminacy of statistical tests of deterrence models is the rather arbitrary choice of X. Indeed, a meta-study by Dölling et al. (2009, Table 5) reveals that the choice of control variables has a high influence on finding significance or nonsignificance of deterrence indicators in empirical studies: Dependent on the choice of the control variable, reported average t-values on deterrence variables range from −0.5 to −2.3. The problem of ad hoc specifications is discussed in more detail by Durlauf and Nagin (2010).

On the Impact of Certainty

Early Contributions. The first empirical tests of Becker's *supply of offenses* model have been conducted in the late 1960s and early 1970s of the last century. Early studies such as Tittle (1969) have found significant crime reducing effects in response to increasing certainty (*p*). However, these contributions were flawed by endogeneity problems and ignorance of incapacitation effects. Although follow-up papers such as Ehrlich (1973) used two-stage least squares techniques to account for simultaneity problems, identifications strategies such as use of lagged endogenous variables would be considered problematic from the current viewpoint of modern econometrics (see also Durlauf and Nagin 2010). Ehrlich's (1973) results were intensively discussed, and not all studies agreed on the evidence in favor of the deterrence hypothesis. Many studies argue that the model is too simplistic and empirical findings are not reliable enough to draw *any* conclusion in favor or against the deterrence hypothesis. According to Rupp (2008), this criticism seems to be exaggerated, but the ambiguity of Ehrlich's findings was and still is perhaps the main reason for the lasting debate on Ehrlich's problematic contribution to the deterrence literature.

Ehrlich's (1973) article also received prominent attention as a significant contribution to the theoretical literature. He modified Becker's theoretical model by using a time allocation model. This framework widens the perspective because it includes leisure time as a source of utility besides utility from time spent on legal and illegal activities. This makes theoretical predictions less clear than in Becker (1968), where utility is achieved either from illegal or from legal activities. Ehrlich (1973, p. 530, footnote 13) draws attention to the point that the unambiguous negative sign of deterrence effects only holds when individuals are risk neutral or risk averse.

Survey of Surveys and Meta-studies. In the first three decades after Becker's (1968) seminal article, several surveys on the economics of crime have been published. Rupp (2008) summarizes them in more detail. During the last few years, the frequency and number of surveys seems to accelerate. Surveys by Rupp (2008), Donohue (2009), Durlauf and Nagin (2010), and Ritchie (2011), to name only a selection of remarkable new publications, confirm what has been found by earlier studies, that is, that the deterrent effect of the certainty of sanctions far outweighs the severity of punishment.

Eide et al. (1994) is a good starting point in order to provide a sample of typical estimates of the deterrent effect of the certainty of sanctions. The authors summarize 20 international cross-sectional studies based on a variety of model specifications, types of data, and regressions. They find the median value of the 118 elasticity estimates of crime rates with respect to various measures of the probability of punishment to be about −0.7. The median of the somewhat fewer severity elasticities is about −0.4.

Donohue (2009) focuses on the effect of the imprisonment rate in six studies based on aggregate data and finds that most studies show a negative effect of incarceration rates on crime. However, the estimates of the elasticity of crime range considerably between −0.70 for robbery and results on all index crimes which suggest that marginal imprisonments would even increase crime. Donohue (2009, p. 17) admits that his best guess for the elasticity is "*highly uncertain*", most likely being between −0.10 and −0.15 but "*conceivably within the broader interval between −0.05 and −0.40*". Durlauf and Nagin (2010) discuss the papers of Donohue's survey at some length. They criticize the statistical methodology employed in these studies and dismiss Levitt (1996) as the sole author of the survey who convincingly addressed the simultaneous interdependencies between crime and imprisonment rates. A further problem of studies relying on the imprisonment rate as the sole indicator of p is that it covers compound effects which might cause an omitted variable bias (see the subsequent subchapter on *Decomposing the Certainty Effect*).

Durlauf and Nagin (2010) consider studies based on police manpower more persuasive than those based on imprisonment rates. Their sympathy seems to be affected by the highly influential paper by Levitt (1997) and its critics on the choice of meaningful instruments. Durlauf and Nagin (2010) summarize the findings from these studies and further replication studies and mention an average elasticity of −0.3 for most estimates relating total crimes and police presence. However, given the high dependency of results on the type of crime under consideration (see below), such *typical* results covering the whole range of crime categories can hardly be considered useful for practical public policy purposes (which is in line with Donohue's "*uncertainty*" about his best guess).

A recent extensive meta-analysis based on 700 empirical studies with 7,822 estimates of the crime-preventing effect of general deterrence (certainty or severity of sanctions) by Rupp (2008; see also Dölling et al. 2009) reveals a large variation of effects depending on the choice of the deterrence variable. For instance, using the indicator *ratio of convictions to reported crimes* produces a highly statistical evidence in favor of the certainty of sanctions (median t-value = −3.5), whereas using the clearance rate would produce less significant results (median t-value = −1.9; Dölling et al. 2009, Table 3). Results also differ with respect to the crime category under consideration. Rupp (2008), Table 3.43, p. 126 finds that among the offenses which have been in best accordance with the deterrence hypothesis are speeding (median t-value = −2.2), tax evasion (−2.1), severe theft (−2.1), and fraud (−2.0), whereas sexual assault (−0.5), manslaughter (0.0), and drug dealing (0.0) were only rarely found to be consistent with the deterrence hypothesis. Thus, very prominent in the group of consistent types of crimes are nonviolent crimes, while the discordant part seems to incorporate violent crimes and drug-related offenses.

Decomposing the Certainty Effect. Testing the theoretical prediction of p, that is, the certainty of sanction, requires empirical measurement of the joint probability of detection *and* subsequent punishment. Many empirical models are restricted to only one indicator such as clearance rates (Entorf and Spengler 2000) or number of police officers (Levitt 1996). However, variations in clearance rates may not change the threat of expected sentences when prior to judicial decisions cases are dismissed or discharged by the public prosecutor. Moreover, expected sentences differ in response to court decisions, which can be dismissal, unconditional imprisonment, probation, (financial) fine, or other sanctions such as educational measures. Thus, to improve the consistency of empirical models with their theoretical counterparts and in order to analyze the effectiveness of the various sources of deterrence, it is necessary to decompose the certainty effect p into its components. In its simplest way, this can be done by distinguishing between the probability of detection (clearance rate), p_{cl}, and the conditional probability that a suspect is sentenced, $p_{s|cl}$ (probability of a sentence, conditional on detection), that is,

$$p = p_{cl}\, p_{s|cl}. \tag{4}$$

The variation of certainty effects becomes more transparent when changes in clearance or arrest rates are separated from the ones of courts and sentences. To fully understand such variations, changes in $p_{s|cl}$ can be further decomposed into changes of the indictment rate (driven by public prosecution), $p_{court|cl}$ (i.e., the probability that a suspect is brought to court), and those stemming from court decisions, $p_{s|court}$ (i.e., the probability that a suspect is convicted, given he or she is brought to court), eventually leading to $p_{s|cl} = p_{court|cl}\, p_{s|court}$. In both the US and European legal systems, the (high) discretionary power of the prosecutor is to determine which case should be disposed of before trial either by dismissal of the charges or by imposing certain obligations on suspects in exchange for laying the file aside. The picture is still incomplete unless the risk of the most severe outcome conditional on detection has been covered, that is, the certainty of a (unconditional) prison sentence. After including $p_{pris|s}$, that is, the probability of imprisonment given a conviction, the full decomposition of the probability of imprisonment (conditional on detection) looks as follows:

$$p_{pris|cl} = p\, p_{pris|s} = p_{cl}\, p_{court|cl}\, p_{s|court}\, p_{pris|s}. \quad (5)$$

Not surprisingly, also empirical indicators of $p_{pris|cl}$ vary across time and space (see Entorf and Spengler 2013) Thus, to summarize, the probability of a sanction depends on the interplay of many factors, and all of them are far from being constant parameters.

Reasonable public policy analysis and recommendations should take the role of all key players and their decisions, that is, interplay of police, prosecutors, and courts, into account. Only few studies also cover the risk of convictions, for example, by the ratio of convictions to arrests. Cornwell and Trumbull (1994), who were among the first applying panel econometrics for testing general deterrence models, present exceptional work because of their comprehensive list of law enforcement variables containing the probabilities of arrest, conviction (conditional on arrest), and imprisonment (conditional on conviction) as well as the severity of sanctions. However, the overall impression is that only few studies are taking account of a comprehensive list of factors.

In particular, the interplay of conviction rates and sentence lengths, that is, the essential components of certainty and expected severity of punishment, has been neglected. However, it is obvious that components of general deterrence do not work independently of each other. Missing factors of the law enforcement system might cause severe omitted variable biases (Entorf and Spengler 2013).

On the Impact of Severity

Death Penalty. The severity of punishment is the fundamental idea of capital punishment: "*. . . if rational people fear death more than other punishment, the death penalty should have the greatest deterrent effect*" (Ehrlich 1977, quotation found in Rupp 2008, p. 22). Although this statement is questionable, either because the expected sentence would be nil when there would be no (perceived) risk of detection or because "*rational*" suicide bombers expect going to paradise with the infamous 72 virgins, the focus of most studies in the aftermath of Ehrlich (1975) lies on the absolute deterrent effect of capital punishment. Most publications refer to US evidence, as can be seen from the fact that 71 out of 82 studies evaluated by Rupp (2008), p. 22, use US data and 5 are based on Canadian data. Ehrlich's (1975, 1977) articles have fueled an ongoing debate about the effectiveness of the death penalty. His results have been criticized for data errors, misspecification problems, and other methodological problems. Numerous subsequent studies have rejected but also confirmed significance of the death penalty. Donohue and Wolfers (2005) summarize several studies on the death penalty in the United States. They conclude that all outcomes are too fragile and that the number of executions is too low to draw any noteworthy and robust conclusion. This result is in line with the meta-study on the significance of death penalties by Dölling et al. (2009, Table 10), where median t-values of effects range between −0.5 and +0.1, that is, below usual significance levels. This survey is not the right place to summarize all facets of the complex debate on the death penalty which is interesting for its methodological aspects, but most probably the large majority of scientists from industrialized countries outside the USA would not consider it a practical and ethically tolerable alternative to lifelong sentences.

Evidence on the Length of the Prison Sentence and Prison Conditions. According to the aforementioned meta-study (Dölling et al. 2009, Table 3), most results using the average length of served prison sentences as an indicator of the severity of sanctions do not show statistical significance (median t-value = −0.6). This result is in line with the tenor of previous and recent surveys such as Eide et al. (1994), Durlauf and Nagin (2010), or Ritchie (2011). However, Durlauf and Nagin (2010) correctly state that most effects are measured as marginal effects in addition to already existing long sentences. Thus, more reliable evidence would be based on discontinuous jumps of severity. Levitt (1998) has found a significant drop in the offending of young adults when they reach the age of 18, that is, the age of jurisdiction for adult courts in Florida.

Other abrupt and unexpected changes of deterrence come from natural experiments. Maurin and Ouss (2009) and Drago et al. (2009) study the effect of external variations arising in response to collective pardons in France and Italy, respectively. Maurin and Ouss (2009) show that 5 years after release, those who have received a reduced sentence as a consequence of the pardon had a 12 % higher rate of recidivism than those who had received no reduction. In the case of the Italian clemency, inmates received a *conditional* reduction of prison sentences. In case of reoffending, they had to serve the remaining amount of their sentence (in addition to the new sentence). Drago et al. (2009) find that the threat of increased sanction continued after release: For every month the former prisoner would have to serve if convicted, there was a 1.2 % reduction in the propensity to recommit crimes. Both studies touch the problem of *specific deterrence*, that is, whether individuals would avoid future imprisonment because they are deterred by their own previous sentencing experience. However, in particular the study by Maurin and Ouss (2009) also tests the deterrent effects of longer prison sentences, though based on a subgroup of former inmates. In the case of Drago et al. (2009), the effect is a combination of certainty and severity because the threat of serving the remaining sentence also depends on the probability of detection and conviction.

Limitations and Extensions of the Classical Deterrence Model

Predictions of the fundamental model (as presented in Section 2) are based on a static model under regular neoclassical assumptions. The classical rational-choice model needs to be reconsidered in the face of challenging recent findings of behavioral economics. In particular, the (objective) detection probability and the disutility from punishment need to be adjusted given insights from prospect theory, myopia, and dynamic deterrence:

$$C_t = C(\underset{(-)}{\pi(p)},\ \underset{(-)}{\beta_c^{t+\tau} C_{C.t+\tau}},\ \underset{(-)}{\beta_{nc}^{t+\tau} E_{NC.t+\tau}},\ \underset{(-)}{E_{NC.t}}\, X). \tag{6}$$

The new elements of a *behavioral supply of offenses model* (Eq. 6) are to be introduced: Criminological research suggests that offenders have unusually high discount rates, that is, they place high value on immediate utility gains, whereas future events are strongly discounted, that is, they consider them as less important for current decisions than noncriminals. As consequences of criminal activities, if any, would have to be faced at some unknown time in the future, this so-called present bias (also called impulsiveness or myopia) leads to underestimation of expected *future* costs from punishment, $C_{C.t+\tau}$. In particular, adolescence, alcohol, or drug misuse (not to mention mental impairment) may lead to a very small personal weight of future consequences, that is, $\beta_c << 1$.

The classical static deterrence model also neglects future consequences of illegal activities which a rational forward-looking individual would take into account. Given the person will be detected and punished, she would expect diminished reemployment chances, reductions in social capital, relational problems, etc. Thus, rational individuals would also be deterred by the potential future reduction of expected legal utility gains, that is, shrinking $E_{NC,t+\tau}$, in response to the stigma of a criminal record. This potential threat is also called *dynamic deterrence*.

A related but different deviation from classical rational-choice and general deterrence models is the existence of *subjective* probabilities of detection and punishment, $\pi(p)$. These should be more precisely called decision weights because they do not satisfy the classical probability axioms. Allais (1953) was the first who criticized expected utility theory for its inconsiderate use of objective probabilities, that is, $\pi(p) = p$, in models of human behavior. Kahneman and Tversky (1979) developed an alternative model called prospect theory. They emphasized that "… *people are limited in their ability to comprehend and evaluate extreme probabilities, highly unlikely events are either ignored or overweighted […] Consequently, π is not well-behaved near the end-points*" (Kahneman and Tversky 1979, pp. 282–283). Experiments show that individuals overweight low probabilities of gains, that is, $(1 - \pi(p)) > (1 - p)$ in case of criminal gains, which implies $\pi(p) < p$, that is, underweighting the risk of being caught and punished. The overestimation of the criminals' own ability to avoid any apprehension and sanction is also known as *overconfidence* in the behavioral economics literature (McAdams and Ulen 2009).

The perceived risk of detection of re-offenders is of particular importance because of the high share of crimes committed by recidivists. Piquero and Pogarsky (2002) argue that criminals behave according to the belief that "lightning won't strike twice": They underestimate the probability of being detected and convicted because they (erroneously) believe that the risk of being punished again is very low. Some further details and discussions on the *perceived* (instead of objective) risk of being punished can be found in McAdams and Ulen (2009) and Ritchie (2011).

The Threat of Punishment When Trust in Criminal Law Is Absent

One of the stylized facts in empirical criminological research is the individual victim-offender overlap. A prominent explanation of the victim-offender overlap is the subculture-of-violence approach (Singer 1981), according to which individuals who attack others risk retaliations from former victims. Rational-choice theory seems to be generally questioned by such "*irrational*" retaliatory behavior of victims and criminals. However, retaliation can be seen as a rational deterrence strategy in a *prelegal* or *pre-societal* community. Given lacking access or trust in the public institution of criminal law systems in modern societies, victims might be tempted to take the law in their own hands. In particular in disadvantaged neighborhoods and subcultural societies where the retaliatory ethic of the *code of the street* (Anderson 1999) is used in lieu of criminal codes, the credible threat of punishing by strong retaliation might deter potential future perpetrators.

Rational-choice models are often criticized because they ignore that cognitive restrictions and emotional factors such as time pressure, peer group influence, or anger restrict the long-run *optimality* of individual decisions. As regards the overlap of victimization and offending, anger seems to be the major motivation of retaliatory behavior, as also stressed by many criminological and psychological research papers. Anger in response to perpetrated injury, frustration, and unfair treatment can be a triggering event that motivates *striking back*, not necessarily to the perpetrator himself but also to noninvolved bystanders and other available victims, also at some later point in time. Such behavior is often the consequence and origin of norms of honor and respect (or fear of dishonor and shame, respectively), prevailing and potentially escalating in subcultural societies (Anderson 1999) and serving as a deterrent factor when trust in criminal justice systems is absent. Such retaliatory behavior is not restricted to deprived subgroups: As suggested by findings in Fehr and Gächter (2002), punishing unkind behavior of others or *negative reciprocity* seems to be a social norm rooted in general human behavior. Participants in their experiments revealed some *altruistic punishment* behavior, that is, they punished defectors even when they had costly disadvantages from the retaliation. This so-called pro-social behavior has its origin in the notion of fairness as can be seen from the outcome of many ultimatum-game experiments: Responders often destroy any portion of their (guaranteed) gains when they perceive the proposal of the proposer as unfairly low. Thus, anger about unfair treatment is the individual motivation, but its social effect could be deterrence.

Future Directions

Certainty and severity of sanctions form the two cornerstones of general deterrence. This survey reveals that its underlying classical rational-choice theory has been reconsidered by recent research, yielding important insights from bounded rationality and behavioral economics. Future research will continue to analyze the threat of punishment, but the focus will be on the role of hyperbolic discounting, overconfidence, perceived risk, ambiguity, prospect theory, and dynamic models, just to name only a few of many interesting fields. Also the empirical approach has changed dramatically during the last 10 years or so. Modern criminological research is often based on laboratory and (quasi) natural experiments (such as changes in legislation or clemencies) which create convincing external variations of deterrence variables. From a criminal policy point of view, the problem of cost-efficient use of deterrence instruments has a high potential for future research. Given the relatively small effect coming from the severity of sanctions, one might be tempted to shift resources from imprisonment to policing. Though certainly high on the political agenda, one should nevertheless be aware of the limited empirical evidence (mostly coming from the USA and dealing with marginal effects of already long sentences). Moreover, alternative (long-run) cost-benefit considerations such as shifting scarce resources to education and families should be taken into account, since both poor education and family background are identified as the major reasons of lacking legal opportunities over the life cycle and resulting criminal careers.

Child Pornography

Richard Wortley
Jill Dando Institute of Security and Crime Science, University College London,
London, UK

Overview

The pictorial and written portrayal of children as sexual objects has existed through the millennia and across civilizations, with examples dating back to ancient Greece, Rome, China, and India (Bullough 2004; Linz and Imrich 2001). In the modern era, the nature and availability of child pornography has been driven by technological advances, first the invention of the camera in the early nineteenth century and more recently the advent of the Internet and associated digital technologies towards the end of the twentieth century. The Internet, in particular, has transformed the production, dissemination, and consumption of child pornography, increasing exponentially the amount of material available and the number of people accessing that material. Prior to the Internet, images were traded furtively in hard-copy form among relatively small groups of dedicated users. The technical quality of the images was poor, the range limited, and the distribution networks unreliable and highly restricted (Ferraro and Casey 2005). By the early 1980s, law enforcement agencies could justly claim considerable success in stemming the international and domestic trafficking of child pornography. With the Internet and digitization came the ability to access vast quantities of technically high-quality images, cheaply, apparently anonymously, and all from the comfort of home.

It is argued in this chapter that the current child pornography problem is the result of the interaction between two factors. First, child pornography would not exist if there was not a pool of individuals – mostly men – who derive sexual gratification from viewing sexual images of children. This pool comprises those who have a preferential sexual attraction to children, but it also includes many individuals with a latent, casual, or ill-formed potential to become aroused by sexual images of children. Second, the scale of the child pornography problem that confronts society in the twenty-first century is a function of the increased availability and ease of access of child pornography provided by the Internet. The Internet is not simply an alternative delivery mechanism by which dedicated offenders satisfy their sexual cravings, viewing material that they would have otherwise obtained through some other means; the Internet has played an active role in stimulating the growth of child pornography, drawing in many individuals who, in the pre-Internet era, would have had neither the necessary drive nor the know-how to seek out and obtain child pornography.

What Is Child Pornography?

Child pornography is defined as a legal term for the purposes of investigation and prosecution and as a working construct for the purposes of research, prevention, and advocacy. A problem with legal definitions is that the meaning of both "child" and "pornography" varies from jurisdiction to jurisdiction. The age of consent around the world can be as low as 12 years (e.g., some parts of Mexico) and as high as 18 years (some jurisdictions in the United States), with 16 years perhaps the most common in the Western world (e.g., the United Kingdom, the Netherlands, New Zealand, Canada, and most parts of Australia) (e.g., Avert n.d.). Likewise, definitions of pornography also vary, and acts that are illegal in some countries may be legal in others. Generally, however, legal definitions distinguish between obscene material and artistic portrayals of nudity and eroticism, judging what is acceptable or unacceptable against community standards. Typically, more stringent standards are applied to images involving children than to images involving adults; child pornography need not necessarily involve obscene behavior but may include acts that are lascivious or suggestive.

The International Centre for Missing and Exploited Children (2008) conducted an audit of child pornography legislation among the 187 members of Interpol. It found that 36 countries do not specifically criminalize possession of child pornography, while a further 95 countries had no child pornography legislation at all. For countries that do define child pornography, there are variations in the exact content of the legislation. Apart from the age of the child, there is disagreement about whether computer-generated images are legal. For example, in a recent Australian case, a cartoon depicting Bart and Lisa from the Simpsons engaged in sexual acts was found to be pornographic, a judgment that could not occur in the USA.

Nonlegal definitions of child pornography can be more broadly framed than legal definitions and so avoid some of the debates around specific elements. According to the Office of the United Nations High Commissioner for Human Rights (2002), "Child pornography means any representation, by whatever means, of a child engaged in real or simulated explicit sexual activities or any representation of the sexual parts of a child for primarily sexual purposes." Child pornography may include still photographs, videos, audio recordings, and written material. It also may involve a wide range of acts that vary in degree of explicitness. Taylor et al. (2001) developed the COPINE scale that delineated ten levels of child pornography severity, ranging from nonsexualized pictures of children collected from legitimate sources such as magazines to

Child Pornography, Table 1 The COPINE scale

Content	Description
1. Indicative	Nonsexualized pictures collected from legitimate sources (e.g., magazines)
2. Nudist	Naked or semi-naked pictures of children in appropriate settings collected from legitimate sources
3. Erotica	Photographs taken secretly of children in which they reveal varying degrees of nakedness
4. Posing	Posed pictures of children in varying degrees of nakedness
5. Erotic posing	Pictures of children in sexualized poses and in varying degrees of nakedness
6. Explicit erotic posing	Pictures emphasizing the genitals
7. Explicit sexual activity	Record of sexual activity involving a child, but not involving an adult
8. Assault	Record of children subjected to sexual abuse involving digital touching with an adult
9. Gross assault	Record of children subjected to sexual abuse involving penetrative sex, masturbation, or oral sex with an adult
10. Sadistic/ bestiality	Record of a child subjected to pain or engaging in sexual activity with an animal

Source: Adapted from Taylor et al. (2001)

graphic depictions of children engaging in sexual acts with other children, adults, and even animals (Table 1). In a content analysis of child pornography identified by the Internet Watch Foundation (2010), 73 % of victims were assessed as being under 10 years of age, and around two-thirds of the images involved penetrative sexual activity between the victim and an adult, equivalent to levels nine to ten on the COPINE scale.

It should be noted that many researchers and advocacy groups object to the term child pornography, believing that it trivializes the severity of the behavior and may facilitate excuse-making by offenders by linking it to consensual adult erotica. It is argued that every so-called child pornography image is a record of a child's sexual exploitation. Alternative terms include child abuse images, child sexual abuse material, documented child sexual abuse, and child exploitation material.

Child Pornography and the Internet

The Internet and associated technologies have transformed the way that child pornography is produced, how it is distributed to users, and how those users view and retain it. While child pornography may be produced professionally by organized crime groups, the ready availability of inexpensive electronic recording devices (digital cameras and video recorders) permits individual offenders to create "high-quality," homemade images involving records of their own sexual abuse exploits. The Internet then provides an unparalleled distribution network, connecting producers and users from all corners of the world. As with the production phase, the distribution of child pornography may involve organized crime rings, but the Internet also allows offenders to interact directly with one another, exchanging files and providing information and social support. For users, the Internet means that vast quantities of child pornography can be acquired inexpensively and accessed with apparent anonymity at any time or place. The downloaded images do not deteriorate and can be conveniently catalogued, stored, and retrieved.

The Internet provides a number of methods by which child pornography can be distributed and accessed. Child pornography websites may be posted on the World Wide Web. Around three-quarters of these child pornography websites are commercial enterprises (Internet Watch Foundation 2008). In order to thwart detection efforts of authorities, images are often hosted on temporary websites, and customers may need to negotiate numerous redirects before they arrive at the target site. If a particular website is closed down, the images may reappear shortly thereafter at another location. Nevertheless, the open web is a relatively risky place to seek child pornography and tends to attract novice offenders; through the vigilance of the police and Internet service providers, the more dedicated and experienced offenders are increasingly being driven to deeper levels of the Internet (Jenkins 2001). Offenders may communicate directly with one another via chat rooms, newsgroups, bulletin boards, and peer-to-peer networks (Ferraro and Casey 2005; Wortley and Smallbone 2006, 2012). Entry into these offender networks may be highly controlled; potential members may need to gain the trust of existing members, and a password may be required to order to participate. As discussed further on, infiltration of these groups by undercover police is a major priority of agencies tasked with controlling child pornography.

Estimates of the size of the Internet child pornography problem are notoriously rubbery, usually involving little more than someone's best guess. Various indices have been used. The number of offenders worldwide has been estimated in the millions (National Center for Missing and Exploited Children 2005); the number of children estimated to be victims of child pornography is between 10,000 and 100,000 (Maalla 2009); at any one time, there are estimated to be over one million pornographic images of children on the Internet, with 200 new images posted daily (Wellard 2001); offenders have been arrested with as many as a million downloaded child pornography images (NewsFlavor 2011); and child pornography on the Internet is estimated to turn over between $3 billion (Ropelato 2003) and $20 billion (Hoover 2006) per year. Some have cautioned against the uncritical acceptance of such figures and being swept along in a moral panic (Jewkes 2010; Schottenfield 2007). Nevertheless, most commentators agree that child pornography is a serious problem that has escalated dramatically with the growth of the Internet.

Who Are the Offenders?

Perhaps the most remarkable feature of identified child pornography offenders is their general lack of remarkable features. There is no single offender type and nor is there a consistent set of sociodemographic or psychological characteristics that distinguish offenders from nonoffenders. Those arrested for downloading online child pornography have come from all walks of life and have included judges, dentists, soldiers, teachers, rock stars, and police officers. In a survey of 605 individuals arrested for possession of child pornography in 2006, Wolak et al. (2011) found that most were white (89 %), male (99 %), 26 years of age or older (89 %), and in full-time employment (61 %). Thirty-one percent were married or living with a partner, 29 % earned more than $50,000 per year, and 16 % were college graduates. A minority had previous sexual (9 %) or nonsexual (27 %) offence convictions.

Psychological assessments of offenders have produced mixed and sometimes conflicting findings, with few clearly distinguishing features emerging. Few arrestees have been found to be mentally ill (6 %) or sexually disordered (5 %) (Wolak et al. 2011). Laulik et al. (2007), using the Personality Assessment Inventory, found that fewer than 10 % of offenders scored in the clinically significant range on any of the clinical scales, with the exception of depression (30 %), borderline features (17 %), and schizophrenia (13 %). Tomak et al. (2009) compared child pornography offenders with incarcerated contact sexual offenders on the Minnesota Multiphasic Personality Inventory. Mean scores fell below the clinically significant levels for both groups, with the child pornography offenders scoring significantly lower than the other group on the psychopathic deviation and schizophrenia scales. Babchishin et al. (2011) conducted a meta-analysis of studies that have used psychological inventories to compare child pornography offenders with other sex offenders. In general, online offenders had fewer problems with victim empathy, cognitive distortions, and emotional identification with children, and there were no differences in loneliness and self-esteem. However, online offenders showed greater sexual arousal to images of children than did contact offenders, suggesting higher levels of pedophilia. One explanation for this latter finding is that the laboratory conditions under which sexual arousal was measured closely resemble the actual behavior of online offenders. In other words, sexual arousal on online offenders may be specifically triggered by sexual images of children, but this may not necessarily indicate a generalized sexual attraction to children in an offline environment (Wortley and Smallbone 2012).

It should be noted that almost all studies examining the characteristics of child pornography offenders have involved incarcerated samples. This is problematic because police tend to target the most serious offenders for investigation, and so results of research on these offenders are likely to be skewed. In a rare exception, Seigfried et al. (2008) anonymously surveyed 307 general Internet users. They found that 30 respondents admitted to having accessed child pornography online. Most surprisingly, ten of the users were females, representing a rate of offending that far exceeds official arrest figures. Overall 16 % of males and 6 % of females admitted accessing child pornography. There were no differences between users and nonusers on the "big-five" personality dimensions (extraversion, neuroticism, openness, conscientiousness, and agreeableness), but users scored lower on internal moral choice and higher on amoral dishonesty, suggesting that they were more likely to construe their behavior as morally acceptable. Overall, these findings indicate that there is a significant "dark figure" of child pornography use and that differences between offenders and non-offenders shrink when the full range of offenders is taken into consideration.

Perhaps the most contentious issue concerning the characteristics of offenders is the extent to which users of child pornography also engage in contact sexual offending. Conceptually the relationship between online and contact offending may take several forms. Child pornography may be sought out by individuals who have an existing sexual attraction to children; child pornography may have a long-term corrosive effect, and individuals may become increasingly attracted to child pornography and desensitized to the harm experienced by victims; or child pornography may be the sole outlet for an individual's sexual attraction to children and may even help him resist engaging in contact offending (Wortley and Smallbone 2006). In a meta-analytic review of the research, (Seto et al. 2011) found that on average 12 % of child pornography offenders also had official contact sexual offending histories, with the range reported in individual studies between 0 % and 43 %. Examining self-report data, the average prevalence of contact offending was 55 % with a range of 32–85 %. However, the studies examined by Seto et al. did not distinguish between child pornography users and child pornography producers. A great deal of the available child pornography involves offenders recording their own sexual abuse exploits and so necessarily involves contact offending. Again, too, all of the research in this area has been conducted on convicted offenders who, because of the priorities set by police when selecting cases to investigate, may be more likely than undetected offenders to also commit contact offences. It remains unclear how many individuals who view child pornography also commit contact offences.

While the research reviewed in this section generally indicates that on average child pornography offenders exhibit few distinguishing sociodemographic or psychological, some studies have reported considerable within group variation. It may be that averaged findings mask the existence of distinct subtypes of offenders. Cooper et al. (1999) suggested a three-category typology of general Internet pornography users that may be useful when considering the particular case of child pornography users. The categories are:

1. *Recreational users*: They access pornography sites on impulse, out of curiosity, or for short-term entertainment. They are not seen to have long-term problems associated with pornography use.
2. *At-risk users*: They are vulnerable individuals who have developed an interest in pornography, but may not have done so had it not been for the Internet.
3. *Sexual compulsive*: They seek out pornography to satisfy existing pathological sexual interests.

This typology, while not yet empirically verified for child pornography offenders, has good face validity and can help explain the dramatic escalation in the child pornography problem that has accompanied the growth of the Internet. While it may be comforting to divide the world neatly into pedophiles ("them") and nonpedophiles ("us"), in reality the potential to become sexually attracted to children falls along a continuum, and under the "right" conditions many men may be tempted to view child pornography (Wortley and Smallbone 2012). For the individuals in categories 1 and 2 of Cooper et al.'s (1999) typology, the Internet has provided the easy opportunity for them to explore hidden thoughts and desires in order to satisfy their sexual curiosities. Moreover, the virtual world is a disinhibiting environment that encourages individuals to engage in riskier behavior than they would ever consider in the real world (Quayle and Taylor 2001). Had these individuals lived in the pre-Internet era, it is likely that most would not have gone to the effort to seek out hard-copy child pornography. To be sure, there are offenders (those in category 3 of the typology) who are unambiguously attracted to children and who will determinedly and repeatedly seek out opportunities to access child pornography. Even for these offenders, however, had they lived in the pre-Internet era, the task of locating child pornography would have been much more difficult, their choice would have been restricted, and their collection of images would have been much smaller.

Policing the Net

The investigation of child pornography on the Internet presents unique challenges for law enforcement agencies (Wortley and Smallbone 2012). The Internet is complex network of networks with a decentralized structure that makes it difficult to screen content, enforce legislation, and track offenders. Even if one pathway to a child pornography site is blocked, there are many alternative pathways that can be taken to reach the same destination. Moreover, the reach of the Internet is global, and local citizens may access child pornography images that were produced and stored on another continent. Most investigations of child pornography on the Internet, therefore, will cross jurisdictional boundaries and require cooperation among agencies, often at an international level. International cooperation is in turn impeded by a lack of effective legislation in many countries and inconsistencies between countries where legislation does exit (International Centre for Missing and Exploited Children 2008). There is variation, too, in the capacity and commitment of countries to enforce child pornography laws and to act against offenders, either because of cultural reasons, through a lack of resources and know-how, or because of corruption (UNICEF 2009). In addition, rapid technological developments such as peer-to-peer networks, anonymous remailers, and file encryption make it easier for offenders to avoid detection (Ferraro and Casey 2005). Finally, the sheer volume of child pornography on the Internet and the number of offenders accessing that pornography can simply overload police resources. Police cannot hope to arrest every offender of whom they become aware and must prioritizetheir effort, for example, by targeting those offenders who possess "first-generation" (i.e., previously unknown) images that indicate the offender has made a record of his own sexual offending.

In order to meet these challenges, police must acquire new knowledge about the characteristics and modus operandi of child pornography offenders, develop specialized technical expertise in online offending, and forge links with other police agencies, the Internet industry, and nongovernment organizations. Many larger police departments will have dedicated Internet child exploitation teams. These teams may be supported by national agencies that provide specialized expertise and training, maintain centralized databases, track offenders and victims across jurisdictions, and help coordinate investigations. The activities of national agencies may in turn be coordinated through various international agencies and programs. An example is the Virtual Global Taskforce (VGT), an international partnership comprising nine members – national agencies from seven counties (Australia, Canada, Italy, New Zealand, the United Arab Emirates, the United Kingdom, and the United States) and two international agencies (Europol and Interpol). The VGT conducts coordinated international law enforcement operations and helps track down victims and offenders across borders.

Krone (2005) suggests that police investigations can be divided into four main types. The first type of investigation involves the targeting of individual offenders. Investigations may begin with information received from the public, for example, via one of the various child pornography hotlines. Child pornography may also be discovered during the investigation of contact child sexual abuse cases. There are also a number of documented cases in which computer repairers have found child pornography on an offender's hard drive and notified police. The most notorious case this category involved the pop singer Gary Glitter.

The second type of operation targets offenders who are members of covert groups and who operate in closed chat rooms, newsgroups, and peer-to-peer networks. Investigation may require police to operate undercover, infiltrating an offender group in the guise of a prospective member. Once the group has been infiltrated, the arrest of one offender and the interrogation of his Internet records can quickly lead to the arrest of other members of the group. There have been a number of international operations targeting covert groups, including Operation Cathedral, Operation Ore, and Operation Rescue (Wortley and Smallbone 2012). Operation Rescue, for example, involved the investigation of a covert newsgroup that was run from the Netherlands and had 70,000 members across the United Kingdom, the United States, New Zealand, Australia, and Thailand. The group was detected in 2007 by investigators in Australia and the United Kingdom, and an operation was launched, coordinated through the VGT. Officers infiltrated the group and took over the account of the UK administrator, giving them access to the member list. The Dutch founder of the group was jailed and 640 members were identified, 184 of whom were arrested.

The third type of operation targets website subscribers. These are offenders who purchase access to child pornography sites, which are typically set up as commercial enterprises. Because offenders need to pay for images, once accounts of the business are seized, offenders are usually tracked through their credit card details. The operation targeting Landslide Productions (called Operation Avalanche in the United States and Operation Ore in the United Kingdom) is perhaps the best known in this category. Landslide Productions was a child pornography company run by from Ft Worth in Texas and involved a complex network of some 5,700 computer sites around the world. Online customers, of whom there were more than 250,000, provided credit card details to obtain network access. The investigation began in 1999 when the US Postal Inspection Service discovered that Landslide's customers were paying monthly subscription fees into a post office box or via the Internet. A joint investigation between the Postal Inspection Service and the Internet Crimes Against Children Task Force (ICAC) was conducted over 2 years. Landslide's accounts were seized and officers tracked down the owners of credit cards used to pay for site access. There were 120 arrests in the United States, including the ringleaders in Texas and 1,300 arrests in the United Kingdom.

The fourth type of operation involves police stings. Stings may take a number of different forms. Undercover police may enter youth-oriented chat rooms posing as children and engage predatory pedophiles lurking in the group. Police may also set up "honeypot" traps, the best known example of which was Operation Pin. The operation was started in 2003 by West Midlands (UK) police and expanded to include other VGT members (the FBI, the Australian Federal Police, the Royal Canadian Mounties, and Interpol). A bogus website was set up purporting to contain child pornography. Visitors to the site were required to go through a series of web pages and at each point it was reinforced that they were in a child pornography site. If they ultimately tried to access an image, their credit card details, which they were required to provide to log in, were captured. The operation has resulted in numerous arrests although precise numbers are not available.

Prevention

Despite the best efforts of police, arresting offenders is not a viable long-term solution to the problem of Internet child pornography.

Certainly, offenders – and especially those involved in the direct sexual abuse of children – ought to be targeted by law enforcement personnel and arrested where possible. But no more than a few thousand people are arrested annually for child pornography offences in the United States (Wolak et al. 2011) and fewer still in other countries. As has been discussed, even highly successful coordinated international operations typically result in fewer than a couple of hundred arrests worldwide. If we accept that the number of individuals actively accessing child pornography via the Internet is in the millions, these figures represent a drop the bucket. For similar reasons, we cannot rely on the therapeutic interventions with known offenders – the usual response of psychologists – to make any significant dent in the problem. The prevention of Internet child pornography cannot be approached simply as a problem of individual sexual deviancy. The proliferation of child pornography in the Internet age has been a function of the increased opportunity offenders have been given to access images, and tackling the child pornography problem in any serious way must be centered on reducing that opportunity.

The task of reducing the opportunities offered by the Internet can be viewed in terms of the situational crime prevention model (Clarke 2008). This involves increasing the effort, increasing the risks, reducing rewards, removing excuses, and reducing provocations associated with accessing child pornography. The following discussion provides an example of each of these strategies. The list is not intended to be exhaustive (see Wortley and Smallbone 2012, for a more detailed analysis).

Increasing the effort involves making it more difficult for offenders to access images on the Internet. The principal strategy is to reduce the amount of child pornography that is available. When police become aware of child pornography on the Internet in many jurisdictions, they are empowered to issue a notice and take down (NTD) order, requiring Internet service providers (ISPs) to remove or filter (i.e., block the pathway to) the offending images. Arguably there has been some success in reducing the volume of child pornography in open areas of the Internet such as the World Wide Web. The Internet Watch Foundation (2010) reported that they took action against nearly 17,000 child pornography domains in 2010 and that it has on average 500 domains on its blacklist at any one time. One consequence of police activity has been to drive offenders to deeper and more secure levels of the Internet. While this is of concern, it is evident that offenders feel vulnerable in open areas of the Internet. The more hidden child pornography becomes, the more difficult it is for the offenders themselves to access it.

Increasing the risks most obviously involves making it more likely that the offender's online behavior will be detected. As has been discussed, however, even with active policing of the Internet realistically, an individual's chance of being arrested is in fact very small. But the risk of detection and the *perceived* risk of detection are two different things. Police stings described earlier demonstrate the importance of this distinction. It is noteworthy that the launch of Operation Pin was accompanied by widespread media coverage. The police did not hide fact that they were setting up honeypot traps, but rather they gave offenders explicit forewarning. Their aim was not to maximize the number of arrests but to create the uncertainty in the mind of potential offenders about safety of sites that they were considering accessing.

Reducing rewards involves frustrating attempts by offenders to derive benefits from child pornography. This strategy has been used particularly to target the distributers of child pornography who are seeking to benefit themselves financially. The Financial Coalition Against Child Pornography (FCACP) is a grouping of 35 ISPs, credit card companies, banks, and other companies providing online payment services. The goal of FCACP is to undermine the commercial viability of child pornography by tracking the flow of money in child pornography transactions and blocking payments for illegal downloads. The Financial Coalition Against Child Pornography (2011) claim that there has been a 50 % drop in the number of commercial child pornography sites following their activities. There has also been a dramatic increase in the cost of commercial child pornography as a result of the financial squeeze that has been applied, with monthly subscriptions rising from around $30 per month in 2006 to as much as $1,200 per month.

Removing excuses involves permitting offenders fewer opportunities to minimize the seriousness of child pornography offending. Offenders may take comfort in the belief that viewing child pornography does no harm (e.g., "They are just images not real people") and even that it is not illegal. Some countries (e.g., Norway) include an additional element in the NTD procedures designed to challenge these excuses. When access to a child pornography site is blocked, instead of a standard error message, the person trying to access the site receives a "stop" page containing a warning message. The precise wording of the stop page can vary, but the general intention is to make it clear to the potential offender that the behavior he is contemplating is illegal.

Reducing provocations involves removing situational factors that might trigger the impulse to view child pornography. For many offenders involvement with child pornography is an insidious, progressive process (Quayle and Taylor 2003). One pathway to child pornography is through legal adult-focused pornography and child pornography embedded within legal sites may be particularly problematic. Individuals may first encounter child pornography without having to actively seek it out and when they are already sexually aroused. While law enforcement agencies rightly focus resources on the most serious forms of child pornography, which typically appears on dedicated sites, attention should also be given to embedded child pornography.

Conclusion

While child pornography has a long history, the scale of the problem has increased exponentially since the introduction and rapid growth of the Internet. There are undoubtedly many more child pornography images available now, and many more individuals accessing those images, than would have been the case images had the Internet not existed. The Internet has created opportunities for individuals with no more than a casual interest in child pornography to satisfy their sexual curiosities and has allowed dedicated offenders to give full expression to their obsession, amassing collections that may exceed a million images. The Internet is not just an alternative method by which child pornography may be accessed; the Internet is a *cause* of child pornography.

Policing the Internet presents unique challenges for law enforcement. Despite the establishment of dedicated police units to tackle child pornography, and unprecedented international cooperation, the sheer volume of the problem threatens to overwhelm policing resources. Capturing personal details of offenders and launching prosecutions against those individuals is time consuming and resource intensive, and police become aware of many more offenders than they could possibly arrest. As well as prioritizing efforts on the most serious offenders, greater attention must be given to prevention. If the current child pornography problem is a product of the increased opportunities afforded by Internet, then solutions to the child pornography problem must seek to reduce these opportunities. Admittedly the task is not an easy one and it is easy to become pessimistic about the chances of success. But it is undoubtedly true that without the current prevention efforts, the problem would be much worse than it currently is.

Overview

Looking at civil remedies through the broad prism of opportunity theory – which includes situational crime prevention (SCP) and its related theoretical and practical approaches – has a number of advantages for those whose primary interests lie either in civil remedies or in SCP. For those interested in civil remedies and third-party policing (TPP), this analysis does the following:

- Provides an integrated set of articulated concepts, with linkages to other similar approaches, for examining how civil remedies can be used for crime-prevention purposes
- Highlights some of the untapped crime-preventive potential of civil remedies

For those interested in SCP, this analysis aims to make the following clearer:

- How SCP operates to prevent crime opportunities
- How it might operate differently if civil remedies were used more often
- How it might be expanded to look at the mechanics of the crime-prevention process in more detail

This entry defines, in detail, SCP, civil remedies, and TPP, and discusses classification systems that have been used to highlight important features of both SCP and civil remedies. It uses four different "approaches" based on SCP and other related opportunity theories to examine how civil remedies could be used as part of SCP. Approach 1 focuses on the 25 techniques of situational crime prevention, finding that almost all of the techniques appear to be compatible with the use of TPP. Approach 2 looks at 25 individual SCP measures, how they operate to limit crime, and how they might be able to be adapted to incorporate civil remedies. Approach 3 looks at the different types of routine-activity controls available in relation to a crime event, how these controls could operate to prevent crime in terms of the SCP techniques, and how civil remedies might be able to be used to assist this process. Finally, Approach 4 uses a single crime script to illustrate the application of a civil remedy to a crime-prevention initiative, for use in planning, implementation, and evaluation. In effect, it unpacks and repackages the multiple layers of control involved when civil remedies are used in crime prevention. Although the potential uses of civil remedies are very broad, the need for careful assessment of potential effectiveness and efficiency, and the possibility of overregulation and other unintended consequences, is stressed. Caution is also recommended with the possible expansion of the use of civil remedies into criminal lifestyles as part of an opportunity-theory approach.

Fundamentals

An Opportunity-Theory Approach: Situational Crime Prevention and Related Approaches

"Situational crime prevention" refers to the attempt to alter settings or "situations," in which potential offenders might otherwise find themselves, so that it is less likely for crimes to occur at that time or place, in that manner, against that target, or with as severe an effect (see Clarke chapter in Wortley and Mazerolle 2008). It does not rely on understanding any long-term motivational characteristics of these potential offenders. Instead, it uses a variety of techniques to block crime opportunities or otherwise make crime less attractive for potential offenders. Its focus is on the more proximal causes of behavior and is intended to limit the harm before it occurs.

A number of different theoretical and practice perspectives have influenced the development of SCP theory and practice since it was developed initially by Ron Clarke and others (see discussion in Clarke 2010). Only two of these perspectives are discussed at length here – the routine activity approach (RAA) and the rational choice perspective (RCP). Although other perspectives, e.g., designing products against crime (see Ekblom 2005), and crime pattern theory (see, e.g., Brantingham and Brantingham chapter in Wortley and Mazerolle 2008), are useful for understanding the full scope of the use of civil remedies in crime prevention, RAA and RCP are particularly useful for highlighting the features of SCP that provide the sharpest focus for understanding civil remedies and third-party policing in terms of SCP and the opportunity-theory approach.

Civil Remedies

A civil remedy has been defined as "an action taken by an authoritative body – a legislature, a court, or an administrative agency – to enforce compliance with prescribed conduct or to impose a cost for failure to comply" (Mann 1992, p. 1908). As Cheh (1991) has pointed out, traditionally, with the exception of behaviors subject to regulatory safeguards, those who harm another person have been potentially subject to criminal law sanctions brought by the state or to civil law remedies sought by the harmed party. Only in the last 40 years or so has the civil law been used by the government, in her example, by the US federal government to bring divestiture and treble damage actions against businesses run by both white-collar and organized-crime offenders under the Racketeer Influenced and Corrupt Organizations Act (RICO). At its best, the threat of this civil action is meant to disrupt criminal activities in a manner that may not be achieved through the ordinary workings of the criminal law where punishable behavior is set out in a statute and then punished if carried out. The civil aspect of this legislation not only focuses on other aspects of the crime or crimes, it allows the government to use a branch of the court system that has a lower standard of proof than is required in a criminal proceeding, where guilt beyond a reasonable doubt is used. Although Cheh (1991) pointed out some legal limitations to their use, civil remedies can be used both when the focus of the remedy is on the primary actor, the offender, and when they are used against another party who is not directly involved in the criminal activity. Because they are available and legal, however, does not necessarily mean that they are suitable, in terms of their crime-preventive effects, or desirable, in terms of their unintended consequences. These issues are discussed below in the section entitled "Potential Controversies."

Third-Party Policing

"Third-party policing" (TPP) is the term used by Buerger and Mazerolle (1998, p. 301) to refer to "police efforts to persuade or coerce nonoffending persons to take actions which are outside the scope of their routine activities, and which are designed to indirectly minimize disorder caused by other persons or to reduce the possibility that crime may occur." They noted that, in practice, this persuasion or coercion most often operates through civil law regulations. The "third party" is the one who is forced to do the "policing." The term refers to actions undertaken through a variety of partnerships between police and other agencies and addresses both crime-preventive aims and crime control (Mazerolle and Ransley 2005). One could argue also that efforts by other crime-fighting elements within the government, such as a prosecutor carrying out community prosecution (Boland 2001), are also included under the TPP umbrella.

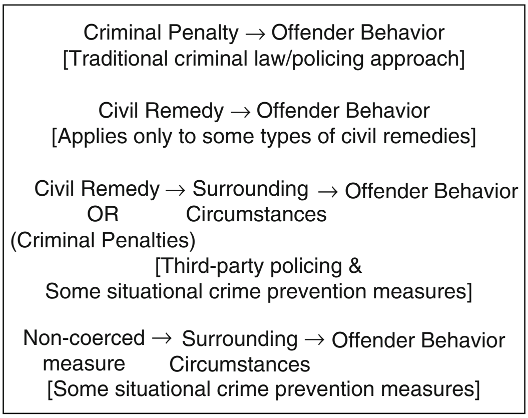
Civil Remedies and Crime Prevention

Civil remedies include such a broad group of actions that they do not easily fit under a single label developed for discussing crime prevention. For example, in the well-known typology of crime prevention developed by Brantingham and Faust (1977), which uses a public-health-model approach to the prevention of crime, a civil remedy such as a zoning code could be used as a form of primary prevention to prevent clubs from opening in an area, thereby changing what might otherwise be a potentially favorable environment for selling drugs. Another civil remedy, such as a curfew, might be used as a secondary crime-prevention measure to prevent teens (a group at risk for delinquency) from driving after midnight except in special circumstances. While a third civil remedy, such as an offender-notification provision, might be targeted at convicted felons as a form of tertiary prevention (of those who have displayed the unwanted behavior or condition).

Civil remedies can also be examined according to the means used to achieve a crime-prevention result. In terms of social prevention, the civil remedy is used to change social relations as a way of preventing crime in the future. For example, civil injunctions have been used to prevent gang members from associating with other gang members (Maxson et al. 2005), with the intention of disrupting the group's social relations. In terms of situational crime prevention (SCP), civil remedies can be used as part of an effort to reduce the opportunities for a potential offender to do crime in a particular setting or situation. An example of this type of application is when a city uses housing-code enforcement to get a landlord to alter the physical environment around a public housing unit so that many of the conditions favorable to drug sales are eliminated (Green 1996). Although civil remedies can operate within a variety of crime-prevention frameworks, in this entry, the focus is on using the integrated concepts associated with SCP, and its related theoretical perspectives, to examine how civil remedies are or can be used to effect opportunity reduction.

One major advantage of the situational approach, when compared to traditional rehabilitative or early-prevention approaches, is that it does not require preventers to be able to identify who the offender or potential offender is. This has implications for the use of civil remedies as part of a situational scheme, namely that preventive techniques or interventions that do require identifying offenders are not, strictly speaking, examples of SCP. Thus, they are subject to the same types of constraints related to detection that traditional post-offense policing faces. But they face another type of constraint or criticism that does not usually relate to SCP: The state is trying to impose a negative sanction on behavior without providing criminal law safeguards, as noted previously (see, e.g., Cheh 1991; Mann 1992).

Just as not all civil remedies fall under an SCP umbrella, not all SCP fit under a TTP umbrella. While a situational measure *can* be carried out by non-policing parties who are subject to civil sanctions for nonperformance of some required action, SCP does not *require* that the measures be carried out either with non-policing third parties nor does it *require* a threat of civil sanctions for these parties to carry out situational measures. Figure 1 sets out a simple framework for understanding the usual legally derived mechanisms that operate to influence potential



Criminal Penalty → Offender Behavior
[Traditional criminal law/policing approach]
Civil Remedy → Offender Behavior
[Applies only to some types of civil remedies]
Civil Remedy → Surrounding → Offender Behavior

[Some situational crime prevention measures]

Civil Remedies, Fig. 1 Simple comparative framework of the causal influences of different types of incentives on potential offenders' criminal behavior

criminal behaviors. The "surrounding circumstances" that civil remedies (and criminal penalties) may influence are the situational aspects of behaviors, including those controlled by third parties.

Legal Framework for Understanding Civil Remedies

In their book on third-party policing (TPP), Mazerolle and Ransley (2005, pp. 74–75) looked at the broad range of legal actions that could be used for some type of crime-prevention enforcement through a third (non-law enforcement) party. In their table on legal frameworks (pp. 74–75) for TPP, they presented a typology of the four types of authority that can be involved in legal enforcement actions:

1. Statutory provisions (such as a statewide or nationwide law)
2. Subordinate or lower-level legislation (such as a citywide ordinance)
3. Contracts (agreements between individual parties)
4. Torts (based on the legal duties between parties, which can arise based on the relationships between parties or on statutorily imposed duties of care)

Statutory provisions and subordinate legislation can include both civil and criminal ramifications for those whose behavior falls within the provisions set out. Contracts and torts are both subject only to civil law enforcement. Law enforcement agencies, on the other hand, do not ordinarily use contracts and torts as formal enforcement measures, although these agencies may work in partnerships with other parties who can use contract or tort enforcement to try to achieve a crime-preventive purpose. It is important to understand the legal framework underlying the civil remedy used when planning a preventive campaign that seeks to use such a remedy because this will help the preventer gauge the mechanism of the control available, as well as its obvious legal limitations.

Types of Civil Remedies

When planning for a crime-prevention campaign, it is also very important to understand all of the different types of civil remedies that might be available for use. Within the legal framework they set out, Mazerolle and Ransley (2005, pp. 74–75) also provided examples of types of interventions that use the civil law as an enforcement mechanism. They list seven types of statutory remedies:

1. Orders to control behavior of offenders, which includes both precursor behaviors and behaviors associated with more serious types of criminal actions
2. Movement and association limits, which includes limits imposed on types of people and types of situations with which a party can interact
3. Conduct licensing, which relates primarily to retail or service establishments
4. Formalized surveillance, which focuses on those who have been convicted of a crime
5. Property controls, which relate to real property owned or managed by private or public parties
6. Mandatory reporting by professional service providers
7. Civil forfeiture, which focuses on the proceeds of crime

As noted previously, these types of civil remedies fall under the general umbrella of SCP to the extent that they are situationally, and not offender, focused.

Mazerolle and Ransley (2005) also included three categories of subordinate legislation:

(1) orders under regulatory codes primarily related to health and safety issues; (2) product and service standards such as those that might make crimes associated with the products easier to carry out; and (3) controlled zones that limit or allow certain types of behavior within them. Product standards legislation falls under the general category of designing crime out of products, an area of opportunity theory that has seen a great deal of theoretical expansion recently (see Ekblom 2005). Crime pattern theory (CPT), which centers on the theory and practice of environmental criminology (see Brantingham and Brantingham chapter in Wortley and Mazerolle 2008), emphasizes the study of movement patterns of potential offenders and crime targets, along with other types of crime patterns. This aspect of opportunity theory is particularly useful for studying the effects of zoning – a civil regulatory remedy.

Approach 1: Focusing on the Situational Crime-Prevention Techniques Themselves

To understand how SCP works in practice and how this practice relates to civil remedies and TPP, one place to start is with a general introduction to the types of opportunity-reducing techniques that are considered to be situational and how they may operate to reduce crime. Here, the focus is on the most-recent SCP classification scheme – 25 techniques organized according to how they operate to affect offender decision making (see Cornish and Clarke 2003). Cornish and Clarke set out a table that organized the 25 specific techniques into five general categories of techniques with five specific techniques each. Smith and Clarke (2012) have recently produced a parallel table that sets out an explanation describing each of the 25 techniques and the five organizing categories. Here, the five general categories from Cornish and Clarke (2003) are provided along with summaries of their descriptions from Smith and Clarke (2012, pp. 306–307). The descriptions from Smith and Clarke included references to the concepts of offender, crime target (or victim), and target guardian derived from the routine activity approach (RAA), which is discussed in detail in this entry under "Approach 3," and in the following section.

- **Increase the effort** – which focuses on blocking the *offender's* actions or movement, thereby stopping the crime from happening – includes the following techniques:
  1. **Target harden** – affect how an offender might get to or use a target
  2. **Control access to facilities** – limit how an offender might gain access to a place
  3. **Screen exits** – monitor how an offender might exit from a setting where a crime can occur
  4. **Deflect offenders** – change potential offender's movement patterns
  5. **Control tools/weapons** – limit access to or use of things that make it easier to do the crime
- **Increase the risks** – which focuses on the *guardian's* potential role in detecting the crime and capturing the offender – includes the following techniques:
  6. **Extend guardianship** – encourage unofficial guardians
  7. **Assist natural surveillance** – make it easier to see criminal behavior
  8. **Reduce anonymity** – increase likelihood of identifying offenders
  9. **Utilize place managers** – use new or existing employees
  10. **Strengthen formal surveillance** – provide official guardians or increase their effectiveness
- **Reduce the rewards** – which focuses on decreasing the value of the *target* for an offender or otherwise making it harder for the offender to achieve his or her purpose – includes the following techniques:
  11. **Conceal targets** – limit offenders' ability to see targets
  12. **Remove targets** – take potential targets away or reduce their value
  13. **Identify property** – mark potential targets
  14. **Disrupt markets** – make the transfer of proceeds difficult
  15. **Deny benefits** – make it difficult to use targets for the purposes intended

- **Reduce provocations** – which focuses on the *situational stimuli* that may, in some situations, lead to crime – includes the following techniques:
  16. **Reduce frustrations and stress** – make settings and procedures calm
  17. **Avoid disputes** – limit situations that encourage disputes
  18. **Reduce emotional arousal** – limit insulting behaviors in a setting
  19. **Neutralize peer pressure** – lessen stimuli that encourage the desire to gain approval through crime
  20. **Discourage imitation** – limit details of modus operandi that can be copied
- **Remove excuses** – which focuses on strengthening the *situational controls* that may limit the offender's ability to excuse or ignore his or her criminal behavior in that situation – includes the following techniques:
  21. **Set rules** – detail which behaviors are unacceptable
  22. **Post instructions** – set out how to behave in the setting
  23. **Alert conscience** – put up reminders about behavioral requirements
  24. **Assist compliance** – make it easier to do acceptable behaviors
  25. **Control drugs and alcohol** – make it easier to limit intake of behavioral disinhibitors

In terms of TPP, only strengthen formal surveillance (technique 10) on its face, focuses on more formal types of policing. Yet, even with this technique, two of the three measures set out in the original table by Cornish and Clarke (2003, p. 90) – "burglar alarms" and "security guards" – can be used by third parties.

Approach 2: Looking at Particular Situational Measures and Civil Remedies

This approach also focuses on the 25 SCP techniques set out in Cornish and Clarke (2003), but it explores in more detail whether civil remedies could, at least theoretically, be used to help achieve the type of modification to the situation intended with the SCP measure. Table 1 looks at each of the 25 techniques, focusing on one measure set out as an example in the original table (Cornish and Clarke 2003). Each row of Table 1, performs the following: (1) links these measures to a crime, (2) sets out how the measure operates (drawing on the discussion in Smith and Clarke 2012), (3) includes the focus of the preventive measure (discussed in Smith 1998), (4) identifies the controller, using concepts derived from the routine activity approach (RAA) that are discussed in the next section, (5) provides the probable super controller (drawing on the work in RAA and also discussed in detail below), (6) describes the potential source of authority of a civil remedy (Mazerolle and Ransley 2005, discussed above), and (7) includes the type of intervention, also using the terminology of Mazerolle and Ransley (2005) set out earlier in this entry.

In Approach 1, which looked just at the technique itself and how it tended to work to affect a potential offender's behavior, only one technique (technique 10 – strengthen formal surveillance) appeared to be unlikely to allow TPP incentives to be used with it. Looking specifically at the examples of potential measures that were set out in the original table, however, demonstrated that this conclusion was overbroad because individual measures that use this technique could be carried out by third parties and not just police personnel. The analysis set out in Table 1 confirms that it is important to look at specific measures in order to understand the types of incentives that might be used to carry them out. Here, another type of measure, roadside speed display boards (a measure that can be used to alert conscience (technique 23)) may be used primarily by police agencies and may not be amenable to the use of a civil remedy incentive, even though the technique itself is not so limited.

Table 1 has several other uses as well. It allows a prevention planner to see how different types of measures could be used in terms of their theoretical and operational purposes, unpacking the variety of controls that may be operating when a situational technique is used. It also illustrates that many of the measures in the original Cornish and Clarke (2003) table are linked to place and consequently to place managers. This

Civil Remedies, Table 1 Using civil remedies to implement 25 situational crime-prevention measures

Technique (Cornish & Clarke, 2003)	Crime to be prevented	Measure (Cornish and Clarke 2003)	How the measure works (Smith and Clarke 2012)	Focus of control (Smith 1998)	Controller of this measure (RAA)	Usual super controller (Sampson et al. 2010)	Potential sources of authority (Mazerolle and Ransley 2005)	Potential type of civil remedy (Mazerolle and Ransley 2005)
Increasing the effort (for the offender)								
1. Target harden	Car theft	Steering-column locks	Harder for thief to start the car	Target	Guardian	Regulatory	Statute	Product standard
2. Control access to facilities	Bombing	Baggage screening	Harder to get offender and needed instrument to place	Prop/ place	Prop controller/ manager	Regulatory	Statute/subordinate legislation	Controlled zones
3. Screen exits	Fare evasion	Ticket required for passenger exit	Controls leaving place after offense	Place	Manager	Financial/ organizational	Subordinate legislation	Service standards
4. Deflect offenders	Prostitution	Street closures	Alters parties' movement patterns	Place	Manager	Regulatory	Subordinate legislation	Controlled zones
5. Control tools/ weapons	Illegal arms dealing	"Smart" guns	Alters access to instrumentalities	Prop	Prop controller	Regulatory	Statute	Product standards
Increasing the risk (that a guardian will act)								
6. Extend guardianship	Street robbery	Go out in group at night	Encourages unofficial guardians	Target	Guardian	Groups	Contract	Incentives – e.g., group discounts
7. Assist natural surveillance	Street robbery	Improve street lighting	Increases the potential for guardians to see	Place	Manager	Organizational	Subordinate legislation/contract/ tort	Regulatory code order/enforce conditions/action for negligence
8. Reduce anonymity	Sexual assault	Taxi driver IDs	Increases the potential for identification	Place	Manager	Regulatory	Subordinate legislation	Conduct licensing
9. Utilize place managers	Vandalism	CCTV for double-deck buses	Uses employees as guardians	Place	Manager	Organizational	Statute/subordinate legislation	Product standards
10. Strengthen formal surveillance	Traffic violations	Red light cameras	Allows more effective official guardians	Place	Manager	Organizational	Subordinate legislation	**Regular policing – no TPP**
Reducing the rewards (of the target)								
11. Conceal targets	Car theft	Off-street parking	Limits ability to see targets	Target/ place	Guardian/ manager	Regulatory	Subordinate legislation	Regulatory code order

12. Remove targets	Theft from cars	Removable car radio	Removes target from car	Target	Guardian	Markets	Statute	Product standards
13. Identify property	Burglary	Property marking	Makes items traceable to owner	Target	Guardian	Financial/ organizational	Statute	Product standards
14. Disrupt markets	Theft	Monitor pawnshops	Makes property transfer difficult	Target	Guardian	Regulatory	Subordinate legislation	Conduct licensing
15. Deny benefits	Shoplifting	Ink merchandise tags	Takes away value of property	Target	Guardian	Financial/ organizational	Contract	Incentives
Reduce provocations (related to situational stimuli)								
16. Reduce frustrations and stress	Harassment	Efficient queues and polite service	Encourages efficient and calm setting	Place	Manager	Organizational	Tort	Actions for negligence
17. Avoid disputes	Assaults	Separate enclosures for rival soccer fans	Limits situations that promote conflict	Place	Manager	Organizational	Tort	Actions for negligence
18. Reduce emotional arousal	Sexual assaults	Controls on violent pornography	Limits insulting behaviors in a setting	Place	Manager	Regulatory	Subordinate legislation/contract	Controlled zones/condition enforcement
19. Neutralize peer pressure	Drunk driving	"Idiots drink and drive"	Lessens desire to gain acceptance through crime	Place	Manager	Organizational	Statute	Conduct licensing
20. Discourage imitation	Vandalism	Rapid repair of vandalism	Limits access to details of how to do crime	Place	Manager	Organizational	Subordinate legislation	Regulatory code order
Remove excuses (by strengthening situational controls)								
21. Set rules	Drug use by visitors	Rental agreements	Lists unacceptable behaviors and consequences	Place	Manager	Organizational	Contract	Condition enforcement
22. Post instructions	Trespassing	"No parking"	Provides information about setting requirements	Place	Manager	Organizational	Subordinate legislation/tort	Regulatory code orders/actions for trespass
23. Alert conscience	Speeding	Roadside speed display boards	Provides situational reminders of rules	Place	Manager	Organizational	Subordinate legislation	**Not TPP – unless on nonpublic road**
24. Assist compliance	Library book theft	Easy library checkout	Makes it easier to do acceptable behaviors	Place	Manager	Organizational	Contract – e.g., service provider and institution	Condition enforcement
25. Control drugs and alcohol	Drunk driving	Breathalyzers in pubs	Makes it easier to limit the taking of mind-altering substances	Place	Manager	Organizational	Subordinate legislation	Conduct licensing

suggests the importance of place in crime prevention (since common measures were in the table) and also suggests the overall importance of place in crime commission.

Approach 3: Focusing on Controllers and Third-Party Policing (TPP)

Examining the *manner* in which a situational change is affected (which is what SCP has traditionally focused on) has limitations for understanding how SCP and opportunity theory can be linked to the use of civil remedies. This is because it does not necessarily dictate *who* can deliver or implement the needed change. Even the descriptions set out in Smith and Clarke (2012) do not cover all of the possible controls that might be operating with each technique. This distinction can be illustrated using SCP technique 18, reduce emotional arousal. For example, enforcing good behavior on the soccer field (the second measure listed under technique 18 in Cornish and Clarke's (2003) original table, not shown here) can be carried out by someone who controls the venue, someone who is protecting the target of the potential offense, or by someone who can influence an offender, or by all three types of people present in the situation. This focus on *who* "controls" the elements that converge to produce a crime event is central to the routine activity approach and is also central to understanding how civil remedies are, or could potentially be, used to persuade or coerce a third party to act to carry out an SCP measure.

The Routine Activity Approach (RAA)

The routine activity approach has developed from the theory set out by Cohen and Felson in 1979 that looked at, among other things, the three minimum elements that had to converge for a crime to occur at a particular time and place: the presence of a likely (or motivated) *offender*, the presence of a *target* (or victim) for the crime, and the *absence of a guardian* capable to protect the target and interrupt or prevent the crime. Since 1979, RAA has been expanded to include the following: (a) an additional element needed for a crime, i.e., place; (b) additional parties who could operate on these necessary elements to prevent a crime event from occurring, i.e., a handler to control an offender, a manager to control a place, and a props controller to deal with the instrumentalities of a crime; and (c) the sources of the types of incentives that can motivate guardians, handlers, managers, and props controllers. Most of these developments in RAA were discussed by Brunet (2002). The explanation in this section on RAA builds on Brunet's work by also providing a detailed explanation of how SCP measures may be able to be carried out by those different types of controllers and, in turn, how civil remedies may sometimes be used to induce other actors to change the situation so that the actors closest to crime events can prevent them. This approach focuses on connecting TPP to a measure when viewing the measure from the perspective of the RAA role.

The Target Guardian

The actions of target guardians, or those who protect the target or victim from victimization, can increase the risk of an offender being detected, captured, and convicted. The mere threat of these consequences occurring may also operate to block or limit crime events (see, e.g., Poyner 1992, for his study of the use of cameras on buses to prevent vandalism by schoolchildren). The ultimate goal is to get the guardian to act, but the focus of the intervention itself, in this case the civil remedy, may be on another controller (such as the place manager, discussed below).

This risk-increaser aspect of the guardian's role is well explored in Cornish and Clarke's 25-technique table and in Table 1 (techniques 6 through 10, above). What may be less initially apparent, however, is that target guardians can also operate to increase effort (through technique 1) by making it harder to get to or use a target, such as a car, by strengthening locking devices and to reduce rewards (through techniques 11, 12, and 13) by concealing, removing, or marking a potential target to make it less visible, not present, or not suitable for the potential offender's purposes. Target guardians can also help to reduce provocations in situations through helping those present avoid disputes (technique 17) and reduce emotional arousal (technique 18, as noted previously). The inducements available with TPP may be easily envisioned for some of these measures. For example, legislation may be passed that requires car owners to put steering-column locks on their vehicles (see Webb 1997). Regulations that focus on steering-column locks for new vehicles require the participation of different types of target guardians than would be true for legislation requiring the device be placed retroactively on used vehicles; however, in both cases the guardian would not need to be physically present to influence the likelihood of the event occurring.

The Handler

In 1986, Felson expanded the players affecting the commission of crime events by discussing the role that offender handlers could play in controlling a potential offender. Although Felson took an expansive view of the role of the handler as a social control agent, more recently Tillyer and Eck (2011) have argued that it may be useful to look at the preventive and explanatory role of handlers, particularly in terms of the situational aspects of these roles. And, although the context is situational, the influence itself may rely to some extent on the existing social relationship between the offender and the handler. Tillyer and Eck (2011) set out four primary factors they saw as possibly effecting handler effectiveness: (a) social closeness; (b) willingness to intervene; (c) opportunity to intervene; and (d) knowledge of the situation and environment in relation to the offense. Thus, if one is expecting offenders to be influenced by those likely to be present when crime events are about to happen, then, given the factors identified as possibly important by Tillyer and Eck, it is friends, girl friends, and potential co-offenders – and possibly teachers, parents, or bystanders – who would be available to be utilized as handlers in this context. Although this was not discussed by Tillyer and Eck (2011), each handler is a potential focus of a third-party policing initiative that might operate as a legal inducement to handling potential offenders, if an appropriate means of regulating the behavior of these potential handlers could be identified. The use of civil or criminal parental responsibility laws, or curfews that punish parents for their child's noncompliance, could be used as inducements for potential handlers (see Brunet 2002).

There is another way that SCP theory may provide some guidance for thinking about the possible roles of handlers in TPP. In keeping with Tillyer and Eck's (2011) contention that the situational roles of handlers have not been often explored, most of the examples of SCP measures set out in Cornish and Clarke's (2003) 25-technique table would not normally be carried out by handlers. Nevertheless, there are a number of techniques that appear, on their face, to be open to handlers. For example, handlers could be used to do the following: deflect offender movements away from potential targets (technique 4); control the tools or weapons offenders might use (technique 5); and reduce the anonymity of potential offenders by convincing them to wear name tags or uniforms in particular types of settings (technique 8). In addition, four of the techniques that focus on providing situational controls (removing excuses) appear to fit fairly directly with the role of a handler who has some relationship with a potential offender, in particular: setting rules (technique 21); alerting conscience (technique 23); assisting compliance (technique 24); and controlling drugs and alcohol (technique 25). Similarly, four of the techniques in the "reducing provocations" category – avoiding disputes (technique 17); reducing emotional arousal (technique 18); neutralizing peer pressure (technique 19); and discouraging imitation (technique 20) – could be carried out, in some situations, by handlers. Interestingly, these last two categories of techniques – reducing provocations and removing excuse – were seen by Cornish and Clarke (2003) as special cases. Reducing provocation, in their view, involves life-threatening cases or cases in which there is repeated exposure to situationally provoking stimuli. Removing excuses would tend to be used for minor criminal acts, either ambiguously criminal or antisocial, and for novice offenders or those not commonly doing serious crimes. These types of acts might be amenable to interventions from handlers present in the situation, perhaps precisely because they are special cases either of particularly unusual situations that might not be normally covered by other types of guardians or because handlers might be better able to convince fairly novice or minor offenders not to do the offense. If handlers are present, they may have "knowledge about the situation and environment that allow and/or provoke the offense," "social closeness to the potential offender," "willingness to intervene due to personal investment, either economic or emotional," and "an opportunity to intervene" (Tillyer and Eck 2011, p.184). When viewed in terms of TPP, two questions arise: (1) How would such a civil inducement be framed to focus precisely on the needed control? (2) Is a civil remedy the most effective inducement to use for each of these situations? The general issues raised by these questions are discussed briefly at the end of this entry.

The Place Manager

Another expansion of the routine activity approach came when Felson (1986) discussed the importance of *place* in the convergence of offender and target, without a capable guardian present. Building on this growing number of crime event elements and guardians, Eck (1995) identified the importance of *place managers* in controlling the conditions in which crime opportunities might be present.

The power of the place manager role can be seen by looking back at Table 1 and noting that techniques 1 through 5, and 15 through 25 can easily be performed by someone who controls the place in which the prevention measure can be carried out. For example, if the target of a residential burglary is an apartment house, then the owner could be the place manager who installs sturdy window and door locks (target hardening the house – technique 1) to make it more difficult for an offender to enter. Place managers can also reduce frustrations (technique 16) by providing more seating in a bus terminal or set rules (technique 21) and require hotel guests to register. In addition, techniques 7 (assisting natural surveillance), 8 (reducing anonymity), and 9 (utilizing place managers) can each involve place managers as controllers, depending on the particular measures used. Examples of measures that fall within these classes include cutting foliage around parking lot fences (to prevent theft of or from cars), requiring those attending schools to wear uniforms (to allow school administrators to identify when students are leaving the school building to be truant), and setting up CCTV to monitor student behavior on buses. Similarly, place managers can disrupt markets (technique 14) by requiring employees to check serial numbers on goods in pawnshops and deny benefits (technique 15) by requiring graffiti cleanup on their property.

In terms of TPP, many of the regulations commonly used in communities center on places – where people live, work, spend their leisure-time activities, or travel through on their way to these places. For example, housing and building codes provide guidelines for construction and upkeep. Safety regulations set up restrictions on the types of protective gear that must be worn at certain workplaces. Licensing requirements determine what types of beverages are sold in an establishment and fire codes set capacity limits on the number of patrons who can be present. Vendor licensing limits who can sell goods on the sidewalks and where the sellers can operate. The enforcement of each of these types of restrictions can, in some cases, induce place managers to act in ways that make crime less likely in a particular place.

Props Controllers

Smith (1998), in her analysis of the role that civil remedies can play in SCP, identified a fourth type of controller, the props controller. The importance of props in the crime commission process had been identified previously in the SCP classifications tables of Clarke (1992) and Clarke and Homel (1997) in the technique of "controlling facilitators," and more recently in the 25-techniques table of Cornish and Clarke (2003) in the technique of "controlling tools/weapons." Cornish (1994) used the term "props" – drawing on the dramaturgical aspect of the

Civil Remedies, Table 2 Planning for an anti-vandalism campaign

Scene/ function	Script action	Situational control	Mechanism	Type of intervenor	Focus of control	Medium of control	Type of inducement	Inducement enforcer
Preparation	Buy spray can	Sales regulation	Increase the effort	Businesses	Prop	Controller	Criminal law	Government agency
	Find good setting	City paint-out program	Increase the effort	Multiagency partners	Scene/ place	Manager	Civil remedy	Government agency
Entry	Enter setting	Access control	Increase the effort	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
		Entry-exit screening	Increase the effort	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
Precondition	Loiter	Surveillance	Increase the risk	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
Instrumental precondition	Select target	Remove target	Reduce the rewards	Individual owner	Target	Guardian	Non-coercive inducement	Individual owner
Instrumental initiation	Approach target	Surveillance	Increase the risk	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
Instrumental actualization	Reach target	Protective screens	Increase the effort	Individual owner	Target	Guardian	Non-coercive inducement	Individual owner
		Legal target provided	Remove excuses	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
Doing	Spray graffiti	Graffiti-resistant paint	Increase the effort	Individual owner	Target	Guardian	Non-coercive inducement	Individual owner
Post-condition	Get away quickly	Moisture-activated alarm	Increase the risk	Individual owner	Target	Guardian	Non-coercive inducement	Individual owner
Exit	Leave setting	Entry/exit screening	Increase the effort	Individual owner	Scene/ place	Manager	Non-coercive inducement	Individual owner
Doing (later)	"Getting up"	Rapid cleaning	Reduce the rewards	Individual owner	Target	Guardian	Non-coercive inducement	Individual owner

Source: Adapted from Smith (1998) and Cornish (1994)

crime script – to describe these instrumentalities of crime. Despite the importance of these crime facilitators, the role of the "props controller" has not gained wide acceptance in the RAA literature (but see Mazerolle and Ransley, 2005). This is probably because props are not a necessary element of all crime events and the term "controller" has developed a more generic meaning. Nevertheless, "props controller" is used here in keeping with its more crime-specific role (see Table 2, as part of the regulation of spray paint sales to disrupt a graffiti tagging crime script).

Which Type of Controller?

Sometimes it is difficult to determine exactly how a particular civil remedy operates to affect the prevention mechanism. One example of such a complex case is where local regulations require taxi drivers to post their identification in their vehicles. If the crime that is being prevented is sexual assault of female passengers by drivers, then the question becomes who or what is being controlled. Is it the offender, the place, or the victim? In effect, it can be all three, although usually one of these elements is the one that is primarily affected and the other two elements may change, or be changed, in response. In the case of displaying taxi driver credentials, the potential offender, if he is a licensed driver, is controlled because he loses his anonymity and the risks associated with a sexual assault increase. In effect, the offender has been "handled" by the display of his identity information. The potential target, the passenger, can act as her own guardian as she has the information needed to help her determine whether the driver is bogus and she needs to get out, or better yet, not enter. But both of these reactions to the control cannot occur unless the place is first controlled by the place manager, usually the owner of the taxicab, who is being induced to post driver credentials by the regulation. The owner of the cab may be its driver, but he or she would be acting in the role of the place manager, not the potential offender, by posting the identification. Thus, an issue that first appeared as one of "which type of controller" is operating, can be seen as a situation in which multiple levels of control must operate – the place controller and the handler or the place controller and the guardian – for the crime to be prevented.

Super Controllers

Recently Sampson, Eck, and Dunham (2010) have identified a different type of level of factors that they see as affecting all three categories of controllers – handlers, guardians, and managers. They term these factors "super controllers." This classification system is similar to "inducement type" identified by Smith (1998, p. 76) as "non-coercive encouragement, civil remedies and criminal penalties," but it is more extensive (with 11 types) and covers a larger variety of possible influences on controllers. These incentives include the following: (a) formal – organizational, contractual, financial, regulatory, and courts; (b) diffuse – political, markets, and media; and (c) personal – groups and family. The three main categories are types of controls used. The super controller is given the name of the incentive source, with the incentive playing the role of a super controller of controllers. This is a different type of role than that seen previously in RAA where the roles were less abstract and more easily assignable to a real person either in planning or in practice.

This conception of incentives expands RAA and in a very neat manner ties together RAA and RCP. Sampson et al. (2010) do this by suggesting that super controllers manipulate the same rational choice factors – effort, risk, reward, provocation, and excuses – when seeking to influence controllers' likelihood of controlling potential crime elements that were identified as important for potential offenders in the SCP 25-techniques table of Cornish and Clarke (2003). This linking together of the elements from rational choice theory which influence potential offenders, with the decision-making elements of ordinary actors who may act as controllers, provides support for Cornish's (1993) contention that the rational choice perspective should be seen as a meta-theory, or a theory of action, for criminological theory. Sampson and her colleagues said that these five rational choice factors could be used to help understand why controllers – handlers, guardians, and managers – may not always act to control their associated crime elements – offenders, targets/victims, and places – and to help preventers figure out how to overcome these influences.

Thus, there are two ways that this new view of incentives can be useful to TPP: (1) it focuses on the processes that influence controllers (potential TPP actors) – i.e., risk, reward, effort, provocations, and excuses; and (2) it can highlight what is already going on to control crime and this can allow preventers to see if more can be done through employing the types of TPP discussed by Mazerolle and Ransley (2005). This view of super controllers can be applied to TPP even though: (a) TPP overlaps with only two categories of super controllers – regulatory incentives and courts incentives – and (b) regulatory super controllers include not only governmental regulators but also private regulators.

Approach 4: Being Crime Specific – Crime Scripts and Civil Remedies

The rational choice perspective of Cornish and Clarke (see chapter in Wortley and Mazerolle, 2008) was developed to help explain why SCP works. Using concepts such as "purposive behavior" and "bounded rationality," it adopted a crime-specific approach to examining three different types of involvement decisions related to crime commission – involvement, habituation, and desistance – and two different types of models of the crime event – the event model and the crime script. Applying lessons from research, it stressed the importance of risk, reward, and effort in the decision making of potential offenders. This last aspect of RCP is reflected in the 25-techniques table of Cornish and Clarke (2003), which was discussed in relation to Approaches 1 and 2, above. The crime script, initially developed by Cornish (1994), takes a different approach and focuses on the requirements of the crime itself, the processes that need to occur for the crime event to be completed. When Cornish listed these required actions, he also showed that one could link other factors related to these needed actions, such as reasons for an action to fail or SCP measures that could block an action. In 1998, Smith expanded the number of factors that could be linked to an SCP measure, such as the type of intervenor, the focus of the SCP control, the medium of control (or controller, as discussed in Approach 3 above), the type of inducement (essentially the type of super controller, also discussed above), and the inducement enforcer. Table 2 has been constructed based on the discussion in Smith (1998) as a tool for examining the part that a civil remedy commonly plays in a prevention initiative – in this case, disrupting a tag-writing script.

The distinctly crime-specific approach of the expanded crime script is particularly good for planners to use when one single technique is unlikely to be able to block the crime in the setting where the prevention initiative is needed. Because Table 2 attempts to "unpack" each measure that could be used, in addition to its use in planning, it may also assist at the implementation and evaluation stages when it is important to be clear how each measure may be affecting each action in the crime script. Thus, it is particularly well suited for the application of civil remedies that may require the intervention of a number of different stakeholders or members of a partnership in addition to the usual police intervenor.

Potential Controversies

By noting the many ways that civil remedies might be able to be used to block crime opportunities does not necessarily mean that all of these uses are either problem free or desirable. They may not be the most effective means of inducing someone to act nor the most efficient in terms of money and effort, and there are potentially many unintended consequences possible with both the use of civil remedies and SCP. While there are a number of sources in which these issues are discussed, Mazerolle and Ransley (2005) examine many of the arguments related to the use of civil remedies, particularly those related to overregulation, and von Hirsch, Garland, and Wakefield (2000) present arguments questioning the use of SCP measures that may overreach in terms of privacy interests. Arguments in defense of SCP are clearly set out in the chapter by Clarke in Wortley and Mazerolle (2008). Given the wide range of both civil remedies and SCP measures, it would be wise for planners to assess the types of civil remedies and SCP measures to be used in a particular location carefully prior to implementation. Planners may choose to favor noncoercive measures over the use of civil remedies whenever possible or choose the less-intrusive form of opportunity reduction where there is little difference expected in the crime-reduction outcome. Unintended consequences, such as an increase in fear of crime following an initiative, should not be ignored by planners just because they may be difficult to assess. The potential impact of a measure on area users, as well as potential offenders, must be considered.

Unresolved Issues and Future Controversies

At several points in this analysis, it was not clear exactly how an intervenor would attempt to frame a civil remedy to induce a controller to act. For example, how exactly do you convince a friend or a co-offender to "handle" an offender with a civil remedy? The situation, with its signals of possible danger, might be enough inducement for a co-offender to act, but what about a friend? Not only might it be difficult to envision what might work in such a situation, other than a desire to protect a friend from him or herself, it is not at all clear that the most desirable tool to use in this situation is one that involves coercion by the threat of legal action.

Another unresolved issue or future controversy centers on the place that lifestyle should hold in an opportunity-theory approach. All of the involvement models of RCP list "lifestyle" as an important consideration in the three main stages of offending – initiation, continuation (or habituation), and desistance (see Cornish and Clarke chapter in Wortley and Mazerolle 2008). Cornish (1994) also discussed lifestyle as a future consideration in terms of developing crime scripts. This factor has not been explored widely in SCP, but may be an important factor to consider when thinking about the broad scope of some civil remedies. Caution, however, is warranted since the use of civil remedies to disrupt "criminal lifestyles" would tend to produce more regulation and this regulation might not always be targeted to those parts of the lifestyle that are most closely linked to, or part of, a crime script. Limiting regulation to activities linked closely to crime commission means that it will be less likely to impinge on liberties, such as those involving protected aspects of movement or association.

Bias in Forensic Science; Confirmation bias; Contextual influences; Forensic Science and bias

Overview

Human judgment stands at the center of criminal justice. Forensic science is no exception; it is the human examiner who is the main instrument of analysis in most forensic disciplines. It is the forensic expert who compares visual patterns and determines if they are "sufficiently similar" to provide evidence that they originate from the same source (e.g., whether two fingerprints were made by the same finger, whether two bullets were fired from the same gun, whether two signatures were made by the same person). Such determinations are governed by a variety of cognitive processes. Without objective scientific criteria and quantification instruments, these judgments are subjective.

The cognitive nature of subjectivity is that it can be influenced and biased by extraneous contextual information. Forensic scientists work within a variety of such influences: from knowing the nature and details of the crime to being indirectly pressurized by detectives, from seeing the "target" to working within and as part of the police, from computer generated meta-data to appearing in courts within an adversarial criminal justice system, and so on and so forth – the contextual influences are many and they come in many forms, some of which are subtle. After over 100 years of using forensic evidence, only recently has the forensic community begun to acknowledge the role of cognition and bias in forensic work, establishing a new field we term as Cognitive Forensics.

Cognitive forensics does not only refer to issues of interpretation and bias, but includes a whole array of cognitive issues relating to forensic work. Therefore, Cognitive Forensics deals with how cognition relates to forensic science and how cognitive knowledge can guide and enhance forensic work. In this entry, we provide some cognitive background, illustrate their relevance to forensic domains, show different types of contextual influences, and suggest ways of minimizing their effects so as to increase objectivity in forensic science and enhance its value.

Fundamentals of Human Cognition

Information Processing

People, in everyday life and in their professional work, process information. We hear, see, touch, and receive input information from a variety of sources. The brain and cognitive system process this information and often produce an output in a form of a decision or an action. The information coming into the cognitive system is processed as "bottom-up" information. One of the things that make humans intelligent is that they do not process such information in a vacuum. Along with the "bottom-up" components, the human cognitive system uses a variety of "top-down" processes. These include past experience, knowledge, expectation, and a variety of other factors that take part and greatly influence how incoming information is processed.

Top-down cognitive information processing is widespread and takes part in most cognitive operations. This is critical because the brain has limited information processing capacity, and the top-down processing helps to deal with the huge amount of information coming into the brain. The incoming bottom-up input is too much information for the brain to fully process, and a variety of cognitive mechanisms, such as selective attention, chunking, and automaticity, enable the brain to effectively handle the bottom-up information.

These top-down mechanisms stand at the core of human intelligence and expertise. For example, cognitive attention mechanisms select the more relevant and important information based on our past experience, context, expectations, and a whole host of top-down information. While certain information is selected, other information is ignored and disregarded.

Expertise

As we gain more experience and knowledge, our top-down cognitive mechanisms get more and more powerful, until we eventually become experts. Expertise entails top-down cognitive mechanisms that improve performance and result in superior abilities.

However, with more and more reliance on top-down cognitive mechanisms and more effective information processing, potential weaknesses and vulnerabilities arise. Expertise and top-down processes entail computation trade-offs, and they – along with overall superior performance – can also result in restricted flexibility and limited control, may cause the experts to miss and ignore important information, introduce tunnel vision and bias, and can cause other effects that degrade performance and can result in error. Such phenomena are not specific to forensic experts, they are inherent cognitive side-effects of expertise, per se, and are a professional challenge in the medical domain, as well as in the military, policing, and other highly skilled expert domains (Dror 2011).

It is important to emphasize that the nature of the cognitive mechanisms that cause the vulnerabilities work at a level without awareness, meaning that the experts do not intentionally and consciously take these actions. They take place automatically and without awareness. This is critical, because not understanding the underlying cognitive mechanisms involved in these phenomena often results in ineffective ways to countermeasure their effects. For example, considering cognitive biases as an ethical issue is not only an ineffective way of combating them but is also unfair to the experts because it suggests that they are doing something wrong intentionally and that they can stop doing it by mere willpower – a misconception and misunderstanding of the very nature and mechanisms of cognitive bias (see, e.g., Page et al. 2012).

Forensic Evidence

Although forensic evidence is very powerful and important in criminal justice, we need to understand its limitations and to improve it based on cognitive understanding of its vulnerabilities. Objectifying forensic investigations through data based analyses is an important development; however, it is not sufficient. Since the forensic examiner is the main instrument of analysis in many, if not all, forensic impression and pattern evidence disciplines, cognitive factors play a major role in forensic casework, stressing the need for Cognitive Forensics: A field that overarches the different forensic disciplines and addresses a whole range of cognitive issues that relate to forensic work.

This is because the evidence from the crime scene (be it a fingerprint, a bullet, a handwritten note, etc.) does not ever match the suspect perfectly – there are always variations and thus they are never totally identical. It is up to the forensic examiner to determine the evidential strength with respect to the question whether they come from the same source or not – based on their relative similarity. However, there is almost always no objective instrumentation or quantitative data available to determine the evidential strength of the comparison (e.g., "sufficient similarity" or discrepancies that can (or cannot) be explained). It is to some degree subjective and in the "eye of the beholder." Therefore, the cognitive mechanisms of the human examiner play a critical role in this determination – the new area of Cognitive Forensics.

Cognitive forensics not only plays an important role in the final determination of forensic identification, but even in the initial analysis of the evidence. For example, when expert fingerprint examiners determine the minutia features in a fingerprint, they do not only differ among themselves, but the same expert – examining the same prints – often vary in the features they find. Therefore, the lack of objective criteria in some forensic disciplines introduces not only inter-examiner inconsistencies but also intra-examiner inconsistencies (Dror et al. 2011; Ulery et al. 2012).

As we discussed earlier, the cognitive top-down mechanisms play a large role in such expert determinations, and because they are susceptible to influences, expert forensic examiners may be biased, as we detail below. However, it is important to emphasize from the onset that such influences affect different examiners in different ways and that they are most powerful in difficult and hard to call cases (e.g., in DNA mixture interpretation; see Dror and Hampikian 2011). Furthermore, the existence of influences and bias does not mean that it determines the final decision outcome. There are many factors that are involved and they interact with each other in a variety of ways.

Forensic traces, by their very nature, are often collected at crime scenes, and therefore are often far from ideal. These traces may then become evidence examined by forensic examiners who in most cases are part of the police or work within an adversarial legal system (see Giannelli 1997; National Academy of Sciences 2009). The examiners cognitive processes, subjectivity, and susceptibility to contextual influences has not been well understood by the forensic community for a long time, and therefore appropriate measures have not been taken. For example, often the examiners are exposed to a whole range of contextual information which is sometimes irrelevant and not needed for their work, but may affect and bias their judgments.

It is important to realize that much of this contextual information, like confessions, eyewitness testimonies, and outcomes of other forensic investigations, may well be very important for the case (see ▶ Forensic Science and Criminal Investigation), that is, for the judge or jury to reach their ultimate decision (or even for the detective, to determine lines of investigation, etc.), but not relevant to – and potentially psychologically contaminating – the forensic examiner. What the forensic expert can provide is a piece of the puzzle: The evidential value of their forensic evidence, based on estimates of the probabilities of the evidence given at least two hypotheses. This evidential value determination can then be used by others (e.g., a judge, jury, detective) to make legal or investigatory decisions. One probabilistic framework to do this is the Likelihood Ratio approach for the interpretation of forensic evidence (see Evett 1998; Stoel and Sjerps 2012), and the forensic science community is slowly progressing toward such an approach.

Cognitive Forensics

Four things have contributed to the emergence of Cognitive Forensics:

Theoretical Work

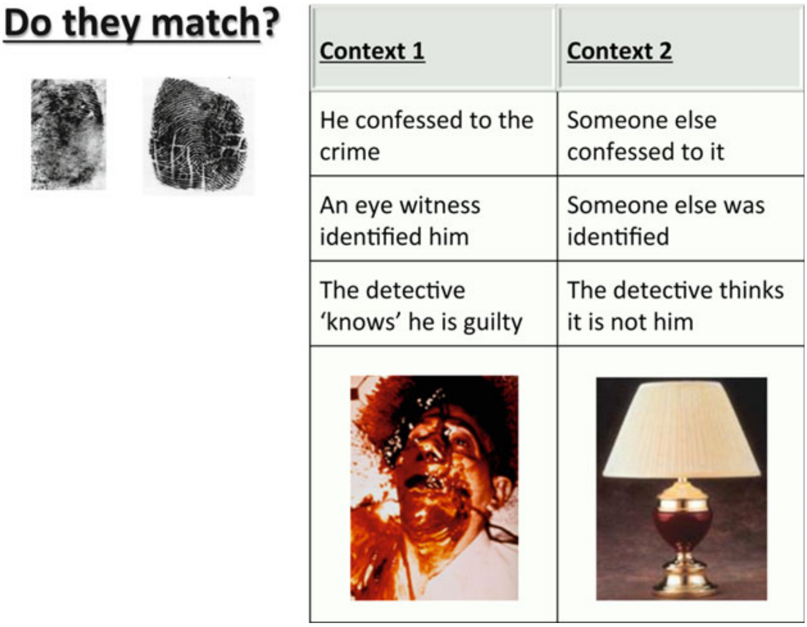
Theoretical work based on cognitive science understanding of the brain and the cognitive system, and research in other expert domains, has suggested that forensic science work may be affected by extraneous information and may be biased. Such work covers many forensic domains and some of it goes back a long time. For example:

- In handwriting, back over a hundred years – Hagan (1894) suggested that “Where the expert has no knowledge of the moral evidence or aspects of the case in which signatures are a matter of contest, there is nothing to mislead him, or to influence the forming of an opinion.”
- In fingerprinting, also a hundred years ago – Faulds (1912) suggested that “In finger-print cases... mistakes may be made... over-anxiety to prove his case that may distort his view.”
- In forensic odontology, “It appears that the current practice of bitemark analysis is rich in sources of potentially biasing influences... fundamental recognition that some form of bias is likely to exist” (see Page et al. 2012).
- In fire investigation, “Various circumstances conspire to make fire scene cause and origin investigation particularly susceptible to the affects of cognitive biases” (see Bieber 2012).
- Etc...

A landmark paper theoretically addressing these issues was a 2002 paper by Risinger, Saks, Thompson, and Rosenthal, which discussed “observer effects.” It made the theoretical case that based on cognitive and social psychology many forensic examination results are doubtful because they are vulnerable to distortion by the context and the state of the forensic examiner.

Empirical Research

There has been sporadic and anecdotal empirical research examining whether forensic examiners are indeed affected by contextual information. This research consisted of an experimental set up that involves showing different examiners evidence within different contexts as part of a research or training (e.g., document examination (Miller 1984), fingerprinting (Langenburg et al. 2009), and hair examination (Miller 1987)). Such between-subject experimental design compares different examiners, and therefore results can be attributed to individual differences among the different examiners.



Context 1	Context 2
He confessed to the crime	Someone else confessed to it
An eye witness identified him	Someone else was identified
The detective 'knows' he is guilty	The detective thinks it is not him

Cognitive Forensics: Human Cognition, Contextual Information, and Bias, Fig. 1 The same examiners can reach different conclusions when the same evidence is presented within different extraneous contexts

A strong demonstration of biasing effects in forensic science was established in 2006 when data was collected from examiners as routine casework without their knowledge. This is very critical, because when examiners are not doing casework and taking part in research, they perform differently. As Dror and Charlton (2006) state "If you want to know how people drive, then their performance during a driving test is not very insightful and revealing, neither is their driving when they know they are near speed cameras or radars. One must try to observe and examine performance as well as collect data in the normal routine setting with minimal (or no) knowledge of the people involved" (p. 604).

This is especially vital when studying contextual influences – for them to affect performance, the participants must really believe them. This occurs in real casework, but not in contrived experiments. Furthermore, and perhaps critically important, in Dror et al. (2006) and Dror and Charlton (2006) studies, the same experts examined the same exact evidence on two different occasions (see Fig. 1). Depending on the difficulty of the case, the level of contextual information, and the type of conclusion, some examiners reached different decision outcomes. With all being equal (same examiners, same evidence) except the contextual information, one can confidently attribute the different conclusions to the effect of context.

Although these studies (as well as others) have found bias in forensic science, other studies have not found such affects. The existence of the latter studies with null findings, along with potential criticism of the former studies (e.g., small sample sizes) may suggest that there is no definite proof that forensic investigations are affected by contextual information. However, one must understand and remember that:

1. The existence of bias in forensic science is not only based on research in forensic science, but it rests on a large amount of theoretical and empirical research in a variety of expert domains, as well as on understanding the brain and cognitive mechanisms involved in expertise and making such decisions.
2. The existence of bias does not mean it necessarily affects the final forensic determination. As we state earlier, there are many factors that affect the forensic decision and interact with bias (such as difficulty of the case, type and strength of the bias, the examiner). Therefore, although bias affects the decision process, it does not necessarily affect the decision outcome.

Errors in Casework

Along with the theoretical and empirical research, a number of high-profile cases of errors in forensic identification brought attention to contextual influences and bias in forensic science work. Perhaps the most influential case was of Brandon Mayfield. He was incorrectly identified as the Madrid bomber by a number of FBI fingerprint examiners. A number of inquiries into this case all concluded that bias was a contributing factor.

The Office of the Inspector General (2006) inquiry concluded that "a significant cause of the misidentification was that the LPU examiners' interpretation of some features in LFP 17 was adjusted or influenced by reasoning "backward" from features that were visible in the known prints of Mayfield. This bias is sometimes referred to as "circular reasoning," and is an important pitfall to be avoided" (p. 7), and "working on a high-profile case influenced Green's initial judgment and created a mind-set in which his examination became biased by an expectation that the prints were a match" (p. 128).

Inquiries and Expert Working Groups

There have been a number of official inquiries into specific errors of forensic identification that further established the area of Cognitive Forensics. For example, the recent inquiry into the McKie erroneous identification (Campbell 2011) Recommendation 8 (Para 35.139) states that: "The SPSA should consider what limited information is required from the police or other sources for fingerprint examiners to carry out their work, only such information should be provided to examiners, and the information provided should be recorded" (p. 741), as well as "The SPSA should review its procedures to reduce the risk of contextual bias" and "The SPSA should ensure that examiners are trained to be conscious of the risk of contextual bias" (Recommendations 6 and 7 (Para 35.137 and Para 35.138), p. 741).

There have also been general inquiries into the state of forensic science. Most notable is the US National Academy of Science Inquiry (see ► Critical Report on Forensic Science). It concluded that: "a body of research is required to establish the limits and measures of performance and to address the impact of sources of variability and potential bias. Such research is sorely needed, but it seems to be lacking in most of the forensic disciplines that rely on subjective assessments of matching characteristics. These disciplines need to develop rigorous protocols to guide these subjective interpretations and pursue equally rigorous research and evaluation programs. The development of such research programs can benefit significantly from other areas, notably from the large body of research on the evaluation of observer performance in diagnostic medicine and from the findings of cognitive psychology on the potential for bias and error in human observers" (National Academy of Sciences 2009, p. 8).

Furthermore, a number of professional working groups have been established to examine these issues. The US National Institute of Standards and Technology (NIST) and the US National Institute of Justice (NIJ) have jointly formed a working group consisting of a large group of leading scientists and practitioners to examine these issues. After 2 years of work, this working group has acknowledged these issues and the need to deal with them.

The Forensic Regulator in United Kingdom recently concluded that "cognitive bias (also referred to as contextual bias or observer effects) is an issue that is relevant to forensic science" and that "organisations who undertake fingerprint examination should demonstrate within their accredited quality management system that they understand the potential for cognitive bias and build into their technical procedures safeguards to minimise the risk of bias and peer pressure" (Forensic Regulator 2011, p. 12).

Wider Influences on Criminal Justice: The Biasing Snowball Effect

The growing acknowledgment that bias may play a role in forensic work has helped establish the area of Cognitive Forensics and its importance. However, Cognitive Forensics does not stand alone in isolation. It affects the rest of the criminal justice system, which then affects it back, by what we term the "Biasing Snowball Effect." Many lines of evidence play a role in criminal justice, not only a variety of different forensic domains but also other lines of evidence, such as eyewitnesses and confessions. These should all be independent, but in reality, they can often affect and bias each other, resulting in a violation of evidentiary independence.

A firearm examiner, for example, knowing that the suspect's fingerprint was found on the gun, may be biased in their investigation of the bullets. Across lines of evidence, knowing the findings of one line of evidence can contaminate and bias another line of evidence. For instance, take the Willingham case in Texas, where erroneous forensic arson conclusions influenced eyewitness testimonies (Grann 2009), or the Jackson case in Las Vegas where an innocent person confessed to a crime he did not commit because of erroneous DNA identification (e.g., Mower and Mcmurdo 2011).

Bias may effectively give the right conclusions, but for the wrong reasons. So, although it may be "helpful" in some ways, it can also cause and reinforce miscarriages of justice (see examples above). Thus, by taking into account contextual information, forensic experts may well become more likely to interpret their evidence correctly, in the sense that they reach a conclusion that correspond to what actually happened. However, in doing this, the ability of the trier of fact to determine the truth is undermined. The crux of this criminalist paradox is that "By helping themselves be 'right' such analysts make it more likely that the justice system will go wrong. By trying to give the 'right' answer, they prevent themselves from providing the best evidence" (Thompson 2010, p. 130), therefore undermining themselves as objective scientists as well as their role in the judicial system.

Bias Countermeasures

Minimizing the effects of bias and other contextual influences is important and needed in forensic science. Nowadays, with the growing acceptance that these issues are real and relevant, it seems appropriate to take steps to deal with and countermeasure them. With increased implementation of such steps, they should be the accepted norm, and forensic evidence from laboratories that will not take such actions should be treated with doubt and reservation.

Best Practices and Standard Operating Procedures

The everyday working procedures of forensic laboratories must take into account bias and cognitive influences. As a first step, forensic examiners should not be exposed to information that is irrelevant to their work but that can bias them (for example, whether or not the suspect confessed to the crime or not, whether or not there are eyewitnesses or other evidence against the suspect, what the investigating detective thinks, and many other case details). It is relatively easy to deal with this kind of bias.

More complex situations arise when information that is potentially biasing may also be relevant to the examiner's work. In such cases, one must consider the relative importance of this information vs. the relative biasing influences it may have. If such a cost-benefit analysis does not provide clear results, one can examine whether or not this information makes a difference by giving this additional information only after initial conclusions have been reached. If the conclusion is maintained with this extra information, then that strengthens the results; if the new information suggests revising the conclusion, then the examiner must explain and detail the reasons. These types of procedures force to detail and account for the cognitive factors in the forensic decision making processes (Dror 2012).

There are more complex types of biases, some of which are very difficult to combat, for example, base rate information. Base rate information is organization- and discipline-specific information by means of which estimates may be made about the outcome prior to any investigation. For example, in airport security, the X-ray examiners have a base rate information that bombs will be detected very rarely. In the criminal justice system, for example, base rate information can cause a very high expectation for verification.

Best practices may involve artificially inserting fake cases into the normal workflow (with opposite conclusions) to the control and counter the effect of base rate information (Dror 2009). Such solutions are easy to implement in some domains, for example, using Threat Image Projection (TIP) software that occasionally adds threat items, such as knives and guns, to routine airport X-ray of ordinary bags (Schwaninger 2006). In forensic science it may be more tricky to implement because of the difficulty to create realistic cases, with the experts not being aware that the case under consideration is a fake case.

It is important that bias minimizing procedures, like context management, are both cognitively informed and pragmatic. They must be cognitively informed because forensic examiners who do not specialize in human cognition are limited in their ability to develop procedures to deal with bias. One must understand these phenomena in order to determine the best way to deal with them. On the other hand, cognitive scientists do not understand the realities of forensic laboratories and can come up with unrealistic procedures that cannot be implemented. Therefore, a cooperative effort between forensic practitioners and cognitive scientists is needed in order to move forward effectively.

Training

Best practices and appropriate procedures are critical, but without training their effectiveness is limited. Forensic examiners must understand the reasons and cognitive science behind the procedures and why they are needed. Training about cognitive factors in making forensic comparisons is essential. Indeed, forensic laboratories in different countries have begun to provide such training to their forensic examiners (e.g., New York and Los Angeles in the United States, Victoria Police in Australia, Greater Manchester Police and the London Metropolitan Police in the United Kingdom, and the Netherlands in Europe).

However, most forensic laboratories do not provide cognitive training to their examiners. As a result, most examiners lack cognitive understanding and its role in their work. An example of that is that a common, but incorrect, believe among forensic examiners is that cognitive bias does not effect them (i.e., they can be exposed to contextual information without being affected – see Dror et al. 2013 for debating this issue), or that bias is an ethical matter and that it can be dealt by mere will power (e.g., Thornton 2010).

Furthermore, proper cognitive training can help examiners understand when bias is most influential. This is important as it enables not to treat all cases in the same way, requiring the same bias countermeasures to be taken, thereby helping to selectively apply rules that are fit to purpose. A triage approach can be a practical and effective way of combating potential bias (for details, see Dror 2009).

Technology

Technology can be an important ally in combating bias. Computers carry out their algorithms "blind" to context. However, one must remember that they are programmed by humans and therefore may have biases within their algorithms. Furthermore, the technology may bias the human examiners working with it.

For example, Automated Fingerprint Identification Systems (AFIS) provide a list of potential candidates for the human experts to examine. However, recent empirical research has revealed that forensic experts are biased by this meta-data: They spent less time as they go down the list and are biased that if there is a correct match it will be at the top of the list. Therefore, they are more likely to make an erroneous identification on fingerprints that are on the top of the list and miss identifications that are lower down on the list (Dror et al. 2012).

Such technology-induced bias can be effectively reduced by providing shorter lists, by randomizing the order of candidates, or by planting correct matches further down the list as test cases to cognitively engage the examiners and as a quality control measure. This is just an example of how cognitive research and understanding is important for forensic science, not only to identify problems but also to provide solutions.

Selection

Being a forensic scientist is a highly sought-after profession, and many people apply to get into this domain. Nevertheless, there are not enough scientifically based and validated tests that quantify the specific abilities needed for doing the job. Most laboratories do not use any testing, and those who do, either use general tests that do not measure the specific abilities that are needed for the job, or they use inappropriate forensic evidence as test items. For example, many latent print laboratories use a test called Form Blindness. However, this test is built to test defects, not for quantifying special abilities and talent to perform fingerprint examination. This is not only a conceptual and theoretical difference, but it has practical implications. For example, "defect" testing, such as visual acuity and the Form Blindness test, should only test for minimal threshold requirement (i.e., if you do not pass, you should not be a fingerprint examiner). Such "defect" testing does not provide scores that enable to judge and rank the relative talent of the candidates. Furthermore, the Form Blindness test was developed over 80 years ago. This is decades before cognitive psychology had even emerged and very long before brain scans and other cognitive neuroscience tools and methodologies had been developed. In the past 80 years, our knowledge and understanding of the human brain and the cognitive system, and in particular visual cognition, has increased substantially. And finally, it lacks proper validation even in the area it was designed for implementation and use, that is, for handwriting examination.

It is important that forensic disciplines to have tests that are scientifically developed and validated to select the right people for the profession. Such tests should measure the specific abilities and skills needed to do the job, that is, the raw talent.

Research

Finally, more research is needed to understand how cognition relates to forensic work and how it can benefit forensic science (for example, when considering what factors determine the effects of bias (the examiners, difficulty of the case, types of bias, etc.) and how they interact). Through better understanding of these cognitive phenomena, we can determine how forensic science can best countermeasure their effects.

For example, the use of ACE (Analysis, Comparison, and Evaluation) in fingerprints (similar approaches exist in other forensic disciplines) is often not carried out linearly, one step at a time, sequentially, and independent of each other. In the initial, "Analysis" stage of ACE-V, a latent is assessed for its suitability for comparison. Suitable prints are then compared to potential matching prints. Cognitive understanding suggests that suitability judgments may differ in the presence of a comparison print due to the cognitive influence of contextual information (e.g., Folk et al. 1992; Awh et al. 2012).

We suggest that the ACE be conducted (and documented) linearly and sequentially, each phase independent of each other (see Dror 2009, for details). Although most laboratories do not subscribe to linear ACE, such changes have been implemented by the US Federal Bureau of Investigation (FBI) and the Netherlands Forensic Institute (NFI). For example, the revised Standard Operating Procedures (SOPs) of the FBI "include some steps to avoid bias: examiners must complete and document analysis of the latent fingerprint before looking at any known fingerprint" and "instructs examiners conducting analysis of a latent fingerprint to analyze it for evidence of distortion, determine whether it is 'of value,' and document the data used during analysis" (OIG 2006, p. 27).

Because the initial latent analysis in isolation may lack the benefit of direction guided by the comparison print, Dror (2009) suggests that examiners may be allowed to return and revisit the analysis stage, but they must document and justify it. Indeed, the Office of the Inspector General (2011) clearly takes this cognitively informed approach on board, citing this approach in its report: "a solution to bias may be requiring initial analysis of the latent fingerprint in isolation from the known fingerprints, but also permitting, with clear and detailed documentation, some 'reanalysis' of the latent print after comparison" (p. 28). A recent Expert Group set up by the National Institute of Standards and Technology (2012) has reached similar conclusions and has recommended that: "Modifications to the results of any stage of latent print analysis (e.g., feature selection, utility assessment, discrepancy interpretation) after seeing a known exemplar should be viewed with caution. Such modifications should be specifically documented as having occurred after comparison had begun" (Recommendation 3.2; see National Institute of Standards and Technology 2012). Furthermore, Dror recommends that examiners be restricted to the extent that such reanalysis be allowed (e.g., that "clear" features during analysis not be changed, but "ambiguous" ones can benefit from hindsight cognitive attention); for details, see Dror (2009).

This is an example of how research and cognitive understanding can directly suggest practical ways to enhance forensic work. Cognitive forensics, the domain of using such cognitive insights to enhance forensic science, covers a whole range of issues because human cognition plays many roles in forensic work.

Summary and Conclusions

Forensic evidence is an important component of criminal justice. However, it still often lacks objective criteria and quantification instruments and remains therefore subjective. With subjectivity comes the potential of being influenced and biased by extraneous information. Erroneous identifications, theoretical and empirical research, and official inquiries – all in the past few years – have made these issues very apparent. There is growing understanding and acceptance of these issues by the forensic community, which we term Cognitive Forensics.

Cognitive forensics cuts across forensic science and addresses the examiners – which are the instrument of analysis. It focuses on the underlying cognitive processing and how this can be optimized to produce the highest possible forensic results. With the growing field of Cognitive Forensics, more and more improvements will emerge which will help support criminal justice through strengthening forensic science.

Cognitive/Information Processing Theories of Aggression and Crime

L. Rowell Huesmann
Institute for Social Research, University of Michigan, Ann Arbor, MI, USA

Overview

Over the past several decades, it has become clear that an understanding of how human cognitive processes operate is necessary for an understanding of human social behavior in general and aggressive and criminal behavior in particular. Extensive empirical research on cognitive/information processing coupled with theoretical elaborations from cognitive science constructs has led to the emergence of a unified model of cognitive/information processing in aggressive behavior. The model identifies three processes in social problem solving during which emotional arousal, activated schemas, and situational cues interact to make aggressive and criminal behavior less or more likely : (1) cue attention and interpretation, (2) script retrieval, and (3) script evaluation and selection. In addition, two processes have been identified that change stored cognitive schemas, scripts, and beliefs to increase or decrease the long-term likelihood of aggressive and criminal behavior: (1) observational learning through imitation, inference, and emotional desensitization, and (2) conditioning that increases or decreases the accessibility of encoded cognitions. While these processes may first require cognitive control in the developing child, they eventually seem to operate as relatively automatic cognitive processes.

People attend to environmental cues differentially and interpret the cues differently as a function of predisposing neurophysiological factors, their emotional arousal, the kinds of cognitive schemas they have acquired, and which schemas are activated. More aggressive individuals tend to focus on fewer cues and cues that are more frequently symptomatic of hostility, tend to interpret ambiguous cues more readily as symptomatic of hostility, and tend to believe that the world is more hostile. This is particularly true when the individual is angry, either because of situational factors or a predisposition toward more general hostility. More aggressive individuals also have a greater proportion of aggressive scripts encoded in memory with more accessible links to everyday cues. They have been found to rehearse more often their aggressive scripts through aggressive fantasizing and to recall more often aggressive scripts from ambiguous cues. It has been shown that, while young children do not have well-defined or stable normative beliefs about the appropriateness of aggression, older children do have well-formed beliefs, and those beliefs influence how they evaluate retrieved scripts. Finally, aggressive individuals often do not expect their own aggressive behaviors to have bad consequences for them.

From the social/cognitive perspective, once a youth begins to perceive the world as hostile or antisocial, begins to acquire scripts and schemas emphasizing aggression and antisocial behaviors, and begins to believe that aggression and law-breaking is acceptable, the youth enters a vicious cycle that is difficult to stop. Cognitions, behavior, observations of others, and the responses of others, all combine to promote aggression and criminality. If not interrupted, the cycle can be expected to continue into adulthood, maintaining aggressive and antisocial behavior throughout the life span.

Introduction

One of the essential ways in which humans are different from all other species is in their well-developed ability to symbolically represent, process, and communicate information. The psychological processes that humans invoke to perform these tasks are called *cognitive processes*, and the internal representations of information utilized in these processes are denoted as *cognitions*. Some reflexive behaviors may usually involve only peripheral processing, but more central cognitive processes often override these reflexes, e.g., one can will oneself to keep one’s hand on a hot coal. From this perspective, all human social behavior, including aggressive and criminal behavior, is mediated by the cognitions and cognitive processing of the participants. This does not mean that cognitive processes “cause” social behavior. Rather as mediating processes they connect biological, environmental, and situational inputs to behavioral outputs. However, different patterns of cognitive processing are more conducive to one kind of social behavior than to another.

An information-processing model of social behavior is a description of the cognitive data structures a person utilizes and the sequence of cognitive operations the person uses in order to process whatever information is encountered by the person in order to decide on a social behavior. It is most analogous to a computer program that describes the output a computer produces from given input. Cognitive/information-processing theories of aggression and criminal behavior explain the occurrence of aggression and crime and individual differences in the risk for occurrence in terms of individual differences in these cognitive data structures and the associated information-processing operations. The cognitions and information-processing operations are not viewed as ultimate causes of crime or aggression but rather as what connects innate predisposing causal factors and past and current environmental causal influences to current behavior, whether antisocial or prosocial.

History of Cognitive/Information-Processing Models of Social Behavior

The use of cognitive/information-processing models to describe human behavior first emerged in the late 1950s in studies of human problem solving (Newell and Simon 1972; Simon 1969) probably because the expertise in computer programming that such modeling requires tended to be concentrated in that area. However, it was quickly recognized that the formalization and detailed specification of processes required in information-processing models make them more valuable than either natural language or mathematical statistics for modeling any kind of human behavior. In the early 1960s, two books – Feigenbaum's (1963) *Computers and Thought*, and Miller, Galanter, and Pribram's (1960), *Plans and the Structure of Behavior* – stimulated thinking about information processing in many areas of psychology, and by the mid-1960s Abelson (1968), Gullahorn & Gullahorn, Loehlin, Simon (1969), and others had begun to describe psychological models of a variety of social behaviors in terms of underlying cognitive structures and information processes. By the 1970s and early 1980s, more specific information-processing theories of different kinds of social and abnormal behavior were appearing (Carroll and Payne 1976; Huesmann 1982). The term "social cognition" became popular sometime in the late 1970s (Wyer and Carlston 1979), and with the publication of more often Fiske and Taylor's (1984) book on social cognition, cognitive/information-processing theorizing became part of the mainstream of thinking about social behavior.

The early 1980s also brought the first cognitive/information-processing analyses of aggression. Huesmann (1982, 1998; Huesmann and Eron 1984), building both on Bandura's ideas and Newell and Simon's (1972) thinking, offered a general information-processing model for aggression focusing particularly on observational learning, and Dodge (1993; Crick and Dodge 1994) offered a general information-processing model for aggression focusing particularly on perceptions and attributions. Shortly afterward, Slaby and Guerra (1988), building on Shure and Spivac's analysis of adolescents' adjustment problems as failures in social problem solving, expanded these ideas to analyze delinquent's criminal behaviors in terms of underlying cognitive/information-processing abnormalities. Since then, a variety of elaborations of the models have emerged (e.g., Anderson and Bushman 2002) and a reasonable consensus has developed about the ways in which human cognitions and cognitive processes mediate aggressive and criminal behavior. But before turning to a more detailed discussion of those models, we must review a number of general principles of information processing.

Fundamentals of Cognitive/Information-Processing Models

Cognitive/information-processing models formally lay out the sequence of cognitive processes involved in the occurrence of a behavior much as a computer program lays out the sequences of operations in a computer that produces a particular output. A basic assumption is that the human mind can be viewed as analogous to a computer. Behavior is the output of software programs operating within the biological hardware constraints of the brain. A closely related assumption is that behavior is best modeled with hierarchical levels of explanation (Simon 1969). For example, an aggressive interaction might first be modeled in terms of relevant interacting behavior sequences (e.g., she shouted at him; he told her to shut up; she shouted again; he hit her). The behavior sequence might then be modeled in terms of a higher level program for behavior (e.g., follow rule to retaliate when insulted by female). The operation of such programs might then be modeled by more fundamental cognitive processes, e.g., retrieval of rules by spreading activation; these more fundamental processes might be modeled in terms of neurophysiological reactions which in turn might be modeled in terms of biochemical processes. Different theories of social behavior may use different levels of explanation within, but generally most theories adopt a level analogous to programming in a high level computer language. The formal properties and limitations these programming languages and symbol systems place upon the modeled processes are well understood, and the natural language interpretations of the programs are also usually easily followed by other researchers.

Cognitive/information-processing theories of social behavior assume that a person's social behavior is completely determined by the configuration of hardware, software, knowledge structures, and environmental inputs that the organism has experienced. However, because all these elements are never completely known, behavior can never be perfectly predicted. Specific models sometimes include stochastic elements to model individual variations, but, even without them, complex variations in behaviors and cognitions are obtained because of the wide diversity of experiences encountered by different individuals. Cognitive/information-processing models are models of individuals' social behaviors, not of group means. Different individuals have different hardware, software, and data structures. Different situations generate different inputs. Most often models are developed that assume similar programs and structures for different individuals with well-defined loci for individual differences, e.g., perhaps the procedure for deciding whether or not to attribute hostility to another is the same for most individuals, but the database of past experiences on which they base their decision varies.

Every cognitive/information-processing model has an *executive program* (i.e., operating system) that specifies the overall flow of cognitive processes that are hypothesized, *subroutines* that represent the detailed operation of specific cognitive processes that are available, and multiple data structures in *memory* that represent the modeled individual's cognitions. Some cognitive/information-processing models may include mechanisms for self-modification of the cognitions through a variety of learning processes.

Connectionist Alternatives

One limitation of cognitive/information-processing models is that the relations between the basic information processes and the underlying neurophysiological processes of humans remain obscure. A second related problem is that cognitive/information-processing models most often hypothesize multiple programs that operate sequentially instead of in parallel (probably because until recently the machine languages available to simulate cognitive processes operated sequentially). However, there is significant evidence that many human cognitive processes occur in parallel.

One consequence of these problems has been the emergence of what have come to be called "connectionist" models of cognitive/information processing (Feldman and Ballard 1982). Such models attempt to explain social behaviors using simulated neural networks in which parallel processing is a natural property. The ability of such simulated neural networks to accurately model anything more than the most rudimentary social behaviors remains to be demonstrated. An alternative approach to incorporating parallel processing into cognitive/information-processing models has been to simulate parallel processing with rapid sequential processing. This approach is derived from the empirical finding that it is very difficult to tell if particular information processes in the human brain are operating in parallel or in rapid sequential order (Simon 1969). Information-processing theorists point out that it is important not to confuse "sequential" processing with "linear" models. Nonlinear relations can be modeled quite adequately with sequential information-processing models.

Basic Processes and Data Structures in Cognitive/Information-Processing Theorizing

Cognitive/information-processing models of social behavior have drawn on empirical knowledge about human cognition and human social behavior to define a set of basic processes and data structures that seem to explain different kinds of human social behavior. As mentioned earlier, one can think of any cognitive/information-processing system as consisting of a *memory* in which *data and programs* can be stored and an *executive program* which distributes resources and has overall control over the system. In controlling social behavior, this cognitive/information-processing system accepts inputs of social stimuli that define a particular social situation. The executive program calls upon appropriate subroutines to process the inputs, search memory for relevant information, and generate potential social behaviors for that situation. If a social behavior passes a final test of appropriateness, then it is performed (Anderson 1983).

Memory Structures

Conceptually, human memory consists of a network of nodes and links that represent encoded propositions. The meaning of each node is defined by its associated links which represent labeled attributes whose values are other nodes. Real-world meaning is ultimately given to the symbolic encodings by the connections of the network nodes to representations of external stimuli – visual, auditory, etc., but more immediate meaning is given by the connections to other symbolic nodes. *Elaborative rehearsal* of information generates more links to the rest of the network and more firmly encodes information in the network. Elaborative rehearsal goes beyond simple repetition of information and involves consideration of how the new information fits with other knowledge already encoded.

Memories are *retrieved* by being *activated*. One can imagine a *spread* of activation emanating out from one node to connected nodes. A cue, either an external stimulus or an internally activated schema or mood, activates the first node. As each successive node becomes activated, it is said to be retrieved, but the strength of activation diminishes as greater distance separates linked nodes. Clearly multiple links enhance the likelihood of recall although multiple nodes with similar links may produce inaccurate recall due to *interference*. However, retrieval of information generally is not a blind spreading activation process but rather a more directed *heuristic search*. Particular branches of the network are followed that appear particularly promising and the activated nodes are tested to see if they meet a criterion for what is being sought. Spreading activation occurs automatically at a subconscious level. Activated nodes can emerge into consciousness but can also exert influence while remaining subconscious. When the activation of a node is increased by an external stimulus or a related thought, we say that the node has been *primed*. Within this system, there is a conceptually distinct *short-term or working memory* where information being actively processed resides but from which information decays rapidly. If information is activated long enough in short-term memory, it is likely to be integrated into the unlimited-capacity *long-term memory*. Thus, attention to social information (i.e., maintaining it in short-term memory) can have a direct effect on the likelihood that it will be encoded in long-term memory.

Within this framework, *schema* is a term used to refer to any cognitive knowledge structure encoded in memory that represents substantial knowledge about a concept, its attributes, and its relations to other concepts. Each individual's memory contains "self-schemas," which are organized knowledge about themselves, "world schemas," which are organized knowledge about the world, "event schemas" which are organized knowledge about relations between events and behaviors, "belief-schemas," which are organized sets of beliefs, and so on.

Information-processing theorists have shown that a very few basic information processes operating on such schemas and external inputs can account for very complex behaviors. Among the most basic processes are the *generate-and-test* process (sometimes denoted TOTE – test, operate, test, execute) which involves retrieving information packets repeatedly from memory until one finds one that passes a logical test. Another is the *test and branch* operation which involves changing the sequence of processing operations based on a logical test. Still, another is the *linking or assignment* process which involves connecting two nodes in memory – for example, connecting a node representing an object to an emotion such as anger. Individual differences in the ability to control and sequence these basic operations are common and are often referred to as individual differences in *executive functioning*. A variety of studies including f-MRI studies have suggested that executive functioning is centered in the prefrontal cortex and may be decremented by damage to the prefrontal cortex.

Retrieving Social Information

The ease with which any kind of information or response can be accessed in the human central nervous system depends on how elaborately it has been encoded. Even simple S-R pairings are more likely to be elicited if there are multiple paths from stimulus to response. As described above, activation of social information in memory can be viewed as spreading activation processes with the spread of activation often being guided by already encoded schemas (heuristic search). For example, if you see someone you know as a librarian walking down the street, your mental search for explanations for what they are doing will be influenced by your schema for librarians.

Such memory search is activated by immediate *social cues* which provide the input to begin the search, e.g., the librarian in the above example. However, the speed and success of retrieving social information is also influenced by recent stimuli that may have activated relevant schemas in memory, making them more accessible. As mentioned above, this process is known as *priming*. For example, you may be more likely to recognize the librarian on the street if you have just previously walked by the library and had the library schema activated. *Emotions and moods*, such as anger or depression, also serve as cues that activate related schemas or scripts.

The activation of a particular schema or node in memory has automatic effects on social inference and behavior, but another process called *filtering* may limit the effect of any activated information. Filtering is the testing process through which the executive routine decides if the activated information is the information sought or whether the search should continue. This is an example of the basic generate-and-test information-processing operation described above. Filters may be simple tests of accuracy for the information or they may be tests of appropriateness of the scripts or behaviors activated. The cognitive schemas that guide specific filtering for social behavior have been denoted as self-regulating internal standards by Bandura (1986) or normative beliefs by Huesmann and Guerra (1997).

Automatic and Controlled Cognitive Processing

Studies of cognitive processing have revealed that at least two different modes of processing exist with quite different speeds and demands on conscious resources (Schneider and Shiffrin 1977). *Automatic processes* occur very rapidly, without using many cognitive resources, and without any conscious executive decisions being made about the process. Reading is one example. Many social-perception processes are automatic including "schema-triggered affect" (Fiske and Taylor 1984), memory priming effects, and spontaneous trait inferences (Bargh 1982). *Controlled processes* occur more slowly, require more cognitive resources, and demand conscious executive control. Conscious planning of how to deal with a social situation would be one example. The boundaries are sometimes fuzzy, and many controlled processes may become automatic either as part of a child's development or with repeated practice or rehearsal. For example, in a novel social situation, a person may engage in a controlled search for scripts that could be used in that situation. But highly familiar situations quite probably automatically trigger scripts that fit the situation.

Stress, Mood, Arousal, and Information Processing

The level of arousal that the human information processor is experiencing seems to change information processing in a number of ways. As arousal levels become higher than normal, attention seems to be directed more narrowly at a few cues that seem to be the most salient. Very high levels of arousal seem to decrease working memory capacity, narrow memory search, make activation of weakly associated schemas less likely, and make the activation of the best connected schemas and scripts most likely. For simple tasks, this restriction can produce enhanced performance which may provide an evolutionary explanation for the phenomenon; however, for complex tasks requiring extensive heuristic search for solutions, performance will worsen. Of course, stress is one of the most common causes of high arousal. As a result, in stressful social situations, one can expect that a person will focus on what seem to be only the most salient social cues, activate only the schemas and scripts that are most closely connected to those cues, and generate a narrow range of behaviors. Thus, when stress is coupled with emotions like fear or anger and coupled with situational cues linked to aggressive scripts, only violent schemas are likely to be activated. For example, a young male whose life is being threatened by another young male with a gun may find it very difficult to attend to any other cues in the environment besides the gun, or to retrieve any other scripts than simple scripts for fighting or fleeing.

The Cognitive/Information-Processing Theory of Aggressive and Criminal Behavior

The accumulated knowledge about human cognitive/information processing and social cognition as outlined above provides important insights into the processes involved in many social behaviors including crime. But it is important to realize that social cognition is NOT a cause of aggressive or criminal behavior. Social cognition is a *mediating* process that connects external situations, internal schemas, and social behavior in predictable ways. More generally, the existing research suggests that habitual aggressive and antisocial behavior is a product of *innate predisposing cognitive and emotional factors*, interacting with *exposure to an aggression-promoting social environment* that encourages the development of social cognitions promoting aggression, interacting *with situationally specific precipitating factors*. From a social cognitive/information-processing perspective, the variety of predisposing factors discussed above may make the emergence of certain specific cognitive routines, scripts, and schemas more likely, but these cognitions develop through interactions of the child with the environment and are designed to respond to different environmental situations. In early childhood, these cognitions promote aggressive behavior below the delinquent and criminal level and later promote criminal and violent behavior. Consequently, child aggression predicts adult criminality (Huesmann et al. 2002).

Slightly different cognitive/information-processing explanations for the occurrence of antisocial behavior have been formulated by Huesmann and colleagues (Huesmann 1982, 1998; Huesmann and Eron 1984; Huesmann and Guerra 1997), by Dodge and his colleagues (1993; Crick and Dodge 1994), and by Anderson and colleagues(Anderson and Bushman 2002). However, while they have had different emphases, all draw on Bandura's (1986) social/cognitive theorizing emphasizing self-regulating internal cognitions and draw on Berkowitz's (1990) neo-associationist ideas. Furthermore, all agree that there is a common set or core social cognitions and information-processing operations that explain how certain predisposing factors, socializing environments, and precipitating stimuli lead to aggressive and antisocial behavior. Here, one overall summary model is presented that combines the common cognitive/information-processing elements that have been theorized to explain aggressive and criminal behavior.

This model incorporates the premise that social behavior is controlled to a great extent by cognitive *scripts* (Abelson 1981) that are stored in a person's memory and are used as guides for behavior and social problem solving. As described above, a script incorporates both procedural and declarative knowledge and suggests what events are to happen in the environment, how the person should behave in response to these events, and what the likely outcome of those behaviors would be. It is presumed that while scripts are first being established, they influence the child's behavior through "controlled" mental processes (Schneider and Shiffrin 1977), but these processes become "automatic" as the child matures. Scripts that persist in a child's repertoire become increasingly more resistant to modification and change as they are rehearsed, enacted, and generate consequences. More aggressive and criminal individuals are presumed by this theory to have encoded a much higher proportion of social scripts utilizing aggressive and criminal actions.

World schemas stored in a person's memory are the second kind of cognitive schema that plays an important role. World schemas are the database that individuals use to make attributions about others' behaviors. Individuals with schemas representing the world as a more hostile place are more likely to attribute hostility to the behaviors of others and to behave more aggressively. *Normative beliefs* are the third kind of cognitive schema hypothesized to play a central role in regulating aggressive behavior.

Normative beliefs are cognitions about the appropriateness of social behaviors. They are related to perceived social norms but are different in that they concern what is "right for you." Normative beliefs are part of one's self-schema and serve as part of the database used to filter potential scripts that are retrieved from memory. A social script that suggests an aggressive behavior may not be employed if it violates the individual's normative beliefs.

Cognitive/Information Processing Proximal to a Social Behavior

These internalized cognitive schemas are utilized in a specified sequence of information-processing steps at the moment a social problem is encountered to determine how the individual responds. First, individuals attend to some of the environmental cues and evaluate the cues to which they attend on the basis of their world schemas and their own internalized emotional states. Then they retrieve social scripts that might seem to fit the situation and with a heuristically guided generate-and-test process. Each retrieved script is then evaluated not only on the basis of its projected objective outcome but also on the basis of its consistency with the individual's normative beliefs. Thus, at the moment when a social problem is encountered, there are three main processing loci at which individual differences in internalized cognitions and environmental stimuli can influence behavior: (1) cue attention and evaluation, (2) script retrieval, and (3) script evaluation and selection.

Cue Attention and Evaluation. The objective situation for any social problem is defined by the social problem and the environmental cues. However, which cues are given most attention and the interpretation of those cues may vary from person to person and may depend on a person's neurophysiological predispositions, current emotional state, and previous learning history as reflected in their activated world schema. Because emotional states may persist for some time, a person may enter a social interaction in an emotional state that is unrelated to the current situational cues. For example, a person exposed repeatedly to frustrating situations, who attributes the goal-blocking to the actions of others, may enter a social interaction in an aroused state with hostile feelings toward everyone. Independent of one's current emotional state, environmental stimuli cue the retrieval from memory of emotions and cognitions that have been associated with that cue in the past. For example, the “sight of an enemy” or the “smell of a battlefield” may provoke both instantaneous physiological arousal and the recall of thoughts about the “enemy” that give meaning to the aroused state as anger. That emotional state may influence both which additional cues the person attends to and how the person interprets the cues to which he or she does attend. A highly aroused, angry person may focus on just a few highly salient cues and ignore others that convey equally important information about the social situation. Then the angry person’s evaluation of these cues may be biased toward perceiving hostility when none is present. A person who finds hostile cues the most salient or who interprets ambiguous cues as hostile will be more likely to experience anger and activate schemas and scripts related to aggression.

Script activation and retrieval. It is presumed that more aggressive and antisocial individuals have encoded in memory more extensive, well-connected networks of social scripts emphasizing aggressive and antisocial problem solving. Therefore, such a script is more likely to be retrieved during any search. However, the search for a script is also strongly affected by one’s interpretation of the social cues, one’s activated schemas, and one’s mood state and arousal. For example, anger, even in the absence of supporting cues, will make the retrieval of scripts previously associated with anger more likely; the presence of a weapon, even in the absence of anger, will make the retrieval of scripts associated with weapons more likely; and the perception that another person has hostile intentions will activate scripts related to hostility.

Evaluation of scripts and script selection. The third locus for the expression of individual differences and situational variation occurs after a script is activated. Before acting out the script, one evaluates the script in light of internalized activated schemas and normative beliefs to determine if the suggested behaviors are socially appropriate and possible to do and if the expected outcome is likely to be desirable. People with different normative beliefs may thus evaluate the appropriateness of a script quite differently, and the same person may evaluate the same script differently at different times.

On the average, however, the habitually aggressive are expected to hold normative beliefs condoning more aggression and thus will employ more aggressive scripts. For example, if a man suddenly discovers that his wife has been unfaithful, he may experience rage and access a script for physical retribution. However, whether or not the man executes that script will depend on his normative beliefs about the appropriateness of “hitting a female.” More general normative beliefs may also be relevant. The man who believes in “an eye for an eye” and perceives himself as “an avenger” is more likely to retrieve a script emphasizing aggressive retaliation. Even within the same person, different normative beliefs may be activated in different situations and different mood states. The person who has just been to church may have activated quite different normative beliefs than the person who has just watched a fight in a hockey game on TV.

Scripts predict likely outcomes, but people also differ in their capacities to think about the future, in their concern with the future, and in their evaluation of the desirability of an outcome. The more a person focuses on immediate consequences and the less the person is concerned with the future, the more palatable a self-centered solution to a social problem may seem. For example, if the man above who hit his spouse was concerned about what his in-laws will think of him if they hear about it in a few days, he might not have hit her. Of course, people may also misperceive the likely consequences of aggressive acts simply because their scripts are inaccurate in predicting consequences for the current situation. Additionally, people differ in their evaluations of the desirability of an outcome. For some people, the respect of their peers may be the most important evaluative dimension for an outcome from a social conflict while for others, simply ending the conflict may be most important. For other people, the thought of violence may be so anxiety provoking that aggressive scripts are filtered out. However, as described later, those who have been exposed to violence repeatedly and have become emotionally desensitized to violence experience little negative affect when evaluating aggressive scripts and, thus, are more likely to use them.

Emotional arousal, schema activation, script generation, and evaluation. Cognitive/information-processing models of social behavior are sometimes thought of as “cold” models with little room for affect. However, the unified cognitive/information-processing model for aggression described here hypothesizes a key role for emotion at each stage of cognitive/information processing. Both an individual’s absolute arousal level and the valence of the arousal affect aggressiveness at each stage. Existing negative affect interpreted as anger will bias cue interpretation toward hostility, will prime the retrieval of aggressive scripts, and will cue normative beliefs more supporting of aggression. As described earlier, in high states of arousal, individuals search less widely and deeply for scripts and retrieve the best connected scripts; so aggressive behavior becomes even more likely in highly arousing situations for persons with predominately aggressive scripts. For the individual with a large well-learned repertoire of simple, direct aggressive scripts for solving social problems and a smaller less-well-learned repertoire of complex, indirect scripts for prosocial solutions, the arousal associated with anger will make the selection of an aggressive script even more likely than priming from the anger would by itself. Furthermore, one can expect similar effects for script evaluation. A person in a highly aroused state of rage because of a provocation will evaluate scripts less carefully and focus on retaliation beliefs in evaluating scripts because his/her rage has primed such normative beliefs.

Cognitive/Information Processing for Acquiring and Maintaining Aggressive Scripts and Schemas

According to social cognitive/information-processing theory, a habitually aggressive or criminal person is presumed to be someone who regularly retrieves and employs aggressive or criminal scripts for social behavior. The theory allows a number of factors that might promote the retrieval and utilization of aggressive and criminal scripts. It may be, for example, that the cues present in the environment trigger the recall only of aggressive scripts. However, the regular retrieval and use of aggressive scripts would suggest above all that a large number of aggressive scripts have been stored in memory. Similarly, the regular execution of such scripts would suggest that normative beliefs and other schemas supporting aggression have been acquired and encoded. How does this happen?

While a variety of preexisting neurophysiological factors can predispose individuals toward particular modes of cognitive processing or toward particular schemas and scripts, cognitive/information-processing theory asserts that the child’s early learning experiences play a critical role in the acquisition of scripts and schemas for social behavior just as early learning plays the key role in the acquisition of procedural and declarative knowledge relevant to intellectual life. Evolutionary forces and random variation create communalities and individual differences in the biological mechanisms underlying cognition and behavior. These individual differences in biology interact with individual differences in environment to mold the schema encoded in memory into those that promote nonaggressive prosocial behavior or those that promote aggressive antisocial behavior. Both enactive learning processes (i.e., conditioning, elaborative rehearsal) and observational learning processes (i.e., imitation, desensitization) are involved in the encoding of these social cognitive schema.

As Huesmann and Kirwil (2007) have described, social scripts, world schemas, and normative beliefs are all initially acquired through imitation and inference (observational learning). Imitation is an innate process in humans. It is established that human infants begin mimicking behavior when they are only a few months old but advance in early childhood to imitating entire scripts and inferring world schemas and normative beliefs from what they see others doing. Imitation is not a low level cognitive process but rather a complex high level process in which the scripts, schemas, and beliefs detected to be held by others are encoded into one’s own memory.

During the observational learning process, the person's current emotional state and current memory contents influence which existing schemas are activated. The activated schemas in turn influence how well the observed schemas can be encoded and integrated into memory. If the activated schemas are discrepant with the observed schemas, encoding is difficult; if they are consistent, it is easier. When highly aroused and angry, for example, persons may view a physically aggressive or antisocial script as more appropriate than they would otherwise. A young boy who can only recall seeing aggressive behaviors is more likely to encode a newly observed aggressive behavior than is a boy whose mind is filled with memories of prosocial solutions. A child with normative beliefs accepting of aggression is much more likely to encode new aggressive scripts for behavior. Consequently, violent and criminal behaviors become contagious. Violent and criminal behaviors tend to beget other violent and criminal behaviors in those who observe them.

Once it is encoded, the accessibility of a script in memory is influenced by the extent to which its use produces desired consequences, i.e., by instrumental learning. One might think that, because aggressive or criminal behavior very often produces negative consequences for the aggressor, the retrieval of aggressive scripts would extinguish. However, instrumental learning depends as much on how the individual interprets society's response to the behavior as it does on the response. As described above, very often, because of the schemas activated, the aggressor does not attribute the negative reaction of society to the specific script that the aggressor employed, and no learning takes place. The boy who is harshly punished by a teacher for pushing another child out of line will not unlearn the behavior if he interprets the cause of his punishment as dislike by the teacher.

As with all learned information, for a script or schema or normative belief to stay highly accessible, it needs to be rehearsed from time to time. The rehearsal may take several different forms, from simple recall of the original scene, to fantasizing about it, to play acting. The more elaborative, ruminative type of rehearsal characteristic of children's fantasizing is likely to generate greater connectedness for the script, thereby increasing its accessibility in memory. Also, through such elaborative rehearsal, the child may abstract higher-order scripts representing more general strategies for behavior than the ones initially stored. Of course, rehearsal also provides another opportunity for reevaluation of any script. It may be that some scripts initially accepted as appropriate (under specific emotional and memory states) may be judged as inappropriate during rehearsal.

Empirical Data on Cognitive/ Information processing and Aggression

Empirical Data on Cue Attention and Evaluation

Extensive research shows that more aggressive individuals tend to perceive hostility in others where there is no hostility, i.e., display a hostile attributional bias (Dodge 1993). Longitudinal analyses have suggested that a propensity toward hostile attributional bias mediates the relation between early childhood aggression and later antisocial behavior. Furthermore, recent experiments with random assignment of subjects have shown that improving the accuracy of intent attributions decreases the likelihood of aggressive behavior in children.

Empirical Data on Script and Schema Acquisition and Activation

While it has been methodologically more difficult to assess the kinds of scripts that individuals have encoded, one can assess the kinds of scripts they are most likely to retrieve and make inferences from those data. The available evidence suggests that, in fact, the more accessible scripts for more aggressive children are more aggressive. The scripts retrieved by more aggressive children to solve hypothetical problems tend to incorporate more physical aggression and manipulation actions. Priming by negative intent cues is more likely to activate an aggressive script in aggressive children. Aggressive children are less likely to generate more subtle prosocial scripts to solve social problems and there is some evidence that, as hypothesized, a narrower search process for a script is associated with more aggressive behavior.

There is also extensive evidence that the observation of aggressive or criminal scripts in real life or in the mass visual media leads to the encoding of such scripts. Children growing up observing violence around them in their neighborhood behave more violently (Guerra et al. 2003) and those observing such violence frequently in the mass media behave more criminally even 15 or 22 years later (Huesmann et al. 2003; Huesmann and Eron 1992). Numerous laboratory and field experiments and everyday observations of "copycat" crimes have demonstrated the encoding of specific scripts from observations of violence and crime. It is also clear that new aggressive scripts are abstracted out of the elements of specific scripts being observed. Thus, the aggressive scripts that children display after being exposed to violent scenes are not exactly the same as the scripts observed. As cognitive/information-processing theory predicted, rehearsal of antisocial scripts through fantasizing about them has also been shown to increase their accessibility and likelihood of use (Huesmann and Eron 1984, 1992).

There is also significant empirical support for the premise that even quite different specific aggressive scripts and schemas are linked together in one's memory network by a common "hostility" node and thus can be primed by other aggressive ideas or cues, even if they have no substantive connection. For example, Berkowitz and LePage (1967) showed that even the brief sight of a "gun" increases the likelihood that a provoked person will behave more aggressively in ways that have nothing to do with guns.

Empirical Data on Evaluation of Scripts

Once a script has been activated, it still may not be employed if it is evaluated negatively. The behaviors involved may be evaluated as inappropriate when filtered through an individual's normative beliefs about aggressive and antisocial or criminal behavior. Its expected outcome may be evaluated as undesirable when environmental responses are considered; or it may be evaluated as undoable when filtered through conceptions of self-efficacy. A variety of studies have shown such filtering effects. Huesmann and Guerra (1997) showed that normative beliefs that aggression is unacceptable reduce the likelihood of a youth behaving aggressively as does a priming of self-schemas that the person is nonaggressive. On the other hand, Baumeister and colleagues have demonstrated that a self-schema that includes an extremely positive evaluation of oneself (a narcissistic evaluation) promotes the selection of aggressive scripts when a person threatens that self-evaluation. Not only are self-schemas relevant to script evaluation, schemas about others are relevant too. For example, schemas about others which promote deindividuation allow the utilization of aggressive scripts which might otherwise be unacceptable.

The evaluation process for a generated script also includes an assessment of outcome "desirability." In fact, there is accumulating evidence that more aggressive children tend to believe that aggressive behavior will have more desirable outcomes, and prosocial behavior will have less favorable outcomes (Crick and Dodge 1994). Desirability also appears to be evaluated in terms of how the anticipated behavior and outcome "feel" to the person. If thinking about behaving criminally or violently makes one feel bad, one is less likely to behave that way. Repeated exposure to others behaving violently or criminally emotionally desensitizes people so they do not feel so bad when they think about it (Huesmann and Kirwil 2007). Thus, it becomes easier for them to behave criminally or violently.

The above studies have shown that aggressive youth differ from other youth in the beliefs and schemas they use to evaluate the appropriateness and effectiveness of potential scripts. However, there is also evidence that some youth are more aggressive because they do not devote much cognitive effort to this filtering step. For example, empirical data suggest that certain children, e.g., ADHD children, are neurophysiologically predisposed toward minimizing this evaluation step. The result is what many observers would call impulsive behavior (Kendall and Braswell 1985). If the first scripts activated are aggressive or criminal scripts, the result is aggressive or ciminal behavior even if the child "knows" upon reflection that the behavior was inappropriate.

Empirical Data on Gender Differences in Aggression and Crime

Males are much more likely to behave physically aggressively and much more likely to commit crimes. Some of these differences can be explained by differences in encoded cognitive schemas and differences in social cognitive development (Bennett et al. 2006). While many people hold normative beliefs that aggression by males is appropriate in some situations, that is not so true for females. Additionally, females acquire social cognitive skills earlier in life than males and consequently have better elaborated prosocial scripts for social problem solving. Such scripts may also work better for females because of females' superior (on average) verbal ability. Finally, differential socialization by society which disapproves of aggression in females leads to lower accessibility of aggressive scripts for females.

Communities and the Police

Jack R. Greene

Overview

> *One generation plants the trees; another gets the shade* – Chinese Proverb

This entry considers how research has come to understand the idea of "community" and its implication for civic governance, most particularly in respect to the public police. At the same time, this entry considers what has been learned about the role that each (community and the police) plays in the loosely connected network of social control, and the implications of communities' characteristics and processes for policing more broadly, as well as for their capacity to validate the law and the police.

For several years, reformers, community advocates, and policy makers have emphasized that communities have broader roles to play in policing (Greene 2000). This prompts a consideration of whether communities can indeed coproduce public safety, particularly in residential neighborhoods, and what constrains or facilitates communities in adopting such roles? Lastly, in a late-modern world the question arises, "Can we expect communities to be fully engaged in such activities, or have our notions of social cohesion and integration been inextricably altered?" Such questions explore the ways in which communities contribute to policing, broadly cast, and the limitations or restraints on such contributions.

This entry considers the idea of "community" as a central concept of social theory, more specifically in crime theory, the ways that the idea of community has evolved, and the implications of such evolution for social control and policing. It is an attempt to address what are often juxtaposed ideas: the mechanisms of informal (community) and formal (police) social control and how they impact one another in neighborhood settings. It also addresses the idea that to be effective and accepted, legal sanctions and legal actors need community validation and support, particularly in democratic societies, posing an additional criterion of institutional legitimacy in the discussion of the interactions between community and police. This entry first considers shifting conceptions of community and how they are related to crime and crime control theories. Second, the focus shifts to how the police have come to the idea of community attachment, and some of the complexities of such interactions. Third, this entry considers how police and communities form alliances for crime prevention and what evidence supports the effectiveness of such an approach. And, lastly a consideration of whether there is a broader role for the community in such matters is undertaken.

The Community Perspective: Key Issues

> *The impersonal hand of government can never replace the helping hand of a neighbor* – Hubert H. Humphrey

The idea of the community or *gemeinschaft* was introduced in the late 1800s by Ferdinand Tonnies (1887), a German sociologist. Tonnies' *Gemeinschaft* refers to associations among individuals that orient their identity and behavior to the common mores, customs, and beliefs helping to unify the collective, what he referred to as the "unity of will." Being part of this collective, bound by shared beliefs and shared places, undergirds ideas about what it means to be part of a community. While the family is often seen as the model for *Gemeinschaft*, other associations not based on birth status include communities defined by proximity, as well as those more dispersed, yet connected by beliefs or association (*Gesellschaft*). It was Tonnies' central contention that modern societies gradually moved from *Gemeinschaft* to *Gesellschaft*; from groups based on primary associations (such as kin and close neighbors) to secondary associations (such as workgroups).

In such arrangements, social action, as defined by Weber (1991), takes into consideration the behavior of others, orienting social and group relations. Communities shape and reinforce social relations, providing identity and meaning to those in the community. The idea of community, then, is a social construction, creating shared social realities and interpretations among members, and orienting individuals to others, typically through face-to-face interaction. Such conceptions of community have historical referents, the applications of which are not always clear in the modern world. Nonetheless, the notion of the *Gemeinschaft* community in the conceptions of Tonnies and Weber persists, symbolically and nostalgically.

In discussions of what "community" means, a prime consideration is the type and strength of solidarity in social relations, and the type and degree of social integration in a society. Solidarity, it is said, binds people to social relations (their neighbors and external others) outside the immediate family, and the level and strength of solidarity produces a range in group cohesion and collective identity. Durkheim (1949) was concerned with how to reconcile individual autonomy and collective action in society, that is, how the social order takes shape and is maintained. Durkheim (1949) distinguished between mechanical and organic solidarity as ways in which the social order and social cohesion are affected by the division of labor. In simple societies, kinship and shared values produce social cohesion ("conscience collective") and solidarity, generally through "likeness," that is, the similarity of people in social groups. In more complex societies, an organic solidarity is produced by linking of people through similar work, educational backgrounds, religious affiliation, or lifestyle. Social solidarity, then, arises through kinship ties as well as broader affiliations associated with work or through the interdependence of social arrangements, producing a range of communities, the older ones structured by close ties, and more modern communities being loosely coupled.

The idea of community has been explored from many perspectives, most of which see communities as having dense social and emotional connections, a sense of shared norms and beliefs, social reciprocity, and varying degrees of social responsiveness (Day 2005) (i.e., the *Gemeinschaft*' type). Of course, most of these characteristics of communities are also shaped by close geographic proximity – people living together.

While there is considerable variation in discussions about the most central elements of community, and how these elements have been transformed in the modern and late-modern worlds, the layperson conception of community persists; a collection of persons who share membership (sometimes tightly, sometime loosely) in a social grouping, often but not exclusively constrained by geography, and reinforced by social integration, accommodation, and responsiveness. Whether such definitions can persist in a cyber-networked world or in the face of declining community affiliation remains an open question. Nonetheless, over the past 35 years or so, governments have been systematically reorienting themselves, symbolically if not substantially to better integrate themselves within communities. The rise of the community-government era, with community-health, community-education, community safety, and community policing, among others, is a testament to the power of the idea of community in social, political, and economic life.

Criminology has embraced the idea of community influences in crime for many years, beginning with the work of Shaw and McKay (1942) and continuing to the present. Ideas about crime, most particularly its community roots, suggest that social cohesion in neighborhood or community settings shapes the collective efficacy of that neighborhood, or the level of trust among neighbors, as well as their willingness to intervene in matters of local social control (Sampson et al. 1997). Collective efficacy expresses the idea of neighborhood social cohesion, but perhaps in a less complex and intense way than is the case in previous ideas about community social cohesion. Here the focus is on situated neighborhood collective action rather than broader images of community social action and responsiveness emerging from deep emotional and social bonds. In the modern case, collective efficacy is situational and focused, not broadly cast and diffuse. Nonetheless, the effects of concentrated disadvantage and residential instability with violence are largely mediated by collective efficacy (Sampson et al. 1997).

Collective efficacy also speaks to the ability of communities to exercise whatever social capital is available, that is, to leverage social relations through cooperation and confidence building to achieve larger collective ends. Whereas collective efficacy can be seen as the strength in horizontal bonds between neighbors, social capital can been seen as the capacity of local social networks to vertically integrate within larger political, economic, and social networks, thereby achieving or maximizing local benefit. Knowing something about the level of collective efficacy and social capital in communities, then, tells us something about how that community manages its social affairs and with what effects. Of course, socially dysfunctional and disorganized communities lack both conditions, often succumbing to deviance and criminality, but this occurs in degrees and over time can change.

Community dynamics, then, shape local affiliation and orientations toward collective action, as well as strengthen social networks beyond the local community. From the perspective of modern policing, increasing community collective efficacy and social capital strengthens local social control, the first line of defense in matters of deviance, social disorder, and crime. So as a strategic matter, supporting the development of community collective efficacy and social capital should occupy police attention.

However, as discussed below, policing is not particularly well equipped to directly engage in "community building" other than, perhaps, to attempt to control unruly and disorganized places in the hope of creating an envelope in which community cohesion can grow and strengthen. While it has been argued that community policing has the potential for creating trust in the police, thereby raising community collective efficacy, the conundrum for modern policing is how to use formal processes to support the informal development of "community," or at least some representation of local social control that can strengthen neighbor-to-neighbor bonds, and build social capital. These are difficult arrangements to support. If socially disorganized communities are characterized by poverty, population heterogeneity, transience, and disorderly and criminal conduct, then addressing first-order conditions, such as controlling the streets by the police, does not necessarily lead to improving the stability of these areas. Oftentimes aggressive police action in communities produces mixed responses, with some supporting police interventions and others not. Moreover, it is not clear that in pursuing partnerships with "the community," police and community values can actually align (Thacher 2001).

Moreover, in undertaking such an approach, how communities react to police interventions is not well understood, particularly in light of variations in community composition, structure, and level of social disorganization. How the range of communities are to "partner" with outside agencies is also problematic, given the general findings that (1) identifying a clear voice for community representation is problematic, (2) and community participation in crime-oriented activities and meetings wanes over time.

Understanding what internal community capacities to coproduce local public safety are present and how these capacities (if they exist at all) can be enhanced and sustained are also topics with sparse intellectual and program attention. Lastly, two questions bearing on these matters remain unanswered, (1) what is the tipping point, when communities slide into a place where their capacity to participate in crime prevention erodes substantially, and conversely, (2) what is the tipping point when community social integration is sufficient to create collective efficacy and social capital, thereby enabling communities to engage effectively in such matters?

Such questions assume that police are adept in helping communities build capacity. As Goodman his and colleagues in attempting to measure community capacity in health care interventions (1998, 260) suggested, such capacities include "participation and leadership, resources, social and inter-organizational networks, sense of community, understanding of community history, community power, community values, and critical reflection." Such a wide range of community developmental capabilities are likely beyond the capacity of the police to build, but in partnerships with other community serving agencies, such capacities might be improved. This remains a major obstacle in creating effective police and public crime prevention partnerships, most especially in the communities who need such interventions the most.

Communities as Geographic or Ecological Areas

> *A good neighbor is a fellow who smiles at you over the back fence, but doesn't climb over it* – Arthur Baer

The idea of community has evolved considerably over the years. In some ways, it is a rather elastic concept, a broad umbrella idea expressing patterns of social communication, interaction, and value acquisition in any number of settings. Nonetheless, at its root, it has always implied propinquity, that is, people living together in the same social space, creating patterns of social interaction, from which meaning is derived. In the study of deviance and crime, ecological criminology has centered on the level of community organization, collective efficacy, and social capital as important determinants of effective community action in stemming delinquency and crime (Bursik and Grasmick 1998). The ecological and social-psychological traditions of the Chicago School identify community dysfunction as a primary inhibitor to social control, suggesting that community building could be an important attribute of police-neighborhood policy. Simply put, geography matters, as crime varies geographically, often most prevalent in places ill equipped to marshal social control.

Like criminals, places have criminogenic characteristics. That is to say, some places like some people account for a high incidence of crime and social disorder. Armed with this evidence, the police have identified crime ”hot spots” and attempted to systematically address them, often through aggressive police tactics. The evidence on “hot spots” suggests that targeted police interventions in constrained areas evidencing high rates of crime and social disorganization result in crime reduction, with mixed evidence as to whether some crimes are displaced to adjoining areas, or rather whether such adjoining areas enjoy a “diffusion of benefit,” that is, a similar reduction in crime to the target areas (Weisburd and Braga 2006; Ratcliffe et al. 2011).

While the research literature on the suppression effects of “hot spots” policing has garnered considerable police support and academic attention, more often than not such approaches fail to improve community social networking capacities. Rather, crime is aggressively pursued sometimes displacing its effects to other neighborhoods and sometime not. As it turns out, getting and sustaining community participation in neighborhood policing or community crime prevention efforts is quite difficult (see Skogan and Hartnett 1997, 110–160). This is especially the case in communities where social capital and collective efficacy are in short supply. Moreover, in these same communities, the police and the public are not always in agreement as to what the police should do, nor do they share the same value sets (Thacher 2001). While geography has become a major tool for the analysis of crime, most police responses rely on the police, not the community, for addressing crime and disorder problems, and often through the application of aggressive police tactics. Where the community is not fully “on board” with such actions, or when they are sprung on the community problems emerge, and the legitimacy of the police is called into question. From an analytic and practical perspective geography matters, but what to do with that geography (often referred to as a “community”), is not particularly clear. Moreover, it also appears that in communities where police legitimacy is low, the police are more likely to use force (Kane 2005).

Communities of Interest: Breaking Geographic Boundaries

Give a person a fish and you feed them for a day; teach that person to use the Internet and they won't bother you for weeks – Author Unknown

Consistent with Durkheim's idea of organic solidarity, the modern world is less linked by what were presumed to be deep social and emotional ties at the community level, and more through affiliations associated with work or personal interest. Some have pointed to a significant decline in community affiliation in civic affairs (Putnam 2000) in the latter half of the twentieth century, some of which is related to technological advances in social networking, that is, linking with others, often absent face-to-face interaction.

In a world marked by social networks, the idea of communities has shifted from place to ideas, life styles, near-instant electronic communication, and social fragmentation. Whereas once to be in a community, people actually had to meet, talk, and share their interests, now from the comfort of their own homes, people participate in social communities that span the globe, and perhaps not with the negative side effects of social isolation.

Communities of interests can be organized functionally, for example, business districts or other commercial areas; while being proximate to one another, they are not systematically engaged. Communities can be more dispersed, involving what is now called membership in affinity groups organized to work together but not in a hierarchical way, but rather in a more flexible and decentralized way. Such groups have the characteristics of coalitions, individuals linked to group identities and norms selectively and with indeterminacy, that is, participating in the coalition to the extent that group membership achieves the individual's goals or fosters identity. Such groups are transient, they ebb and flow episodically and they are formed and abandoned as identities shift or one's sense of group affiliation diminishes.

In a Durkheimian sense, such groups do not exhibit mechanical solidarity; rather, they pivot from one form of organic solidarity to another, expressing some social cohesion, but often with limited time horizons. Nonetheless, social networks are social structures (individuals, groups, organizations, nation states) connected by interdependencies, such as friendship, kinship, common interest, financial exchange, dislike, sexual relationships, or relationships of beliefs, knowledge, or prestige. Studies have identified social networks at many levels of social organization, and have demonstrated that social networks are important in determining the ways problems are identified and get solved, as well as the ways network members achieve their goals and understand their social conditions, that is, how they make sense of circumstances and then act upon them. Such social networking also provides for cultural transmission better linking social network and social culture analysis.

Policing as a Community Activity

> *The police are the public and the public are the police; the police being only members of the public who are paid to give full time attention to duties which are incumbent on every citizen in the interests of community welfare and existence* – Robert Peel

Policing has always been a community activity whether or not formally acknowledged. As part of the social control continuum, the police are intimately connected to community notions of acceptable and unacceptable behavior, order and disorder, as well as interpretations of lawfulness and deviance. In turn, the police, the formal apparatus of the state, are directed through representative processes to evenhandedly enforce the law with public support for such enforcement. While the public rarely has a formal referendum on police activity (although news accounts and public protests do occur), people routinely assess the legitimacy of the law and law enforcement – both substantive and procedural justice (Tyler 2006). They seek fairness in the law and in its application.

In democratic societies, the social contract authorizes government to provide an envelope of security, safety, and access for the populace, and expects people to conform to social and legal expectations. As a consequence, governments regulate many forms of social, political, and economic behavior, including those associated with deviance and crime. At the same time, members of the society generally comport with social expectations emphasizing the observance of duly constituted law and social regulation. From a criminological perspective, self-control theory suggests that early socialization and social learning involving the acquisition of values, norms and beliefs, increases self-control, and thereby reduces deviance and crime. Of course, social learning has an important community context as well.

Shaw and McKay (1942) found that delinquency increased in neighborhoods characterized by poor economic conditions, ethnic heterogeneity, and residential instability, the structural correlates of crime. Such neighborhoods were said to be socially disorganized and therefore less capable of controlling delinquent behavior. Refinements of these ideas suggest that individual, family, neighborhood, and community identities are at the forefront of social control, and where communities are socially disorganized, lacking collective efficacy and social capital such identities are the most vulnerable (Sampson and Groves 1989) and at risk.

But even in socially disorganized places, a fragile community precedes the police in matters of social regulation and social control, whether done well or not. Simply put, the community is there first, at the forefront of observing, confronting, and sometimes shaping social behavior, pro-social, deviant, and criminal. While communities are legally discouraged from vigilantism or other aggressive self-protective methods, it is fully anticipated that individuals and communities are self-policing.

That is to say, in democratic systems, the state gains compliance, and some degree of social conformity, from the vast majority of its citizens, through consent, not through police force.

From a social-psychological point of view, compliance is conditioned by beliefs about the legitimacy of the state, its laws and its mechanisms of enforcement, as well as social understandings of rightful behavior and personal comportment. This is seen as social and legal conformity or the voluntary aligning of an individual's behavior with widely held social expectations or norms. Of course, norms may compete with one another across social, economic, and political lines, but generally speaking, conformity involves discerning how others behave and what they expect, and then adjusting one's behaviors accordingly.

In democratic states, such conformity is arrived through social consensus; in totalitarian states, such compliance is conditioned by fear. In either case, governments require self-policing, that is, a large proportion of the populace conforming to the law and social convention, whatever its genesis. While the police enforce the law typically against law breakers, or those suspected of such behavior, it is individuals in community settings that engage in self-policing as well as social regulation that stems from community interactions and local social ethos. This is not just a matter of philosophy, but also a matter of practicality. There is no way that the police would have enough capacity to enforce the rules, absent informal social control. Police in the USA number about 2.5 per 1,000 inhabitants, and in Europe, the range is from 1 per 500 to 1 per 200. While in either case the police are outnumbered and their capacity to control large populations is circumscribed, it does not really matter how many police there are – it is the very essence of a social grouping that the primary way of ensuring conformity to most rules is through personal and informal social control, resulting in self-policing.

The distinction between "police" and "policing" that is made here is important, as the former involves activities of government, while the latter refers to a wide range of individual, civic, private, and public arrangements, each of which contributes to preventing, deterring, or otherwise shaping crime and social deviance. In simple terms, the police are charged with maintaining law and order, while policing is too big to be left to the police alone. On its' broadest scale, "policing" is another term for "maintaining conformity" or ensuring that most of the people follow most of the rules most of the time. So, as a matter of practice many, not few, are involved in policing (Loader 2000). While much of the rhetoric and program focus regarding police crime prevention has been in residential community settings susceptible to crime, other forms of policing permeate residential, commercial, military, recreational, and industrial communities, more broadly, in what Brodeur (2010, 17–42) has called the "web of policing."

Ironically, it is interesting to note that while policing can be seen as having deep connections to community norms, sentiments, and ethos, historically, the police have had a passive-aggressive relationship with their civic constituents. That is to say in several times and places, formalized policing has evidenced an institutional "personality," revealing a pattern of negative attitudes toward the community, accompanied by resistant behavior in the face of community calls for change (Greene 2000).

The police have been the object of reform for more than a century; some reforms have improved policing and police organizations while others have been resisted with prevailing functions and structures unaltered (Mastrofski and Willis 2011). And, of course, in some instances, the police flatly reject ideas associated with community coproduction of public safety and community/police partnerships (Lyons 2002; Herbert 2006). Such rejection has been most evident in communities of color, or those marginalized by ethnicity or economics, in part as a rejection of community capacities or willingness to work with the police but also as a reflection of resistance to police institutional change. In either case, such complexity speaks to the likelihood of the police and community working together on matters of local crime control and social order as being more episodic than permanent.

Policing in Search of Community

> *It is vain to talk of the interest of the community, without understanding what is the interest of the individual* – Jeremy Bentham

While it has been important for policing to consider its "community roots," those roots are complicated by individual variation in values and concerns within any geographic place. Managing value conflict in communities and in larger political settings is a major undertaking in the process of governance. Communities rarely speak with one voice. Consequently, assessing community dynamics is a necessary condition to understanding the underlying value consonance and dissonance in a communal setting. As the police search for "community," they must be wary not to be drawn from one community voice, over others, lest their credibly in the community be compromised.

Moreover, having a police who see themselves as "citizens in uniform" rather than as an occupying force is also a critical component in gaining community acceptance. Organized public policing from its onset recognized that the "police are the public and the public the police" a quote attributed to Sir Robert Peel, founder of the Metropolitan Police of London, the forerunner of modern-day policing. Like the military, the police are "citizens in uniform," a democratic governance idea meaning that the police and the military draw their resources – human, financial, and normative – from the body politic. Correspondingly, the police and the military owe allegiance and fidelity to the society in which they are deeply embedded. Neither the police nor the military "occupy" their civic sponsorship, for to do so would break the social contract empowering democratic governance, while also turning government on the civic body.

In a rather ironic way, the modern police have escaped their community foundations. Instead, the formal and social organization of the police has been distanced from those to be policed despite the anticipated relationship between democratic government and the body politic. There are many reasons for the police to take some distance from the public, some related to a need for institutional and legal independence, and some related to police fear of oversight and public criticism. In either case, policing, a community-focused activity, has gravitated from informal means of social control, to public police as a visible and formal mechanism to achieve the same ends, while at the same time drifting from a close affinity between public and police to one that is often strained, especially in marginal communities. Simply put, public policing has its greatest challenges of connecting with marginal communities when the community and the police do not trust one another. Such social distance poses considerable barriers for the police to lead community renewal efforts.

To some such distancing may seem appropriate to the extent that the impartial enforcement of the law and other formal social regulation under democratic principles requires that the enforcers of the law maintain independence, lest their actions seem biased, or politically motivated. When policing becomes an adjunct to local politics, it divides civic membership between those to be supported and those to be opposed. In the earliest formations of policing, particularly in big cities in the USA, the police were clear adjunct to political machines. This has also been the case in nearly every history of Western policing to one degree or another (see, Critchley 1978). Calls for "taking the politics" out of policing stress the occupational and political distancing of the police and the public, at least symbolically, if not substantively most particularly for the purpose of reducing overt politics in police decision making and practice.

Police grasp of the professional mantel also helped to distance professional from client, while at the same time affirming the status of the professional. As the public police have sought public recognition as a profession, so too have those to be policed become distanced from those doing the policing. This is rather ironic, as historically the police came from the very classes that formal policing seeks to oversee and control.

Finding the appropriate distance (or closeness) of the police and the public has been complicated and at times elusive. Should the police become too close to the public, fear of the corrupting influences of community takes center stage; if the police are seen as too distant from the public, fear of an independent and repressive police rise. So, a too close or too distant police invariably raises concerns of politics and accountability; to who are the police accountable and by what methods?

Despite efforts to distance the police from the public, the police are inherently captured by the social contexts in which they find themselves including those of community life. Policing is localized, it occurs somewhere – neighborhood, highway, business district, or back ally. The social contours of these places shape police actions within them, as the police have and continue to use perceptual shorthand in understanding places as well as the people that inhabit them. Moreover, several have commented on the emergent styles of police that are associated with types of communities.

Such distancing from the public can have adverse consequences as well. Since the times of Sir Robert Peel, it has been recognized that an acceptable public police must engender the respect and trust of the public, lest they be seen as agent provocateurs or spies. Given that the police are outnumbered, meaning there are more of *us* then *them*, public order and community safety require that people police themselves, as well as through a complex system of regulation provided from other agencies, public and civic. That is to say, behavior is partly shaped by the police and partly by the labyrinth of social and institutional regulation part of modern society.

Today, we are regulated from many quarters, some focused on deviance and criminality, but most on broader issues of social regulation (education, health, recreation, and the like) and public management (zoning, taxation, product control, and the like). The role of communities in the web of social regulation under such circumstances is not always clear. Once the bastion of social affiliation and hence social control, communities have been transformed in the post-modern world such that community influence in regulating social behavior is often fragmented and diffuse.

Still policing needs community support to be both effective and legitimate. From the perspective of police effectiveness, it has long been recognized that police are largely mobilized by the community. That is to say, policing in response to community needs is significantly affected by the community's capacity and willingness to seek police assistance. While patrol responses to troubled neighborhoods seek to provide support for "hot spots," knowing where the "hot spots" are, and more importantly what they mean, requires community input. "Hot spots" are based on crime reports, and community members or businesses are the necessary ingredient for reporting crime and other worrisome behavior. Absent community amplification of crime and social problems leading to crime through the identification of crime situations and reporting them, the police would be responsible for detecting crime and/or the circumstances underlying crime independently. This is not the model of public policing most have come to understand. So, if a community lacks the capacity or will to contact the police about criminal victimization, unruly neighborhood circumstances, or business concerns, the police have little in the way of focusing their efforts on particular places, problems, or circumstances. In this way, the police are highly dependent on the community to learn about crime.

Of course what motivates community involvement with the police is a belief that the police can do something to improve circumstances and a level of trust that the police will respond appropriately. Community acceptance of police legitimacy sets the underlying conditions of not only police mobilization, but also acceptance of the police as a source of support, cooperation, or collaboration. Unfortunately, in many socially disorganized communities which often also experience high crime, civic trust of the police is low (for a review, see, Weitzer 2000). What we know about police activity in socially disorganized neighborhoods suggests that the police behave differently there as compared to more stable and/or more affluent communities. Those behaviors are to *under- or over*-police these neighborhoods, leading to much community dissatisfaction with the police and complaints about police misuse of authority and force (Weitzer 2000; Kane 2005).

This discussion calls into question our understandings of what it means to be a community, how communities are shaped and in turn shape individuals, and how this social construct – community – actually works. To call for greater police involvement with the community, community mobilization, community coproduction of crime prevention, or community policing assumes a working and generalizable definition of communities, their social and social-psychological dynamics, especially related to social control, and their ability to influence government policies and actions. If police are to work with communities, then issues of representation, communication of interests, capacity, and sustainability arise. In all cases, communities need to have some way to clarify and then represent their interests and communicate them to others. At the same time, these communities need to have some capacity to bring to bear on the problem at hand, in concert with the police and other service providers, and this capacity needs to be sustainable over time.

The Police and the Community: The Complexity of Alliance

> *The only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others. His own good, either physical or moral, is not sufficient warrant* – John Stuart Mill

Government alliances with communities are invariably complex. Generally speaking they are asymmetric in terms of power and communication, and likely fraught with concerns about the corruption of government policy or the co-optation of local community sentiment toward the government. Depending on whether one takes a conflict or consensual view of the relationships of people to government, communities as an intermediate social aggregate can come to view government as a benign or oppressive force in daily life. Such views are often stratified by race and social class as well as by prior experience with government agents, most particularly with the police. So building community alliances is a difficult proposition for modern-day policing. It is art and science: art in connecting community interests with government agendas, and science in fitting police actions to community needs and local social tolerances.

Building community-police alliances requires “winning the hearts and minds” of both the police and the community, at least in areas where social control and neighborhood safety are at stake. Of course the rhetoric of community/police partnerships often outstrips the reality, for any number of philosophic, theoretical, and pragmatic reasons (see for example, Mastrofski 2006, 44–73).

At the philosophic level, a fundamental dilemma for democratic policing is public acceptance of the imposition of law by the police (Manning 2010). Moreover, as policing has come to be distanced from communities, most especially in disadvantaged communities, the police have also often come to be viewed as an occupying force in unsettled neighborhoods, at least by portions of that community. Of course, much of what the police do occurs in these often neglected communities, placing the police in distressed and often conflict-ridden areas, where support for the police is at best tentative. And, while the police have often genuinely attempted to assuage community concerns with a range of police interventions, it might be said that the police are always one bad incident away from community criticism. Such a precarious relationship adds tensions to police and community interactions, each seeking to protect individual and institutional dignity, as well as social and institutional legitimacy. These circumstances continue to shape police and community expectations about the others’ motivations, as well as conditioning what is expected of each in securing neighborhoods safety.

The idea of the precariousness of community support for the police is illustrated in a long history of community reactions to police interventions. In assessing the wave of riots that swept across urban America in the 1960s and 1970s, for example, the Warren Commission noted that a number of these riots were precipitated by questionable or overly aggressive police actions – actions which ultimately sparked the social unrest witnessed. In a similar fashion in 1991 following the video-taped beating of Rodney King and the riots it sparked, the Christopher Commission documented conflict between the LAPD and racial communities in Los Angeles and widespread distrust of the police. The King incident was perhaps not new to minority communities in Los Angeles, but its widespread viewing not only confirmed others' experiences, but became a rallying point for community riots in that city.

More recently, police interventions in Oakland, California, in 2011 and other US cities have significantly strained police and community relationships once again. This pattern is not restricted to the USA, similar concerns are apparent in the UK as well (Morrell et al. 2011) where youth reported that some were motivated by wanting "to get back at the police" for the earlier shooting of a young man in Tottanham. Similar findings emerge from assessments of the 2007 Paris riots and the role of the French National Police in dealing with these riots. According to Mouhanna (2009) the federal nature of the French Police Service and most particularly the riot police, the complexity of policing in Paris and its immediate surrounds, and the marginalization of minority communities, particularly Islamic communities in France, all contributed to the French riots. As important, many of these riots were seen as being initially triggered by police actions.

In the USA, starting with the political and administrative reforms of the police during the first half of the twentieth century, and in police adoption of the "professional mantel," the nexus between local informal social control and its formal counterpart in the public police and law was strained and perhaps even severed. A managerial gloss over policing led to police fixation with response times, case clearance and arrest rates, all efforts of the police, while at the same time ignoring the supposed outcomes of these efforts, namely, safe and secure communities. In large cities, the police responded to community crime in a less than systematic way, and often have to return to the same communities for reasonably speaking the same reoccurring problems. Police were treating the symptoms of community crime and disorder problems, not the underlying sources of those problems (Goldstein 1990). Perhaps more important, the police rarely sought to reinforce community social control norms, portraying such efforts as being "social work," not real police work. Such attitudes persist today.

Surely communities continue to constrain social behaviors when and where they can, but massive population shifts and the effects of increased urbanization strained community capacity for social control, especially in large cities. Such strain was accompanied by police laying greater claim to being singularly responsible for controlling crime. Crime was on the rise, social turmoil visibly present, and public fear of victimization daily present. This period witnessed a dramatic shift in crime control expectations and governmental apparatus (Garland 2001).

Beginning in the 1990s, community policing, or variations of it, became a national mantra of the American police (see Greene 2000), ultimately being exported to many parts of the world. The language, symbolism, and programs of community policing have sprung up in urban, suburban, and even rural police departments and ideas associated with community policing became a new orthodoxy for cops.

Simultaneously ambitious and ambiguous, community policing promised to radically change the relationship between the police and the public, by address underlying community problems, and improving the living conditions of neighborhoods. The police were admonished to deal with crime, of course, but also with "community quality of life," a circumstance thought injured by physical and social incivility, or in the parlance of the times, "broken windows." The organizing themes of community policing called for law enforcement to be more focused, proactive, and community sensitive, sometimes often competing objectives.

Community policing also suggested significant changes in the social and formal organization of policing. On the level of social organization, community policing was thought to break down the barriers separating the police from the public, thereby impacting formal organization through the use of police generalists and the decentralization of police services, while at the same time inculcating police officers with a broader set of community service ideals seeking to change the social organization of policing as well. Whether community policing simply joined the pantheon of presentational strategies of the police (Manning, 1977) or was an added circumlocution (Klockars, 1988), its political appeal was far reaching. In the US during the 1990s the federal government committed to putting 100,000 community policing officers on the streets and spent nearly $9 billion doing so.

The promises of community policing are many. They include: strengthening the capacity of communities to resist and prevent crime and social disorder; creating a more harmonious relationship between the police and the public including some "power sharing" with respect to police policymaking and tactical priorities; restructuring police service delivery by linking it with other municipal services; reforming of the model of police organization; creating larger and more complex roles for individual police officers; reducing police overreaction and personalizing police services, and increasing civic respect for the police and law through a model emphasizing responsiveness, transparency, and the upholding of democratic values. This new style of policing is said to produce more committed, empowered, and analytic police officers, flatten police hierarchies, and open the process of locally administered justice to those who are often the object of justice decision making. This shift also sought to affirm crime prevention as the ascendant goal of policing, not crime suppression, and in important ways reaffirm the traditional roles of the police (Innes 2007).

While the anticipated outcomes in community policing are indeed broad, there is considerable breadth in the definition of what constitutes community policing as well. The range is rather remarkable, given the centrality of community, often lost in this discussion. Community policing has variously been defined as neighborhood patrol or "policing the patch," reassurance policing, community involvement in crime prevention activities, as well as zero-tolerance policing strategies seeking to deal with small but reoccurring crime and social disorder, such as panhandling, street-level prostitution, public intoxication, gambling, and less serious property and personal crime. Police crackdowns, sweeps, and aggressive police interventions have also been associated with community policing, to the extent that they are supposed to provide the community with welcomed relief from the tyranny of street thugs and gang members.

Under the rubric of broken windows policing, a wide array of police interventions are linked to improvements in communities, although on closer examination, the community is not participant to these strategies; rather, the community is the target of such strategies. With such concept elasticity, it is perhaps inevitable that many activities seek harbor in community policing symbolizations.

However, strategies which do not engage the community or do so only marginally fail to account for variations in community social integration, and rather focus on the community as criminogenic and therefore warranting aggressive police intervention, generally fail the test of improving community collective efficacy or social capital. In using such police tactics, once the visible and immediate problems (crime) are gone or displaced, the community is rarely seen as in need of continued support. This is all the more problematic as recent research suggests that a small number of communities have a consistent trajectory of crime and social disorder (Weisburd et al. 2004), suggesting that these communities may actually cycle through periods of crisis and remission, only to realize crises again. In some unfortunate ways, broadly cast community policing strategies absent community attachment return us to a previous era of "fire-brigade policing," that is, showing up after the fire has been reported, as opposed to preventing the fire from its onset. In some important ways, the idea of "community policing" has been highjacked by historical approaches to policing, saturation patrol, and aggressive police street tactics, masked as community interventions.

Community partnerships with the police are also complicated by the police themselves. There is considerable evidence that the police while publically vocal in support of such connections, privately, within the police occupational culture eschew such community linkages (Herbert 2006). While there are likely many reasons for such contradiction in the public and private faces of police, it is clear that community policing still struggles with "winning the hearts and minds" of line-level police officers, those who would presumably be the front-line boundary spanners in community-police partnerships (Lurigio and Skogan 1994). More recent studies of police attitudes toward community policing suggest that the police do not embrace these ideas, and that police work group cultures either downplay or demean the practice of community policing (Herbert 2006; Lyons 2002).

In other parts of the world, even when community policing practices are observable, the police, when interviewed, cannot articulate the philosophy or the practical implications of community policing. While it is clear that policing in much of the western world has embraced the symbolism of community policing, problem solving, and civic engagement, it is less clear that such ideas have permeated the police organizational and work group cultures, where crime control through aggressive police action continues to dominate police practice.

While it is true that the police struggle to find their footing in the philosophy and implied practices of community policing, so too does the community struggle with its new role in the coproduction of public safety. In some respects, the public is of two minds: The police should continue to "fight crime" when and wherever it appears, but when such actions affect me and my community, the police should become more conciliatory and inclusive. Perhaps, such is the nature of most public policy; collective goods are difficult to individualize, except when you are in need of them or are the object of their interventions. Partnerships require the willingness and capacity of the police and the community to engage in a dialogue on community safety, each bringing a contribution to addressing community crime and disorder problems. While a nostalgic view of community and historical policing may afford some expectation of such capacity, their presence and alignment in today's world is, of course, more complex.

Policing the Community: The Evidence

A wise man proportions his belief to the evidence –
David Hume

Community policing is the product of great pessimism and great optimism – pessimism about the police having become estranged from the community and concerns about community/police reconciliation, and optimism that recontextualizing the police in community trappings would ultimately improve neighborhood safety as well as the relationships between the police and the public. Beginning in the early 1990s and continuing in some measure today, policing in the USA and in other parts of the world embraced the idea and programs of "community policing," a derivation of policing emphasizing, among other things community mobilization against crime and disorder, police connectedness in neighborhood settings where the police had been historically absent, improved police/community interactions and willingness to share information, targeted programs to strengthen community social control and crime resistance, and greater transparency and accountability of the police to the public – big ambitions indeed.

The evidence of the success of such shifts in policing or in police/community partnerships is rather thin. Partly this is the case because community policing interventions have been diffuse in approach and sporadic in application. Partly this is due to concerns with the scientific rigor with which community policing has been assessed. And, part of this struggle to define and measure the implications of community policing can be associated with conceptual or theoretical gaps in how the questions of community policing have been framed.

While there is a rather voluminous literature associated with community policing, the evidence suggests that while such programs may affect fear of crime, they do not impact crime as directly. Moreover, research suggests that improvements to community cohesion stemming from community policing are fleeting (see Taylor 2006). The national evaluation of community policing conducted in the USA (see, Roth and Ryan 2000, 2) found:

> Building partnerships with communities by COPS grantees was commonplace in many of the agencies visited but, all too often, partnerships were in name only or simply standard, temporary working arrangements. Most visited agencies did some form of problem solving, but form and visibility varied widely from agency to agency. In observed sites, crime prevention efforts abounded primarily manifested as traditional programs now subsumed under the community policing label.

The struggles of community policing are conceptual and operational. They involve assumptions about the capacity and willingness of the police and the community to work with each other. They also invoke ideas about community life and police agency receptivity to change which are tenuous at best. Finally, they require considerable investment to accomplish, as well as a reorientation of what we mean by partnership and neighborhood safety.

Is There a Broader Role for Communities in Policing?

> *A community is like a ship; everyone ought to be prepared to take the helm – Henrik Ibsen*

In the search for a more defined and anchored role for communities in the prevention of crime and in responding to crime and social disorder, many questions arise. These questions largely ask about the inclination and capacity of communities to engage with the public police in establishing greater levels of social control, most particularly in areas where such controls are weak or do not exist. Moreover, these questions seek to better understand the working parameters of community coproduction to assure that the community does not become absent from such discussion (community crime control) or entirely responsible for neighborhood public safety (for example, see Taylor 2006).

So, do communities have broader roles to play in policing? Can these communities coproduce public safety, particularly in residential neighborhoods? What constrains or facilitates communities in adopting such roles? And, in a late-modern world, can communities be expected to be fully engaged in such activities, or have notions of social cohesion and integration been inextricably altered? Such questions ask about the ways in which communities can contribute to policing, broadly cast, and the limitations or restraints on such participation.

To begin to consider the role of the community in the maintenance of social control first requires some idea of how communities might broaden social investment and outcomes. That is to say, what animates community social investment leading to social cohesion and collective efficacy? Here we are drawn back into the nostalgia of "community," a place of deep social and emotional bonds, indelibly shaping social relations and meanings. Unfortunately, such ideas of community no longer capture modern social life nor are they seen as exerting tremendous influence on individual identities. What is shown is that levels of social capital and collective efficacy help to distinguish levels of community crime (Sampson and Groves 1989), suggesting a variable community role in such matters, depending on the presence or absence of crime and community social cohesion.

Continuing studies of communities and crime reinforce these earlier findings, yet questions concerning mechanisms for adequately increasing collective efficacy and social capital, and especially those involving the police remain unanswered. Nonetheless, there is evidence that the police need to be concerned with their instrumental *and* expressive contributions to community life if changes in community social cohesion and collective efficacy are to improve.

Community policing has been associated with improving community social conditions to the extent that in addressing community crime and social order problems, community fear of crime appears to subside. In short, community policing has been shown to reduce fear of crime, although not crime itself. These findings suggest that the police's focus on crime in neighborhood settings have had the expressive by-product of reducing fear of crime.

In addition to the general effects of community policing on fear, "hot spots" policing models and assessments of them clearly represent an instrumental way of thinking (see Weisburd and Braga 2006, 225–244), that is, these findings apply where the police are evaluated by what they directly produce, most particularly their ability to make arrests and reduce reported crime. The focus on crime analysis, Compstat, and similar technologies see crime reduction through targeted and often aggressive police actions as the products of public policing. Such findings do not suggest that community social capital or collective efficacy necessarily improves as crime and fear subside; rather, these findings anticipate that such police actions will influence the underlying conditions thought to detract from community cohesion, especially community fear of victimization or retaliation. For example, Markowicz and colleagues (2001) suggest that social cohesion, disorder, and fear are linked to the extent that fear of crime may reduce an individual's community involvements, thereby decreasing community collective efficacy.

Such findings, coupled with a long series of analyses suggesting a fear reduction outcome for community policing, support the idea that such efforts by the police might help communities find their own collective voice once some modicum of order is established (in this case by the police). But how these efforts translate to collectively stronger communities is not known. In this regard, the instrumental achievements of the police are necessary but perhaps not sufficient. Evidence of this causal sequence remains thin.

An alternative expressive model of police suggests that public confidence in the police is tied more to public concerns about community cohesion and the role of the police in protecting community values and norms than to the instrumental efforts and outcomes of the police. Here research by Jackson and Sunshine (2007) show that public evaluations of community cohesion, moral trust, and social consensus significantly condition community support for and trust of the police. Such reasoning suggests that the community is looking for police help and support for the community and its sense of control over community life. Bellair (2000) finds that informal community surveillance by neighbors – neighboring – together with residential stability positively influences neighborhood surveillance activities. But Wells and colleagues (2006) found that "... residents of geographic areas characterized by lower levels of collective efficacy are no more or less likely to intervene in the face of local problems than are residents of other areas (540)."

Expressive values are central to ideas of collective efficacy as it is the attachments and involvements of community members as well as the meaning such interaction provides, which define collective efficacy. Unfortunately, evidence to date does not support the notion that police support for community by reducing low levels of social disorder necessarily increases community social cohesion or collective efficacy as broader social forces shape insecurity (Jackson et al. 2009). Nonetheless, if communities are to have more involvement in matters of public safety, it is clear that expressive values need to be included in this discussion.

This entry has examined the distinctions between police and policing, the role that communities might play in policing, and the limitations on such participation, as well as the changing role of the public police in the broad fabric of social control and public safety. Whereas 50 or so years ago, the public police had considerable monopoly on these matters, today these are shared undertakings. People are self-policing; communities and other socially based institutions shape public behavior and attitudes including those associated with crime and deviance, the justice system in all its fragments exercises control, as do other civic and economic institutions. As stated preciously, the police are charged with enforcing the law, but policing is too big to be left to the police alone. Garland (2001) refers to this as the "responsibilization strategy" suggesting that governments are relinquishing power and sovereignty by enlisting participation from citizens and nongovernmental actors to control crime. Aas (2007, 134–36) suggests the regulatory state is now composed of new technologies and rationalities shifting social control from governments to a broader base of civic involvement.

Correspondingly, conceptions of communities have changed over the years as well. Whereas the idea of community conjures ideas of social integration and collective social action formed by dense and complex social and emotional ties, today the idea of community is being reshaped in a global and technologically wired world. No doubt, some idyllic communities continue to exist, but in the main, they have become ideas in a sea of practical constraints on communal social action. Despite claims to community resurgence in social and political life, the evidence does not fully support the claim. In a late-modern world, communities and community identities have been fractured.

Globalization, information capitalism, and a culture of consumption have altered the social condition and hence our sense of what it means to be part of a community. Communities of interest, practice, communications, and belief are broadly cast and not restricted to confined geographic areas. While policing has been place bound since its inception, the policing of such a far-flung enterprise perhaps calls for new forms of policing and new forms of community involvement in social control. Such forms of social control are likely to produce new strains between the police and those policed. Of course under such circumstances, it will be difficult for the police to "occupy" the community as has been the general strategy for many years. Instead sharing information and at times following community leadership will challenge the institution of the police, which has been characterized as police centric in its ways of doing business.

In a globalized world with internationalized crime and much broader community connections policing in the twenty-first century and beyond will likely be confronted with the need to expand its role from crime fighting to peacekeeping, while at the same time being engaged in what are new and emerging forms of governance (see Aas 2007, 186–189). The crime implications of globalization include among others cyber-crime, terrorism, and the global trafficking of people, weapons, and drugs. At the same time, globalization also shifts people across the world and seeks greater connection among groups who were previously marginalized. In the Western world and elsewhere, this has involved issues of immigration, and often difficult responses to migrant peoples. As these "new communities" emerge supported by a wide array of human rights groups, policing will need to once again consider the underlying values that have historically undergird state-sponsored police. As Aas suggests (2007, 189) "issues of national justice can no longer be separated from issues of global justice." In a globalized world, crime and community identity are far reaching and notions of communities and the police yet evolving.

Overview

Communities That Care (CTC) is a community-based operating system for decreasing risk, enhancing protection, and reducing problem behavior in youth community wide. The approach has been developed and modified through community input and formative evaluation over 20 years. CTC provides communities with a structure for engaging stakeholders to improve youth development; a process for establishing a shared community vision; tools for assessing levels of risk and protection experienced by community youth; and a framework for prioritizing risk and protective factors, implementing evidence-based programs to address them, and monitoring and assessing attainment of specific, measurable community goals. CTC has been implemented in over 500 communities across the United States and countries including Australia, Canada, Croatia, Germany, the Netherlands, and the United Kingdom. All materials needed to implement CTC can be downloaded from http://www.communitiesthatcare.net. CTC has been found effective in reducing youth delinquency, violence, and tobacco and alcohol use in the Community Youth Development Study (CYDS), a randomized controlled trial conducted in 24 communities in seven states across the United States. This entry describes the theory underlying CTC, key features of successful community mobilization efforts, the five phases of CTC implementation, system- and youth-level findings from the CYDS, implementation challenges, and steps to broader dissemination.

Foundation

Over the past 35 years, prevention science has emerged as a discipline built on the integration of life course development research, community epidemiology, and preventive intervention trials. Researchers have identified longitudinal predictors, like family conflict or early academic failure, that increase the likelihood that young people will engage in problem behaviors associated with significant morbidity, and in some cases, mortality (Catalano et al. 2011; Hawkins et al. 1992b; Patton et al. 2009). Other predictors, like strong bonds to positive adults or the development of specific competencies, are protective, associated with reducing problem behaviors and increasing favorable outcomes like academic success, even in the presence of risk (Catalano et al. 2011). Many risk and protective factors are predictive of multiple adolescent problem behaviors, suggesting that improvements can affect a broad set of outcomes simultaneously.

Researchers have designed interventions to reduce risk and enhance protection and in controlled trials have found a number of preventive interventions to be effective in reducing prevalent and costly problems, including adolescent substance use and delinquency. There is a growing evidence base of what works to prevent youth problem behaviors and promote healthy development, and several lists of tested and effective programs have been made available to the public (see, for example, the list of programs identified at www.colorado.edu/cspv/blueprints, www.cochrane.org, and www.campbellcollaboration.org).

In spite of these advances, tested and effective approaches to preventing youth problem behaviors have not been widely adopted (Ringwalt et al. 2009). Reasons include a lack of knowledge about scientifically proven prevention programs, difficulty marshaling resources for science-based prevention and health promotion efforts, and failure to implement proven programs with fidelity. The Communities That Care (CTC) prevention system, which mobilizes community stakeholders to collaborate on the implementation of a science-based community prevention system, was developed to address these issues (Hawkins et al. 1992a) and has been refined over more than 20 years through community input and formative evaluation. This entry describes the CTC approach to prevention, steps involved in implementation, major findings from a randomized controlled trial, challenges in implementing CTC, and next steps in the dissemination of CTC.

Community Mobilization Efforts to Prevent Youth Problem Behavior

Community mobilization has been promoted as a strategy for reducing risk, enhancing protection, and improving youth outcomes (David-Ferdon and Hammond 2008; Fagan et al. 2011b; Hawkins et al. 2010). Typically, at the center of these efforts are locally based coalitions composed of diverse stakeholders committed to positive youth development. Community mobilization is promising because of coalitions' intimate connections to and knowledge of the local environment, capacity for sharing information and resources among service providers and others, and potential to efficiently provide prevention services in an organized manner and without duplication. Coalition responsibilities often focus on planning and coordinating prevention activities, which may involve implementing specific prevention programs to address local priorities, altering the environment by changing local policies and norms, or both.

In spite of their promise, community mobilization strategies have often had little success in meeting prevention goals, and many have been ineffective in reducing risk and problem behaviors (David-Ferdon and Hammond 2008; Fagan et al. 2011b; Hallfors et al. 2002; Merzel and D'Affliti 2003). Lack of success has been attributed to insufficient guidance in implementing prevention strategies, a mismatch between services and goals or inadequate service "dosage," and failure to select and use tested and effective prevention programs and strategies (Fagan et al. 2011b). Hallfors et al. (2002) suggested that coalitions could increase their chances of success by adhering to several criteria: (a) establishing focused and manageable goals, including well-defined, measurable outcomes; (b) using evidence-based programs, receiving adequate training to carry them out effectively, and monitoring implementation with attention to both dose and quality; and (c) evaluating impact by using meaningful indicators that correspond to overall goals as well as the programs chosen. CTC's design incorporates these recommended features.

The Communities That Care Prevention System

CTC mobilizes a broad base of community stakeholders to improve youth outcomes through the development and implementation of a science-based community prevention system. CTC "communities" are geographically defined places large enough for educational and human services to be delivered at that level. They can be incorporated towns or suburbs, or neighborhood or school catchment areas within larger cities. The community population for a CTC initiative should range from 5,000 to 50,000.

CTC is guided by the social development model, a theory of youth development which hypothesizes that to develop healthy, positive behaviors, young people must be immersed in family, school, community, and peer environments that communicate healthy beliefs and clear standards for behavior. When strong bonds exist between youth and prosocial individuals and groups, youth are more likely to adopt positive beliefs and healthy behaviors. Bonds are fostered when youth are provided with *opportunities* to be actively involved in meaningful, developmentally appropriate activities, *skills* to be successful in those activities, and *recognition* for their efforts, achievements, and contributions to the group (Catalano and Hawkins 1996). Communities That Care, Fig. 1 CTC model of community change

supporting the implementation of evidence-based prevention practices that reduce risk and enhance protective factors, CTC encourages community stakeholders to adopt the social development model in their daily interactions with young people and ensure that they are provided developmentally appropriate opportunities, skills, and recognition, as well as healthy standards for behavior. The social development model also underlies CTC community mobilization and training efforts. CTC creates opportunities for all interested stakeholders to participate in developing a shared vision for positive youth development based in prevention science. Diverse community representatives develop skills to work together effectively and are recognized for their efforts and contributions to youth development. Social bonds among coalition members enhance their commitment to science-based prevention work.

CTC's theory of change is depicted in Fig. 1. Training and technical assistance by certified CTC trainers serves as a catalyst for the development of the community prevention board, which commits to using a risk- and protection-focused approach to preventing youth problem behaviors. The coalition utilizes survey data to identify elevated risk factors and depressed protective factors within the community and then prioritizes which to address through evidence-based prevention programs targeting their priorities. The coalition facilitates broader prevention service system transformation by encouraging collaboration and the adoption and faithful implementation of tested and effective prevention programs aimed at prevention goals. Community prevention actions are expected to lead to reductions in risk and enhancements in protective factors, which in turn are expected to lead to more positive youth outcomes. Community-level impacts on risk and protective factors are expected 2–5 years following faithful implementation of tested and effective programs, and community-wide changes in youth outcomes are expected to occur within 4–10 years.

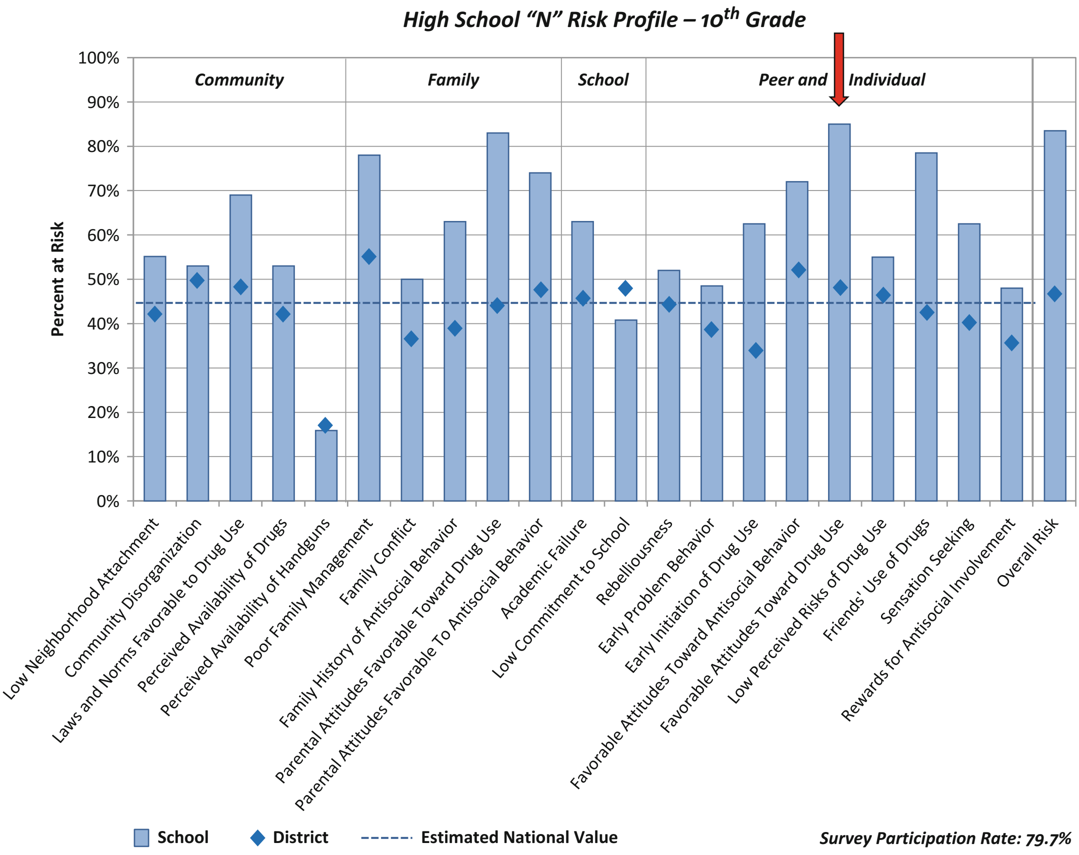
CTC Implementation: Providing Communities with the Tools, Skills, and Knowledge to Achieve Local Prevention Priorities

A major challenge for prevention scientists committed to applying research in the "real world" is increasing the use of tested and effective prevention practices while recognizing that communities differ from one another and need to decide locally what effective policies and programs to use. Local control is built into CTC from the beginning. CTC provides education and tools to build community capacity for using prevention science to decide which risk and protective factors and outcomes to prioritize and which tested and effective programs and policies to implement to address community-specific concerns. It takes communities approximately 1 year to complete CTC's five training phases and develop the skills and knowledge to choose and faithfully implement evidence-based prevention programs addressing local priorities (Hawkins et al. 2008b; Quinby et al. 2008). Each phase has specific milestones and benchmarks and includes training and technical assistance provided by a certified CTC trainer.

Phase 1**: **Get Started. In this phase, community leaders concerned with preventing youth problem behaviors assess community readiness to adopt the CTC system, as well as any barriers to implementation. Readiness requires collaboration among multiple stakeholders and a shared belief that reducing risk and improving protection can prevent problem behaviors. Community stakeholders need to be willing to establish shared goals and collaborate to achieve them. If these attitudes are not present, community readiness needs to be improved before implementing CTC. Other major activities include identifying one or two key leaders to champion CTC, hiring a coordinator to manage CTC activities, and obtaining school district support for conducting a youth survey that will provide local epidemiological data on risk, protection, and youth behaviors.

Phase 2**: **Organize**, **Introduce**, **and Involve. The major task in Phase 2 is to identify and train two key groups from the community in the principles of prevention science and the CTC prevention system. The first group consists of key community leaders and influential stakeholders (the mayor, police chief, school superintendent, and business, faith, community, health, social service, and media leaders) who are introduced to CTC during a half-day *Key Leader Orientation* that includes information about prevention science and the relationship between youth risk and protective factors and problem behaviors. Key leaders are responsible for securing resources for preventive interventions identified through the CTC process and identifying candidates for the CTC Community Board, a demographically diverse and broad-based coalition charged with carrying out CTC planning and prevention activities. The second group, the Community Prevention Board, participates in a 2-day *Community Board Orientation*. The board develops a vision statement to guide its prevention work and establishes workgroups to perform core implementation and maintenance activities: board maintenance, risk and protective factor assessment, resource assessment and analysis, public relations, youth involvement, and funding.

Phase 3**: **Develop a Community Profile. In Phase 3, the CTC board develops a community profile of risk, protection, and problem behavior among community youth; targets two to five risk and protective factors for preventive action; and identifies existing prevention resources and gaps. The first two activities are accomplished in a 2-day *Community Assessment Training*. The major source of data for the community profile is the CTC Youth Survey (Arthur et al. 2007), a school-based self-report questionnaire administered to students in Grades 6, 8, 10, and 12 that measures risk and protective factors experienced by young people, as well as their involvement in problem behaviors like substance use, delinquency, and violence. These data are summarized in a community profile, like the one shown in Figs. 2, 3, and 4. Each profile is unique to the community. Among 10th-grade students in the alternative high school depicted in Fig. 2, survey data indicate a number of elevated risk factors compared to school district averages. Many are drug-related risk factors, and not surprisingly, as shown in Fig. 4, both lifetime and current drug use by 10th-grade students in this school were considerably more prevalent than among 10th graders nationally, as measured by the Monitoring the Future survey (Johnston et al. 2000). Figure 3 shows that, while a large majority of

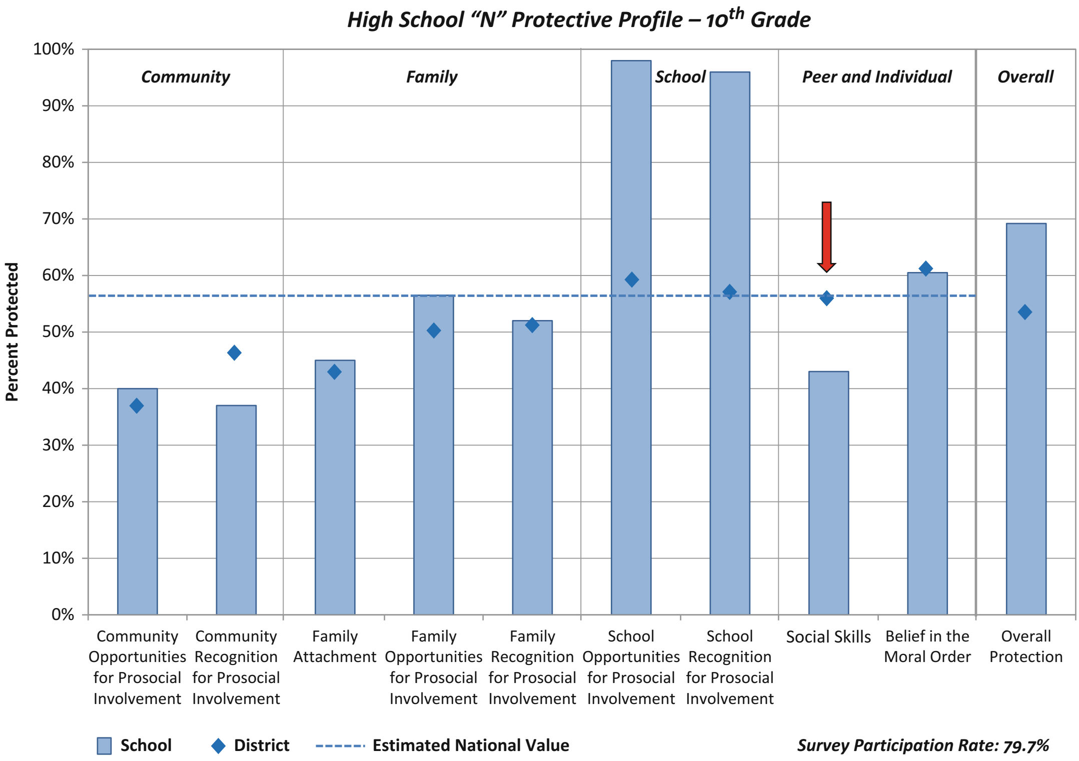


Communities That Care, Fig. 2 Sample community risk factor profile

10th-grade students in this alternative school reported that the school provided many opportunities for active involvement and much recognition for student effort and achievement, many fewer students had strong social skills, including skills to avoid or refuse trouble or problem behaviors. Based on these data, this community's CTC board chose to reduce the risk factor "favorable attitudes toward drug use" and strengthen the protective factor "social skills."

Following a *Community Resource Assessment Training*, board members survey service providers who deliver preventive intervention targeting their prioritized risk and protective factors to assess whether there are existing research-based prevention programs already available in the community. This ensures that any new prevention programs chosen by the board fill existing gaps rather than duplicating effective prevention programs already in place in the community.

***Phase 4**: **Create a Community Action Plan**.* In Phase 4, board members use information gathered in Phase 3 to develop a Community Action Plan. A 2-day *Community Plan Training* provides tools and knowledge to select tested and effective programs, policies, and actions targeting priorities established in Phase 3 to fill gaps in prevention services. The board chooses programs from the *CTC Prevention Strategies Guide*, a compendium of prevention programs (including parenting skills, school curricula, mentoring, after-school, and community-based programs) found effective in changing risk, protection, and problem behaviors in at least one high-quality

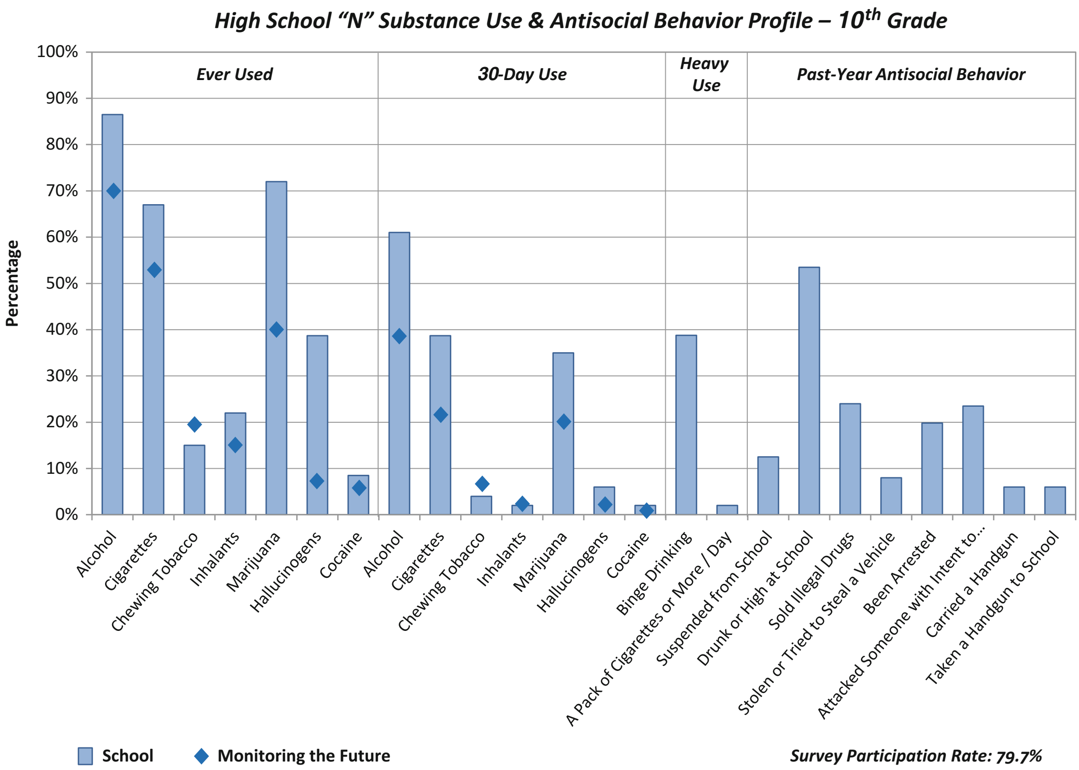


Communities That Care, Fig. 3 Sample community protective factor profile

controlled trial. The Community Action Plan specifies how the coalition will implement the chosen prevention programs, monitor implementation quality, and assess improvement in risk, protection, and problem behaviors.

Phase 5**: **Implement and Evaluate the Community Action Plan. The last phase consists of implementing the Community Action Plan. The *Community Plan Implementation Training* emphasizes the importance of adhering faithfully to the content, dosage, and high-quality delivery specified in program protocols. Communities are directed to prevention program developers for training and technical assistance in the programs selected. Board members and program implementers learn to track implementation progress, assess changes in participants, and make adjustments to achieve program objectives. Monitoring is accomplished through the use of program-specific implementation checklists, observations, and participant pre- and posttests. During this phase the board also engages local media to educate the community about risk and protective factor priorities and generate public support for the preventive interventions selected.

When they complete Phase 5, communities have the knowledge, tools, and skills to faithfully implement tested and effective prevention policies and programs to address locally prioritized risk, protection, and youth problem behaviors. The CTC process is ongoing. Every 2 years the CTC Youth Survey is readministered, and resource assessment data are updated. The CTC board reviews these data to evaluate progress and revise action plans as needed. As previously noted, community-level changes in youth risk and protection are expected to occur 2–5 years after tested and effective prevention programs are implemented. Community-level effects on youth behaviors are expected 4–10 years following implementation.



Communities That Care, Fig. 4 Sample community problem behavior profile

The Community Youth Development Study: A Test of Communities That Care

CTC has been evaluated in the Community Youth Development Study (CYDS), a multisite community-randomized trial initiated in 2003 involving 24 communities in Colorado, Illinois, Kansas, Maine, Oregon, Utah, and Washington. Participating communities are small- to moderate-sized incorporated towns with their own government, education, and law enforcement structures (population range: 1,500–50,000, $M = 15{,}633$, $SD = 10{,}147$). Communities were matched in pairs within state on population, racial and ethnic diversity, economic indicators, and crime rates. After receiving commitments from each community's mayor or city manager, the police chief or lead law enforcement officer, and the superintendent of schools to participate in the study, one community from each matched pair was assigned randomly to the intervention (CTC) or control condition. At the study's start, none of the communities had advanced in the use of science-based prevention to the point of selecting and using tested, effective preventive interventions to address prioritized community risks (Brown et al. 2009; Hawkins et al. 2008b). Youth in CTC and control communities did not differ at baseline on key outcome variables including substance use and delinquency (Hawkins et al. 2008b).

To date, intervention effects on prevention systems and youth risk and problem behaviors have been evaluated during the intervention period and up to 20 months after intervention support from the study ended. Prevention system effects were evaluated based on reports of key community leaders, prevention coalition chairs, coordinators, and board members from CTC and control communities. Intervention effects on youth risk and problem behaviors were evaluated based on reports of a longitudinal panel of 4,407 children from intervention and control communities who completed the CTC Youth Survey annually from Grade 5 through Grade 10. Major intervention effects are summarized in Table 1 and are described in the following sections.

CTC Leads to Sustained Prevention System Effects

The CYDS evaluated community efforts to faithfully implement (a) the core principles of the CTC prevention system and (b) tested and effective prevention programs with respect to content and delivery specifications. Broader effects on community prevention systems were also evaluated. CTC communities were supported by training in the first year and technical assistance throughout the first 5 years of the trial and achieved high implementation fidelity at the system and program levels.

High-Fidelity Implementation of the CTC Prevention System. At baseline, CTC and control communities did not differ in their use of a science-based approach to prevention (Hawkins et al. 2008b). The CTC Milestones and Benchmarks Survey was used to track progress in implementation of core components of the CTC prevention system. In each intervention year, CTC communities implemented an average of 90 % of the key features of CTC, including developing a community board, prioritizing risk and protective factors, selecting tested and effective preventive interventions from the *CTC Prevention Strategies Guide*, implementing selected prevention programs with fidelity, and periodically assessing risk and protective factors and child and adolescent well-being through surveys of students (Fagan et al. 2009; Quinby et al. 2008). Control communities did not make this progress over time in completing CTC milestones and benchmarks, implementing scientifically proven prevention programs, and monitoring program impacts (Arthur et al. 2010). CTC communities were able to sustain these gains 20 months after study-provided training and technical assistance ended (Gloppen et al. 2012).

Faithful Implementation of Tested and Effective Prevention Programs. Over the course of the trial, the 12 CTC communities demonstrated faithful implementation of 17 different school-based, after-school, and parenting interventions (shown in Fig. 5) selected from a menu of 39 possible tested and effective programs for fifth-through ninth-grade students contained in the *CTC Prevention Strategies Guide* (Fagan et al. 2011a, 2008, 2009). On average, CTC communities implemented 2.75 tested and effective prevention programs per year (range: 1–5). High rates of fidelity were achieved consistently over time with respect to adherence to program objectives and core components (average = 91 %–94 % per year) and dosage (number, length, and frequency of intervention sessions; average = 93 %–95 % per year) and were sustained 2 years after CYDS support ended. Although control communities did not implement as many tested and effective prevention programs as CTC communities, they, too, reported implementing tested, effective prevention programs during the intervention and 2 years into the sustainability phase of the study. However, compared to CTC communities, control communities did not reach as many children and parents, nor were they as likely to monitor prevention program implementation quality during the intervention and sustainability periods (Fagan et al. 2011a).

Prevention Service System Transformation. CTC's theory of change illustrated in Fig. 1 suggests that several characteristics of the prevention service system in communities are important to achieving desired improvements in youth risk, protection, and problem behavior. By the third year of the intervention, important signs of system transformation were observed in CTC but not control communities. Key leaders in CTC communities reported a significantly higher stage of adoption of science-based prevention in their communities, meaning that they had a greater understanding of major prevention science concepts like risk and protection, and reported that their communities empirically assessed community levels of risk and protection, used tested and effective prevention practices, and monitored prevention program implementation and outcomes more than did key

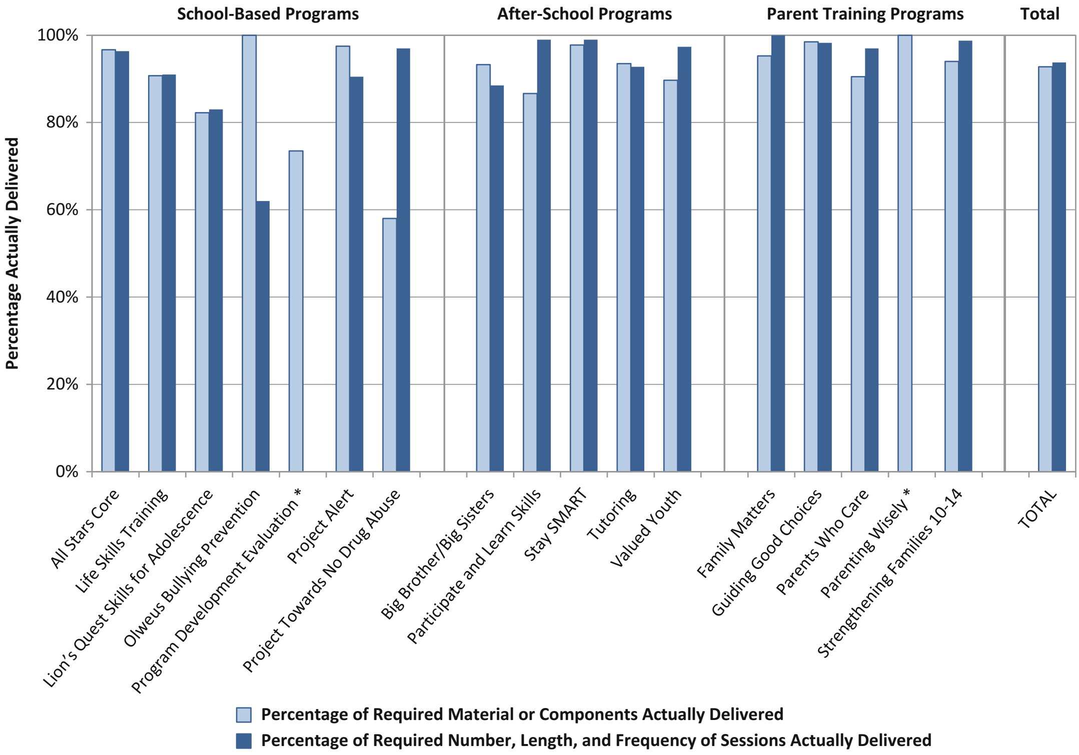
Universal effects	Generally benefited equally from CTC, regardless of differences in gender, baseline risk, early substance use, or early engagement in delinquency	Oesterle et al. (2010)		
Benefit-cost analysis	CTC was estimated to return $4,259 per youth in net present benefit or $5.30 per $1.00 invested	Kuklinski et al. (2012)		

[a] Communities were matched in pairs within state on population, racial and ethnic diversity, economic indicators, and crime rates. They were randomly assigned by coin toss to the CTC or control condition. At baseline, CTC and control communities did not differ in their knowledge and use of science-based prevention. CTC and control community youth did not differ with respect to levels of risk, protection, and key outcome variables including substance use and delinquency. Youth risk and behavior outcomes were from a panel of 4,407 youth initially constituted in Grade 5 and surveyed annually through Grade 10

[b] Prevention system sustainability phase outcomes are reported at latest measurement



** No session fidelity forms submitted.*

Communities That Care, Fig. 5 CTC communities implemented prevention programs with fidelity (average results over four intervention years) leaders from control communities (Brown et al. 2011). Adoption of a science-based approach to prevention is hypothesized to be a key to achieving better youth outcomes through CTC. Key leaders in CTC communities also were willing to allocate a greater percentage of funding for prevention programs than key leaders in control communities, providing some evidence of increased community support for prevention in CTC communities. Although levels of collaboration did not differ in CTC and control communities at the third year of intervention, high levels of collaboration were observed in both. Effects on adoption of a science-based approach to prevention and desired prevention funding were sustained 18 months after the intervention phase of the Community Youth Development Study ended, and, at that point, key community leaders in CTC communities reported stronger community norms against adolescent drug use than did key leaders in control communities (Rhew et al. 2013).

CTC Leads to Sustained Prevention of Youth Risk, Delinquency, and Substance Use

CTC communities each prioritized 2–5 risk factors to target with tested and effective prevention programs, as shown in Table 2. Effects on youth risk and problem behaviors were first observed in Grade 7, after less than 2 full years of intervention and earlier than CTC's theory of change suggested. Effects have been sustained through Grade 10, 1 year after the trial's intervention phase ended.

Effects on Risk Factor Exposure. Longitudinal panel youth in CTC and control communities reported similar levels of targeted risk in Grade 5, when the intervention began (Hawkins et al. 2008a), but targeted risk exposure grew more slowly for youth in CTC communities between Grade 5 and Grade 10 (Hawkins et al. 2012). Significantly lower levels of targeted risk were first reported by CTC panel youth 1.67 years into the intervention, in Grade 7, (Hawkins et al. 2008a) and have been sustained in CTC panel youth reports through Grade 10.

Effects on the Initiation of Delinquency and Substance Use. Panel youth from CTC and control communities also reported similar levels of delinquency, alcohol use, and cigarette smoking at Grade 5 baseline. However, between Grades 5 and 10, CTC had significant effects on the initiation of these behaviors. Significant reductions in the initiation of delinquency were first observed in the spring of Grade 7 (Hawkins et al. 2008a). Panel youth from CTC communities were 25 % less likely than panel youth from control communities to initiate delinquent behavior, and they remained 24 % less likely to do so in Grade 8 (Hawkins et al. 2009). Significantly lower delinquency initiation rates were sustained through Grade 10 (Hawkins et al. 2012), when panel youth from CTC communities were 18 % less likely to initiate delinquency than panel youth from control communities.

Preventive effects on alcohol use and cigarette use were first observed in the spring of Grade 8, 2.67 years after intervention programs were implemented. Grade 8 youth from CTC communities were 32 % less likely to initiate alcohol use and 33 % less likely to initiate cigarette smoking than Grade 8 youth from control communities (Hawkins et al. 2009). Preventive effects were sustained through Grade 10 (Hawkins et al. 2012), when CTC panel youth were 29 % less likely to initiate alcohol use and 28 % less likely to initiate cigarette smoking than panel youth from control communities.

As shown in Fig. 6, differences in the initiation of delinquency, alcohol use, and cigarette smoking from Grade 5 through Grade 10 led to cumulatively lower rates of initiation over time: 62 % of 10th-grade youth in the panel from CTC communities had engaged in delinquent behavior compared with 70 % of 10th-grade youth in the panel from control communities; 67 % versus 75 % had initiated alcohol use; and 44 % versus 52 % had smoked cigarettes.

Reductions in the Prevalence of Delinquency, Violence, and Substance Use. CTC also significantly reduced the prevalence of youth problem behaviors in Grades 8 and 10. In Grade 8, the prevalence of alcohol use in the past month, binge drinking (five or more drinks in

a row) in the past 2 weeks, and the variety of delinquent behaviors committed in the past year were all significantly lower in CTC panel youth compared to control community panel youth (Hawkins et al. 2009). A subset of the delinquency items was used to create a measure of violent behavior. The CYDS found significant effects of CTC in reducing the prevalence of delinquent behavior and violence in the past year in the spring of Grade 10 (Hawkins et al. 2012). Tenth-grade students in CTC communities had 17 % lower odds of reporting any delinquent behavior in the past year (t (9) = −2.33; *p* = .04; AOR = .83) and 25 % lower odds of reporting any violent behavior in the past year (t (9) = −2.51; *p* = .03; AOR = .75) compared to students in control communities.

CTC's Effects Are Universal. CTC was designed as a universal intervention, and the universality of its effects on the prevalence of substance use and delinquent behavior was tested based on outcomes observed in panel youth in the spring of eighth grade (Oesterle et al. 2010). Four groups of students were established using baseline Grade 5 data: boys and girls, high baseline risk versus all others, early substance users versus nonusers, and early engagers in delinquency vs. non-engagers. Results generally supported the universal effectiveness of the CTC intervention with respect to the prevalence of delinquent behavior and substance use within groups. There were two exceptions. The effect of CTC on reducing the prevalence of substance use in eighth grade was stronger for boys than girls, and the effect on the prevalence of delinquency was stronger for students who were non-delinquent at baseline.

Communities That Care, Table 3 CTC is a cost-beneficial intervention

	Stakeholders			
	Participants	Taxpayers	Others	Total
Per-youth benefits[a]				
Smoking	$671	$140		$812
Delinquency		$2,033	$2,405	$4,438
Total benefits	$671	$2,173	$2,405	$5,250
Per-youth costs[a]				$991
Per-youth net present benefit[a]				$4,259
Benefit-cost ratio				$5.30

[a]All benefits and costs are expressed in discounted 2004 dollars

CTC is a Cost-Beneficial Intervention

A cost-benefit analysis was undertaken to determine whether CTC is a sound investment of public dollars based on significant preventive effects on cigarette smoking and delinquency initiation found in Grade 8 (Kuklinski et al. 2012). Findings are summarized in Table 3. CTC's long-term financial benefits from reduced initiation were compared to a conservative CTC implementation cost of $991 per youth over 5 years. Most communities spent significantly less, roughly $513 per youth. Approximately 37 % of the total went toward a CTC coordinator and the coalition; 35 % to prevention programming; 23 % to CTC training, technical assistance, and monitoring; and 4 % to miscellaneous expenses. Implementation costs were more than offset by CTC's estimated financial benefits of $5,250 per youth. The benefit-cost ratio indicates $5.30 is returned to society for every $1.00 invested, evidence that CTC is a cost-beneficial investment.

Challenges to Implementing CTC

Like other community mobilization strategies, CTC can be challenging for communities to implement and sustain. In our experience, communities need to overcome five types of challenges to successfully own and operate CTC.

Be Ready to Implement a Comprehensive Approach to Prevention. Communities must be ready to initiate comprehensive evidence-based prevention in order to fully implement CTC. This requires readiness along several key dimensions. Differing views among stakeholders about the most effective approach to addressing youth problems must be considered. If particular groups advocate only exclusionary approaches such as arrest and incarceration, or exclusive reliance on treatment approaches, they may need further education about the potential effectiveness of prevention prior to engaging in the CTC process. If communities have an unsuccessful history of collaboration, characterized by conflict and competition for scarce resources, building trust through collaborative efforts to achieve smaller specific goals, like closing a crack house or getting a crosswalk installed on a busy street, may be necessary prior to initiating CTC.

Recruit and Engage Key Leaders. If CTC is to succeed, key community leaders who control resources and shape opinions, like the mayor, school superintendent, and police chief, must decide to bring the CTC system into their community. Their recruitment and engagement is essential to CTC's success. Without ongoing "buy-in" from key leaders and influential champions who have access to resources, CTC will not be viable because local resources will need to be committed and often redirected to prevention.

Evidence-Based Prevention Often Competes with Usual Practice. The board needs to advocate for a risk- and protection-focused approach to preventing problem behavior and for the use of tested and effective preventive interventions to address local priorities. At times, this can mean giving up programs that are rooted in community tradition or are local favorites if they lack research evidence of effectiveness.

Faithfully Implement and Evaluate. Achieving prevention goals requires high-quality implementation of the CTC system and prevention programs and monitoring outcomes over time. Monitoring community-wide implementation and making needed adjustments can be a challenge when programs are implemented in multiple classrooms, agencies, and community settings. Evaluation of changes in risk, protection, and outcomes at the community level is also a challenge. At the local level, it may be several years before community-wide reductions are achieved, requiring long-term commitment to the CTC approach.

Ensure Adequate Resources. CTC coalitions and community coordinators represent critical human resources needed to run CTC. Maintaining board engagement and recruiting and orienting new members to CTC and the coalition's progress to date are essential to long-term sustainability. Securing ongoing funding for coalitions and coordinators, prevention programs, and training and technical assistance can be a challenge for coalitions. In the CYDS and in a second quasi-experimental study of CTC in Pennsylvania (Feinberg et al. 2008), coalitions were aided in initial implementation efforts by seed money for coalition organizing and training and implementing chosen effective prevention approaches. Many coalitions in both studies have demonstrated success in generating ongoing resources for CTC. Those most likely to obtain funding were well functioning and planned for financial sustainability as part of their regular operations (Feinberg et al. 2008).

Steps to Broader Dissemination of CTC

All manuals and materials needed to implement CTC have been placed in the public domain by the US Substance Abuse and Mental Health Services Administration of the Department of Health and Human Services and are freely available at http://www.communitiesthatcare.net. CTC is currently being implemented in communities across the United States and in countries including Australia, Canada, Croatia, Germany, the Netherlands, and the United Kingdom. The CTC tests in both the Community Youth Development Study and the Pennsylvania quasi-experimental study were conducted with certified providers of training and technical assistance, as well as monitoring and oversight of implementation, including reviewing and providing feedback on annual plans. State and federal governments, local philanthropic organizations, the United Way, and other local funders could assist in broader dissemination of CTC by supporting training, technical assistance, and monitoring of processes and outcomes. Efficiencies can be achieved by offering CTC training through state governments, who can then train state prevention workers and contractors to deliver CTC training and technical assistance to local communities. A national CTC training and certification center could support the training of state and community personnel in CTC and share lessons learned from the implementation of CTC.

Conclusion

Policymakers and researchers increasingly recognize the need for clear and compelling evidence about how best to prevent prevalent and costly problem behaviors in youth. Delinquency and substance abuse are problems that begin in late childhood and adolescence, often with lifelong consequences. The results of the Community Youth Development Study show that *Communities That Care*, a coalition-based prevention system employing a risk- and protection-focused approach, is a cost-beneficial, effective way to prevent delinquency, violence, and tobacco and alcohol use in youth. Intervention communities were able to faithfully implement the CTC prevention system and evidence-based programs designed to address community-specific prevention priorities, and they sustained this success after the intervention phase of the Community Youth Development Study was over. These efforts were related to significant, meaningful, and sustained reductions community wide in the percentage of youth in intervention communities initiating delinquent behavior, alcohol use, and cigarette smoking, and in the prevalence of current involvement in smoking, delinquency, and violence when compared to youth from control communities.

Acknowledgments The Community Youth Development Study was supported by research grant R01 DA015183-03 from the National Institute on Drug Abuse, with co-funding from the National Institute of Child Health and Human Development, the National Cancer Institute, the National Institute of Mental Health, the Center for Substance Abuse Prevention, and the National Institute on Alcohol Abuse and Alcoholism. Community Courts

Rachel Swaner
Center for Court Innovation, New York, NY, USA

Overview

A community court, often called a neighborhood or community justice center, is a neighborhood-focused court that applies a problem-solving approach to local crime and safety concerns. Emphasizing improved outcomes for offenders (e.g., lower recidivism) and for communities (e.g., safer neighborhoods), community courts strive to prevent crime by addressing its underlying causes (Berman and Feinblatt 2005; Rottman and Casey 1999). Most community courts handle low-level criminal cases arising in a set of target neighborhoods. Some community courts are multi-jurisdictional, handling housing disputes, juvenile delinquency matters, or other case types in the family court system as well. Community courts are typically located in a separate courthouse situated within the targeted neighborhoods, although some community courts do operate out of a centralized "downtown" court.

In 1993, the first community court was started in Manhattan, New York City. It was opened to address quality-of-life crimes such as prostitution, illegal vending, vandalism, and minor drug possession in the central business district of Midtown, which included Times Square, then the home of much low-level crime. Since then, over 60 community court projects have opened worldwide. In the United States alone, there about 40, while there are at least 17 in South Africa, 13 in England and Wales, and one each in Australia and Canada (Henry and Kralstein 2011). These courts seek to bring a neighborhood-focused, problem-solving approach to local crime, social disorder, and safety concerns, focusing on alternatives to jail and fines, instead giving sanctions such as community service, social service, and treatment for drug addiction.

This entry outlines the principles and theories of community courts and summarizes the current research regarding the effectiveness of community courts on expanding sentencing options, improving compliance rates for court mandates, lowering recidivism, and reducing costs. As will be discussed in further detail, the evaluation literature shows that community courts do indeed dispense more types of sanctions (e.g., community and social services) than regular courts; though jail is still used, it is mostly as a resentencing option. Mandate completion rates have shown to be higher than in more traditional courts, though more research may be needed in this area. Findings on differences in recidivism rates have been mixed; while some studies have shown lower recidivism rates for community court participants, other studies have failed to show an effect, which may in part be due to small sample size or no true comparison group. Finally, studies have shown mixed results on cost savings as well.

Background Description

One of the main components of community courts is the use of alternative sanctions, the goals of which are twofold: first, to pay back the community that may have been harmed by the offense through visible community service work projects in the neighborhood, such as cleaning local parks and painting over graffiti. Second, social services such as drug treatment and job training are assigned to link defendants with programs that address the problems that may have played a role in leading them to commit crimes. This combination of accountability and help seeks to reduce chronic offending. In order to understand local problems and priorities, community court staff also commonly venture out into local neighborhoods, attending community meetings and serving as a convener and problem-solver between criminal justice agencies (e.g., police, prosecutors, or probation) and the citizens they serve.

However, there is no one concrete model for community courts, which makes it difficult to develop one standard definition. But as Berman (2010) outlined, community courts are usually guided by the following six key principles that differentiate them from more traditional courts:

1. *Enhanced Information* – Community courts seek to make as much information as possible available about the individual defendant and the community context of the crime at the defendant's first court appearance. This allows for improved decision-making by judges, attorneys, and other justice officials, enabling them to match the defendant to appropriate sanctions and services.
2. *Community Engagement* – Community courts seek to assign offenders to community service projects in places where neighbors can see what they're doing, welcome observers and visitors, make information about courtroom activities easily accessible to the public, and involve the community in addressing crime-related problems.
3. *Collaboration* – Government agencies, social service agencies, and other community organizations work together under a single roof, where the physical proximity facilitates closer and more coordinated working relationships.
4. *Individualized Justice* – Community courts link defendants to individually tailored, community-based sanctions such as community service, job or educational training, and drug treatment.
5. *Accountability* – Community courts insist on regular and strict compliance monitoring, with clear consequences for noncompliance. Additionally, community courts often escort offenders immediately to the place where they will receive their community or social service assignment, greatly increasing the likelihood that they will comply with their

sanction. These mechanisms work to improve the accountability of the offenders.

6. *Outcomes* – Data collection and analysis are important tools at community courts. Data help to answer questions related to case processing (how many and how quickly), status and compliance, as well as to perceptions of the court, procedural fairness, and local quality of life.

Expanding on the sixth point above, community courts usually follow one or more of the following theories of change for attempting to achieve these outcomes, as outlined by Lee et al. (2013).

Procedural Justice and the Social Construction of Legitimacy

As Tyler (2001) suggested, public trust and confidence in police and courts is not related to performance or outcomes but to how fairly people feel they were treated. The idea of fairness vis-à-vis justice was clearly defined by John Rawls (1971) in his *A Theory of Justice*. He said that perfect procedural justice had two characteristics: (1) an independent criterion for what constitutes a fair or just outcome of the procedure and (2) a procedure that guarantees that the fair outcome will be achieved. Tyler (1990) put forth that citizens generally hold favorable views towards institutions that are perceived as unbiased, while holding negative views of those that are believed to be partisan or discriminatory. Procedural fairness is present when people perceive that they are experiencing the following in their interaction with judges (Tyler 2004: 443–47):

- ***Respect***: People are treated with dignity and their rights are respected.
- ***Neutrality***: Honest and impartial decision-makers base their decisions on facts.
- ***Participation***: Each party has an opportunity to express his or her viewpoint to the decision-maker, and conversely, decision-makers clearly articulate the basis of their decisions in ways that litigants can understand (without jargon).
- ***Trustworthiness***: Decision-makers appear benevolent, caring, motivated to treat parties fairly, and sincerely concerned about people.

Research has endeavored to assess the meaning of procedural justice for those who come in contact with the criminal justice system. As Wissler (1995), Lind and Tyler (1998), and Paternoster et al. (1997) have demonstrated, people are more willing to accept decisions when they think criminal justice officials or legal institutions are acting fairly. Similarly, Tyler (1990) has argued that citizens generally hold favorable views towards institutions that are perceived as unbiased, while holding negative views of those that are believed to be partisan or discriminatory. Elsewhere, Tyler (2001) has suggested that public trust and confidence in police and courts is related to how fair people feel they were treated; performance and outcomes are secondary factors.

Research has also attempted to understand the relationship between procedural justice and the public's law-related behavior, as there is growing concern that perceived injustice itself causes criminal behavior (LaFree 1998; Mann 1993; Russell 1998; Tyler 1990). Tyler and Huo (2002) have proffered that when citizens perceive justice system agencies to be fair, they are more likely to comply with the law, legal authorities, and court mandates, increasing institutional confidence. Compliance, Tyler (2004: 307) further explains, is linked to legitimacy – "the property that a rule or an authority has when others feel obligated to defer voluntarily" – and that to the extent that people regard the courts as legitimate, they are more willing to accept the directives of the courts.

To put it another way, legitimacy develops out of the use of fair procedures and the provision of respectful treatment. Procedural justice, then, is the key antecedent to legitimacy, voluntary compliance, and lower recidivism: the greater the legitimacy, the less the likelihood of defiance, hostility, and resistance to laws, legal authorities, and legal institutions.

Community Involvement

In addition to building legitimacy through procedural fairness, community courts seek to strengthen ties to the community so that residents and merchants see themselves as allies of the court and are therefore more likely to reinforce social norms that the court espouses. When the whole community comes together to reinforce norms that do not accept crime and disorder, neighborhoods will become safer as crime decreases. When community courts actively involve the community in decision-making and give back to the community in some tangible way, there will be improved perceptions of the court. Community courts engage the community in four primary ways:

- ***Visible community service***: By sanctioning offenders to community service work in places where neighbors can identify them as offenders and see what they are doing, community members will better understand the court's role in restoring the community that had been harmed. These community service projects usually involve work such as graffiti removal or trash cleanup, serving as a tangible reminder of the offender's membership in and responsibility to the group (see Herrschaft 2012).
- ***Giving the community voice***: By regularly asking the community what their needs and concerns are – through neighborhood surveys (see Swaner 2010), advisory boards, and community meetings – community courts are better able to offer programs and services that are relevant and address the desires of local residents and merchants.
- ***Collaboration***: Allowing community-based organizations to have space to run programming in the community court building, supporting community events organized by local organizations, and partnering with local groups to offer comprehensive programming and co-sponsoring events helps develop a strong neighborhood identity as well as community-based informal social controls that research links to crime reduction.
- ***Voluntary programming***: Community courts offer voluntary programs for all persons living within the court's jurisdiction – regardless of whether or not they have a court case. These programs can include after-school programs for local youth, job training, educational classes, an open computer lab, health and mental health services, and mediation sessions. Offering these programs helps the court to be seen as an asset to all members of the community, not just a place for those who commit crimes.

Deterrence

In 1982, Kelling and Wilson's now famous "broken windows" theory was introduced to the criminology world, and it is the theoretical underpinning of many community courts. The basic premise behind this theory is that when the physical and visible conditions of a neighborhood – graffiti, illegal dumping, public intoxication – are not controlled and monitored, it produces more social disorder, and, eventually, these neighborhood problems escalate to more severe crimes. Community courts focus on trying to fix the problems when they are small so that further petty crime and antisocial behavior will be deterred and, hence, will not lead to more severe crimes. In this way, community courts tend to focus on cleaning up minor "quality-of-life" crimes under the assumption that this will lead to reductions in other types of crime as well.

Focusing on "broken windows" also helps to reinforce that a particular community does not accept crime. Looking at the surrounding environment – whether it is clean or dirty – gives cues to individuals as to the social norms of the community. If it is a place that has broken windows and other visible signs of disorder, this is a signal to potential lawbreakers that any crime they commit is likely to be overlooked. If, on the other hand, it is a place that does not have broken windows, this is a signal that the community does not accept crime, and there would be certain punishment for committing a criminal act, serving as a deterrence to violating social norms. This means that in order to design an effective deterrent, community courts must consider the *certainty* of punishment. Research indicates that the certainty of punishment is the most important element in the potential criminal's decision whether or not to commit a crime (Nagin and Pogarsky 2001). Criminal behavior is not deterred if lawbreakers do not think they will be caught or given meaningful punishment if they are.

Accordingly, community courts replace sentences that lack ongoing obligations of any kind with meaningful sanctions for even the most minor of offenses. They have an intense focus on misdemeanor offenses that create visible signs of disorder and also focus on sanctioning offenders to community service that repairs those conditions of disorder.

Intervention

The intervention theory of change assumes that sanctioning offenders to social service interventions will help them address the underlying problems that may have caused them to commit crimes (or have other legal problems) in the first place. For example, drug offenders may have an underlying addiction that causes them to offend. Assigning them to a drug treatment modality such as outpatient/detox or residential treatment may help them overcome the addiction that led them to commit a crime. Other offenses such as public intoxication, driving under the influence, and drug possession also frequently result from addiction to alcohol or drugs. Providing people with appropriate interventions such as short- or long-term treatment, anger management workshops, job training programs, or GED programs may help them break cycles of recurrent criminal behavior caused by social dislocations such as drug addiction, lack of employment opportunities, and educational disadvantages. The same principles animate community court practices when handling non-criminal cases. For instance, landlord-tenant disputes that escalate to a case in housing court may reflect the tenant's need for employment assistance or for help accessing public benefits. Thus, community courts that handle housing matters commonly provide tenants with resources and referrals that may help them meet their payment obligations.

State of Art

Due in part to the recent proliferation of community courts, there is scant research literature on their impact. Comprehensive impact evaluations have been carried out in only Midtown, Manhattan (Hakuta et al. 2008; Sviridoff et al. 2000a, b, 2001); Hennepin County, MN (Eckberg 2001; Weidner and Davis 2000); Philadelphia, PA (Cheesman et al. 2009, 2010); Yarra, Australia (Ross et al. 2009); and Red Hook, Brooklyn (Lee et al. 2013). Methodologies applied in these sites included process evaluations; quasi-experimental studies testing impacts on case processing, outcomes, offender compliance, and/or recidivism; cost-benefit analyses; community surveys; and ethnographic observations and interviews with local offenders. The results of these impact evaluations and other smaller-scale evaluations are summarized by key themes below.

Expanded Sentencing Options

Confirming the central role of diversified sentencing options, a global survey of community courts (Karafin 2008) found that 92 % of community courts routinely mandate defendants to community service, and 84 % mandate defendants to social services, including treatment readiness classes (64 %), individual counseling (64 %), job skills (64 %), life skills (56 %), anger management (52 %), and substance abuse treatment (48 %). Two separate evaluations of the Midtown Community Court – one focusing on its early years and the other on recent impacts – both found that the court made significantly greater use of "alternative" sentences than the centralized Manhattan court. These studies also found that Midtown made less use of jail and less use of "walks," defined as sentences such as fines or time served that lack any ongoing obligation (Hakuta et al. 2008; Sviridoff et al. 2001).

Yet, despite sentencing a lower percentage of its defendants to jail, both studies found that when Midtown did use jail, the resulting sentences were longer on average. In addition, one evaluation found that Midtown was more likely to impose meaningful jail time as a "secondary sanction" due to noncompliance with what was initially an alternative sentence (Sviridoff et al. 2001). These dynamics meant that Midtown did not ultimately produce a significant net reduction in jail days served by its defendants.

Similar results were found in an evaluation of the Red Hook Community Justice Center (RHCJC) (Lee et al. 2013). Red Hook grants fewer "walks" than the downtown court.

Convicted RHCJC defendants are much less likely than downtown defendants to receive a conditional discharge with no real conditions other than staying out of trouble (15 % of convictions vs. 26 %) or a sentence of time served (3 % of convictions vs. 32 %). Red Hook defendants are also less likely than downtown defendants to have their cases dismissed (17 % of cases vs. 21 %) or to receive an adjournment in contemplation of dismissal (which involves a promise of dismissal within 6 months) (ACD) without community service or social service conditions attached (31 % of ACDs vs. 76 %). Of those defendants who do receive a sanction, however, RHCJC sends a larger share to community service and social service programs and a smaller proportion to jail – largely using jail as a resentence option with those defendants who are initially noncompliant.

Though only 1 % of Red Hook defendants receive jail as an initial sentence, when used as a resentence, the average number of days is longer than downtown (75.1 days, compared with 3.88 days). The net effect of this difference in the use of "secondary jail" sanctions is that fewer RHCJC cases ultimately receive a jail sentence (7 % vs. 17 %), but RHCJC cases ultimately average more time sentenced to jail (4.75 vs. 3.06 days among *all* defendants or 82.3 vs. 39.9 days among just those defendants who receive a jail sentence of any length).

Compliance with Court Conditions

As compared with the local centralized courts, the Midtown and Hennepin County community courts produced significant increases in offender compliance with community service mandates, from 50 % to 75 % in Midtown (Sviridoff et al. 2000a, b, Sviridoff et al. 2001) and 29–54 % in Hennepin (Weidner and Davis 2000). At the Red Hook Community Justice Center, between 2000 and 2009, 80 % of defendants mandated to community service and 69 % of defendants assigned to social service sanctions other than long-term drug treatment successfully completed their mandates.

At the Neighbourhood Justice Centre (NJC) in Yarra, successful completion of community-based orders (CBOs) over the course of 1 year (September 2008–August 2009) at the NJC was 75 %, compared to a 65 % successful completion rate for all CBOs statewide. For community service by offenders, the completion rate for assigned hours is marginally higher than the state average (88 % vs. 85 %), and each NJC offender performs an average of 105 h of unpaid work compared with 68 h for Victorian offenders in general (Ross et al. 2009).

An evaluation of the East of the River Community Court (ERCC) in Washington, D.C., found that between 2007 and 2009, 60 % of defendants who stayed on the ERCC calendar successfully completed the ERCC program (Westat 2012).

Effects on Recidivism

An evaluation of the Midtown Community Court failed to detect an effect on reoffending by individual offenders but did detect a drop in prostitution and illegal vending crime in the Midtown neighborhood, perhaps due to a displacement effect (Sviridoff et al. 2001). A study of recidivism of misdemeanants convicted in the Philadelphia Community Court (Allen and Schulman 2009) was conducted on offenders who completed all of the conditions of their sentence in 2007, reporting an overall 9 % recidivism rate, with lower rates reported for offenders that were required to complete a program. Cases removed from the Philadelphia Community Court before completing all of the terms of their sentence reported a higher 17 % recidivism rate. No recidivism data on a counterfactual comparison group, however, was conducted in that study.

Two evaluations, respectively of the Seattle (WA) and Liverpool (England) community courts, showed mixed results. In Seattle, there was not a significant difference in the probability of rearrest, but there was a smaller average number of rearrests among those processed in the community court than among those processed in a centralized court during a pre-implementation period (Nugent-Borakove 2009). Similarly, in Liverpool, there was not an impact on the reconviction rate, but the community court produced a small reduction in the total number of reoffenses (falling just short of statistical significance; see Jolliffe and Farrington 2009).

A recidivism study for the community court in Yarra showed that offenders sentenced by the Neighbourhood Justice Centre who received services at the center showed a lower rate of reoffending than a comparison sample of offenders sentenced at other courts (34 % vs. 41 %). However, this estimate was based on a relatively small sample of cases (100) and the difference between the NJC and comparison group was not statistically significant. In addition it was not possible to take into account any variations in the risk of reoffending associated with the NJC and comparison offenders (Ross et al. 2009).

At the East of the River Community Court, a survival analysis showed that recidivism was significantly lower among the ERCC diversion program and treatment court defendants than among the Metropolitan Police Department 5th District defendants. However, these findings only included data from the D.C. CourtView online records system. Analyses were conducted on the recidivism rates of only those defendants that participated in an ERCC diversion program compared to a matched group of defendants arrested in the MPD 5th District. Reoffending was 60 % lower among ERCC defendants than among MPD 5th District defendants 360 days after the case filing date. During the second follow-up period, recidivism was 42 % lower among ERCC defendants than among MPD 5th District defendants 360 days after the trigger case disposition date (Westat 2012).

A quasi-experimental evaluation of the Red Hook Community Justice Center showed that over a 1 year period, RHCJC defendants appeared less likely to be rearrested than the downtown sample (28 % vs. 31 %) and were also arrested fewer times on average (0.57 vs. 0.66). Over a 2 year period, differences between the RHCJC and the downtown court were somewhat greater. RHCJC defendants were significantly less likely than downtown defendants to be rearrested (36 % vs. 40 %) and averaged significantly fewer rearrests (0.95 vs. 1.16). An additional survival analysis demonstrated that the lower rate of recidivism for RHCJC defendants persisted over more than a 4 year maximum tracking period (Lee et al. 2013).

Cost Savings

Evaluations in Midtown, Hennepin, Yarra, and Red Hook included cost studies, but their findings differed. In Midtown, the evaluation identified approximately $1.3 million in annual savings based on a reduction in pre-arraignment detention time, reduced jail sentences on shoplifting cases (jail time was not reduced on other cases), and reduced prostitution arrests in the Midtown neighborhood (Sviridoff et al. 2001). The evaluation of the Neighbourhood Justice Center in Yarra also found that the court saved money; for every Australian dollar invested, the expected return was AUS$1.09–1.23. For the activities included in the NJC evaluation to return a positive net benefit, a change in reoffending behavior needs to be maintained for just over 4 years (Ross et al. 2009). The evaluation of the Red Hook Community Justice Center included a cost-efficiency analysis that found that the community court was cost-effective relative to the downtown court, but its cost-efficiency is reduced when it serves a small number of defendants (Lee et al. 2013). The Hennepin study, on the other hand, found that the community court was more expensive than regular case processing (Weidner and Davis 2000).

Possible Controversies

While many of the evaluations have shown positive results, it is important to understand some of the critiques that have been made of community courts.

First, community courts involve criminal justice agents and social service professionals working together in a coordinated way to best serve the offender and the community. But as Berman (2010) discussed, the guiding philosophies of criminal justice agencies and social service providers often differ in significant ways. Whereas law enforcement officials tend to promote harsher sanctions for defendants when they fail to comply, social workers, who have a better understanding of mental health and addiction, believe in giving second chances when an offender relapses.

This tension plays out in other ways as well. While community court judges have greater sanctions at their disposal, this also gives them control over assigning social service interventions to offenders. While judges are seen as being experts in law and the administration of justice, they may not have the social work training necessary to know which mental health interventions are most appropriate – and for how long – to meet offenders' needs. Community courts, then, may inappropriately extend the reach of the court into people's lives, transforming the judge into a powerful figure that transcends that of a traditional judge.

Moreover, while some social service sanctions seek to address the underlying problems that caused someone to commit a crime, many times larger socioeconomic factors – not individual pathology – are what contribute to crime. While community courts may offer job training or resume-building workshops, when there is a bad economy and a lack of available jobs, such social service sanctions will not be effective prevention measures.

Another critique is that one of the underlying program theories of community courts – "broken windows" – itself is flawed. This theory links disorder and crime prevention by using coercive social control to manage social disorder. However, just because disorder and crime are correlated, it does not mean that one causes the other. Moreover, research has shown that the link between the two is very weak. Broken window policing policy, then, tends to unfairly criminalize the poor, minorities, and homeless, and, as Malkin (2003) points out, "quality of life policing is not necessarily what residents envision as a response to their quality of life concerns" (1585).

Finally, money may be a source of controversy. Community courts may be competing with community-based social service agencies and other local organizations for limited public and private resources. Given their potentially higher level of political and cultural capital, community courts may be taking funding away from community groups who may be better suited to efficiently and effectively run the programming (see Malkin 2003). Community courts also require an initial influx of money to start-up – money to open a new building or renovate an existing one, hire new staff, and obtain necessary technology. Additionally, there are significant costs to run the social service programs that are essential to community courts. Critics might suggest that most of the key elements of community courts could be done more efficiently and with lower case management, staffing, and program costs within a centralized courthouse than a new, separate court.

Overview

This entry deals with the characteristics of community policing, discusses its varieties and its problems and possibilities. Subsequently, the following aspects are examined: historical backgrounds, related police models (such as problem-oriented policing, disorder policing and reassurance policing), the Chicago Alternative Police Strategy, implementation, governance and accountability, and the effectiveness of community policing.

Introduction

Community (or community-oriented) policing has been a very popular term during the past few decades in many parts of the world. It has even been described as the new organizing paradigm in public policing, a revolution in police work, or even a new orthodoxy (Bayley and Shearing 1996). However, despite its popularity, community policing has a multitude of meanings (Rosenbaum 1998; Ponsaers 2001). This has given some authors occasion to describe the concept as vague or as nebulous, one that seems to justify more or less any police program or activity. Brogden and Nijhar (2005) describe community policing as a buzzword that comes in all shapes and sizes.

Three factors are relevant to understanding why it proves so difficult to have an unequivocal definition of community policing, one that is generally recognized and accepted. First, the vagueness of the concept is probably one of the factors that contributes to its popularity. As Rosenbaum (1998) said, community policing seems to be something that everyone can identify with. Who would be against "community"? Secondly, in practice, the activities known as community policing do not rest on one single model of policing, but on a multitude of them (Ponsaers 2001). Finally, it is often assumed that community policing does not represent a more or less coherent or identifiable set of practices and activities; rather, it is a more general organizational strategy for the police. In line with this, it is seen more as a sort of police philosophy, which cannot be reduced to certain specific activities. In Skogan's (2006) terminology, community policing is more a process than a product.

Nevertheless, there have been many attempts to define community policing. One of the best known is the one by Trojanowicz and Bucqueroux (1990): "Community policing is both a philosophy and organizational strategy to allow community residents and police to work together in new ways to solve problems of crime, physical and social disorder and neighborhood decay."

In addition to this definition, there have been many other endeavors to describe what community policing is and what should be seen as its main ingredients. Many of these broader definitions, however, lack a certain coherence, for example, because they not only concern police strategies, but also the organization of the police force. For instance, both elements can be found in the well-known definition by Skogan and Hartnett (1997), who make a distinction between five central elements of community policing: organizational decentralization, a two-way communication between the police and the public, a broadly focused, problem-oriented policing strategy, responsiveness to citizens' demands, and a commitment to helping neighborhoods solve crime problems on their own.

Another factor that may contribute to a lack of coherence is that definitions of community policing may also contain elements of other police models. An example of this is the definition of community policing given by Bayley (1994), who speaks of CAMPS: consultation, adaptation, mobilization, and problem solving. However, the latter element can better be seen as belonging to the problem-oriented police model (see also below).

If elements of other police models and organizational features are left aside, there remain five elements of community policing that are often referred to in the international literature. Despite all kinds of varieties in the organization and practice of community policing, there seems to be a general consensus about the relevance of these elements: bridging the distance between the police and citizens; a focus of the police on a broad range of problems in the neighborhood (not only crime, but also social disorder and feelings of insecurity); a preventive approach in addition to a reactive one; cooperation with other agencies in the prevention and control of crime, disorder, and other neighborhood problems; and the promotion of citizen involvement. The question of whether or not these five elements are achieved in practice is a matter for empirical research.

Backgrounds

Community policing started in the United States in the 1970s as a reaction to the failures of the dominant police styles of those days. Kelling and Moore (1988) divide the history of American policing into three different eras. First there is what they call the Political Era, which continued until the early 1900s. In those years, American police forces gained their authority from local political leaders and were adjuncts to local political machines. The police provided a wide range of services to citizens. The primary tactic of the police was the foot patrol. Although the police were organized at a local level, their organizations were highly centralized and quasi-military. This political strategy had significant weaknesses, such as the rise of police corruption, discrimination against strangers, and relative inefficiency.

The second era is called the Reform Era, which started in the early decades of the twentieth century with the work of A. Volmer and later on O.W. Wilson, who wanted to reform the police organization and strategy. These reformers rejected politics as the basis of police legitimacy. Instead, the law and police professionalism were presented as the new basis for the legitimacy of the police. As a result, police departments became relatively autonomous organizations. The reform policy narrowed the main function of the police to law enforcement and control of crime. The police officers' work became standardized and uniform. The relation between the police and citizens came primarily to be defined in neutral and remote professional terms. Citizens were seen as passive recipients of professional crime control services. Preventive patrol by car and rapid response became the main strategies of this reformed police force.

In the 1960s and 1970s, it became clear that this professional police model (as it was called, although it was not at all very professional, as Stone and Travis (2011) have argued), had serious shortcomings. Several factors contributed to this: the rising level of crime and fear of crime, complaints – especially from members of ethnic minorities – about the way they were treated by the police, and the new critical awareness as a result of civil rights and antiwar movements. Moreover, scientific research revealed that many of the central strategies of this professional police force (such as preventive patrol by car or standardized criminal investigation) proved to be highly ineffective.

The third era, starting in the 1970s, may be seen as a reaction to the failures of the standard police model. In this Community Policing Era (Kelling and Moore call it a Problem-Solving Era), there is a renewed emphasis on close relations with the community and the citizens. The definition of the police function broadens into a community strategy. According to Kelling and Moore (1988), organizational decentralization is inherent to community policing. The involvement of police officers in the diagnosis of and response to community problems makes it necessary to locate the power of operational and tactical decision making at lower levels within the organization. Community policing requires intimate relations with citizens and instead of a claimed monopolistic responsibility for crime control, there should be strategic alliances with neighborhood and community groups. Community policing is based on a wide variety of strategies, such as foot patrol (rediscovered as an important instrument for regaining citizens' trust and promoting feelings of security), information gathering, problem solving, victim services, and others.

Although this analysis by Kelling and Moore deals with developments in the United States, there are certainly similarities with the background to the rise of community policing elsewhere. The failures of the standard police model, a loss of police legitimacy and citizens' trust, and higher levels of crime and feelings of insecurity contributed to the adoption of this new police model, in addition to the wish of police organizations elsewhere to imitate and follow the American police models, which enjoyed a high reputation.

The historical backgrounds to community policing are even more complex than this standard view of the history of American policing reveals. The shift from a standard police force to community policing is also related to changes in the prevailing views on democracy and the relation between the state and society. Moreover, in some cases, especially in the United States, the model of community policing may be related to more or less romantic notions of community (Herbert 2006). This seems to be of less relevance in some European countries, for example, where community or neighborhood is more often viewed as relatively neutral scales for the organization of the police and police-citizen relations.

Related Police Models

For the past few decades, community policing has become a dominant policing perspective in many countries. Other policing models were introduced, which are often seen as related or even integral to this community policing perspective. These models may also be viewed as responses to the failure of the (so-called professional) standard police model, but they diverge in their strategies and priorities. Nevertheless, such models are conceptually close to community policing and often they are assumed to be innovations in community policing. Three such models are briefly discussed here: problem-oriented policing (Goldstein 1990), disorder policing (or broken windows policing) (Wilson and Kelling 1982), and reassurance policing (Innes 2004).

Problem-Oriented Policing

The concept of problem-oriented policing was introduced by Goldstein (1990). In his view, much police work suffers from what he calls a means-over-ends-syndrome: police work is often defined more in terms of the "means" of police work (such as rule enforcement, surveillance, or rapid response) than by its goals. According to Goldstein, the work the police do requires them to deal with a wide range of behavioral and social problems that arise in the community.

Often police work mainly consists of ad hoc responses to a seemingly endless stream of isolated and recurring incidents. A problem-oriented approach is meant to make an end to this unproductive process. The police should conduct a detailed, systematic analysis of the causes and factors underlying a series of comparable events and incidents. Interventions by the police should be based on such detailed analyses and will differ for each problem (Goldstein 1990). This should contribute to a more preventive form of policing. Problem-solving strategies should not only be based on the traditional instruments and resources available to the police, but also on those of other agencies. In this respect, problem-oriented policing is a form of partnership or multiagency policing.

Several reviews of studies that evaluate police work have concluded that community policing may only be effective if it is applied in combination with a problem-oriented approach (Eck 2004; Skogan and Frydl 2004). In spite of this, there are also important differences between problem-oriented and community policing. First, the relevance of a problem-oriented approach is not confined to community policing (Tilley 2003). Moreover, one of the main goals of community policing is to contribute to an improvement in or restoration of the relations between the police and citizens. Insofar as citizens are involved in a problem-oriented approach, there is only a functional relation between the police and the citizens, who primarily are seen as the "eyes and ears" of the police (Tilley 2003).

Disorder Policing

According to the model of disorder policing, the police should focus on the restoration of physical and social order in neighborhoods. In this way, the police might reduce feelings of insecurity among citizens, enhance their trust in the police, and prevent and counter crime. This theory achieved recognition, thanks to a classical article by Wilson and Kelling published in 1982, entitled "Broken Windows."

The broken windows theory assumes that forms of physical and social disorder (such as incivility, physical deterioration, or disorderly social conduct), especially if they accumulate and persist for a relatively long time, will result in feelings of insecurity and the breakdown of informal social control in the community. Wilson and Kelling (1982) explain that a broken window acts as a signal to potential offenders that people living in this area are indifferent to what is happening in their neighborhood. As a consequence, one broken window (which is not speedily repaired) will result in more broken windows and more serious forms of crime in the neighborhood. Instead of reducing the police to playing the role of the criminal justice system's "front end," keeping the peace and maintaining social order should be restored as the force's main tasks (Kelling and Coles 1996). The main goal for the police should be to promote informal social control.

Many scholars view broken windows policing and community policing as opposites. Broken windows policing is identified as an aggressive approach to minor offenses and disturbances. In that case, community-oriented policing is associated with a more "gentle, friendly, concerned, or low-key method."

According to a second view, disorder policing is a specific instantiation of community policing. According to this line of thought, the broken windows theory is considered a source of inspiration for the well-known form of community policing that was developed in Chicago in the 1990s.

Reassurance Policing

In the last decade, a new model of policing has come to the fore, called reassurance policing. A central assumption in this model is that the presence of visible, uniformed authorities will reassure citizens, reduce feelings of insecurity, and restore trust in the police. This model was presented in the UK in reaction to the fact that since the mid-1990s, the objective level of crime had improved, while many citizens still perceived public safety as a serious, even worsening problem (Tuffin et al. 2006).

According to this model, the police should focus on problems that have the greatest impact on citizens' feelings of security ("signal crimes"). According to Innes (2004), visible and troublesome incidents are occupying the "collective memory" of residents; they function as warning signs for future threats. The police should develop "control signals," actions that communicate a sense of regained peace and order. These signals convince citizens that police officers are concerned about local security.

Although this model places great emphasis on the importance of visibility, accessibility, and proximity of the police, these conditions, although perhaps necessary, are not seen as sufficient to promote feelings of security and trust in the police. Evaluations of reassurance policing in the UK show that, in addition to police visibility, other important factors are problem-solving strategies, citizen involvement, and the promotion of citizen initiatives (Tuffin et al. 2006). Extending the notion of reassurance with problem-solving strategies, cooperation with other agencies, and the focus on "signal crimes" makes this theory quite complex.

The Chicago Experiment: CAPS

Disorder policing takes the "community needs" of residents as its starting point. In Wilson and

Kelling's terms, the neighborhood indicates what the "appropriate level of public order" should be. The police should make use of the "preventive capital" of citizens. In *Disorder and Decline* (1990), Wesley Skogan reflected on the problematic nature of determining order. In heterogeneous neighborhoods, neither the police nor citizen-organizations can claim that their vision of order is authoritative and liable to impose compliance. In these conditions, Skogan says, it is a challenge to involve citizens and other relevant parties explicitly in determining and selecting disorder problems that should be tackled. Order is negotiated rather than imposed. In this way, policing becomes the object of an open, deliberative process.

Actually this view formed the starting point of an ambitious, intensive police innovation program, the Chicago Alternative Police Strategy (CAPS). This program "reinvented" some of the core features of earlier community policing approaches (prevention, cooperation, problem solving, etc.), but added some "new" aspects: encouraging residents and other stakeholders to find solutions for local security problems and giving priority to problems of disorder.

Since 1993, CAPS has been implemented in all of Chicago's 279 police beats. All beats have monthly meetings attended by residents, police officers, and other professionals, the aim being to identify and prioritize local problems together, and to develop plans for dealing with them.

The police explicitly accepted the broken windows philosophy, and consequently also the expansion of the police mandate. Nevertheless, CAPS was launched by the city administration. The most difficult task was to recruit the police force's support for the program (Skogan 2006). The innovative element of CAPS lies not so much in its methods of citizen participation, but rather in the rigorous, long-term organization and political will to establish and maintain partnerships in every neighborhood.

Evaluation studies (Skogan and Hartnett 1997; Skogan 2006) show that the monthly beat meetings are attended by an average of 20 citizens. CAPS attracts residents who had not participated earlier in other programs. Increased participation of women, blacks, and poor citizens was noted. A remarkable finding is that participation in black neighborhoods is just as high as in white ones, even in high crime districts where the police were unpopular.

Between 1994 and 2003, confidence in the police increased considerably. Citizens' views of police effectiveness, responsiveness and demeanor within the "three Chicago's" (white, black, and Latino) improved substantially (Skogan 2006). After studying Chicago beat meetings, Fung (2004) pointed out several problems. Some beats failed to address priority problems. Police resources were often allocated inequitably. The "natural" course of participation led to "conflictual paralysis" in one beat and domination by wealthy and well-educated residents in another. Often, energetic facilitators succeeded in breaking through this "laissez faire, first come, first served" style, managed to put problems of under-represented subgroups on the agenda, and called in intervention teams to take action against drug houses (for example). Thus, beat meetings need powerful facilitators. Fung argues that even in neighborhoods that lack resources or have serious internal conflicts, citizens gain more from the new deliberative arrangements than from the bureaucratic organizational forms that existed prior to the introduction of CAPS.

In a case study of a neighborhood watch group in Beltway, a suburban district in Chicago, Carr (2005) shows that citizens received support from the police and other local public services only after CAPS had been introduced. As a result, small groups of active citizens were able to mobilize resources and initiate partnerships. Carr challenges the assumption that neighborhoods need strong social cohesion in order to get crime and disorder under control. Without CAPS, Carr stresses, Beltway activism would have been impossible. The main factor that drives citizen participation is trust in public professionals. Even in poor ethnic neighborhoods, consultation and partnerships may be successful. What is important is to overcome "legal cynicism" and the tendency of residents to tolerate antisocial behavior (Carr 2005).

Implementation

A recurrent complaint about community policing concerns its implementation. In Mastrofski's (2006) view, police work in the United States still does not meet the high ambitions of community policing, despite more than two decades of reform and the formal commitment of many police organizations to this model. In practice, there are many obstacles to full and effective implementation. According to Mastrofski, community policing in the United States did not transform the police in the way that was originally envisaged. Klockars (1988) was still more pessimistic, even in the early days of community policing. In his view, the rhetoric of community policing wraps the police in romantic, powerful, and unquestionably good aspirations, which the police, however, cannot realize in practice but only in what he calls "*ersatz terms*."

Although the past few decades have seen many studies on community policing, there is a shortage of detailed research on the practical implementation of this police model. Often its implementation is treated as a black box. Many studies focus on formal or organizational aspects of this form of police work, while seemingly disregarding the reality of community policing at street level.

One of the main findings in the limited number of studies that have focused on the street level of community police work is that community police officers often continue to spend a great deal of time doing traditional police tasks. This may be the result of several factors, such as the prevailing police culture (Greene 2000) or limited expertise (Eck 2004). Police leaders may be rather cynical about community policing or may fear that the increased discretionary room allowed to community officers may have adverse implications for their own position. However, the most serious problems in the implementation of community policing may arise in improving relations between the police and citizens, especially in those urban areas that most need community involvement.

Studies in other countries reported comparable results. For example, in Denmark, Holmberg (2002) found that in practice, many of the community policing principles are often embraced only very partially or in unintended ways. The main impediments in this country included large working areas, the burden of a lot of paperwork, and the priority of other tasks.

In the Netherlands, the five main ambitions of community policing (proximity, focus on a wide range of problems in the neighborhood, preventive strategies, cooperation with other agencies in the control of crime and disorder, and promotion of citizen involvement) were only carried through to a limited extent (Terpstra 2010). In contrast to the United States, these problems were not so much caused by a (supposed) police culture nor by romantic notions of community (Herbert 2006). More important was the fact that the concept of community policing still has a vague professional image, even among Dutch community police officers themselves. Moreover, community police work is often rather open and indefinite in nature. Although community policing usually has high ambitions, the officers involved often have only limited resources, skills, and expertise to achieve them. In addition, the support they receive from their management, superiors, and colleagues is often quite meager, and sometimes contradictory.

Governance and Accountability

A common element of community policing initiatives is attempting to bridge the distance between the police and citizens. It is often assumed that community policing may encourage local governance and accountability of the police (Skogan and Hartnett 1997; Somerville 2009). A main argument underlying CAPS was that it would enable citizens to provide local knowledge and resources to the police and that they would be better able to monitor police officers and hold them accountable. Following this line of argument, community policing may even be presented as a form of democratization.

However, community policing is not always seen as beneficial to police accountability. Organizational decentralization, a growing intimacy between police officers and citizens, and the increased use of discretion by police officers may also be viewed as potential threats to police accountability (Brogden and Nijhar 2005; Herbert 2009).

In fact, community police officers are confronted with very divergent forms of accountability, reflecting hierarchical, egalitarian, and more individualist cultures. This complexity results from the fact that a multiplicity of actors, each with their own views and interests, have a stake in the implementation of community policing. The (local) government, (internal) superiors, colleagues, external partners and (representatives of) the public try to "govern" the community officers and hold them accountable. As a result, these officers are not only held accountable within the traditional hierarchical relations, but also horizontally and vertically downward by partners or citizens (Somerville 2009).

In countries where the police organization is not strictly local (which is generally the case outside the United States), it is useful to distinguish between nonlocal and local forms of governance and accountability in community policing. Nonlocally initiated forms are mainly bureaucratic and managerial, representing hierarchical and individualistic cultures, respectively. In addition, community police officers may not only be accountable to the local government and politicians, but also to other police professionals, partners, and (groups of) citizens. These latter local forms of governance and accountability are usually more egalitarian (although there may also be some hierarchical elements). The traditional culture of command-and-control is hard to align with the complexity of community policing, the need for a flexible, tailor-made approach, and the need for officer discretion.

In the 1990s, new managerial forms of governance and accountability were introduced in many police organizations, such as systems of performance management with quantitative targets. These forms do not fit in with the localized nature of community policing work. They often create unintended consequences that are difficult to combine with community policing, such as a standardization of the work or a fixation on those activities that can more easily be quantified and measured.

Professional types of governance and accountability are often presented as a solution to the problems associated with hierarchical and managerial forms. Here the professional discretionary power of the community police officer is highly valued. Community police officers are not only asked to follow rules and procedures, but also to use their autonomy in a professional way and to show their moral involvement with local problem solving. However, these professional forms of governance and accountability are scarcely ever realized in practice, despite being what many community police officers would prefer in their relation with their superiors.

For the past few decades, many countries have witnessed a growing interest in citizen participation in relation to policing and public safety. However, citizen participation scarcely contributes to local police governance/accountability. Control over the police by partners or citizens may be perceived as conflicting with the views, routines, and priorities of the police (Terpstra 2011). In the United States, Herbert (2006) interpreted this as the result both of a police culture that emphasizes police self-protection combined with lofty and unrealistic expectations about "community" and local democracy. Comparable problems were reported in the Netherlands, where more modest and pragmatic meanings of community and the relation between community policing and local democracy prevail. Here the minimization of citizen influence on the police was used by community police officers to reconcile conflicting demands and expectations about their work.

Effectiveness

The issue of effectiveness of community policing raises several important questions. First, what should be meant by the effects of community policing? Generally it is assumed that an evaluation of the impact of community policing should not only focus on the question of whether it results in a reduction of crime and social disorder, but also whether it contributes to feelings of security and to greater levels of citizens' trust in the police. Secondly, how are the (potential) effects of community policing to be measured? Studies evaluating the impact of complex programs like community policing require a longitudinal and quasi-experimental research design. An adequate interpretation of the results of such an impact evaluation demands in addition that a detailed process or implementation evaluation should be used. If there is a shortage of reliable information about the implementation of the intervention or program, the effects or impact will be hard to interpret.

The internationally best known evaluation of community policing is that of the Chicago Alternative Policing Strategy (CAPS) done by Skogan and his colleagues. This study shows that opinions about the police in Chicago steadily improved in the years that CAPS was implemented. An increasing number of citizens feel that the police in their area are dealing with problems that concern residents and that the police are prepared to cooperate with residents in solving these problems. The increasing visibility of the police (partly a result of more frequent foot patrols) improved citizens' evaluation of the police. Moreover, many residents feel less insecure, partially because they see the police more often. Fear of crime declined substantially among the groups experiencing the greatest levels of fear. In Chicago, many forms of crime (both violent crime and property crime) declined sharply. However, in general, the fall was comparable to trends in other American cities. The evaluation of CAPS also showed that residents in certain areas reported sharp improvements in neighborhood conditions. African-American residents in particular reported improvements in relation to, for instance, abandoned buildings or graffiti, and different forms of social disorder. In summary, community policing according to the CAPS model had a positive impact on citizens' opinions about the police, feelings of security, and neighborhood problems and disorder (Skogan and Hartnett 1997; Skogan 2006).

Since the late 1990s, especially in the United States, there have been several meta-evaluations of the effectiveness of community policing, often comparing it with other police models and strategies. Sherman et al. (1997) showed that community policing which does not explicitly focus on specific risk factors, generally, has no impact or only a minor one on the level of crime. According to this review, the effectiveness of community policing may be improved if it is supplemented with a problem-solving approach or if residents are involved in the assessment of police priorities in their area.

Skogan and Frydl (2004) concluded that in general, the effectiveness of community policing is hard to determine because this concept is used for a wide variety of police practices and strategies. They found no evidence that methods that are often associated with community policing, like neighborhood watch, general foot patrol, storefront offices, or community meetings, contribute to a reduction of crime. However, community policing may have a positive impact on neighborhood problems. Improved relations between the police and residents may also diminish fear of crime and may cause residents to perceive less social and physical disorder in their neighborhood. According to Skogan and Frydl (2004) community policing may have a greater impact on the reduction of crime if it is supplemented with elements of two other police models: hot spot policing and problem-oriented policing.

Although available research gives important indications of the potential impact of community policing, there are still major questions left. Community policing is an internationally heterogeneous concept and practice. It is often unclear if conclusions from mainly American studies may be generalized to other jurisdictions. There are also indications that the effectiveness of community policing may differ between different types of neighborhoods and for different categories of citizens.

Future Direction

The conclusions of studies on the implementation and effects of community policing have raised serious questions about the value and practical feasibility of the community policing model. They have tempered naïve and optimistic ambitions that were sometimes connected to the model (Herbert 2006). In some countries, such as Norway, community policing never gained a dominant position. The reform of policing in that country for the past two decades was more strongly motivated by a problem-oriented approach (Larsson 2010).

In addition, in some European countries like the Netherlands, both an increasing emphasis on managerial discourse and a shift to a more repressive and punitive political climate meant that community policing lost much of its dominance (although it remains an important part of police work) (Terpstra 2011). Moreover, since the introduction of this model, police organizations were confronted with other fundamental changes that did not fit neatly within the framework of community policing (such as cybercrime). As a result, community policing lost some of its attraction as an overarching framework for the police (Stone and Travis 2011).

Despite these developments, one might expect that community policing is here to stay, although perhaps in a more pragmatic, modest way. The fundamental notion was and remains that for the promotion of a legitimate, fair, and effective police, it is essential to close the distance between citizens and the police and to create different forms of cooperation between them at the neighborhood level. It may be expected that as a result, community policing will continue to be an important element in the future, although adapted to very different and changing circumstances.

Community Service in Europe

Frieder Dünkel[1] and Tapio Lappi-Seppälä[2]
[1]Faculty of Law, University of Greifswald, Greifswald, Germany
[2]National Research Institute of Legal Policy, Helsinki, Finland

Overview

Community service orders have been introduced in England and Wales 1972 and since then have become one of the most important community sanctions in many European countries and outside Europe. Community service has gained importance, in particular, for offenders who are not able to pay a fine, but also to replace short-term imprisonment. It has an essential role as the principal community sanction in Spain, Hungary, England and Wales, Scotland, Latvia, and all Nordic countries. The scope of application varies considerably when looking at the range of hours that can be imposed. In Europe, one regularly finds a scope between 40 and 240 h, in the USA, between 100 and 500 h. Empirical studies have shown that the implementation of community service has been successful. In this regard, it is important that most offenders assigned to community service programs are completing their working hours. The available evidence suggests that community service is (at least) a promising alternative in terms of reducing recidivism. Several results point to significant differences between offenders who are sentenced to imprisonment and offenders who participate in community service. Recent meta-analyses demonstrate a stronger effect size (.07) than earlier ones, which may be explained by the better structured programs considering "what-works" criteria. The authors advocate to extend community service and to ensure that it comes to replace imprisonment (instead of replacing other noncustodial sanctions).

Historical Development

Historically forced labor has a long tradition in human history. In penal history, it was one of the core elements of prison life. Forced prison labor is still widely accepted and exempted from the ban on forced labor as expressed in international human rights standards. First efforts to ban forced labor date back to 1930 when the International Labour Organisation (ILO) initiated the Convention No. 29 and in 1957 a second one (Convention No. 105) after ILO had been linked to the UN in 1946. Both Conventions aimed at fighting against slavery and any other form of involuntary (forced) labor (see de Jonge 1999, pp. 321 ff.). The ban on forced labor can also be found in art. 8 of the International Covenant on Civil and Political Rights (ICCPR) and in art. 4 of the European Convention for the Protection of Human Rights and Fundamental Freedoms (ECHR). Art. 8(3) (c) of the ICCPR, however, allows for forced or compulsory labor "normally required of a person who is under detention in consequence of a lawful order of a court, or of a person during conditional release from such detention." The ECHR in the same wordings allows for forced labor only during detention and on conditional release. Strange enough to permit forced labor during the post-release stage, both Conventions do not clearly differentiate between remand and sentenced prisoners. Theoretically, one could think of forced labor in remand custody, but as a consequence of the presumption of innocence (see art. 6 ECHR), it is a common opinion and jurisprudence to exclude remand prisoners from compulsory work. The ILO Convention No. 29 had allowed forced labor only for sentenced prisoners, not for remand prisoners or those conditionally released (see de Jonge 1999, p. 327). The German Constitution as many other national laws allows forced labor only for sentenced prisoners (see art. 12(3) Federal Constitution, *Grundgesetz*).

Therefore, from an international human rights view, it might be difficult to justify community service as an independent sanction as far as it is not strictly bound to replace a prison sentence. In that case, it can be justified with the argument *a maiore ad minus* that forced labor in the community is a less intrusive sanction than imprisonment plus forced labor. If, however, community work does not replace a prison sentence, but other alternatives such as fines or conditional discharge without intervention, it can be questioned as being a violation of the ban on forced labor.

The German Constitutional Court has found a way out of this dilemma by going back to the roots of the ban of forced labor in the German Constitution after World War II: The constitutional ban was implemented as a fundamental human right with regard to forced labor in the preceding Nazi-era, where thousands of people were killed by hard labor in concentration camps and elsewhere. The legislator wanted to outlaw such inhuman hard labor, which in no way is comparable with some few hours of labor, in particular if its purpose is the rehabilitation (resocialization, education) of the offender (see *Bundesverfassungsgerichtsentscheidungen*, BVerfGE 74, pp. 102 ff., 122 ff.).

Germany did not introduce community service as an independent sanction in the Criminal Law for adults of at least 21 years of age, but only as a substitute sanction to prevent imprisonment for fine-defaulters (1983). This is different in the field of juvenile justice where the German Juvenile Justice Act (JGG) provides for community service as an independent sanction as well as a condition of diversion or of a suspended sentence (see Dünkel 2011a). The practice extensively uses community service: 44 % of all sentenced juvenile and young adult offenders (aged 14–21) in 2010 received a community service order (see Dünkel 2011a; Heinz 2012).

First community service programs were introduced in the USA with female traffic offenders in Alameda County, California, in 1966, with local initiatives following in several counties throughout the USA (Wright 1991, p. 40). The aim of different initiatives was to create community service programs as a viable alternative to incarceration (van Ness 1986, p. 194).

Community service as an alternative to prison in Europe first has been introduced in 1972 in England and Wales. Other European countries followed in the 1980s: Italy 1981, Denmark and

Portugal 1982, France 1983, the Netherlands 1985 (see Albrecht and Schädler 1986).

With the exception of Denmark, the Scandinavian countries introduced community service only in the 1990s. Denmark started an experiment with community service – as mentioned – already in 1982. However, the sanction was not introduced in a wider scale in the Nordic sanctions systems until the 1990s. Community service appears in different forms. Finland and Norway treat community service as an independent sanction (although Norway renamed "community service" in 2001 as "community punishment"). In Denmark and Sweden, community service is attached either to conditional imprisonment or a probation order. In Finland, long (over 1 year) conditional prison sentences may be combined with a short (20–60 h) community service order. In Denmark, community service can be combined also with fines and unconditional imprisonment. In addition, community service may be attached with separate conditions concerning residence, school attendance, or work. Also Norway allows specific conditions regarding the offender's dwelling, work, and treatment. The maximum number of community service hours varies from 200 (Finland) to 420 (Norway). The range of community service in Denmark was from 30 to 240 h, but the maximum was raised to 300 h in 2012.

Countries differ also in the sense, how strictly community service has been defined as an alternative to imprisonment, and not to other sanctions. Finland has followed the strictest policy in this respect, by adopting a specific *two-step procedure*. First, the court is supposed to make its sentencing decision by applying the normal principles and criteria of sentencing without considering the possibility of community service. Second, *if* the result of this deliberation is unconditional imprisonment (and certain requirements are fulfilled), the court may transform the sentence into community service. In principle, community service may therefore be used only in cases in which the accused would otherwise have received a sentence to unconditional imprisonment. Other countries are less strict in this point. In connection of the 2001 reform in Norway, the scope of community punishment was extended to be used, not only instead of imprisonment, but as a replacement penalty for juvenile offenders who had previously been sentenced to supervised conditional imprisonment. In Iceland, the decision over community service is taken by the prison administration, not the courts. This avoids effectively the risks of net-widening (but could raise questions from constitutional point of view in some other countries).

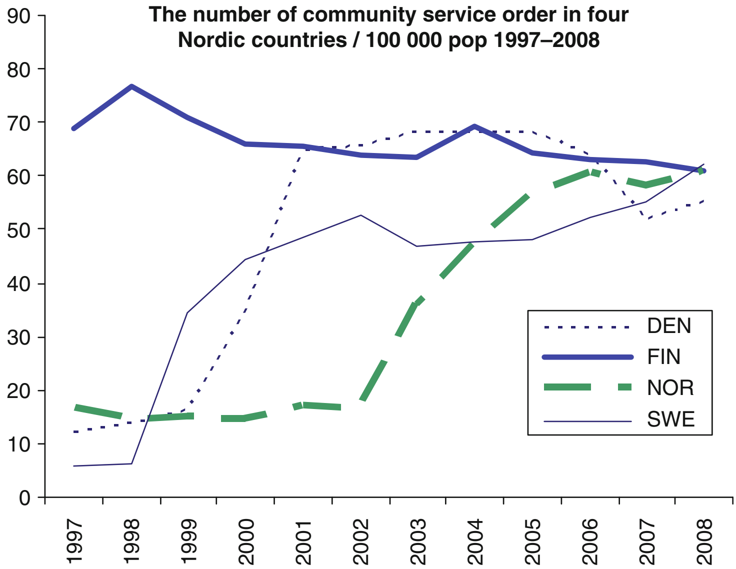
The Use of Community Service Sentences in Scandinavia in 2008–2009

Figures per 100,000 pop and % of court dispositions

	Fin %	Swe %	Den %	Nor %
Unconditional prison	130 (11 %)	158 (19 %)	160 (24 %)	219 (45 %)
Community service	64 (5 %)	64 (8 %)	59 (7 %)	54 (13 %)

In the turn of the 2000s, several Scandinavian countries completed law reforms in order to increase the use of community service. Sweden created a combination of community service and suspended sentence, thus increasing the number of annual cases from 2,000 to around 4,000. Denmark changed its policy in 2000 by allowing community service to be used also for drunken driving (which was previously forbidden). Within a period of two years, this increased the number of sentences from 1,000 to 4,000. Norway, in turn, tried to increase the credibility of community service by changing the title to community punishment by including also other elements in the sentence and by expanding the scope of application also to drunken driving. This resulted in an increase from around 500 cases to the present little over 2,500 cases (Table 1).

Relative to population community service is used roughly on a same scale in all countries, with Finland and Sweden on the lead (64) and Denmark and Norway following (59 and 54). A longer trend from 1997 onwards shows that three out of four countries expanded the use of community service in the shift of the millennium, while Finland had used this alternative more extensively already from the mid-1990s (Fig. 1).



Community Service in Europe, Fig. 1 The number of court-imposed community service orders/ per 100,000 population

Non-European countries have introduced community service as well, in particular in the Anglo-Saxon world (Australia, New Zealand, South Africa, and USA), but also in South America, recently, community service is developed as an alternative sanction. In these countries (as in Europe already earlier), juvenile criminal law is a forerunner for reforms of the sanctions system (all juvenile justice jurisdictions dispose of community service orders, see Tiffer-Sotomayor 2000).

Legal Conditions and Basic Philosophies of Community Service

Community service involves the performance of unpaid work, during leisure-time and within a given period, for the good of the community. The offender "shall pay back to the community via unpaid work" (Goldson 2008, p. 78; Dünkel et al. 2011, p. 1673). Thus, the original philosophy of community service fits very well with the special preventive aim of punishment (resocialization or with regard to juvenile justice: education) as well as to the idea of restorative justice. In the context of restorative justice, another orientation is outlined by Wright (1991, p. 44): "The emphasis of community service is not on punishment nor on rehabilitation; rather, it is on accountability." It focuses "not on offenders' needs but their strengths; not on their lack of insight but their capacity for responsibility; not on their vulnerability to social and psychological factors but their capacity to choose. These differentiate a rehabilitative response from a restorative/community service response to crime. And punitive elements of community service orders may attend its imposition, within a restorative system, only as by-products of the offender's commitment of time and effort" (Wright 1991, p. 44).

However, in the last 20 years, some countries have redefined community service and also renamed it as "punishment in the community" or "community punishment" and thus emphasizing the repressive goal of retribution. This was particularly the case in England and Wales (1998), but also in Norway (2001). Therefore, the nature and content of community service may be rather different from jurisdiction to jurisdiction.

The status and contents of community service may vary. It may:

- be imposed as an independent sanction or as an adjunct to another sanction
- replace only prison sentences or also other penalties

Although community service is widely accepted in the field of juvenile justice, some countries explicitly exclude the very young age groups, e.g., under 16 (England and Wales) or 15 (South Africa).

The *range of hours* (and implicitly the range of prison sentences that can be replaced) varies considerably:

In Europe, the range mostly is from 40 to 240 h, often with a maximum of 120 h for juvenile offenders. Even in countries with normally great similarities in their penal policy such as the Scandinavian countries, large variations can be seen: In Finland, the maximum is 200; in Denmark, 300; in Norway, 420 h.

In South Africa, the range is from 50 to 240 h (to be completed in 1 year).

In New Zealand, the range with 40–400 h is considerably wider. Up to 200 h should be computed in one year, more than 200 h in two years. If offenders do not meet the requirements of the sentence, up to three months of imprisonment or a fine of up to 1,000 $ (NZ) can be imposed (see http://www.corrections.govt.nz/community-assistance/corrections-in-the-community/community-work.html).

In the USA, the range is regularly between 100 and 500 h (to be computed in one year).

International Human Rights Standards Concerning the Imposition and Execution of Community Service

Human rights aspects are of major importance in the decision-making process as the principle of proportionality (*Verhältnismäßigkeitsgrundsatz*), derived from the principle of *Rechtsstaat* (rule of law, art. 20(3) of the Constitution), is to be considered for the imposition of community service, i.e., the number of working hours imposed must be related to the seriousness of the offense. In most countries, therefore, the maximum number of hours is fixed by law. In Germany, where community service as an independent sanction is available only in juvenile justice, no maximum is fixed by law. Therefore, the principle of proportionality is of special importance to avoid unjustified high number of several 100 h.

The Recommendation of the Council of Europe concerning Community Sanctions or Measures (CSM) of 1992 (Rec. (92)16) stipulates that "the nature, content and methods of implementation . . . shall not jeopardise the privacy or the dignity of the offenders or their families, nor lead to their harassment. . . . Safeguards shall be adopted to protect the offender from insult and improper curiosity or publicity" (Rule 23).

The European Rules for Juvenile Offenders Subject to Sanctions or Measures (ERJOSSM) of 2008 (Rec. (2008)11) – as earlier Recommendations of the Council of Europe and the UN – assess that "sanctions or measures shall not humiliate or degrade the juveniles subject to them" (Rule 7). And: "Sanctions or measures shall not be implemented in a manner that aggravates their afflictive character or poses an undue risk of physical or mental harm" (Rule 8). In the commentary to these rules, reference is made to some forms of community work that can stigmatize offenders such as wearing special uniforms which identify them as offenders and which would not be consistent with the rules (Council of Europe 2009, p. 37). The practice of wearing orange uniforms as it is the case in England and Wales as well as in the Netherlands (and in the USA or South Africa) therefore is a violation of these human rights standards. From a European point of view, totally violating basic human rights standards has been the practice in some US states (and still is in Arizona) to make offenders work in so-called chain gangs, i.e., stigmatizing them by working in a kind of medieval outfit tethered together.

Two more human rights issues have to be mentioned in this context: Rule 37 of the ERJOSSM states that the costs of implementation shall not be borne by the juveniles or their families. And community work shall not be undertaken for the sole purpose of making a profit (Rule 45 ERJOSSM). Therefore, the demand of the South Australian Corrections Service to make the communities pay 200 $ per a day of community service with good reasons has been rejected by the local authorities (see http://www.abc.net.au/news/2012-04-05/community-service-charge-council/3934500).

Statistical Developments: Europe and Scandinavia

The use of community service as compared to other community sanctions and measures and imprisonment can be examined most effectively on the basis of enforcement statistics. The Council of Europe's penal statistics Space I (survey year 2009) and Space II (survey year 2010) provide information both on stock rates and flow rates (/100,000 population) in Europe.

Figure 2 displays the number of persons serving community service or other community sanctions under the supervision of probation services at a given day (31.12.2010). Figure 3 displays the same information on the base of flow statistics.

Community service has a noteworthy role in over 20 European nations with data in the Council of Europe's Space II survey. It has an essential role as the principal community sanction in Spain, Hungary, England and Wales, Scotland, Latvia, and all Nordic countries.

Many of the countries with high rates of community sanctions are also countries with relative high incarceration rates (see Dünkel/Lappi-Seppälä/Morgenstern/van Zyl Smit 2010, 1058 ff). Figure 4 compares the use of community service and imprisonment on the base of enforcement statistics.

Stock- and flow-statistics give the same result. There is no correlation between the number of people in community service and in prison at any given day (stock). Neither is there a correlation between the number of people starting community service or entering in prisons during the year (flow). The latter finding is, however, heavily influenced by one outlier (Spain). Should this observation be excluded, one would find a weakly positive correlation. In other words, countries that use extensively community service use also imprisonment more. This finding is confirmed by a comparison between all community sanctions and measures and imprisonment (below) (Fig. 5).

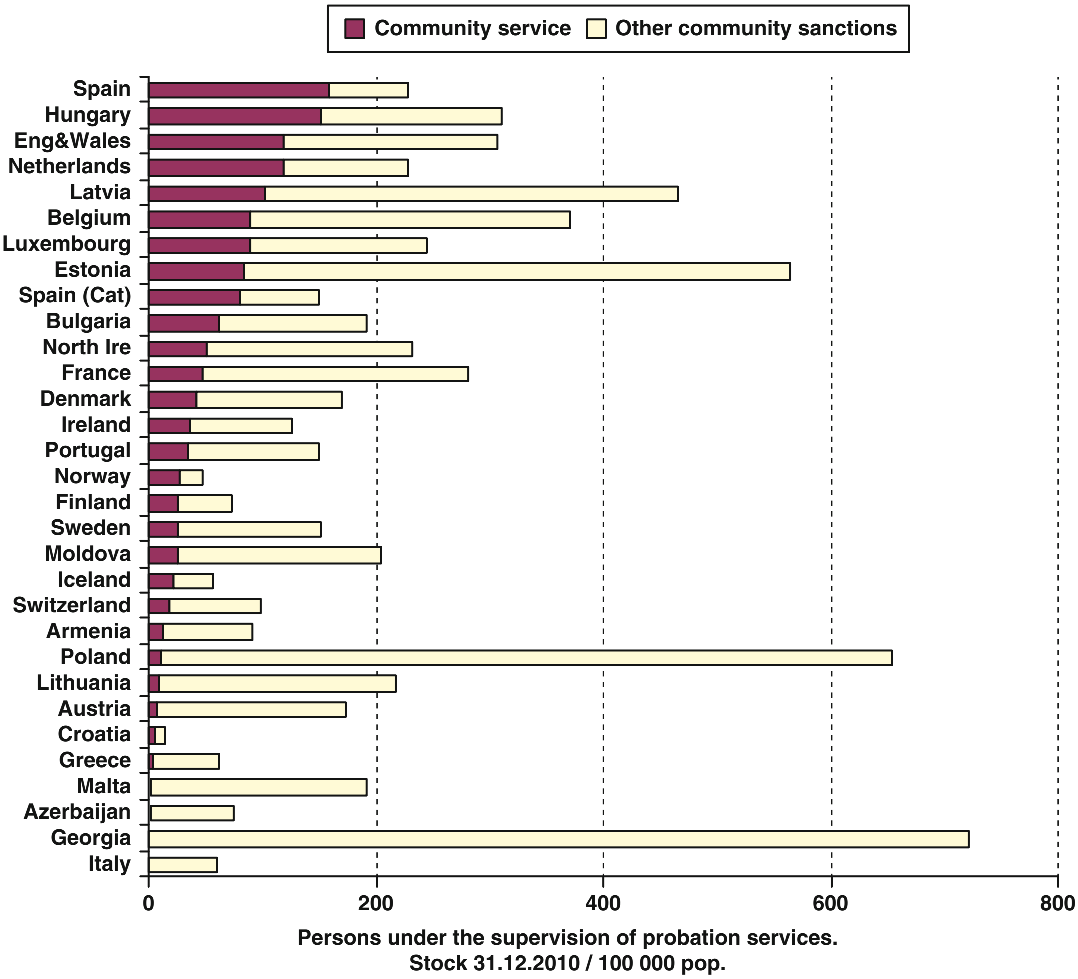
It seems that, in general, the use of imprisonment is not compensated by community sanctions. Countries with high incarceration rates are often (but not always) countries with high community sanctions rates. And countries with low incarceration rates seem to manage also with lower rates of community sanctions. However, one needs to take into account that this comparison includes only community sanctions with supervision under the probation service. It excludes formal types of sanctions such as suspended and conditional sentences without supervision, as well as fines. Should these measures be taken into account, low incarceration countries like the Nordic countries and Germany would rank high in the scale of noncustodial sanctions, but low in incarceration (see Lappi-Seppälä in this volume in the chapter on fines).

Evaluation Research: Recidivism and Reintegration into Society

Completion of Community Service Orders, Implementation of Programs, etc.

Community service in most countries is organized by the probation service and/or private nonprofit organizations of offender rehabilitation. One major problem in implementing community service is to organize working places and to allocate offenders to adequate working facilities. In particular, in large rural countries or local municipalities, it is sometimes difficult to find working possibilities close to the offender's residence. As community work has to be unpaid, the kind of work should be of a nature not to compete with regular paid work in the first labor market. Therefore, trade unions are keen to restrict community service to extra work which cannot be provided by normal enterprises.

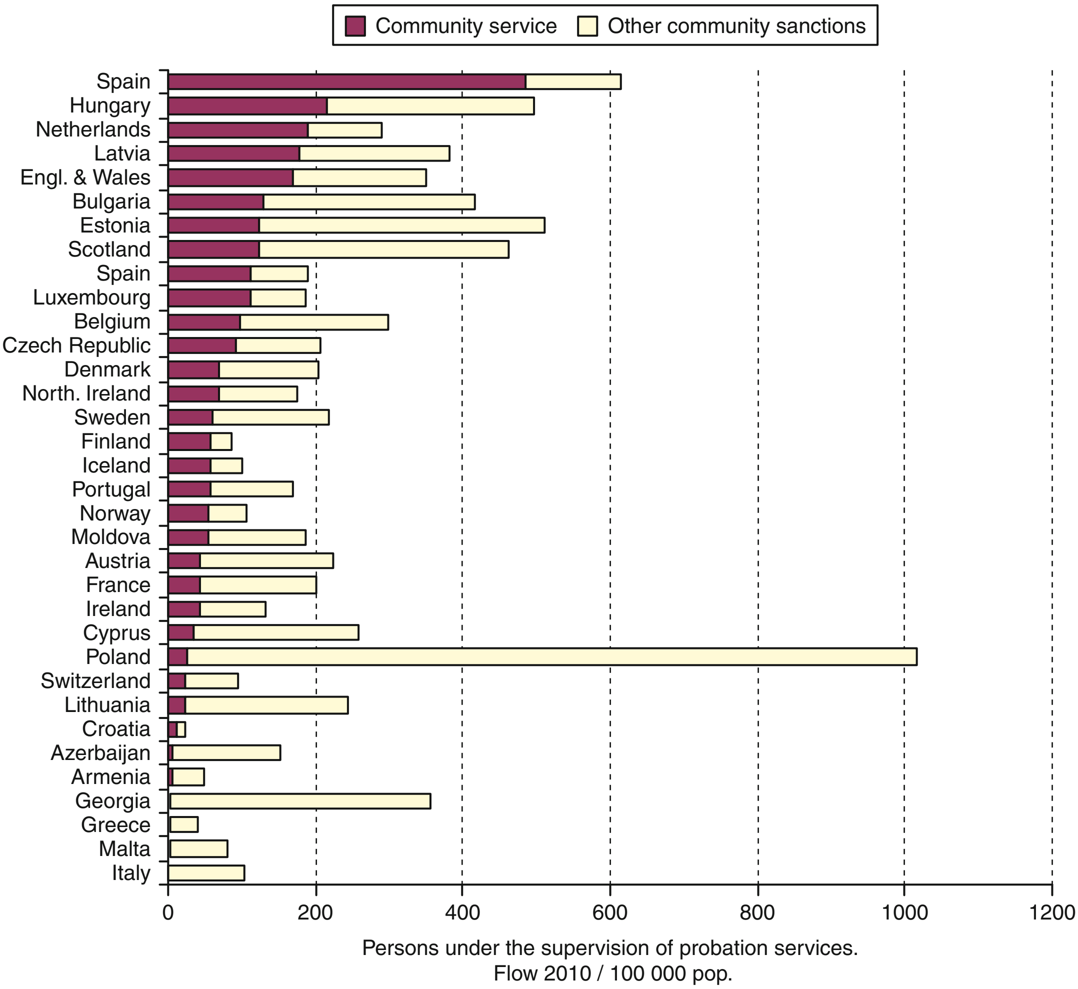
Empirical studies have shown that the implementation of community service has been successful in many countries (see above) and today is the most important alternative sanction apart from fines and suspended sentences (probation). In this regard, it is important that most offenders assigned to community service programs are completing their working hours. Only a small minority fails. Factors for noncompliance or failure to complete the sentence are a too high number of hours imposed



Community Service in Europe, Fig. 2 Persons under the supervision of probation services. Community service and other community sanctions and measures. Stock 31.12.2010 (Space II 2010 and Hildebrandt 2012 for the Nordic countries)

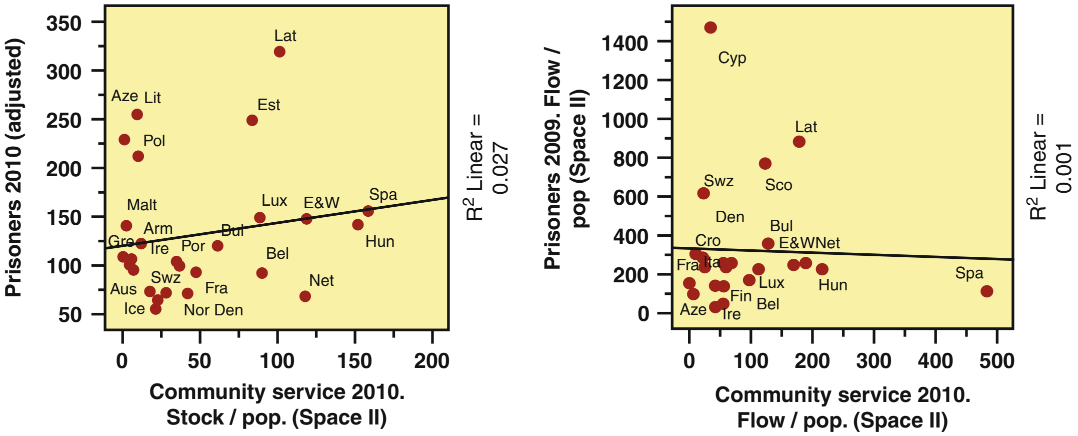
and/or personal problems of the offender to get to work (problems with alcohol and/or drugs, personality problems, unstableness, lack of practical experience with work, refusal to work etc.). The experience of the probation services shows that offenders in these programs often show multiple problems of reintegration which demonstrates the necessity of further rehabilitative measures compared to the sole allocation to a working facility.

One remarkable program in Germany should be mentioned. In Germany, community service is provided only for fine-defaulters as a substitute to imprisonment for nonpayment of a fine (Norway has in 2012 introduced a similar type of sanction ("Bötetjeneste") and also Finland currently is considering one). The German programs go back to the year 1983, but until the mid-1990s, most federal states ran those programs on a rather limited scale. The federal state of Mecklenburg-Western Pomerania had a specific problem as 22 % of prisoners in adult prisons were fine-defaulters. Therefore, in 1998, a state-wide project was founded that systematically created working facilities and in particular a system of contracting offenders who did not pay and react to the imposition of fine-default imprisonment. The restructuring of probation and private offender rehabilitation services resulted in

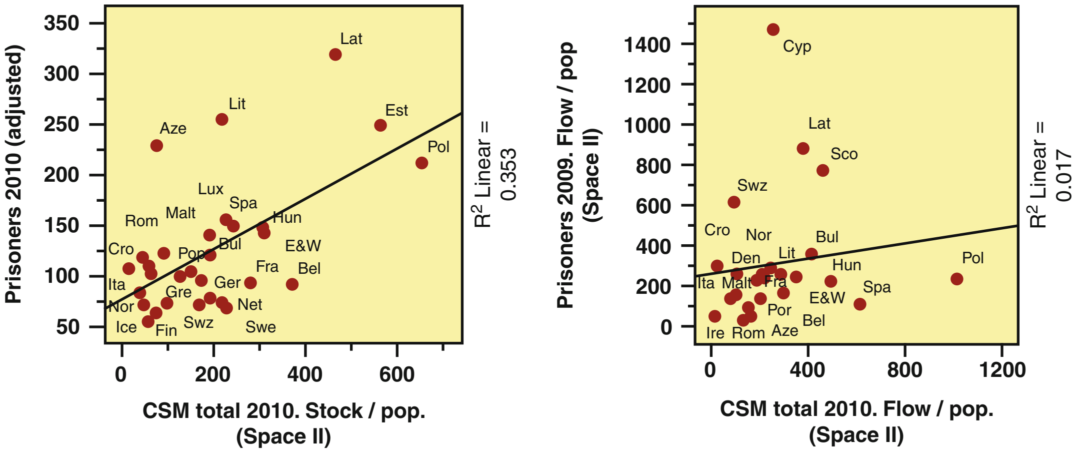


Community Service in Europe, Fig. 3 Persons under the supervision of probation services. Community service and other community sanctions and measures. Flow 31.12.2010 (Space II 2010 and Hildebrandt 2012 for the Nordic countries)

a structure of systematic allocation to 1,600 working facilities all over the large federal state of Mecklenburg-Western Pomerania. One special element of the project was to deliver social work and care for specifically difficult offenders who otherwise would not have completed community work. About 70 facilities have established such intensive care programs for fine-defaulters. Another pillar of the project was that fine-defaulters, even after they had been sent to prison, were allocated to community service programs and therefore often were released after a few days. The results during the 3-year pilot project starting in 1998 were remarkable: Daily numbers of fine-defaulters decreased from around 120–100 to 50–70, i.e., were reduced by half (see Dünkel and Scheel 2006). The results were so convincing that the Ministry of Justice decided to permanently appoint six social workers who are occupied with electing and allocating offenders to working facilities. The project has achieved a sustained success (the last numbers are from 2010), keeping fine-defaulters in prison almost at a low level achieved in 2001. The placement in community service facilities was in about 75 % of the cases successful, i.e., the offender completed at least partly community service and thus the state saved money by



Community Service in Europe, Fig. 4 Prisoners and persons under community service Stock 31.12.2010 and flow 2009 (Source: Council of Europe, Space I and II)



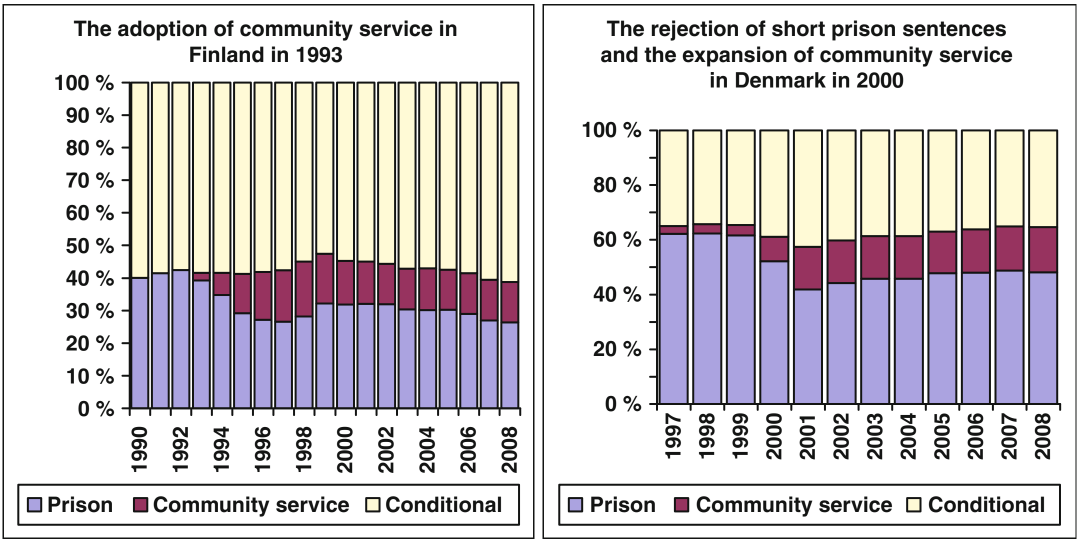
Community Service in Europe, Fig. 5 Prisoners and persons under supervision (all sanctions). Stock 31.12.2010 and flow 2009 (Source: Council of Europe, Space I and II)

avoiding imprisonment. In total, the state of Mecklenburg-Western Pomerania in 2010 saved about 1.6 million €, whereas the cost for the project (mainly the six social workers mentioned above) is about 450,000 € per year. Thus, the cost-benefit is more than one million € per year (see Dünkel 2011b).

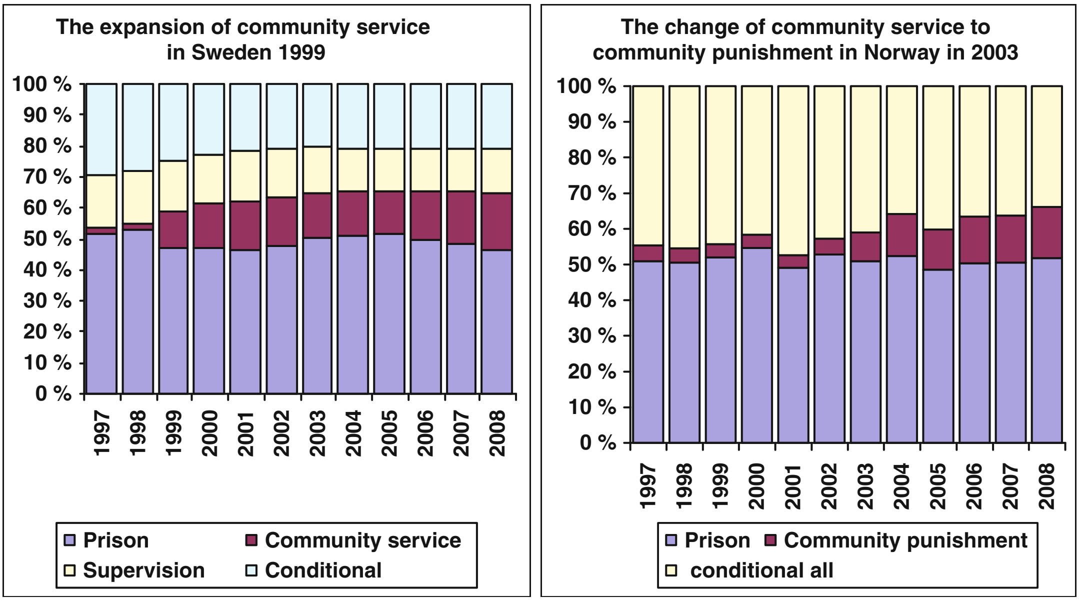
Replacing Imprisonment or Net-Widening? The Example of Scandinavian Countries

All Nordic countries adopted or increased the application of community service in the 1990s and early 2000s. The following diagrams illustrate how these changes in the sanction structures were reflected in the application of other community sanctions and imprisonment in Denmark, Finland, Norway, and Sweden (see in more detail Lappi-Seppälä 2008) (Figs. 6, 7).

In Finland, community service came to replace prison sentences in 1993 without any notable net-widening. In Denmark, the extension of community service coincided with the reform that abolished the short-term (1–2 weeks) prison sentences. As it appears, the community service came to replace part of these prison sentences. But it also seems that part of previous



Community Service in Europe, Fig. 6 The relative share of community sanctions and imprisonment (/100,000) – Finland and Sweden (Source: Lappi-Seppälä 2012)

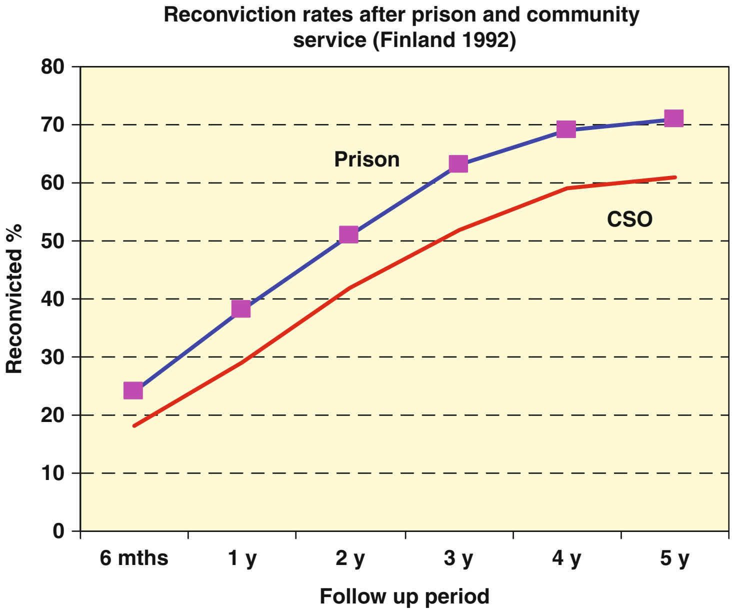


Community Service in Europe, Fig. 7 The relative share of community sanctions and imprisonment (/100,000) – Sweden and Norway (Source: Lappi-Seppälä 2012)

short-term prison sentences was replaced also by conditional sentences (Figs. 6, 7).

In Sweden, the expansion of community service in the year 2000 has replaced both conditional sentences and prison sentences. In 2002 Norway changed the name of "community service" to "community punishment" in order to enhance the credibility of the sanction. This increased the use of the sanction. However, this increase does not seem to be reflected in the share of prison sentences, but rather in the decline in the use of conditional imprisonment.

Community Service in Europe, Fig. 8 Reconviction rates after prison and community service in Finland, 1992



It looks like four out of five Nordic countries (Iceland included) have been successful in replacing prison sentences by community service. This success is associated with legislator's aims and intentions. In Finland, it was clearly stated that community service should be used only in cases where the accused would otherwise have received an unconditional sentence of imprisonment. This was ensured with specific legislative arrangements. Results were also seen in the statistics. Along with the increase in the number of community service orders from zero to 3,500, the number of unconditional sentences of imprisonment decreased by a little over 3,000. In Finland, annually some 3,500 community service orders are imposed by the courts. This represents around 35–40 % of the sentences of imprisonment which could have been converted (sentences of imprisonment of at most 8 months). This corresponds to some 400–500 prisoners (10–15 % of the prison population) of the daily prison population.

Assessing Reoffending Effects and Other Benefits

A Finnish study used quasi-experimental design and compared two matched groups of offenders: one sentenced to community service in that part of the country where community service was in use on experimental basis, and the other group of offenders with similar background and convicted for similar offenses (mainly drunken driving, which has been the major offense in Finland for community service). The follow-up period was 5 years. Only new sentences leading to conditional or unconditional imprisonment or community service were counted as recidivism. The study revealed a constant pattern showing that community service group had fewer reconvictions throughout the follow-up period. The differences in reconviction rates varied depending on where the counting was started. If started from the court's decision the difference after 5 years was 60 % for community service and 66 % for prison group. If started from the completion of the sentence, the figures were 62 % and 72 %. And if counting of the follow-up period in the community service group starts from the court's decision and in the prison group from the release to parole (which would be sensible), the difference in reconvictions would be 60 % (community service) and 72 % (prison, see Muiluvuori 2001) (Fig. 8).

In Denmark, Susanne Clausen (2007) has examined the preventive effect of community service compared to imprisonment. The study is limited to two offending categories: violent crime and traffic violations, including drunk-driving. In the case of traffic offenders, a change in the Danish penal code in 2000 made it possible to convert short prison sentences (up to 60 days) to CS. Capitalizing on this reform, Clausen compares recidivism levels between individuals sentenced to CS *after* the reform took place and those sentenced to unconditional imprisonment *before* the reform. As far as violent offenders, the quasi-experimental properties of the research design emanate from a change in the judicial policy that took place in the late 1990s. Within a relative short time period, the Danish courts increased the use of CS for violent offenders by a significant margin. In Clausen's research, the treatment group consists of violent offenders sentenced to CS in 2000–2001 while the control group includes individuals sentenced to prison in 1997–1998. To further enhance the comparability between the offender groups, Clausen's research controls for the impact of a large number of common risk factors, including age, gender, ethnicity, drug or alcohol misuse, mental problems, housing situation, education, employment, family type, and income. The subjects were tracked for 2 years for new crimes, starting from the date of conviction or release from prison (see Clausen 2007).

Findings from multivariate models suggest that, in general, characteristics like age, income, and prior criminality are more important as predictors of recidivism than the nature of the criminal sanction. On the other hand, the results provide some evidence of reduced recidivism associated with CS. For example, young traffic offenders (under age 25) were 36 % less likely to reoffend than those sentenced to prison. Among violent offenders, the unemployed seemed to benefit the most from community service. To explain these findings, Clausen suggests that CS protects young traffic, but also violent offenders from the stigmatizing from the stigmatizing effects of a prison sentence. On the other hand, by providing mandatory employment, CS may restore a sense of responsibility and routine for the previously unemployed offenders, thus enhancing their ability to reintegrate in the mainstream society. These benefits notwithstanding, Clausen's study failed to confirm that CS helps to lower recidivism across most offender populations. The modest effects associated with CS may reflect the fact that it was compared to either conditional or very short prison sentences which, in most cases, are unlikely to create much damage. At the same time, there is little reason to suspect that CS will *increase* recidivism. Thus, to the extent it is less costly and considered more humane than prison sentence, it seems like an attractive alternative. In a methodologically advanced study, Killias et al. 2010a divided offenders randomly in community service and control group (prison). Recidivism was studied using four indicators: (1) whether offenders were convicted and (2) the number of convictions; whether (3) offenders were arrested and the (4) number of arrests. In addition, the authors compared how much the offenders had advanced, how many arrests they had before and after the sentence. By all measures, the community service group survived better. However, the small size of the sample kept the statistical significance rates low. In 2010, Killias and colleagues published evidence from two controlled, randomized experiments that assess the causal effect of community service and electronic monitoring on different post-sentencing outcomes (Killias et al. 2010a, b). While the first study (Killias et al. 2010a) finds no difference between community service and traditional custodial sentences, the finding of the second study (Killias et al. 2010b) suggests marginally significant differences between two types of noncustodial sanctions, electronic monitoring and community service, in favor of the former. However, the evidence is still relatively limited, particularly as most of the existing studies rely on rather small samples, which may explain the frequent result that the effects found are nonsignificant.

Problems related to sample sizes have been effectively avoided in a largest study based on longitudinal official record data on adult offenders in the Netherlands (Wermink et al. 2010). The study compares recidivism after community service to that after imprisonment with a sample of 4,246 offenders. To account for possible bias due to the selection of offenders into these types of sanctions, a large set of confounding variables was checked using a combined method of "matching by variable" and "propensity score matching." The findings demonstrate that offenders recidivate significantly less after having performed community service compared to after having been imprisoned. In relative terms, community service leads to a reduction in recidivism of 46.8 % compared to recidivism after imprisonment. This finding holds both on the short term and long term, and for male and female offenders (Wermink et al. 2010) (Table 2).

The available evidence suggests that community service is (at least) a promising alternative, in terms of reducing recidivism (using the Maryland University methodology scoring, see, for example, MacKenzie 2006). Several results point to significant differences between offenders who are sentenced to imprisonment and offenders who participate in community service. The recent meta-analysis of Bonta et al. (2006) demonstrates a stronger effect size (.07) than earlier meta-analyses, which the authors explain by the better structured programs since 1995 considering "what-works" criteria (Bonta et al. 2006, p. 115).

In connection with community service, also other "non-reconviction benefits" need to be taken into account. These other beneficial features include positive contact to work life (and the resulting enhancement of offender's economical situation), better self-control over substance abuse, and better preservation of family ties. "Importantly, results also indicate that community service participants fare better with regard to long-term social benefit dependency and income, especially when we disregard the possible effects of time trends" (Andersen 2012, p. 26). In addition, violent offenders and offenders convicted for misdemeanors showed lower recidivism rates than the imprisonment group. A problem, still deserving attention is how to deal with offenders, whose substance abuse prevents the use of community service. One answer is provided in the form of Swedish contract treatment.

Community Service in Europe, Table 2 Recidivism rates after community service compared to imprisonment

Study	Results
Muiluvuori (2001) Finland	*Recidivism: New prison sentence in 5 years from the court decision*
Quasi-experimental (during the experimental reform)	Community service (60 %)
	Prison (66 %), nonsignificant
Matched groups by age, sex, and prior convictions	*Recidivism: New prison sentence in 5 years from the completion of the sentence*
	Community service (62 %)
	Prison (72 %), significant
Clausen (2007) Denmark	*Recidivism: New recorded offense 2 years from the court decision*
Quasi-experimental (before and after the reform)	Traffic. Reoffending risk for young traffic offenders (drunk-driving) 36 % lower in CS group
Multivariate analyses (central socio-demographic factors)	Violence. Largest benefit of CS for unemployed
Killias et al. (2000) Switzerland	*Recidivism: Convicted in 2 years*
Randomized experiment	Community service (21.4 %)
	Prison (25.6 %), nonsignificant
	Recidivism: Number on convictions in 2 years
	Community service (0.39)
	Prison (.64), nonsignificant
	Recidivism: Arrested in 2 years
	Community service (33.3 %)
	Prison (38.5 %), nonsignificant
	Recidivism: Number of arrests in 2 years
	Community service (0.76, but before 1.66)
	Prison (2.18, before 1.69), nonsignificant
	But see marked change in arrest rates before and after (above)
Wermink et al. (2010). Netherlands	Community service leads to a reduction in recidivism of 46.8 % compared to recidivism after imprisonment
Matched comparisons variable by variable	

(*continued*)

Community Service in Europe, Table 2 (continued)

Study	Results
Andersson and Alexandersson (1994) Sweden	No significant difference in recidivism rates in regression analyses
Bonta et al. (2002) Canada	Meta-analysis (37 studies)
	Effect size – 0.03 (= 3 % less recidivism)
Bonta et al. (2006) Canada	Meta-analysis (57 studies)
	Effect size – 0.07 (= 7 % less recidivism)

Outlook: The Potential of Community Service to Reduce the Prison Population and Increase the Reintegration of Offenders

European sanction policies have been characterized by two different trends during the 1990s and 2000s: an increasing use of prison and the adoption of new community sanctions. The first one reflects the growing punitive and populist trends in national crime policies; the latter seeks to counteract this development by offering more constructive, rational, and humane substitutes to incarceration. The overall effect of the expansion of community sanctions may appear disappointing: The number of alternatives has grown along with the increasing number of prisoners. Neither does it seem that countries that use extensively community alternatives have – in general – lower incarceration rates. Still, it would be premature to conclude that the efforts to enhance the use of community sanctions have been futile. Some jurisdictions have gained true success, giving thus also information of the models that do work. Failures, on the other hand, may offer important lessons on what not to do. In short, community sanctions do provide one functional tool against the overuse of imprisonment, once a number of lessons from different jurisdictions have been drawn upon. The key questions are: (1) how to ensure that these sanctions are applied in the first place, (2) how to ensure that they come to replace imprisonment (instead of replacing other noncustodial sanctions), and (3) how to uphold and maintain the general credibility of these sanctions. Current problems and achievements have been summarized as follows (Lappi-Seppälä 2003, see also van Kalmthout 2000):

1. Extra barriers should be constructed in order to ensure that the new alternatives are really used instead of imprisonment. In most countries, community service seems to substitute prison sentences only in roughly 50–60 % of cases. This rate can be improved by demanding directly – as is the case in Finland – that only prison sentences may be commuted to community service (leading to a "replacement rate" of over 90 % in Finland). Another way would be to define new alternatives as modes of enforcement of prison sentences, as has been done in Iceland.
2. *Effective use of new alternatives and coherent sentencing practices require clear (statutory) implementation criteria.* The courts should be given clear guidance as to when and for whom new sanctions are to be used. The role and position of new alternatives in the existing penal system (how they relate to other sanctions) should also be clarified.
3. *The overall success of any community sanction requires resources and proper infrastructure.* Community-based sanctions can only be applied within a community-orientated infrastructure geared to the specific requirements of these sanctions. Their implementation is dependent on the existence of an organization like the probation service. Often cooperation with private, semipublic, and public organizations or institutions is also required. The state and the local communities should provide the necessary resources and financial support.
4. *Supervision, support, and swift reactions are needed in order to keep the failure rates down and to maintain the general credibility of new sanctions.* The less control and supervision, the higher is also the dropout rate. There should also be a clear and consistent practice when the conditions of the sentence are violated. Varying and sloppy practices create

mistrust and resistance on the part of public prosecutors, the judiciary, and the public.

5. *Arrangements should be made in order to enhance the motivation of the offender for cooperation and mutual trust.* New alternatives usually require the offender's consent and cooperation. Treating the offender, not as a passive object of compulsory measures, but as an autonomous person, capable of reasoned choices, is a value by itself, and as such, it should be encouraged whenever possible. In addition, experience indicates that explicit and well-informed consent is a highly motivating factor for the offender. Through his/her consent, the offender has also become committed to the required performance in a manner that gives hope for good success rates.
6. *Issues of equality and justice must not be neglected.* Community sanctions may often lead to discrimination, since they are easily used for socially privileged groups of offenders. Measures must be taken to avoid social discrimination. Clear and precise implementation rules and procedures are one important means to this end. Another way is to tailor the system of community sanctions to meet the demands of different offender groups with their different problems. Sweden, for example, has a specific sanction – "contract treatment" – for those who suffer from drug or alcoholic addiction as a substitute for short-term prison sentences. Finland adopted in 2011 electronically monitored supervision order, supported by program work for offenders who are excluded from community service due to their addiction problems.
7. *The idea has to be sold over and over again.* Initial success does not guarantee that things will go well also in the future, just by themselves. Prosecutors and judges may lose their confidence, the enforcement agencies may lose their motivation, and the general public may withdraw its support. Maintaining the general credibility of the community sanctions and demonstrating their appropriateness is an ongoing process which does not end with the adoption of the requisite legislation and the arrangement of an initial training phase. The key groups, responsible for the implementation of the sanctions, must be given constant training and general information of the general benefits of community sanctions and the drawbacks of the wide use of custodial sanctions. Taking care of community relations is also important: The community should be informed of the benefits and crime control potential of community sanctions. Also the value of volunteer work needs a clear recognition. Finally, the practices must be subject to impartial scientific evaluation in order to obtain necessary information for further development.
8. *Do not turn community service into a mere punishment in the community.* The original objective of community service was to provide a socially constructive and less damaging alternative to imprisonment. Community service has rehabilitative and reintegrative potential, which must not be "sold" during the efforts to widen its applications and finding political support. Policy planners should resist the temptation of presenting community service to the public only as a "credible" and "demanding," if not outright humiliating, alternative – as has taken place in some jurisdictions. Community service should be oriented toward the restorative justice and the rehabilitation ideal and implemented that way (which would be in line with international human rights standards) and not be left to penal populism and repressive orientations of "punishment in the community."

Overview

Comparing sentencing arrangements is a vital part when developing and studying criminal sentencing. Few reform programs move ahead and little research is done without consulting experiences within other jurisdictions. To some degree, the United States represents an exception to this rule. This is because comparative research between federal states has become more common than earlier. Comparisons with other countries, be they European, South American, Asian, or African, remain less frequent. This is despite the efforts of a number of leading scholars who refer to experiences and sentencing models in other countries.

This entry gives an account of the subject matter of comparing criminal sentencing, the purposes of comparing, and the typical approaches of comparing criminal sentencing. In so doing, the entry discusses the issues at stake when comparing and the limitations that flow from the different approaches to comparing criminal sentencing. The entry's last section devotes special attention to the relevance of globalization to the act of comparing across borders.

The Subject Matter of Comparing Sentencing

For the present purposes, criminal sentencing covers actions through which it is determined what penal sanctions an offender must be subjected to following a criminal offence. Although this description, like any other, is ethnocentric, it does cover the process of police, prosecutorial, and court decision-making, the sanctioning that follows, just as it includes the organizational structures that sustains and develops the decision-making processes.

Typically, three different subject matters come into play when comparing criminal sentencing. The most frequent is the outcome of sentencing: the sanction type (prison, alternative sanctions, fines, etc.) and the amount of sanction (length of prison term, size of fine, hours of community service). For example, comparing the rate of imprisonment per capita or the number of prison sentences in the United States and in England and Wales. Another subject matter of comparison targets the legal structures that govern the sentencing decision-making, for example, comparing the many different constructions of numerical sentencing guidelines that have been built in different jurisdictions in the United States since 1980 or comparing the Swedish statutory sentencing law with any of these numerical guideline systems. A third subject matter of comparison takes seriously the social practices of the everyday handling of cases and the organizational framework of sentencing, in court as well as in prosecution. Inspired by the traditions of socio-legal scholarship, these studies rely neither on the law nor aggregate sentencing outcomes but compare the organization, operations, and views of those who handle criminal cases, for example, comparing judges' views on sentencing in Finland and in England and Wales or comparing court systems and their political roles in industrialized nations. These different subject matters should not be mistaken for one another. They bring different consequences to the comparative analysis and most importantly provoke us to ask how things would look with a different subject matter of comparison.

Purposes of Comparing Criminal Sentencing

As in comparative criminology in general (Nelken 2011), we can discern three typical purposes of comparing criminal sentencing decision-making: (1) the policy purpose, (2) the social scientific positivistic purpose, and (3) the contextual or interpretive purpose. The three purposes often overlap, yet are distinct.

First, there is a long tradition for using comparative methodology in policy research. In most sentencing reforms policy-makers look to other jurisdictions' experiences as a tool to find the best solution to their own challenges of sentencing reform. This practice of transferring sentencing experiences from one jurisdiction to another raises a number of comparative concerns. These are addressed later in the entry. Second, the social scientific positivistic purpose is about comparing sentencing decision-making and its organization to test theories about relevant causes and effects of criminal sentencing. For example, testing the explanatory value of income inequality to the level of prison rates in different countries or explaining the change from discretionary to numerical guideline informed sentencing in many jurisdictions in the United States. The third and interpretivist purpose of comparing is to unravel the contextual embeddedness of criminal sentencing and studying how sentencing decision-making, its regulation, and its procedures and sanctions are differently constructed. One example would be to show that sentencing discretion and its boundaries are intrinsically linked to local cultures.

Approaches to Comparing Criminal Sentencing

The approach to comparing is intertwined with both the purpose and the subject matter of comparing. Indeed, as the headings below confirm, there is a close connection between the different purposes of comparing sentencing and the different approaches to it. Nevertheless, it is both important and helpful to make the distinction when presenting three widespread and different approaches:

1. The legal categorical approach
2. The predictive and explanatory social scientific approach
3. The interpretivist approach

Legal Categorical Approach

A legal categorical approach is deeply connected to the legal structure as subject matter and has legal scholarship and dogmatics as its basis. The approach is used to categorize sentencing laws and systems, typically based on functional characteristics and their legal historical heritage. This approach helps to elucidate important structural properties of sentencing laws, but it also functions to cover the many relevant social, cultural, and political differences between jurisdictions. The best-known categorization in wider comparative studies is that by comparative legal scholars Kötz and Zweigert (1998) in their introduction to comparative law. They systematically organize the different legal systems in legal families: the Anglo-American, the romanistic, the germanistic legal family, the Nordic legal family, then add the law in the Far East, and finally religious legal systems. In comparative sentencing research, the categorization is most often seen in the simple distinctions between Anglo-American common law and continental models of civil law. The Nordic countries are sometimes placed in the continental and civil law category and sometimes recognized as also carrying elements recognizable in the Anglo tradition of law.

Though it is disputed whether distinctions such as civil law and common law and adversarial and inquisitorial law can serve as units of analysis, it is indisputable that these distinctions are actually used and that they at least historically carry some legitimacy. Civil law and inquisitorial models arose from Roman law and were subsequently shaped by European continental legal developments. Common law and the adversarial model have their origin in English law which subsequently spread to the United States of America and other places where the English sought influence. Common law is characterized by the central role of the trial, the judicial decisions, and the recorded precedents, all of which are important vehicles for the development of law. Contrary in civil law models, through codification, every offence is ideally preconceived in written legal statutes and the judge has the role of reading, understanding, and applying the statute content correctly – and most importantly has the final word. In a sense, the key axis in this model is that between the legal subject and the written rule, whereas in the common law model, it is rather that between the legal subject and the trial.

How does this help to compare criminal sentencing? First of all, a distinction is often made between the civil law tradition of structuring sentencing through legal statutes and the common law tradition of governing sentencing through trial experiences. This is a frequent way of comparing continental European and Anglo-American sentencing law. Indeed, France and Germany do have complete criminal codes defining every offence and stipulating the sentencing options for each. Many Anglo-Saxon jurisdictions still have no general criminal code, and still place the courts and the trial in a comparatively more significant role in sentencing. The basic structures of sentencing law are different. One could point to the adversarial nature of plea bargaining in England and Wales and in the United States and contrast it to the continental styles of legality in sentencing procedure. Both in Germany and in France, it is the judge who has the final decision, even when procedures involve consensual elements. Problems with these distinctions between common and civil law arise when they are used to describe entire countries and sentencing systems. Despite the historical heritages, sentencing laws and practices have evolved remarkably over time, and today it is problematic at best to describe entire systems as common or civil law and as inquisitorial or adversarial. As Pizzi (2008) illustrates, it is difficult to categorize the entire sentencing systems of the United States as common law systems as such. More than half of its jurisdictions have, since 1980, implemented legal sentencing rules that place the court under substantial legal control. The techniques employed include minimum sentencing laws and administrative sentencing guideline systems combined with various administrative governance institutions and enforced monitoring mechanisms. In England and Wales legislative structuring of sentencing has increased since the middle of the twentieth century. Today the sentencing approach towards many criminal offences is governed by binding sentencing guidelines, promulgated by a national sentencing council, and enforced by the upper courts. It is more descriptive then in these jurisdictions to emphasize the joint structuring of sentencing by the upper courts, the more recent administrative sentencing guidelines, and the legislature.

In the same way it makes little sense to categorize the Italian system as a civil law system as the country has implemented plea bargaining in a wide area of criminal cases. Most other continental countries have implemented some version or other of consensual procedures, eating away at the traditional principle of legality and central role of the judge assuring the law to rule sentencing (Thaman 2010). This does not mean that these basic distinctions between civil and common law and between inquisitorial and adversarial systems serve no analytical purpose. First of all, the distinctions are a welcome tool to reduce the otherwise dominant use of jurisdictional borders as a key distinction (Nelken 2007). Second, if we handle these concepts as representing legal traditions in the way that Glenn (2010) does in his comparative legal theory, we could use the distinctions as carriers of norms and legal forms, travelling from one country to another, constantly evolving with the local and different pressures of law, politics, and culture in each jurisdiction, and only expressing themselves in much more concrete ways as rules, practices, and arrangements that reflect more than a singular legal tradition (Field 2009). As such these distinctions do serve the purpose of sorting out general lines of traditional sentencing and procedure to further investigate their concrete implementations.

There are attempts at breaking free from the dominant distinctions of civil law and common law. For example, Frase (2008) explores the use of the established comparative criminal procedure model developed by Damaska (1991). Justice systems are categorized on two diagonal dimensions. In one dimension, systems are tending to be hierarchical or to be coordinate systems of justice. In the other dimension, systems are tending to be policy implementing or conflict solving. This does allow more flexibility with respect to legal categorical comparisons. However, it does not change the problem that legal categorizations of entire systems using such simple categories or dimensions lack significant descriptive and analytical power.

More fundamentally, comparative legal theory has evolved to challenge the legal categorical approach. Recognizing the increasing traffic between borders of legal ideas, constructions, and institutions, advanced comparative legal theory today seeks to accommodate for the mixed legal systems that have resulted. It is accordingly put forward that most legal systems are mixes of different legal constructions and solutions. They therefore represent different traditions and countries from which ideas and models for legal constructions and institutions have been borrowed, imposed, codeveloped, or other. The above described widening use of plea bargaining or similar consensual procedures are good examples, as are sentencing commissions and councils, sentencing guidelines systems, sentencing information systems, problem-solving courts, alternative dispute resolution mechanisms, and prosecutorial diversion programs. The headlines that are used to make sense of these developments include "legal transplants" (Watson 1993), "legal irritants" (Teubner 1998), "law as transposition" (Örücü 2002), and "legal borrowing" (Nolan 2009). Partly the concern here is to accommodate for the significant role that borrowing plays in comparative studies. Partly the concern is if such transport of legal institutions from one jurisdiction to another makes sense at all within the framework of comparative legal theory. The fundamental question is if a legal rule is bound to its social and cultural meanings, how can it move elsewhere without lousing this meaning?

Yet, despite these significant developments, the distinctions between civil and common law and between adversarial and inquisitorial procedures continue to play a substantive role in scholarly writings on comparative criminal sentencing law.

Predictive and Explanatory Social Scientific Approach

As positivistic social science in general, this approach compares variation in sentencing arrangements between jurisdictions, such as countries, states, or regions, in order to identify the causes and consequences of sentencing arrangements. Different from the legal classificatory approach, all social phenomena can be used in the study of sentencing whether legal or not. The approach is used to compare various aspects of sentencing. For example, comparing the degrees of voluntariness in sentencing guidelines to see the effects on levels of punishment, comparing fine levels or the frequency and length of prison sentences, comparing different paths that reduce prison sentences, comparing the use of alternatives to imprisonment and their sentencing arrangements, comparing the effects of sentencing reforms on court practices. comparing to explain increases in prosecutorial authority in criminal sentencing, comparing the consequences of political culture on criminal sentencing and court practice, identifying the causes and effects of different sentencing policies and the structural reforms of sentencing, (Tonry and

Hatlestad 1997; Tonry 2007, 2009; Tonry and Frase 2001), and comparing in order to test arguments about correlations between penal levels and sentencing ideologies. Though these many approaches differ from one another, they can all be broken down to accounts of variation between jurisdictions in the correlation between dependent and independent variables.

Four issues are particularly sensitive when using this approach. The first concerns the sample and population. Predictive and explanatory models make use of sample countries to generalize, but the extensive variation between countries makes it difficult to generalize both regionally and globally about sentencing. For example, Cavadino and Dignan (2007) argue that penal levels, measured by overall imprisonment rates, vary with the type of political economy. The four proposed typologies are the neoliberal (USA, UK, Australia, New Zealand, South Africa), the conservative corporatist (Germany, France, Italy, the Netherlands), the social democratic (Sweden, Finland), and the oriental corporatism (Japan). Their aim is to find similarities between groups of countries on significant variables that simultaneously distinguish those countries from others belonging to different typologies. Using sample countries from North America to east Asia, the authors can make the claim of sampling a global scale of modern industrialized countries. However, many countries pointing in different directions are not included. For example, what would happen if China is in the comparison? China has a very high rate of imprisonment, but does not adhere to a neoliberal societal model (Nelken 2011). Within the African scale of modern industrialized countries, it is only South Africa that is included in the comparison. However, Kenya is equally a comparatively large market economy in Africa, yet with much lower prison rates than South Africa.

Similarly, Lappi-Seppälä (2011) compares correlations between prison rates and a number of social and political structures in 30 different countries. He argues that among others, moderate penal policies are related to consensual and corporatist political cultures with high levels of social trust and political legitimacy. The sample consists of 30 countries from continental Europe (hereunder Russia), North America, and it includes Australia and New Zealand. Yet, it does not include any Asian (apart from Russia) or African countries. For the present purposes we are reminded that explanatory models are limited to the countries chosen for comparison and that it is problematic to generalize both regionally and globally about correlates to sentencing and sanctioning.

The second issue concerns the dependent variable. Whether it is prison rates, the use of alternative sanctions, fines, the legal framework of sentencing, or sentencing uniformity, it is central to a positivistic approach that the dependent variable is comparable across jurisdictions. When comparing prison rates, what counts as prison? Is weekend prison and open prison with daily outside working or educational activities outside included? Is electronic monitoring and home imprisonment included? Does it make sense to compare sentences served under the conditions in local prison facilities in the state of Virginia with those of Germany? Furthermore, increasingly important is the measuring of alternative sanctions. Its features, characteristics, and use have expanded rapidly over the last decades. But while many of the headlines are the same across borders, the content of alternative sanctions rarely is. Some are keenly aware of this challenge (Farrington et al. 2004). Taken wider, the issue here is that looking at criminal sentences across nations assumes sufficient non-variation both in sanctioning mechanisms and in competing social sanctioning mechanisms. For example, in the context of Japan in which disciplinary culture varies markedly from that of England and Wales and that of the United States, there is a range of other measures that are used for social control. South Africa, even though it does represent a punitive system, also represents local governance technologies that are applied to situations in which other countries, like England and Wales, France, or Norway, would use formal sanctions of imprisonment and community service. A social scientific predictive or explanatory approach must consider these factors.

The third issue that must be considered relates to the independent variables. When comparing two or more jurisdictions, everyone of the independent variables needs to be comparable across jurisdictions and relevant variations between them must be reflected. This includes both criminal offence variables, procedural variables, and variables related to the criminal offenders, and it includes the social, political, and cultural structures of the sentencing jurisdiction. Both legally and empirically, violent offences may look different, the offenders may belong to different groups of society and the form of trial may vary from place to place. In some countries less serious offences are not categorized as crimes but as administrative wrongs and are handled accordingly. Some countries rely on police and prosecution to finish many cases before they reach court. In some jurisdictions, like England and Wales, timely confessions are awarded measurable reductions in criminal sentencing, while in other countries confessions only affect the form of evidence and trial. Likewise, in some jurisdictions, there is little space for the inclusion of a personal investigation report, while in others it takes center stage. A further and important concern with independent variables is the covariance between them. For example, Lappi-Seppälä (2011) relates low levels of inequality, democracy, high social trust, and welfare society with moderate penal levels. However true this may be, it is associated with considerable methodological concern that there is a high covariance between these particular variables.

A related concern is to what extent we can meaningfully distinguish sentencing from any of the relevant independent variables. One important example is the ties between sentencing and procedural arrangements. Many criminal justice systems allow for a range of alternatives to trial: case diversions, conditioned charge withdrawals, and plea agreements, to mention but a few examples. Many such procedural dispositions are closely related to the expected sentence. This makes sentencing a procedural variable also and thus makes it difficult to distinguish between sentencing and procedure. Another example is the connection between criminal sentencing, strategies of other justice institutions, and overall penal policies. The typical assumption is that penal policy – to some degree – determines the direction of sentencing practices and that sentencing is distinct from activities of other justice institutions. However, in most Western countries the individual branches of penal administration have increased their interdependencies in a number of different ways such as shared strategies, policies, goals, measures, daily interacting operations, and overall common infrastructures. The consequence is an increasingly larger difficulty of distinguishing the effects of one agency from the other. This naturally makes measuring such variables across borders difficult.

The fourth issue with the positivistic approach is the interpretivist concern that comparing variable elements of sentencing regimes is problematic because every element is subject to the individual meaning structures of the compared systems, societies, and cultures. For example that judicial discretion is deeply imbedded in the cultural constructs of the society in which it is practiced, as are the meaning of "crime" and of "community" sanctions and of "youth" problems. See further below about the interpretivist approach.

There are no easy answers to any of these concerns and questions. Yet, this should not discourage the use of this approach. Rather, important limitations of what can be inferred from such comparisons and the extraordinary care we must take when designing and interpreting comparisons should be borne in mind.

Interpretivist Approach

The interpretivist approach takes off where the explanatory and predictive approach stops. It lays bare the cultural and contextual embeddedness of penal arrangements. For example, on the basis of comparing the United States with France and Germany, arguing that the punitive level in the United States is conditioned by the particular American resistance to state power and drive towards egalitarian social status (Whitman 2003). Another example could be contrasting the judicial discretion in Islamic law courts in

Morocco with that of courts in the United States' jurisdictions, showing how local (cultural) concepts and ideas inform the exercise of judicial discretion. Comparing judges' accounts and views on sentencing in different countries can show that any understanding has to be sensitive to the judges' different perceptions of harm, crime, sanction, and sentencing objectives.

Characteristically, interpretivist approaches use the sentencing and penal arrangements as indicators of wider cultural and political arrangements. However, taking culture seriously is not reserved to the interpretivist approach. Also predictive and explanatory approaches make use of culture. It is oftentimes difficult to spot the difference between the approaches, and in many studies the two are mixed.

The interpretivist approach firstly requires the observation and understanding of local cultural concepts and meanings and of how they manifest themselves in the different structural layers of criminal sentencing. This is a methodologically difficult task demanding linguistic, cultural, and historical sensitivity that only few have and only the fewest have the months and years to invest. Is one barred from taking this approach if one does not speak the language? How long must one stay in a given place? These are relative questions that limit the reliability of interpretive comparative studies, but that should not bar them. Some scholars use the collaboration between two or more colleagues, representing the legal cultures compared, as the central methodology.

Another important issue of the interpretivist approach is that the boundaries of what counts as legal and penal culture around sentencing can at most be loosely defined. We may cautiously characterize it as conveying the sets of ideas, expectations, and values that in practice and in policy-making is held with regard to penal law, the criminal process, and the sentencing.

A third important issue is that far from everything comes down to local cultures. Comparative studies today take seriously that techniques, ideas, concepts, and meanings travel and are sometimes shared by many jurisdictions, however, different concrete shape they acquire locally. In relation to the specific transport of legal concepts and ideas, see also above about the legal categorical approach. For example, many scholars have described a Western development towards curtailing judicial discretion, increasing the level of standardization and formalization of criminal sentencing. Aas (2005) calls this a development towards "sentencing at a distance." A significant body of research has looked at how such transnational trends and ideas merge with local legal and political cultures. Some have described how the policy implementation of three-strikes policies takes on local particularities in different countries. Others have described how transnational movements of new court types result in remarkably different forms of courts when institutionalized in different cultures of criminal justice. Yet another example is the different legal constructions of a principle of equality in sentencing that has emerged in different countries with the otherwise transnational development of standardization and formalization of criminal sentencing. The state of Minnesota provides one of the most prominent examples of numerical sentencing guidelines with a strong institutional tie to prison capacity constraints. Equality takes on the character of equality between formal categories, distancing sentencing from an individualized conception of equality. In Denmark (or Germany, Norway, or Sweden), the narrative guidelines and close ties between legal and appellate guidance of sentencing, institutionalized in the professionalization of judging and sentencing, maintain equality in sentencing in its individualized conception. It is a particular strength of the interpretivist approach that it is well adapted to grasp the reflexivity of transnational and local ideas, concepts, and meanings.

Globalization and Comparative Criminal Sentencing

Disregarding purpose or approach, it is today difficult to carry out comparative studies of any area of criminal justice without regard to the transnational or globalized field that the compared fields of practice are in. Globalization may be described as the way in which societies and communities over the last centuries are increasingly interconnected and in which processes of human and societal development are intertwined. Focusing on the processes that stem from this development, Savelsberg (2011) illustrates with three examples of globalization: well-documented conditions of late modernity, global-level scripts offering solutions to challenges across nations, and a new type of global law has emerged in vast areas of application, including penalty bringing with it both new doctrines and institutions (e.g., the international permanent and ad hoc criminal courts).

Globalization first of all affects a traditional approach to comparative criminal sentencing by questioning the nation state and the jurisdictional borders as key units of comparative analysis. Significant processes involve transnational developments, cross border activities, and entire fields of norms and institutions that have moved to a level of international problem-solving. Does that mean that we cannot compare nation states and their practice of criminal sentencing? No. For sure, an argument can be made that it is significantly problematic not to include a transnational dimension in a comparative study of criminal sentencing. However, globalization does not necessarily move the field of study away from the local level of governance and practice. Rather, globalization has become one of the many forces and institutions that matter on a local level, suggesting that we should rather accept and include in our studies the subtle processes between the local and the global. In that way, it modifies the object of study and it forces us to expand on the methods of our comparison. Fourcade and Savelsberg (2006) have developed well-suited themes to such a process perspective in sentencing: first, increasing the focus on agency which locally constructs global domains through local actions; second, recognizing the mutually constitutive relationship between global and local practice; third, emphasizing that the process of globalization itself is tied to transnational power flows with the United States as the power holder; and fourth, bearing in mind that every transnational and global convergence trend is locally manifested and accordingly is interpreted by local national institutions through the lenses of local historical and local political structures. Judicial courts and sentencing cannot be understood as one or the other but rather as dialectic between forces on the local and the global level.

Conclusion

Comparative approaches are important to policy and research about criminal sentencing. Globalization processes challenge the way that we conceptualize national borders and compare countries. But at the same time, globalization underlines the deep necessity of comparing, however, reflexively. This entry has touched upon important aspects of comparing criminal sentencing, laying bare significant possibilities and issues at stake with the different purposes of comparing, and with the different approaches to comparing sentencing. Accordingly, a legal categorical approach serves valuable purposes of organizing legal traditions but also suffers from the blindness to political, social, and cultural differences. An explanatory or predictive social scientific approach serves to advance our understanding of general questions of sentencing arrangements and provides valid descriptions of causes and effects of national sentencing and sanctioning practices. Nevertheless, it comes with serious concerns about its scientific assumptions, ranging from the units of analysis, its samples, as well as its construction of variables. Finally, an interpretivist approach suffers from the inevitable inability to generalize, yet provides an unparalleled means of understanding the depth and technologies of the relationships between courts, sentencing, and the local cultural context. As such, the interpretivist approach serves to challenge and extend the understanding derived from positivistic approaches. And as with most other things, it is the combination and not the choice of approach that provides the best result.

Comparative; Cross-national; Incarceration; Incarceration rates

Overview

One of the most distinctive features of the criminal justice system in the United States is the large number of individuals incarcerated in its prisons and jails. Since the early 1970s, the United States has experienced approximately 40 years of nearly uninterrupted growth in prison and jail populations. There were approximately 1.6 million people incarcerated in state and federal prisons, and approximately 750,000 individuals were held in county jails in 2010 (Minton 2011). Only in recent years has the growth in incarceration slowed.

Incarceration rates in the United States are several times greater in magnitude than those of other advanced Western democracies. A variety of explanations have been proposed for why incarceration is so much greater in the United States than in similarly developed nations. Some suggest that the United States has much greater levels of crime than in other Western democracies, while others argue that a "tough on crime" movement that has increased penalties is responsible for this growth. Research tends to indicate that the high rates of incarceration are mostly due to differences in sentencing policies and practices and not to exceptionally high levels of crime.

Further evidence that policy changes can have a significant impact on incarceration rates can be found by examining the experience of other countries. In the early 1950s, Finland had an incarceration rate several times greater than that of its Nordic neighbors. A profound shift in the thinking about the use of incarceration led to a series of changes to sentencing practices in Finland. As a result of these changes, Finland has gradually reduced its incarceration rate over the past 50 years and now has one of the lowest incarceration rates in all of Europe. Germany is another nation that has controlled prison population growth through policy changes. The experience of Germany and Finland in controlling growth in incarceration suggests that changes to current sentencing practices in the United States can be effective at reducing prison populations.

Incarceration Rates in the United States and other Western Democracies

The United States incarcerates more of its population than any other country in the world. Despite being home to just 5 % of the global population, the United States incarcerates about 25 % of the world's prisoners (Walmsley 2009). At year-end 2010, there were more than

1.6 million prisoners in US federal and state prisons for a rate of 497 prison inmates per 100,000 US residents (Guerino et al. 2011). As of midyear 2010, there were nearly 750,000 inmates held in local jails for a rate of 248 jail inmates per 100,000 US residents (Minton 2011). These rates are slightly down from their peaks in 2007 when prison and jail incarceration rates were 506 and 259, respectively. When prison and jail inmates are combined, the incarceration rate in the United States at year-end 2010 was approximately 730 inmates per 100,000 US residents (International Centre for Prison Studies nd).

The current level of incarceration in the United States is exceptional by both historical and comparative standards. Current levels of incarceration in the United States are the highest they have ever been in history. Throughout most of the twentieth century, incarceration rates in the United States remained relatively stable at a level of approximately 100 inmates per 100,000 US residents – a rate comparable to those of other Western democracies at the time. The stability of incarceration levels in the United States led Blumstein and Cohen (1973) to theorize that societies maintain stable levels of punishment. The theory did not gain much traction, however, as incarceration rates began nearly four decades of continuous growth almost simultaneous to the publication of the stability of punishment hypothesis.

Incarceration rates in the United States are also exceptional in comparison with other nations. The United States has the highest prison population rate in the world according to the International Centre for Prison Studies. In 2010, the nations that came closest to the level of incarceration in the United States are Rwanda, Georgia, and Russia. Drawing comparisons between these nations and the United States, however, would be misguided as these nations differ along a number of different dimensions such as levels of economic and social development. When one compares the United States to nations that are more similar in terms of economic and social development, however, the difference in incarceration rates is even greater. Incarceration rates of advanced Western democracies such as England, Germany, the Netherlands, Sweden, and Australia are considerably smaller.

While the United States has an exceptionally high incarceration rate relative to other advanced Western democracies, it is not the only nation that has experienced increases in incarceration rates in recent history (International Centre for Prison Studies nd). Incarceration rates in the nations of England and Wales, Scotland, and Australia increased by approximately 50 % between 1992 and 2010, while Netherland's incarceration rate has nearly doubled during that time. Only a few nations have managed to reduce or maintain relatively stable incarceration rates as Finland and Germany have done. Between 1992 and 2010, Finland's prison population rate has dropped by more than 10 %. Germany did experience an increase in incarceration since 1992; however, there has been a recent downward trend since 2004.

Explaining Cross-National Differences in Incarceration Rates

It is important to first acknowledge the difficulty inherent in making comparisons between nations in terms of incarceration use. Differences observed between nations in incarceration may be an artifact of different recording and reporting practices rather than a real substantive difference. One important difference between nations is the determination of who is included in the calculation of the incarcerated population. Some nations may include jail inmates in their calculation of their incarceration rates while other nations may exclude jail inmates. The determination of who should be counted as a prisoner can have a substantial impact depending on the size of the jail population.

With this caveat in mind, there is a relatively small body of literature that has examined and sought to explain cross-national differences in incarceration rates. This research has investigated the relationship between incarceration rates and a variety of social, political, and economic factors. Findings regarding which factors affect incarceration rates have been somewhat inconsistent due to methodological differences between studies. For instance, some studies draw comparisons between a large number of countries which differ from each other along a number of dimensions, while others focus on a smaller number of countries that are more comparable in terms of economic and social development. It is important to keep this in mind as making comparisons between vastly different nations may lead one to draw erroneous conclusions.

The factor most often thought to affect incarceration rates are crime rates. Homicide rates in the United States are about as twice as high as those of other advanced Western democracies, such as Finland, which has one of the highest homicide rates in Western Europe (United Nations Office on Drugs and Crime 2011). However, homicide accounts for a very small proportion of total crime and should not have a very large impact on incarceration rates. Other than homicide, crime and victimization rates in the United States are not significantly different from those of other advanced Western democracies (Farrington et al. 2004; Van Dijk et al. 2007).

Few studies have found support for the notion that differences in crime rates can account for disparities in incarceration rates (Lynch 1988; Neapolitan 2001). Neapolitan (2001) found a significant relationship between homicide rates and imprisonment rates in his study of 148 nations. Lynch (1988) also found differences in incarceration rates between the United States, England, Canada, and West Germany could be explained in large part by differences in the levels and types of crime in these nations.

Most research has found, however, that crime rates are not directly associated with incarceration rates (Young and Brown 1993; Lappi-Seppala 2007). Incarceration rates and crime rates in the United States have moved independently since the early 1970s. Incarceration rates have been increasing in the United States since the early 1970s regardless of changes in crime rates. Despite similarities in crime trends since 1960, Canada has maintained a relatively stable incarceration rate while the United States experienced its incarceration boom (Doob and Webster 2006).

It is more probable that crime rates indirectly affect incarceration rates by affecting attitudes toward punishment among politicians and the general public. Rising crime rates may contribute to increased punitive attitudes and increasingly severe criminal penalties that would result in increased use of incarceration. This may explain the divergent trends in incarceration between the United States and Canada. Doob and Webster (2006) attribute Canada's stable incarceration trend since the 1960s to the lack of changes in sentencing practices despite increasing crime rates. In contrast, the indeterminate sentencing scheme used in the United States came under fire from a number of different fronts in the 1970s. The Martinson (1972) report, which claimed nothing works in rehabilitation, and Judge Marvin Frankel's (1973) criticism of indeterminate sentencing contributed to profound changes in sentencing practices in the United States including the adoption of determinate sentencing, mandatory minimums, habitual offender laws, and the reduction or elimination of parole (MacKenzie 2006).

There is good evidence that suggests these changes to sentencing and correctional policies were largely responsible for incarceration growth in the United States. Blumstein and Beck (1999) attribute 88 % of the increase in imprisonment in the United States between 1980 and 1996 to changes in sentencing practices. During this time, there was an increase in both the number of offenses for which one may be imprisoned and in the length of prison time served.

The type of legal system used in a country is another factor that can affect incarceration rates. Ruddell (2005) and DeMichele (2010) found the common-law legal system used in the United States and other Anglo nations to be associated with significantly higher incarceration rates than nations that operate under a system of Romano-Germanic or Nordic law. Incarceration rates tend to be low under Nordic law regimes (e.g., Finland) and moderate under Romano-Germanic law legal regimes (e.g., Germany). DeMichele (2010) attributes the difference in incarceration rates between legal regimes to several factors including the balance of power among the courtroom workgroup, differences in courtroom practices (e.g., trial structure), and the involvement of lay participants in the judicial process.

Certain aspects of the common-law legal regime, such as the jury trial, increase the involvement of lay participants in making decisions regarding punishment. Heinous crimes that receive heavy media coverage may result in public demands for increasing the severity of punishment. Jacobs and Kleban (2003) found higher incarceration rates occur in nations where the general public has the greatest influence over corrections decisions. The lowest incarceration rates were found in nations where decisions about corrections were made by unelected experts, e.g., judges.

Another political factor that may affect incarceration rates is the level of conservative political strength. Studies done in the United States tend to find a relationship between conservative political strength and incarceration (Sutton 2000; Jacobs and Helms 1996). However, comparative cross-national research has not found this relationship to be significant (Jacobs and Kleban 2003). Jacobs and Kleban (2003) speculate that the failure to find this relationship in other advanced democracies may reflect the fact that decisions about corrections are insulated from popular opinion.

Economic factors provide another potential explanation for differences in national incarceration rates. However, research has failed to find a clear association between economic factors and incarceration. Ruddell (2005) found no relationship between incarceration rates and income inequality, unemployment, or inflation in a sample composed of the richest 100 nations as determined by GDP. Jacobs and Kleban (2003) also fail to find a relationship between incarceration and unemployment. However, they find that the most economically developed nations with the highest per capita GDP are more likely to have higher proportions of their population in prison. Incarceration rates in these nations may simply be higher because they have more resources to build and stock prisons.

Incarceration rates may also be affected by structural factors of the economic system. Sutton (2004) found a relationship between incarceration rates and unemployment, inflation, and income inequality in a study of 15 affluent capitalist democracies. However, the relationship between incarceration rates and these factors disappeared when measures of institutional structure, such as union and left party strength, are considered. Other factors that may affect incarceration rates include out-of-wedlock birthrates (Jacobs and Kleban 2003) and the degree of population heterogeneity in a nation (Jacobs and Kleban 2003; Ruddell 2005).

In sum, there are a variety of social, cultural, and economic factors that account for the disparity in incarceration rates between the United States and other advanced Western democracies. There is mixed evidence that suggests incarceration rates are related to crime rates or economic factors such as unemployment or inequality. Instead, there is a good body of research that suggests incarceration rates are affected by changes in criminal justice policies and the type of legal system used in a nation. Further evidence that changes to criminal justice policies can have a significant impact on incarceration rates will be presented in the next section.

Controlling Prison Population Growth

It is clear that changes to criminal justice policies and practices can have a significant impact on incarceration rates. The operation of the criminal justice system in the United States underwent profound changes in the early 1970s that contributed to incarceration growth. These changes include the switch to a determinate sentencing system, the adoption of mandatory minimums and habitual offender laws, and truth-in-sentencing legislation. Combined, these policies have increased the number of offenses for which one could be imprisoned and increased the amount of time offenders serve in prison.

If these policy changes were responsible for the growth in incarceration, then it is important to ask whether policy changes could reverse the past 40 years of incarceration growth in the United States. The answer to this question may be found by examining the experience of other nations that have dealt with extraordinarily high incarceration rates. In particular, Finland's experience with incarceration could serve as a guide for how incarcerated populations in the United States might be reduced.

In the early 1950s, the incarceration rate in Finland was around 200 prisoners per 100,000 inhabitants. While this rate is a fraction of the current imprisonment rate in the United States, at the time it was nearly twice the rate in the United States and was three to four times greater than other Nordic countries. Lappi-Seppala (2001) identified three possible factors that explained Finland's exceptionally high incarceration rate at that time. These factors include (1) a unique "cultural climate in which severity was not measured on the same scale used in the other Nordic countries" (106), (2) a rigid penal system characterized by high minimum penalties, and (3) severe sentencing practices for relatively common crimes such as drinking and driving.

These three factors also seem characteristic of criminal justice practices in the United States today. Criminal sentences in the United States tend to be more severe than those of other advanced Western democracies, and the greatest disparities in punishment exist among less serious property crimes. In a comparison of punitiveness among eight advanced Western democracies, Blumstein, Tonry, and Van Ness (2005) find that offenders convicted in the United States between 1980 and 1999 served considerably longer periods of time in prison than did offenders who were convicted in other countries. Further, they find the disparity in time served between the United States and other nations is greatest for less serious crimes such as motor vehicle theft. Lynch (1993) had previously found that average sentence lengths in the United States in the 1980s were considerably longer than those in Australia, Canada, England and Wales, and West Germany. However, the amount of time served was relatively similar for violent crimes in these five nations. Prisoners serving sentences for property crimes in the United States spent more time in custody than those in Australia, Canada, and England and Wales.

Changes in these three factors were responsible for the gradual decarceration that took place in Finland since the mid-1950s (Lappi-Seppala 2001). At the time, there was a profound shift in the ideological thinking of criminal justice policy which had till then emphasized (coercive) rehabilitation of offenders. Unlike the movement against rehabilitation in the United States where the punishment philosophy was replaced by the goals of incapacitation and deterrence, the backlash against rehabilitation in Finland was replaced by a philosophy of restitution that emphasized (1) the minimization of costs of crime and crime control to society and (2) creating a fair distribution of costs among the offender, society, and the victim. Rather than serving as the primary instrument of criminal punishment, incarceration was seen to be one possible option among others. This change in philosophy was accompanied by the recognition that the most effective crime prevention may not occur through fear of punishment (deterrence) but rather through increasing the legitimacy of the law and subsequently enhancing the internalization of values and morality.

This change in philosophy and the inability to justify the exceptionally high rates of incarceration in Finland relative to other Nordic countries prompted a series of legislative and policy reforms that would ultimately reduce incarceration levels in Finland. These reforms included reduced penalties for several common crimes, the expanded use of noncustodial alternatives, and the development of sentencing alternatives specifically designed to reduce the number of offenders sentenced to imprisonment. A complete discussion of these reforms can be found in Lappi-Seppala (2001) and Tornudd (1993).

Reduction of penalties for theft and drunk-driving offenses were two reforms that had a significant impact in reducing the number of offenders in Finnish prisons (Lappi-Seppala 2001). These reforms were designed to both (1) reduce the proportion of convicted offenders who would receive a custodial sentence and (2) reduce the sentence lengths of those who were incarcerated. Through a legislative reform enacted in 1972 that redefined serious forms of theft and introduced a new penalty range, the percentage of convicted offenders who received a custodial sentence for theft dropped from 38 % in 1971 to 11 % in 1991. In addition, the median sentence for offenders convicted of larceny dropped from 7.4 months in 1971 to 2.6 months in 1991. Reforms pertaining to drunk-driving offenses focused on replacing custodial sentences with noncustodial alternatives such as community service. Similar to the success of the reforms directed at theft offenses, drunk-driving-related reforms reduced the percentage of convicted offenders sentenced to unconditional imprisonment from 70 % in 1971 to 12 % in 1981.

The expanded use of noncustodial alternatives was another major reform that contributed to reduced incarceration rates in Finland. Specifically, Finland has relied heavily on the use of community service as an alternative for short terms of imprisonment Lappi-Seppala 2004. This alternative was effective at reducing incarceration because it was specifically designed to ensure that the only offenders who would receive it would be those destined for incarceration. While sentencing alternatives have been used in the United States, they have not been very effective at reducing the use of incarceration as a punishment. Instead of diverting convicted offenders from custodial sentences, the use of sentencing alternatives in the United States has contributed to a "net-widening" effect since those offenders receiving sentencing alternatives would not be incarcerated otherwise.

Finland adopted a two-step procedure during the sentencing phase to ensure that only those who were going to initially receive a custodial sentence were eligible for the community service alternative (Lappi-Seppala 2004). In the first step, the court determines a sentence for the offender using the normal criteria for sentencing. If the offender is sentenced to unconditional imprisonment, then the court can decide whether to commute the sentence into community service provided a number of criteria have been met. These criteria include (1) the consent of the convicted person, (2) the determination that the convicted offender is able to carry out the requirements, and (3) that there is nothing in the prior criminal history of the convicted person that would preclude the use of community service (e.g., violent history). After several years of being implemented on an experimental basis, community service orders started being used nationwide in 1994. An examination of trends in Finnish court sentencing practices suggests that community service orders, used in this way, have been successful in reducing the flow of offenders into prison. Since 1994, approximately 30 % of convicted offenders sentenced to an unconditional prison sentence have received a community service order instead.

Even as Finland took these steps to reduce its incarceration rate, crime trends in Finland were remarkably similar to those of its Nordic neighbors (Falck et al. 2003). Crime rates in Finland, Norway, Sweden, and Denmark increased from the 1960s through the early 1990s when they reached a more stable trend. While the increase in crime in Finland was unremarkable when compared to its neighbors during this time, the decline in incarceration rates during this same period was exceptional. In 1950, the incarceration rate in Finland was 187 inmates per 100,000 population. By the late 1990s, the incarceration rate in Finland dropped below 60 – a level comparable to those of its neighbors. Incarceration rates in Finland have since increased; however, all of the Nordic nations have experienced similar increases (National Research Institute of Legal Policy 2011).

Germany is another nation that has taken measures to control the growth of incarceration at a time when crime rates were increasing. Although Germany has not experienced as high of an incarceration rate as has Finland, it has faced problems related to the heavy use of incarceration such as severe overcrowding (Graham 1990). Heinz (2006) traces the history of sentencing practices in Germany as far back as 1882, where nearly 80 % of convicted offenders were sentenced to unconditional prison sentences. Since then, Germany has gradually rolled back its use of custodial sentences in favor of noncustodial alternatives such as fines. Since the mid-1980s, less than 10 % of convicted offenders in

German courts have received unconditional prison sentences, while approximately 70 % of offenders were ordered to pay fines.

While the use of imprisonment has declined throughout the twentieth century, modern sentencing practices in Germany can be traced back to legislation enacted in 1969 (Weigend 2001). The criminal law reforms that took effect in 1969 were explicitly designed to restrict the use of imprisonment to only the most serious cases. This aim was to be achieved through several measures including (1) the abolishment of prison sentences of less than 1 month; (2) the decriminalization of many petty offenses, such as public order and traffic offenses, which were subsequently turned into administrative infractions punishable by fines only; and (3) the discouragement of sentences of less than 6 months. Noncustodial alternatives, primarily fines and probation, were used in lieu of short terms of imprisonment.

The criminal law reforms of 1969 also began a trend in the development of sanctions other than those that have been traditionally used, i.e., imprisonment, probation, and fines (Weigend 2001). Some of these alternative sanctions have not been used very often, such as warning with suspension, while others are being increasingly used by the German courts, such as community service and restitution programs. Not all of these additional sanctions are directed at reducing the number of convicted offenders sentenced to imprisonment. For example, the sanction "warning with suspension of punishment" allows courts to suspend punishments consisting of dayfines and sentence the offender to probation instead. On the other hand, legislation enacted in 1994 allows the courts to mitigate the penalty or suspend sentences of less than 1 year of imprisonment if the convicted offender either participates in a victim-offender reconciliation program or makes some effort to provide financial restitution to the victim.

Finland and Germany's efforts to control and reduce prison populations may serve as an example for the United States to reduce its incarcerated population. While these two nations differ from the United States along a variety of dimensions, they both demonstrate that policy changes can be effective at controlling and even reducing prison populations. Certain features of the United States, such as its common-law legal system, may make it more difficult to achieve the level of success that Finland has had in its history. However, it is unlikely that incarceration rates in the United States will drop to levels of other advanced Western democracies absent any changes to sentencing policies and practices.

Conclusion

The incarceration rate in the United States far surpasses that of any other advanced Western democracy. This disparity in incarceration can be attributed to differences along a variety of factors including sentencing policies and the common-law legal system used in the United States. While some factors may be difficult to control because they are foundational, e.g., common-law legal system, there is evidence that changing sentencing and corrections policies can have a considerable impact on incarceration rates.

Comparative Legal Cultures

David Nelken
Cardiff University Law School, Cardiff, UK

Overview

This entry offers an overview of the main problems in defining and using the concept of legal culture, with special attention to how this may be relevant for scholars of criminal justice.

Scholars of criminal justice may be interested in comparing legal cultures to make sense of similarities and differences in crime levels or punitiveness (Nelken 2000, 2010). Alternatively, they may want to understand how trends in criminal justice spread by means of legal transplants or efforts at harmonization or collaboration as well as how they are reinterpreted or resisted. This entry will first seek to clarify the meaning of the term legal culture and discuss how it may be used in doing research. It will then consider more specifically three of the key issues that arise in carrying out such investigations concerned with generating substantive findings about patterns of law or criminal justice in different jurisdictions. These concern units and boundaries, elements and aggregates, and coherence and change.

What Is Legal Culture?

Studies of law in relation to culture can cover a large range of topics including the role of culture in law (and the challenges of legal pluralism and multiculturalism) to the part played by law as culture, seen as a way of making meaning. Those interested in the relationship between law and culture might wish to study law as a cultural artifact, examine the way it becomes present in everyday life and experience, or through the media, or consider the role of law in accommodating cultural defenses or protecting cultural treasures. This entry, however, is mainly interested in seeing how the concept can be of use in research into cultural variation in how law is experienced in social life and, especially, differences in the role law plays and expected to play. There are obvious implications here for students of criminal justice seeking to tease out the relationship between formal and informal social controls.

Research into comparative legal cultures can involve investigations into the extent to which law is party or state directed (bottom-up or top-down), the role and importance of the judiciary, or the nature of legal education and legal training. It may concern ideas of what “law” means (and what law is “for”). It is possible to discern legal culture in different approaches to regulation, administration, and dispute resolution. There may be important contrasts in the degree to which given controversies are subject to law, the role of other expertises, and the part played by “alternatives” to law, including not only arbitration and mediation but also the many “infrastructural” ways of discouraging or resolving disputes. With reference to criminal justice, the use of legal, non-state, or “informal” forms of social control deserves attention.

But legal culture remains a highly debated term. Even Lawrence Friedman, who pioneered its use in social science, describes it as “an abstraction and a slippery one” and that if he were to start over he might not use it again (Friedman 2006). There are several kinds of disagreements about what legal culture means or should mean (Nelken 1995, 2006, 2007, 2012). There is, for example, the question whether or not legal culture is a useful term as compared to alternative concepts such as legal tradition or legal ideology. Then there is discussion about what the term actually refers to – for example, to attitudes and/or behavior, or whether legal culture refers more appropriately at the popular or at the institutional level.

Confusion can easily arise where what appears to be a debate about the correct interpretations of a given legal culture in fact trespasses into these other areas. Blankenburg, for example, takes Friedman to be arguing that it is “folk” culture – popular pressure for legal change – that shapes differences in legal development and response. He offers, by contrast, a comparison of the very different use of courts in Germany and the Netherlands, countries that he argues, have similar folk cultures and very different institutional outputs. For him, infrastructural arrangements represent the key to differences in legal culture, and in his view, “there is no legal culture outside of institutions” (Blankenburg 1997). Yet, what Blankenburg wants to call legal culture others would call institutions or structures, as seen in the related debate over whether the low level of use of law in Japan is to be attributed to deliberate cultural avoidance of litigation or is rather a result of structural arrangements that block access to the courts (Nelken 1997).

It is also not always easy to tell where definitional questions end and empirical enquiries begin. How are we to distinguish legal culture from political, economic, or religious culture? Or take Friedman’s important distinction between “internal legal culture” which refers to the role in the law of legal professionals and “external legal culture” which refers to those individuals or groups who bring pressure to bear on the law to produce social change. Do lawyers belong to “internal legal culture” (as servants of the courts) or to “external legal culture” as agents of social groups and of individual litigants.

What about the relationship between external legal culture and culture in general? What of the way judges incorporate lay definitions of appropriate behavior into their activities?

It can also be important to distinguish between legal culture and “the culture of legality” (stressing the “legal” before the word culture). The latter term – which corresponds very roughly to what in English is called “the rule of law” – is particularly common in those jurisdictions or parts of jurisdictions, for example, in the former Soviet Union, Latin America, or the south of Italy, where state rules are often avoided or evaded. These are places where – from a state perspective – there is a culture of illegality, and the point of talking of “legal culture” in such cases is to point to the normative goal of getting “legality” into the culture of everyday social and political life. This move seeks to reorient the behavior of such populations toward (state) law and/or encourage state law to respect certain limits of action. Whereas legal culture is a descriptive/explanatory term, the “culture of legality” is a normative and evaluative one. Keeping descriptive and normative meanings apart is necessary if we are to examine the sorts of legal culture that are more or less conducive to creating “the culture of legality”.

But it can also be argued that talk about culture or legal culture is rarely merely descriptive and is more often an interested intervention in debates. For the observer, cultural ideas are contested and connected to relations of power. Cultural repertoires include polarities, such as values and practices, ideas and habits, and innovations along with commonsensical ways of doing things. Culture is the product of historical influences rather than evolutionary change. It is marked by hybridity and creolization rather than uniformity or consistency (Merry 2012). At the same time, however, for social actors themselves, “law” and “culture” are words whose interpretation and definition have illocutionary effects (“this is the law” “that behavior is inconsistent with our culture”). Thus, the term “legal culture” may itself be used by judges, politicians, or others, in the course of making claims about what is or is not consonant with a given body of law, practices, or ideals. This use, as much prescriptive as descriptive or prescriptive through being descriptive, can “make” the facts it purports to describe or explain. Some scholars think the term must capture what these legal actors are trying to do (Webber 2004).

As this suggests, culture is a term that easily lends itself to misuse, providing an easy alibi for resistance to change. For Patrick Glenn, the idea of culture is suspect (as a replacement for talk of race) because of both its origins and its consequences. Usage also includes “essentialist,” overdetermined, overbounded, and xenophobic applications. With cultural analyses, scholars are tempted to orientalize behavior as foreign and irrational and ignore or downplay the importance of economic and related political drivers of behavior (Glenn 2003, 2004). The German word *kultur* indeed emerged as a defensive term used in romantic opposition to the French universalizing idea of civilization (for which today’s discourses of democracy and human rights could be considered equivalents). Yet, there is nothing to stop the scholar from describing (and commenting on) such uses of the concept. And Friedman’s use of the word culture is in fact much closer to the nonessentializing French idea. He stresses convergence and the role of modernity as we move to a global legal culture based round individualism, equality, and human rights (Friedman 2006).

Given that the goal of comparative work is to take us beyond ethnocentrism, we also need to ask whether there can be a universal concept of legal culture. How far is any given conception of legal culture inevitably itself a “folk concept” rather than an “observer’s” concept? For example, the Western idea of law as linked to the nation-state fits uneasily into places with overlapping plural legal systems. Instead of accepting Friedman’s own view of internal and external legal culture as neutral analytical categories, David Engel instead offers a cultural reading of them (Engel 2012). “Two aspects of Friedman’s imagery,” he tells us, “are particularly noteworthy. First, law is spatialized. It has an inside and an outside, and legal culture forms a kind of membrane between the two spaces.
