The focus of RCA theory on individual preferences downplays the extent to which decisions are influenced by the choices made by others. Yet, the decision to offend may be strongly affected by the decisions made by the police, by victims, bystanders or other people involved in crime. Game theory highlights this interactional dynamics of decisions and it offers an important tool for constructing models that make explicit assumptions about people’s preferences, behavioral options and consequences, and the connections between their choices and their expectations of other’s decisions. Although game theory has most often been used to build formal mathematical models of offending, rather than guide empirical research, the propositions of game theory models (GTM) are falsifiable and therefore, subject to empirical test. The following four examples illustrate GTM contributions.

Cressman et al. (1998) use game theory to explore the dynamics between property crime victims, thieves and the police. In their model owners have two choices: they may be passive, doing nothing to guard property, or they may engage in various protective activities such as surveillance. Police also have two choices: actively pursuing offenders or passively waiting until victims contact them. Criminal opportunists choose between theft and non-theft. Owners' increased vigilance will deter theft; however, as crime decreases, the owners' incentive for choosing passivity increases, encouraging their inactivity and increasing the returns to offenders who respond to the inactivity by increasing their involvement in crime. When police actively pursue offenders they increase the likelihood that thieves will be caught, but over time, state policing makes passivity a dominant strategy for owners and theft again becomes dominant for criminal opportunists and offending increases.

Tsebelis (1990b) adds further insight into the relationships between police activity, sanctions and crime. This game begins with the following assumptions: offenders prefer to offend when the police are elsewhere and prefer to follow the law when they are present; the police prefer to enforce the law when it is violated and to not enforce it when it is not. In other words, both players' optimal choice depends on the decision of the other, and both have an incentive to change their behavior in response to the other's actions. These assumptions lead to a situation in which an increase in the severity of sanctions initially decreases crime by diminishing its expected utility. The police have less of an incentive to enforce the law as crime drops, and people respond to their disinterest by increasing their offending. This series of moves and countermoves eventually encourages a new equilibrium in which the increase in penalties has no long-term effect on criminal activity. In short, increasing the severity of penalties has the greatest effect on police behavior, lowering their monitoring and thus decreasing the certainty of arrest. These games reveal some of the processes involved in crime at the aggregate level, and may help explain why stiffer penalties and greater police enforcement may deter crime in the short run, but not over a longer period (a finding often noted in deterrence research).

Bueno de Mesquita and Cohen (1995) expand the list of decision makers in their game, adding the government. The game assumes that people's abilities to meet their preferences are influenced by the following: their level of social status, the value obtained through legitimate opportunities a government provides, the value provided by social assistance programs, the fairness of the government, the probability of apprehension and punishment for offending, and the cost of crime. People can choose to offend or to engage in socially acceptable behavior. Government can treat citizens in two ways: a fair government allows people legitimate opportunities to earn benefits that exceed the value provided by the government's social safety net; an unfair one imposes policies that shift resources from the individual to the government and limit returns.

Solving the game reveals several conclusions. First, an individual's decision to offend is strongly influenced by his level of trust in the government's expected fairness: if people are convinced that their government will treat them unfairly, punishment may have no effect on offending. Second, with level of trust held constant, the fundamental structural features of a society increase the motivation to offend for the poor, relative to those who are wealthy. Indeed, no level of trust is sufficient to reduce crime if poverty is extreme. Reducing crime among the poor requires increases in opportunities to gain social status and the rewards provided by legitimate opportunities. Third, increasing the severity of punishment will have a small impact on the decision to offend, whereas increases in the probability of apprehension have a far greater effect in deterring crime. Fourth, improving social welfare does not discourage offending, and may actually increase it if offenders receive benefits independent of their choice between legal and illegal actions.

An extension of GTM, evolutionary game theory (EGT) relaxes the assumption that people may know the benefits of behaviors when they choose them and allows for unintended rewards that can encourage people to repeat their behaviors and can encourage others to copy them. One of the most ambitious uses of EGT to study crime is Vila and Cohen's (1993) test of hypotheses derived from Cohen and Machalek's ecological theory of expropriation. Expropriation occurs when individuals (or groups) use coercion, deception or stealth to usurp material or symbolic resources from others; in short, when they steal. Cohen and Machalek argue that stealing develops as a strategy because the social organization of production (e.g., the routine patterns of activity, the availability and distribution of resources and mode of production) creates an opportunity structure that invites invasion by non-productive strategies. People adopt or copy others' stealing when they see that it is successful.

In Vila and Cohen's game, people have only two behavioral strategies: produce or exploit. They also know the costs associated with exploitation. Vila and Cohen use computer simulations to estimate models of repeated game playing over 500 generations. The simulations demonstrate that the likelihood of stealing increases when its costs are low and returns are high, and when there is little competition among thieves. It is also more likely when changes in production encourage continual innovation in illegal strategies and when these can be easily transmitted. Consistent with Cohen and Machalek's claim, Vila and Cohen's analysis suggests that expropriative crime is a normal outgrowth of routine economic, social and productive interactions.

Multilevel RCA and Crime

While many studies using a RCA to crime emphasize individual-level preferences and behaviors, recent scholarship focusing on collective processes within neighborhoods offers a multilevel model of crime. Although theories linking individual reciprocity and social structures/collectivities date back to the foundational sociological writings of Emile Durkheim and the Chicago School, contemporary studies reflect a revival in multilevel scholarship, examining the interaction between individuals and aggregate collectivities. The multilevel approach to rational choice offers new ways to analyze the connections between individual preferences and community or neighborhood characteristics. It also provides insights into how individuals and communities encourage or discourage crime. For example, Matsueda (2013) combines a RCA with ideas about neighborhood social capital and collective efficacy to understand the connection between individual utility, macro-level neighborhood phenomena, and crime. Research suggests that social capital – the potential for relationships with others to generate trust and other resources – and collective efficacy – the willingness of residents to actively engage in social control of their neighborhood – both reduce opportunities for crime.

While collective efficacy is often associated with neighborhood structure, Matsueda (2013) contends that it originates in people's attempts to maximize their individual utility. Individuals seek to maximize utility by asking for favors and by doing favors for neighbors such as exchanging information about local politics, problems with children, property or personal victimization or other neighborhood news. This reciprocal exchange fosters obligations and mutual trust; as social capital builds, neighbors' motivations to work collectively to address local problems increases. The interaction between individual-level rational behaviors of exchange, collective efficacy and neighborhood structure represent a multi-level framework for understanding how micro-level behaviors can have macro-level outcomes.

Conclusion

The RCA to crime provides a parsimonious explanation of the process by which individuals choose to offend. It assumes that people actively choose to commit crimes and that this choice is influenced by the same factors that affect the decision to behave in ways that are consistent with legal codes. Thus, both law violating and law abiding behaviors reflect the desire to maximize utility. These choices are however, influenced by attitudes toward risk and time discounting, and estimates of an illegal opportunity's availability, costs and benefits.

Our summary of the RCA suggests that many common criticisms of it are unfounded. According to some critics, the RCA adds little to existing explanations of crime; yet, the RCA grants people more agency than explanations of offending that adopt a deterministic view to explain the effects of socialization, peer associations, and other social conditions and experiences. Other detractors claim that the predictions of the RCA are inconsistent with the reality of crime. Critics charge that the RCA describes offenders who collect all relevant information, and weigh it carefully, systematically and effectively before acting. As is clear from the above summary, the RCA to offending does not make these claims.

Other critics charge that the RCA is only applicable to specific types of illegal behavior, premeditated theft for example, but not crimes of passion. RCA recognizes that an individual's choice to commit a crime may not be rational; however, there are no reasons for assuming that particular types of crime are beyond choice, or that the RCA does not apply to the decision to commit these offenses.

By far, the most important concerns with the RCA are its assumption about preferences and decision-making. As well, findings from the experimental psychology research appear inconsistent with predictions derived from the RCA. Defenders of the conventional RCA note that although a substantial proportion of experimental subjects select options that contradict the RCA, many people's choices are consistent with it. Advocates of RCA argue that combining conventional RCA with a theory of errors can correct many of the observed inconsistencies in predictions derived from the RCA, making it superior to alternatives (e.g., prospect theory and bounded rationality).

Research on the RCA to crime suggests a number of conclusions. First, people who choose to offend, as well as those who do not, have a variety of preferences. It makes no sense to assume that all offenders share the same preferences, or that one preference (e.g., the thrill of crime or its material returns) dominates in offending decisions. Preferences vary, crime provides an array of returns, and people differ in their assessments of crime's costs and benefits. Second, the decision to offend may be strategically chosen given the decisions made by others; its utility may change – from being a dominant to a nondominant strategy – depending on the strategic choices of others. Although people often assume that offenders and the police (as well as victims and other agents of social control) have unique preferences that are oppositional, independent and stable, game theory and deterrence research suggest that each group's preferences can overlap, and may change in response to the actions of the other, as does their choice of strategies.

Overview

This entry reviews sociological contributions to the study of rational choice, deterrence, and crime. It reviews empirical research on the deterrence question, including macro-level studies of aggregate crime rates, micro-level studies of individual perceptions of sanction risk, and experimental studies of specific deterrence and domestic violence. It then shows the relevance of sociological research for specifying the broader context of punishment, which reveals negative externalities of mass incarceration in the USA, such as the pernicious stigmatizing effects of incarceration, the undermining of the legitimacy of the law within disadvantaged communities, and the loss of community cohesion and social capital. Such negative externalities produce criminogenic social conditions, which, in turn, undermine deterrent effects.

Rational Choice, Deterrence, and Crime

The deterrence doctrine is rooted in the writings of the classical school of criminology, and in particular, those of Caesare Beccaria and Jeremy Bentham. Influenced by the prevailing ideas of the enlightenment period, Beccaria argued that human beings freely enter into a social contract with the state, relinquishing some liberty in exchange for the protection of their individual rights. In exchange, individuals would give the state the right to punish those who violated criminal laws, consisting of a written record of the terms of the social contract. Punishments would be swift, certain, and just severe enough to offset the pleasures of crime and thereby deter the public from criminal behavior. The underlying behavioral assumption is that human beings are rational and hedonistic, and weigh the pleasures and pains associated with different behaviors. When the pleasures outweigh the pains associated with criminal behavior, individuals will violate the law. These ideas underlie the system of justice used under Anglo-Saxon law, and motivated early sociological studies of deterrence until a formal expected utility model was specified by the economist Gary Becker.

Expected Utility Models of Crime

Becker (1968) made a seminal contribution to the study of deterrence by specifying a neoclassical theory of criminal behavior. Arguing that the same economic principles explaining decisions made by firms and household members should also explain criminal behavior, Becker (1968:177) drew on von Neumann and Morgenstern's expected utility theory of risky decisions under uncertainty to specify a simple utility function for committing crimes:

$$E(U_C) = (1 - p_c)\ U(R) + p_c U(R - C) \qquad (1)$$

where $E(U_C)$ is the expected utility of crime, p_c is the probability of getting arrested and punished, $(1 - p_c)$ is the probability of getting away with crime, R is the return (both monetary and psychic) from crime, C is the cost of punishment (e.g., a fine or prison sentence), and U is a utility function translating punishments and rewards to a common metric. The expected utility model assumes that individuals have complete and transitive preference orderings for all possible decision outcomes. If we ignore noncriminal behavior or assume that the expected utility from noncrime is absorbed in C as an opportunity cost, we can specify that a crime will occur when $E(U_C) > E(U_N) = 0$, so that from equation (1), a crime will occur when the following holds:

$$U(R) > p_c U(C) \tag{2}$$

That is, when the returns to crime exceed the punishment, weighted by the probability of detection, an individual will commit a crime. The policy implication here is that by increasing the certainty and severity of punishment, the probability of crime will be reduced. Crime can also be reduced by lowering the rewards to crime – by defending public spaces through increasing surveillance, employing security guards, and using technological advances in metal detection, alarms, locks, fences, and the like (see McCarthy 2002). Historically, following Becker's (1968) work, most microeconomic research on crime has focused on the policy implications of increasing the certainty and severity of punishment.

Criminal decisions, of course, consider the utility of noncrime as well as crime, and therefore, one might specify a utility function for noncriminal activity (e.g., Bueno de Mesquita and Cohen 1995):

$$E(U_N) = p_i U(I) + (1 - p_i)\, U(W) \tag{3}$$

where I is income (returns to conventional activity), p_i is the probability of obtaining I (through having high social status, resources, or talent), and W is welfare or the social safety net for those who cannot obtain I (i.e., $p_i = 0$). Combining equations (1) and (3) yields:

$$E(U_C) = (1 - p_c)[U(R) - p_i U(I) + (1 - p_i) U(W)] + p_c U(R + W - I - C) \tag{4}$$

If follows that a crime will be committed when:

$$(1 - p_c)[U(R) - p_i U(I) + (1 - p_i) U(W)] + p_c U(R + W - I - C) > 0 \tag{5}$$

From a policy point of view, the probability of crime can be altered not only through criminal justice policies that increase the certainty and severity of punishments or that change defensible space, but also through policies that increase the utility from noncriminal activity. For example, job training, higher education, and other programs to enhance human and social capital may reduce the attractiveness of crime by increasing p_i, the probability of obtaining a desired income from legitimate activities. Returns to conventional activity include not only income but also social status and prestige, self-esteem, and happiness; policies that increase these quantities by inculcating strong commitments to conventional institutions may help reduce crime.

Limited Rationality and Crime

Criminologists, following cognitive psychologists, have questioned the assumptions of the expected utility model, arguing that criminals are unlikely to have access to full information and unlikely to conduct complex calculations necessary to maximize expected utility. For example, the utility maximization theory is commonly criticized for assuming (1) that the actor knows the probabilities of certainty and severity of crime, and (2) that criminals act on a rational calculation, rather than by impulse, either under the influence of alcohol or in responding to opportunities. In responding to this criticism of rational choice and crime, Cook (1980) drew on Herbert Simon's work on bounded rationality, and suggested that criminals may use standing decisions or rules of thumb in making decisions about crime – particularly in situations of high stress, emotion, or inebriation. Moreover, Cook argued that rational choice theories of crime need a theory of the communication of threats, and pointed to the role of the media, presence of law enforcement, personal experience, and observation of peers as important ingredients of such a theory.

Clarke and Cornish (1985) attempted to integrate rational choice with conventional criminological theories, such as social learning theory, and developed a model in which actors' pursuit of general needs and previous learning (experiences with crime, contact with police, conscience and morality, self-perception, and foresight) led to evaluation of legitimate and illegitimate solutions to produce a “readiness” to commit burglary. Readiness may lead to a decision to commit burglary, which is followed by a proactive assessment of potential middle class targets based on accessibility, police patrols, security, cover, affluence, and no one being at home. The evaluation of target accessibility is consistent with routine activities theory, which hypothesizes that criminal events result from the intersection of motivated offenders, suitable targets, and the absence of capable guardians.

Empirical Research on Rational Choice and Deterrence

Empirical research on rational choice and deterrence has made considerable methodological strides, moving from cross-sectional studies to longitudinal and panel designs, grappling with the identification problem, and considering experimental designs. Beginning with Jeremy Bentham, deterrence theory has traditionally distinguished between general and specific deterrence. General deterrence refers to an act or threat of punishment deterring the general public from committing crimes; specific deterrence refers to the special case of deterring the punished individual from committing future crimes. While these two forms of deterrence are theoretically distinct, may influence people through different mechanisms, and consequently may imply distinct punitive policies, they are often hard to tease apart empirically. Of the empirical work reviewed here, aggregate research – especially studies examining the effect of new punishment policies on rates of offending – often conflates the effects of specific and general deterrence (Durlauf and Nagin 2011). Individual-level studies can be more explicit about separating out the effects of each. We focus here on sociological and criminological studies, as econometric studies are reviewed elsewhere in this volume.

Studies Using Aggregate Data

Over the past four decades, a spate of empirical studies of deterrence by criminologists, sociologists, and economists have used aggregate data to examine whether individuals are deterred by the certainty and severity of punishment (for a review, see Nagin 1998), often employing instrumental variables to identify reciprocal effects between rates of imprisonment and rates of crime. Durlauf and Nagin (2011) provide an excellent review of empirical work on deterrent effects of incarceration, summarizing recent findings as well as identifying important issues in aggregate research on deterrence. Studies of the severity of sanctions – often operationalized as differences in the length of incarceration – have found only modest deterrent effects of severity of punishment. Studies of the deterrent effect of capital punishment – considered the most severe of all state sanctions – have historically yielded disparate results, with recent evidence that findings of deterrent effects of capital punishment were based on incorrect modeling procedures (Durlauf et al. 2012). However, there is evidence of significant deterrent effects of certainty – operationalized as greater police presence on the street, and more aggressive policing practices.

While aggregate research examining change in the crime rate has contributed much to the understanding of the deterrent properties of various policy changes, it has been criticized for several shortcomings. First, aggregate research is unable to distinguish the effect of deterrence from the effect of incapacitation on crime (Durlauf and Nagin 2011). Second, this research has not accounted for heterogeneity (especially at the state level) of policy adherence. This is problematic because systems of formal control differ not only at the state level, but also by county, city, and sometimes community. Additionally, individuals may be most aware, and concerned with, local formal punishment and detection policies rather than those at the county or state level (Apel 2012). Third, most aggregate studies do not distinguish between awareness of deterrence policy, and often assume that individuals have perfect information with which to assess risk of being caught and punished (Durlauf and Nagin 2011). Recent research indicates that there are significant gaps in policy awareness, with experienced offenders being more informed than others (Matsueda et al. 2006; Apel 2012), showing a need to treat utility maximization and possession of information as separate effects of deterrence policy on observed behavior. The next section reviews research on individuals' subjective evaluation of the severity and certainty of punishment, which has emerged as one fruitful alternative to aggregate deterrence research.

Studies Using Survey Data of Individuals

Aggregate tests of the deterrence hypothesis assume that actors know the objective certainty of arrest and imprisonment (Nagin 1998). By contrast, *subjective* expected utility models relax this assumption, replacing the single known *objective* probability with a distribution of *subjective* probabilities. Subjective utility models are still rational models because the statistical mean of the subjective probability distribution is assumed to fall on the value of the objective probability (Nagin 1998). Empirical research from a subjective expected utility framework uses survey and vignette methods to measure perceived risk of punishment directly from respondents, rather than inferring it from behavior through the method of revealed preferences.

Early empirical research by sociologists used cross-sectional data and found small deterrent effects for certainty of punishment but not for severity (e.g., Williams and Hawkins 1986). Respondents who perceive a high probability of arrest for minor offenses (like marijuana use and petty theft) report fewer acts of delinquency. Such research has been criticized for using cross-sectional data in which past delinquency is regressed on present perceived risk, resulting in the causal ordering of the variables contradicting their temporal order of measurement.

To address this criticism, sociologists have turned to two-wave panel models and found, for minor offenses, little evidence for deterrence (perceived risk had little effect on future crime) and strong evidence for an experiential effect (prior delinquency reduced future perceived risk) (see Williams and Hawkins 1986; Paternoster 1987). Piliavin et al. (1986) specify a full rational choice model of crime, including rewards to crime as well as risks, and find, for serious offenders, that rewards exert strong effects on crime, but perceived risks do not.

Recent longitudinal survey research has used more sophisticated measures of risk, better-specified models, and better statistical methods. Matsueda et al. (2006) specify two models based on rational choice. First is a Bayesian learning model of perceived risk, in which individuals begin with a baseline estimate of risk, and then update the estimate based on new information, such as personal experiences with crime and punishment or experiences of friends. Second is a rational choice model of crime, in which crime is determined by prior risk of arrest, perceived opportunity, and perceived rewards to crime, such as excitement, kicks, and being seen as cool by peers. Using longitudinal data from the Denver Youth Survey, Matsueda et al. (2006) find support for both hypotheses: perceived risk conforms to a Bayesian updating process, and delinquency is determined by perceived risk of arrest, rewards to crime, perceived opportunities, and opportunity costs. A recent study by Anwar and Loughran (2011) extends the risk updating model to high-risk offenders, finding further evidence for a Bayesian-style learning model. The study also finds that experiencing a deterrent signal about a specific type of crime results in a generalized posterior where all crimes are considered more risky.

In addition to risk updating, perceptual research has focused on other aspects of individual assessment of risk, such as interpretation of the risk signal. Loughran et al. (2011) build on Lawrence Sherman's distinction between *level* and *ambiguity* of sanction certainty, and test whether individuals are ambiguity averse – that is, interpret uncertainty as an added risk. The authors find support for ambiguity aversion in assessment of sanction certainty, but also observe ceiling effects, where extremely risky and uncertain situations will be perceived as slightly less risky than certain same-level risk. Loughran et al. (2011) additionally find that ambiguity aversion holds only for property crimes, and not face-to-face crimes, noting that property crimes may be more amenable to deterrence.

Vignette surveys examine perceived deterrent effects within a richer depiction of a scenario, which mimics actual situations of crime. Here, a crime scenario is depicted in a short written paragraph, with specific elements of the scenario – such as the presence of police or witnesses and potential monetary returns – randomly rotated across vignettes. Respondents are asked to assess the probability of getting caught or obtaining rewards from the crime and also asked their intentions of committing the crime depicted. By asking their future intentions of committing crime, vignette studies resolve the causal order problem, under the assumption that intentions are good predictors of actual behavior. A weakness of vignettes is the potential for a response effect: respondents who report high risk of arrest may be unlikely to admit to an intention to commit the crime due to social desirability effects. Vignette studies of deterrence and rational choice generally find robust effects of deterrence: certainty has a substantial effect on criminal intentions, while severity has modest effects. This holds for tax evasion, drunken driving, sexual assault, and corporate crime (see Nagin 1998, for a review).

A recent line of research in clinical psychology has focused on linking cognitive developmental differences between adults and adolescents (including middle and late adolescence) to differential decision making and criminal participation. New analyses suggest that cognitive immaturity in older adolescents and young adults, including a lesser ability to engage multiple regions of the brain to problem-solve coupled with increased dopamine activity, causes them to be more impulsive, more vulnerable to peer influence, and more likely to discount the future than adults who are in their mid-twenties and older (see Steinberg 2009). This research provides a developmental basis for differences in adolescent behavior previously noted by sociologists and criminologists, such as committing crime in groups, and discounting future punishment costs. Furthermore, these findings suggest that individuals in their late teens and early twenties may still be in a developmental stage that is not as amenable as adults to current policies of deterrence, which may explain differential rates of young adult participation in criminal activity. Such research has obvious policy implications for the distinction between juvenile and adult criminal justice.

The recent advances in perceptual deterrence have significantly added to the specification of the process by which individuals understand and respond to the policies of deterrence. However, sociological research on consequences of punishment has raised awareness of additional mechanisms that have the potential to alter individual utility functions and undermine the efficiency of deterrence. The next sections outline what is known about the ways in which the current system of punishment in the USA can affect individual utility functions and behavior.

Studies of Specific Deterrence Using Experiments on Domestic Assault

Research on specific deterrence faces the daunting task of addressing non-equivalent treatment (e.g., incarceration) and control groups (e.g., probation). Offenders who are incarcerated are likely to be more crime prone than offenders who are not incarcerated, and thus, unobserved heterogeneity is likely to bias comparisons between incarcerated and non-incarcerated offenders. A line of research that addresses this problem uses an experimental design to examine the specific deterrent effects of arrest for domestic assault on recidivism rates. Sherman and Berk (1984) conducted such an experiment by randomly instructing police to arrest domestic assault offenders versus merely counseling others. Contrasting this with a labeling effect, in which arrest may stigmatize offenders and amplify deviance, Sherman and Berk (1984) found a significant deterrent effect: arrested offenders were less likely to re-offend than non-arrested offenders. As a result, laws mandating arrest for domestic assault offenders spread across the country. Because this study was limited to one city (Minneapolis) and suffered some methodological problems – such as police departing from random assignment – the National Institute of Justice funded a set of replication studies across the USA. Generally speaking, those studies did not replicate the specific deterrent effect: overall, arrested offenders were not significantly less likely to recidivate. They did find, however, that arrest deterred a subpopulation of offenders – namely, those who had stronger stakes in conformity, such as marriage and employment (e.g., Berk et al. 1992). Thus, arrest for domestic assault may deter future assaults for those individuals who are committed to conventional society, and who consequently, have more to lose by arrest and likely incarceration. Commitment to society constitutes a key component of the broader context of punishment.

The Social Context of Deterrent Effects

Sociologists critical of using policies of deterrence as a panacea for the crime problem have emphasized the societal context in which punishment is carried out. Most research on the broader contexts of crime and punishment has not adopted a rational choice framework. Nevertheless, such research has important implications for a rational choice theory of crime, and in particular, for identifying limitations of deterrent effects. A key concept here is stigma. Research has found that small amounts of informal stigma, which is analogous to public shaming, may enhance specific deterrent effects. But widespread or permanent stigmatization of distinct groups of people can have substantial negative externalities, at times amplifying rather than deterring crime. This research has its roots in sociological labeling theory, which stresses the negative consequences of the criminal justice system, and Braithwaite's (1989) theory of reintegrative shaming, which argues that stigmatization without reintegration can amplify the crime problem. We use these ideas to organize research on stigma and crime.

Stigmatization and Crime

Goffman (1963) described stigma as an attribute that spoils an individual's identity, evokes negative stereotyping by others, and causes the individual to adopt coping strategies when confronted by "normals." Research and theory on rational choice and deterrence has shown that a specific mechanism that potentially enhances deterrent effects is informal sanctioning by family members and peer groups. That is, if the arrested or convicted offender is stigmatized by significant others – resulting in a loss of social status – the specific deterrent effect of the arrest or conviction will be strengthened (see Paternoster 1987). This effect could also enhance general deterrence as other members of society observe the stigmatizing effects of punishment. Rebellon, Piquero, Tibbets, and Piquero (2010) show that fear of arrest deters mainly through the expected shame from friends and family of the potential offender. Stigma, however, is a *relative* concept; its negative effects are dependent on its distribution in a population. Having a disfiguring scar may be enormously stigmatizing in a population whose members have no scars, but less so in a population of army veterans in which scars are frequent. Moreover, the deterrent properties of stigma may have within-individual thresholds: if an individual is severely and permanently stigmatized, any future stigmatization or shaming is rendered ineffective. In the following section, we outline how policies of deterrence may be undermined when stigmatization exceeds such population and individual-level thresholds.

Stigma and Population Thresholds

Because stigma is a relative term, its negative effects may exhibit a threshold effect or tipping point in a given group or population. When punishment is a relatively rare event, the stigmatizing effects are dramatic. As the incarceration rate of a subpopulation increases, the status of being a felon becomes more commonplace, and the effects of stigma shrink (Nagin 1998). If all members of the subpopulation receive felon status, stigma reduces to zero. Even if stigma reinforces a deterrent effect, that effect is subject to a tipping point, after which the effect declines. Thus, it is possible that mass incarceration has undermined the stigmatizing effects of having a criminal record, as more and more members of a given group – young African-American men from disadvantaged backgrounds – share the status of having a criminal record. For example, Clear (2007) and Anderson (1999) describe the spatial concentration of incarceration in poor African-American communities, where offenders cycle in and out of neighborhoods in which they resided before initial contact with the law. In such neighborhoods, incarceration may become normative, and felon status may lose its stigmatizing effect. From a rational choice perspective, the cost of incarceration has diminished in such communities, which attenuates deterrent effects.

Within-Individual Thresholds: Shaming, Stigmatization, and Reintegration

Even without reaching population-level thresholds, the effects of stigma can change from deterrent to criminogenic if stigma becomes a serious and permanent experience for an individual. The concept of permanent, self-reinforcing stigma lies at the heart of sociological labeling theories, which posit that negative labeling can at times amplify, rather than deter, crime. For example, minor forms of deviant or mischievous behavior, viewed as play by children, may be seen as bad, evil, or portending of more serious deviance by the adult community. Adults often respond by labeling the child as “evil” or “bad” and informally punishing the child. Repeated negative interactions with the community may leave the child cut off from conventional peers, stigmatized as a bad kid, and caught up with the juvenile justice system, ultimately leading the individual to adopt the stigmatizing label as permanent trait, viewing themselves as a criminal and engaging in criminal behavior. Labeling theorists emphasize the negative effects of labeling and pose the counterfactual: might the youth have been better served if their initial minor forms of delinquency had been treated as mere mischief and avoided the process of negative labeling and deviance amplification?

Braithwaite (1989) elaborated on deviance amplification with his theory of reintegrative shaming. Consistent with labeling theory, Braithwaite argues that often the punitive sanctions of the legal system amplify rather than deter crime by stigmatizing and segregating the offender from conventional society. In contrast, a system of reintegrative shaming would shame the offender – via informal disapproval by significant others (family, friends, and other community members) who are respected and trusted by the offender – followed by a program of reintegration of the offender back into conventional society. Braithwaite argued that punishment is most efficient when administered within a context of respect and love – rather than anger, retribution, and rejection – and within a context in which the offender is welcomed back into society. Consequently, for the offender, the threat of future shaming will maintain a deterrent effect, as the offender has something important – his or her renewed status – to lose.

Empirical research finds some support for ideas of restorative justice and reintegrative shaming. For example, the use of restorative justice as a model for conflict resolution and restitution may result in greater satisfaction for offender and victims compared to a traditional court-centered approach. Offenders who received restorative justice may also have lower recidivism rates than the offenders who receive court-centered justice (Braithwaite 1999). Informal shaming may be a key cost of offending and enhance deterrent effects (e.g., Rebellon et al. 2010).

Theories of labeling and reintegrative shaming provide a theoretical framework within which to review recent sociological research into the social context of punishment. The key theoretical point is that increases in the certainty and severity of punishment may produce a deterrent effect, but in the absence of policies of reintegration, may also produce massive stigmatization of a population, a negative externality that undermines deterrence. This entry emphasizes the unanticipated negative consequences of punishment, as exemplified in the recent trends of mass incarceration and severe problems of reintegration of offenders in the USA. We focus on the USA as an empirical example because massive incarceration over the last four decades has generated a large population of permanently stigmatized offenders. Problems of stigma and reintegration can become particularly acute if the same class (race, gender, and social class) of offenders is segregated from conventional society, perhaps over generations, resulting in a permanent class of individuals who have little invested in conventional activities, and consequently perceive criminal participation as relatively more rewarding. Recent research suggests this is precisely the situation in contemporary America.

Between 1972 and 2000, the US incarcerated population increased by six times. Western (2006) estimates that, among the male cohorts of 1965–1969, one in five black men had experienced prison by their early thirties. The number for white men was 3 out of 100. Moreover, he reports that nearly 60 % of black men who had dropped out of school were incarcerated by 1999. Clearly, the USA is characterized by mass incarceration, which disproportionately affects disadvantaged young black men. These trends have important consequences for examining rational choice, deterrence, and crime.

Sociological Research on the Individual Consequences of Punishment

Individuals who have been arrested, convicted, and incarcerated undergo the stigmatizing effects of the criminal justice system, including being handcuffed, appearing in court in jail uniforms, and being incarcerated away from family and friends. This is only the beginning of the stigmatizing process that hampers an offender's reintegration. Once a felon has paid his or her debt to society, he or she faces additional impediments to reentering society and refraining from future crime. Such obstacles, discussed below, suggest that the US legal system, in conjunction with other institutions, such as labor market and political institutions, operates to stigmatize and segregate the offender from conventional society, working at odds with Braithwaite's (1989) call for reintegrative shaming.

A criminal record reduces – sometimes permanently – an individual's employment and earning potential. Empirical research suggests that ex-felons are less likely to be employed, and when employed, tend to be earn lower wages than their labor market counterparts. These results, however, could merely reflect preexisting differences between individuals with and without a criminal record, such as differences in human capital. Consequently, Pager (2007) used a quasi-experimental audit study, in which matched pairs of individuals applied for jobs. She randomly assigned felon status to one of the pair, then reversed that status to obtain the counterfactual condition – what would happen if the felon statuses of the pairs were switched? – and counted the number of callbacks from employers. She found that non-felons were twice as likely as ex-felons to get a callback. That effect was greater for black ex-felons.

Furthermore, a felony conviction revokes the right to be employed in several occupations, and can be grounds for denial of such welfare programs as subsidized housing and financial aid to mothers with children (Wakefield and Uggen 2010). This exacerbates the precarious financial situation of most ex-felons. Fees and fines administered by criminal courts often create accrued debt, which undermines the solvency of economically marginalized criminals. Thus, as personal wealth and employment opportunities and earnings diminish, opportunity costs to crime decrease and illegal markets become more attractive. These persistent declines in returns to legal employment may also reduce the cost of future arrest or incarceration. At the extreme, if felony status makes legal employment virtually impossible, an ex-felon will have little to lose by re-offending.

In most states in the USA, felony status results in a long-term, and sometimes permanent, loss of voting rights (Manza and Uggen 2006). Because felon disenfranchisement disproportionately affects Democratic turnout, it is possible that recent close elections may have turned out differently had felons been allowed to vote (see Manza and Uggen 2006). Moreover, loss of voting rights undermines civic participation, an important source of integration into conventional society.

These negative consequences of punishment can have spillover effects on other commitments to conventional society. Incarceration, and the reduced economic opportunities it spawns, is associated with lower marriage rates (Western 2006) and difficulties providing for children, each of which undermines commitments to the family unit.

Without strong attachments to work, civic, and family life, ex-felons are unlikely to reintegrate into mainstream society. Strong informal ties to conventional society have been shown to dissuade individuals from criminal behavior (e.g., Sampson and Laub 1993). It follows that weak ties to the labor market, family, and civic institutions reduce the rewards from conventional activities, and in turn decrease the opportunity costs for crime. Thus, the contemporary system of punishment in the USA appears to stigmatize offenders upon release and long after their official punishment is meted out, cutting them off from participation in conventional society.

Sociological Research on the Consequences of Punishment for Communities

Incarceration, particularly on a massive scale, can also have negative externalities for communities. When punishment is repeatedly and disproportionately applied to members of specific communities, it can alienate not only the individuals punished, but the entire community, who may begin to bear the burden of disproportionate punitive targeting. In the long run, such punitive trends may cause community members to view the legal system with a jaundiced eye, ultimately undermining the legitimacy of the system. This may occur in the absence of discrimination against community members; however, when there is evidence of discrimination, such as with racial profiling by police, the problem quickly escalates.

In his ethnography of youth culture in a predominantly African-American disadvantaged inner city, Anderson (1999) documents how perceptions of hostile and racist police practices, coupled with systematic barriers to employment and frequent contact with the law, drive community members to reject conformity with the law, and adopt a view of formal systems of sanctions as unfair and illegitimate. Consistent with the threshold view of the effects of stigma, norms of informally shaming offenders not only disappear, but are replaced by the "code of the street" – a set of norms that celebrates incarceration as a right-of-passage into manhood, and accepts interpersonal violence as a reasonable strategy for obtaining personal safety and social approval. This redefines formal punishment from a social cost within a community to a social reward, undermining deterrent effects. Because the legal system and police are often the principal contact disadvantaged residents have with conventional institutions, alienation from police may lead to distrust of other institutions.

In such disadvantaged neighborhoods, with a high prevalence of incarceration, low rates of conventional economic success, and meager community resources, young people will tend to underinvest in education and careers, which lowers the opportunity costs to crime. Facing grim economic prospects, they will tend to discount the future that, by all accounts, will be bleak (Anderson 1999). This discounting, which becomes part of the code of the street, induces an attitude of "live and die in the moment," undermines delayed gratification and long-term planning, and blunts the deterrent effect of punishment.

High incarceration rates in specific communities result in large proportions of residents cycling in and out of prison, which may disrupt the local community (e.g., Clear 2007). On the one hand, removing an offender who has wreaked havoc on other residents, is isolated from others, and makes few contributions to the community may have a positive effect on the community as a whole. On the other hand, despite having committed a crime, local offenders may also have been fathers, neighbors, and friends, and thereby have been interwoven into the fabric of the local community. Their removal from the community through incarceration reduces social capital by eliminating the social ties they maintained within the community's social network. The result is diminished exchange relationships, a loss of information potential, and weakened social norms. Ironically, this reduction in social capital may be associated with reductions in informal social control, such as collective efficacy, which in turn is associated with higher rates of crime and incarceration (e.g., Sampson et al. 1997). Such informal control includes interdependencies, trust, and mechanisms of control involving community reputations, all of which are destroyed by the constant uprooting of community members. Thus, a community can get caught up in a pernicious feedback loop in which incarceration undermines social control, which increases crime and incarceration, further undermining social controls. Furthermore, an influx of returning ex-prisoners into a disadvantaged community may disrupt local legal economies (shops and restaurants), reducing opportunity costs to crime, and may increase the community's crime rate (e.g., Clear 2007). The devastating effects of mass incarceration at the community level undermine the salience of deterrence for all members, including those who would otherwise be at low risk of criminal behavior.

In sum, research on the social context of punishment and crime suggests a number of negative externalities of incarceration, particularly when carried out on a massive scale. Punitive policies in the USA may have helped deter crime, but have also produced a host of negative externalities – increasing stigmatization, hampering the reintegration of the offender, reducing the opportunity costs of crime, and undermining both social capital and informal social control of communities – all of which may have exacerbated the crime problem and reduced the efficiency of deterrence.

Conclusions and Directions for Future Research

Sociological theories of rational choice and deterrence have made strong contributions to our understanding of criminal behavior and punitive policies. Rooted in rational choice and utility maximization theories of individual behavior, aggregate studies of deterrence have been augmented by individual-level studies of decision making and cognition. In general, research suggests that deterrence has an important role in the causes of crime: based on a variety of research designs, the certainty of punishment appears to be negatively associated with crime. Research on the marginal deterrent effect of increasing the severity of punishment, including the death penalty, has been more equivocal, with effects typically modest in size or statistically indistinguishable from zero.

Increases in punishment rates, particularly mass incarceration, occur in a social context, which may lead to unanticipated consequences and negative externalities. Research in sociology and criminology suggests that a combination of mass incarceration with a failure to reintegrate offenders into the community has pronounced negative collateral consequences, including a reduction in the effectiveness of current deterrence policies. Large numbers of ex-prisoners have been stigmatized, blocked from succeeding in the labor market, prevented from civic participation, and generally isolated from conventional society, resulting in fewer opportunity costs for re-offending. The result is high rates of recidivism, and a constant cycling of predominantly disadvantaged African-American men in and out of the prison system. The removal of large numbers of men from disadvantaged communities may undermine the social organization, social capital, and informal control of those communities. Weakened community social controls combined with fewer opportunity costs for offending likely perpetuates the cycle of incarceration, stigmatization, and re-offending. As Braithwaite (1989) has argued, such a cycle will only lead to spiraling crime rates and diminished deterrent effects of stigmatized individuals; breaking the cycle requires reducing stigma, introducing community shaming, and increasing reintegration of the ex-offender into mainstream society.

Future research is needed to tease apart these countervailing processes of deterrence, stigmatization, and reintegration. Because each of these processes operates endogenously, research is needed that considers their joint nonlinear relationships. This is tricky because such processes will be fraught with feedback loops, as noted above, as well as cross-level effects: an individual decision to commit crime and risk incarceration changes the social context by providing criminal role models, reducing the certainty of arrest, and undermining social capital and informal control – all of which increases the likelihood of crime and incarceration. Research designs using experimental interventions, which provide instrumental variables for estimating treatment effects, may be useful here. Short of such costly designs, econometric methods of analyzing social interaction effects may help, although the identification problems are daunting. Another useful approach would be to estimate the models, and tease out the underidentified parameters using simulations based on game theory (see McCarthy 2002). Regardless of research design, we believe that the next generation of research on rational choice, deterrence, and crime must examine the dynamic interactions between criminal decision making and the broader social context within which decisions are embedded.

Reassurance Policing and Signal Crimes

Andrew Millie
Department of Law and Criminology, Edge Hill University, Ormskirk, Lancashire, UK

Synonyms

Neighborhood policing (UK); Signal crimes perspective

Overview

A reassurance function for policing was first considered by American psychologist Charles Bahn (1974: 338) as "feelings of safety that a citizen experiences when he knows that a police officer or patrol car is nearby." This idea was taken forward in Britain by Martin Innes and colleagues in the early 2000s through the development of a signal crimes perspective. At this time, British policing implemented a National Reassurance Policing Programme (NRPP) where local policing priorities were decided through consultation with local communities. The impact of reassurance policing has since spread and the approach has also been considered in Australia, Belgium, the Netherlands, and Sweden.

In this entry, the background to reassurance policing is considered with particular reference to the work of Charles Bahn and Martin Innes and colleagues. The development of a policy of reassurance policing in Britain is also examined. The successes and limitations of the approach are considered and three main issues identified: that reassurance needs to be a consideration for *all* policing; that increases in visible patrol need to be questioned (especially at a time of budget restraint); and that reassurance policing has the potential to be a model of democratic policing, but only if consultation is truly inclusive, for instance, including those that have been victimized and groups that have been targets of police activity such as young people, the homeless, and other minority and marginalized groups.

Fundamentals

"Reassurance policing" is an approach to policing that emphasizes the importance of the police communicating a positive image to the public, that the public is reassured that the police are doing a good job. It is closely allied to "community policing," "community-oriented policing services" (COPS), and "neighborhood policing." The first to write about the reassurance function of policing was American psychologist Charles Bahn (1974). The context was the publication of the Kansas City Preventative Patrol Experiment (Kelling et al. 1974). According to the then Kansas City Chief of Police, Joseph D. McNamara (Kelling et al. 1974: vii), the experiment showed that "routine preventive patrol in marked police cars has little value in preventing crime or making citizens feel safe." However, Bahn suggested police patrol still had an important function by increasing public awareness of police work and thereby providing visible reassurance (and hopefully making the public feel safer). He defined the reassurance function in the following terms:

> In addition to its more obvious functions, police patrol also has the function of citizen reassurance - providing feelings of safety that a citizen experiences when he knows that a police officer or patrol car is nearby. (Bahn 1974: 338)

Bahn's definition emphasized subjective feelings of safety rather than any objective measure, and the best way to provide reassurance, to make the public feel safer, was through visible and accessible police patrol:

> . . . when the man in the street asks for more police, he is really asking for the police to be on hand more frequently and more conspicuously when he is going about his daily business. (Bahn 1974: 340–341)

After Bahn, there followed a long period during which time the reassurance function was not a major focus for policing. Crime continued to rise and so controlling the level of crime was the clear priority. Rather than focus on patrol, emphases were increasingly on professionalism and crime management, a decision that appeared to be backed by the research. Not only did the Kansas City Experiment question the value of patrol work (Kelling et al. 1974), but also the Newark Foot Patrol Experiment (Kelling et al. 1981). In this study, George Kelling's team found that foot patrol did not reduce crime. However, more positively – and in support of Bahn's position – they also found that foot patrol did have an impact on fear of crime and police satisfaction (see also Clarke and Hough 1984).

Yet, a performance culture evolved in North America, Britain, and many other western nations more focused on crime control and prevention – for example, through forms of zero-tolerance or intelligence-led policing (Innes 2004). In Britain, in the late 1990s and early 2000s, the focus had become volume crime while neglecting more minor disorders and antisocial behaviors (Millie and Herrington 2005). According to FitzGerald et al. (2002: 118), "quantitative performance management was narrowing the focus of police activity in ways that might put long-term investment in police-community relations at risk."

At a time of rising crime, there were also high levels of fear of crime. However, from the mid-1990s onward, recorded crime rates fell in most western nations. This fall in crime was not thought to be matched by falls in fear of crime (Innes 2004). The meaning and measurement of fear of crime are contested and the problem could be exaggerated (Farrall and Gadd 2004). There is not a straightforward relationship between crime rates, police activity, and fear of crime; in fact, in some jurisdictions, an aggressive approach to crime by the police may have resulted in greater fear of crime among marginalized populations (Innes 2004). Also, according to Innes, an emphasis on crime management meant that much police work became behind-the-scenes analysis that was not visible to the public. An unintended consequence was an increased "social distance between police and policed" (Innes 2004: 156).

However, despite claims that the level of fear of crime was a problem, British Crime Survey measures of "worry about crime" did fall from the mid-1990s (Millie and Herrington 2004, 2005). Of greater importance than fear of crime – for a policy of reassurance policing – is public confidence in the police. In Britain, public confidence declined at the same time that recorded crime rates fell (Hough 2003). Furthermore, members of the pubic were unaware that crime rates had been falling; for instance, according to the Audit Commission (1999: 2): "Recorded crime fell by 14 per cent from 1995 and 1997, but fewer than one person in ten was aware that crime had decreased over this period." The disjuncture between falling crime, the public's ignorance of this fall (with many thinking it was rising), and falling confidence in the police became known as the "reassurance gap." Feeding into this were concerns about fear of crime. British police introduced a policy of "reassurance policing" at the start of the new millennium as a response to concern over the "reassurance gap." The answer to falling public confidence in policing was not it seemed greater managerial focus on performance, but a shift in focus to people's perceptions:

> The current over-focus on crime figures as a substitute measure for police performance will not lead to greater public confidence. The public is convinced that the UK is a high-crime society. A reassurance strategy will provide an opportunity to shift people's perception and begin to change the embedded culture of fear of crime. (ACPO 2001: para.5.3)

A focus on perceptions and feelings has been criticized. For some, the approach acquired the nicknames of "there, there policing" or "big hug policing" (Millie and Herrington 2004: 4). For others, it was little more than a public relations exercise and a re-branding of earlier attempts at community policing. According to FitzGerald et al. (2002), giving the impression that the public are safer without also tackling crime rates is hard to justify:

> If reassurance policing yields reductions in crime and disorder as well as reassurance, it is hard to see how it differs from effective policing. If it *doesn't* yield these reductions, the case for it needs scrutiny. It is difficult to justify devoting limited police resources to policing activity that serves only to give people the *impression* they are safer from crime (FitzGerald et al. 2002: 132, emphasis in original).

The UK Home Office embraced the idea of reassurance policing and commissioned a study, "to identify ways to free-up officers' time" in order to perform reassurance policing (PA Consulting 2001: v). According to the PA Consulting report, reassurance policing was defined as:

> . . . any sectoral policing activity that is visible within the community. It is the visibility of the policing effort that provides the reassurance. Hence, reassurance policing includes patrols – either directed or uncommitted, mobile or on foot – as well as visible policing of incidents. Reassurance policing is designed to address not only crime, but the fear of crime (PA Consulting 2001: 1).

PA Consulting extended the definition from Bahn's visible patrols to *any* form of policing that is visible to the public. The emphasis was on visibility as a means to address fear of crime. At the same time, a report by Her Majesty's Inspectorate of Constabulary (HMIC) investigated "the role of police visibility and accessibility in public reassurance" (Povey 2001). For the HMIC report (Povey 2001: 20) reassurance was defined as "the extent to which individuals perceive that order and security exist within their local environment." While PA Consulting focused on visibility, the HMIC report broadened this to "visibility, accessibility, and familiarity" (Povey 2001):

- "Visibility: the level, profile and impact of police resources deployed within local communities.
- Accessibility: the ease with which the public can obtain appropriate police information, access services or make contact with staff.
- Familiarity: the extent to which police personnel know, and are known by, local communities." (Povey 2001: 23–24).

Taking the different definitions together reassurance is a subjective state influenced by perceptions/sense of order and security, and by fear of crime. The job of reassurance policing is to address these subjective feelings through increased police visibility, accessibility, and familiarity. Put simply, according to Innes (2007: 135), the police are assumed to have "an important role to play not just in making people safe but in making them feel safer also."

Key to this is the semiotic quality of police-public encounters, whether this is while on patrol, when an incident is reported, through calls for service or any other mediated communication. Semiotics is an approach that attempts to understand the communicative quality or sign-value of things. Policing communicates different messages to different publics and this may be intimidation and suppression, or more positively, efficiency and reassurance. What the police communicate will be influenced by reputation, levels of trust and respect, experience of police-public encounters, and visual cues such as the uniform, police car, or even station architecture and design (Millie 2010, 2012). Also of relevance here is symbolic interaction. For instance, drawing on Goffman (1959/1990) Innes posits that, "the reassurance function of policing recognises and seeks to harness the dramaturgical power of formal social control" (Innes 2007: 133). In effect, the police officer's role is a *performance* of control and reassurance.

The Signal Crimes Perspective

In Britain, the communicative qualities of policing were the focus of the "signal crimes" perspective developed by a team from Surrey University, led by Martin Innes and Nigel Fielding (e.g., Innes and Fielding 2002). Alongside the influence of Bahn's work on police reassurance, the signal crimes perspective was informed by psychological research into risk perception, especially that of Paul Slovic (1992). According to Slovic, risk can be amplified by a combination of "psychological, social, cultural, and political factors" (1992: 124). Slovic contended that each risk-related event holds a "signal value," reflecting "the perception that the event provides new information about the likelihood of similar or more destructive future mishaps" (1992: 124). For the signal crimes perspective, this idea was transferred to criminogenic risks. According to Innes and Fielding (2002: 3.6):

> . . . public understanding of the seriousness of a risk is not defined solely by the characteristics of the event itself. Rather, it is the nature of the risk, it's semiotic properties, together with the context in which it occurs, that shapes how it is interpreted and understood.

From this perspective, it is not the seriousness of an event (however that is measured), but the signal value of an event that has the biggest effect. This will be influenced by a range of factors including, for example, perception of seriousness and impact on individual or neighborhood, frequency, time and location of event, behavioral expectations, and media coverage. Innes and Fielding went on to state that "the most important incidents in shaping popular fear and anxiety may not necessarily be only those that are traditionally defined by juridical discourses as serious crimes" (2002: 3.6). In fact, they concluded, it could be "relatively trivial" disorders, incivilities, or antisocial behaviors in one situation, but serious crimes in another that have the greatest signal value. According to Innes and Fielding (2002: 5.2):

> A signal crime/event can be defined as an incident that is disproportionately influential in terms of causing a person or persons to perceive themselves to be at risk in some sense.

The signal crime has disproportionate effect on perceptions of security, it is a warning that something is perceived to be wrong with a neighborhood or with society in general. By focusing police attention on whatever is identified as the signal crime(s) for a particular neighborhood, the hope is that there will be bigger gains in improving feelings of security and reassurance. For the police to adopt a signal crimes approach, they need to consult various publics and identify which crimes or disorders act as "signals" in particular neighborhoods. There can be strong and weak signals and not everyone will interpret the signals the same way, or the same in different spatial-temporal contexts; for instance:

> What for young people is merely part of their normal routine and lifestyle (i.e. hanging around on street corners during the evening), may be construed by older residents as signals that they should not go out at night, in order to avoid threats to their safety. (Innes and Fielding 2002: 5.10).

There is a risk that certain "usual suspects" may be unjustly perceived as signals of disorder, for instance, including young people who congregate, the street homeless, or other minority and marginalized populations. If police enforcement policy is informed by a signal crimes perspective, then the disproportionate targeting or "zero tolerance" of those labeled as signals would need to be avoided. A similar criticism has been leveled at the "broken windows" perspective of Wilson and Kelling (1982); in fact, "broken windows" and "signal crimes" have a lot in common. For the broken windows perspective, disorder is "read" as an indicator of decline, causing people to withdraw from disorderly areas leading to a decline in informal social control, thus making crime more likely. In effect, disorder is thought to cause crime to occur. However – drawing on Sampson and Raudenbush (1999) – Innes and Fielding contend that disorder does not lead to crime, but that crime and disorder are functionally equivalent: "Thus disorder is part and parcel of crime itself. Graffiti does not cause robbery, but a lack of informal social control is a cause of both" (Innes and Fielding 2002: 4.3). Alongside certain crimes, disorders, or people having a "signal value," Innes and colleagues posited that the police can act as "control signals," especially through visible patrol. This is supported by the informal social control enacted by active communities.

According to Innes (2004), "reassurance" is a style of policing that can deliver enhanced security and is not in itself an outcome. For Innes (2004), reassurance policing consists of these three parts:

- "high visibility patrols performed by officers who are known to the local public;
- the targeting of 'signal crimes' and 'signal disorders'; and
- informal social control performed by communities" (Innes 2004: 151).

The British National Reassurance Policing Project (NRPP)

From 2002 to 2003, a strategy trial of reassurance policing was run by Surrey Police and the Metropolitan Police in association with the Association of Chief Police Officers (ACPO) and the Home Office. The business case for the strategy trial had five elements:

- *Public confidence* in police choices and solutions through identifying "signal" concerns through public consultation
- *Visible control* – public reassurance by seeing visible proof that their problems are important to the police and are being controlled
- *A targeted, intelligence-led approach* focusing resources on community signals through problem solving
- *Joint action* from the police and other partner agencies
- *Dedicated resources* as much as is practicable (Millie and Herrington 2005)

A range of methods were utilized in order to identify which crimes and disorders acted as "signals" (Innes et al. 2009). In the first instance, drawing on the work of Sampson and Raudenbush (1999) and others, a visual/environmental audit was conducted of a neighborhood to identify potential "signal crimes" and "control signals." Secondly, drawing in particular on the Chicago Alternative Policing Strategy (Skogan and Hartnett 1997), local people were consulted on what were perceived to be signals. This was through the use of public perception surveys and community consultation groups. The Surrey University team also interviewed individual residents using maps to guide responses (Innes et al. 2009).

The full National Reassurance Policing Project (NRPP) was launched in 2003 and operated until 2005 in 16 sites located across eight force areas. The eight forces were Greater Manchester Police, Lancashire Police, Leicestershire Police, Metropolitan Police, Merseyside Police, Surrey Police, Thames Valley Police, and West Midlands Police. The program was evaluated by the Home Office (Tuffin et al. 2006). According to the Home Office evaluation, the NRPP aimed to achieve:

- "Reduced anti-social behaviour and improved quality of life;
- Reduced fear of crime and improved sense of safety;
- Increased public satisfaction with, and confidence in, the police; and,
- Improved social capacity" (Tuffin et al. 2006: xi).

This was an ambitious list. In fact, on the ground, reassurance policing was interpreted as having other additional objectives (Millie and Herrington 2005). For instance, the approach was regarded as a means of gathering community intelligence. Furthermore, it was thought to provide much needed structure to community policing, to lead to improvements in the local environment, and to reduce overall crime. According to Millie and Herrington (2005: 53), the central focus of reassurance policing needed to be to improve confidence in the police and to provide legitimacy for policing decisions. According to the Home Office evaluation, the aims of the NRPP were to be achieved through:

- "Targeted policing activity and problem-solving to tackle crimes and disorder which matter in neighbourhoods;
- Community involvement in the process of identifying priorities and taking action to tackle them; and
- The presence of visible, accessible and locally known authority figures in neighbourhoods, in particular police officers and police community support officers" (Tuffin et al. 2006: xii).

The involvement of communities in identifying policing priorities can be regarded as part of broader "localism" agendas. According to the Home Office evaluation, after program implementation, more people thought crime had decreased, there were positive effects on public satisfaction with the police, and positive effects on perceptions of antisocial behavior and of feelings of safety (but not on fear of crime). Furthermore, there were improvements in levels of police visibility and familiarity and in public engagement. That said, public attendance at meetings was no greater in trail sites than it was in control sites (Tuffin et al. 2006). It was suggested that public consultation should extend beyond standard public meetings to include "street briefings, door knocking and 'have a say days'" (Tuffin et al. 2006: xvi), and when extra effort was put into public engagement, this was noticed by the public. The conclusion of the evaluation was as follows:

> The research did not provide a test of the 'signal crimes' perspective, developed by Martin Innes, but does suggest that a policing approach which targets public priorities can have a positive impact both on crime and on public perceptions. . . . The limited improvements in worry and social capacity indicators suggest the need for further survey work to examine future change in the sites. (Tuffin et al. 2006: 95).

By 2004, policing policy was already moving forward with, in the Metropolitan Police, the emergence of a Safer Neighbourhoods Programme (Herrington and Millie 2006). This evolved into a national Neighbourhood Policing Programme (Innes 2005) and by 2008, Neighbourhood Policing Teams were allocated across all of England and Wales (Millie 2010). Key elements of reassurance policing survived in this new format.

In Britain, policing policy is very much tied in with national politics and in 2010, a new Conservative-led coalition government came into power. The financial crisis led to a decision to cut public sector finance – including a 20 % cut in central government funding of policing (Millie and Bullock 2012). It was not certain how reassurance/neighborhood policing would survive and in what form. That said, the coalition emphasized localism with the first democratically elected Police and Crime Commissioners in Britain introduced in November 2012. Reassurance policing's emphasis on community involvement could be attractive to the newly elected Commissioners.

Issues and Controversies

The Home Office evaluation of Reassurance Policing was broadly positive regarding the approach's effectiveness. The approach may not have had much of an impact on fear of crime or on social capacity, yet the improvements in perceptions of crime and antisocial behavior and public attitudes toward the police were not insignificant. Yet there are potential issues and controversies with the approach, which are outlined here.

Just Another Form of Community Policing

Firstly, there was always a risk that reassurance policing would be viewed as "just another project" or the same as community policing but under a different banner (Herrington and Millie 2006). While some of those involved in the NRPP thought it was the same as before, others saw it as something much more. For one officer involved in the strategy trial, the approach needed to be a "golden thread" running through all policing (Millie and Herrington 2005: 54) and not just a consideration for those involved directly in the project. There is a danger that if reassurance is restricted to a particular project, then those not involved could ruin any advances made by "loose talk" or "loose action." For instance, this could be by disproportionate targeting of "usual suspect" minority populations; or it could be the removal of police identification numbers during public protest, as has occurred in Britain (Millie 2010). If reassurance is a "golden thread" through all policing, then such activities would be questioned.

Reassurance and Visibility

A further focus for reassurance policing is improved police visibility. An original intention for reassurance policing, as outlined by Bahn (1974), was for officers to be a fixed point of reference on the street. This part of Bahn's approach was not incorporated into the NRPP; however, there is scope for improved visible (and fixed point) reassurance through the effective use of police stations and neighborhood bases in a similar fashion to the Japanese system of *koban* (Millie 2010).

Popular politics frequently call for more police officers on the beat, irrespective of their seemingly low effectiveness in reducing crime, as famously demonstrated by the Kansas City experiment. Instead, the police are there to be seen so as to improve people's *feelings* of security. According to Loader (2006: 207), there is a "self-propelling circle whereby popular demands, and the numbers of police supplied in a bid to meet them, are both endlessly ratcheted up." There are clear resource implications of highly visible policing. At a time of fiscal restraint, the deployment of large numbers of locally based officers, with a remit to be highly visible, becomes less of an option.

Reassurance Policing as Democratic Policing

A central focus for reassurance policing is that neighborhood priorities are identified by the community. There is a risk that such locally identified priorities will be in conflict with force or national policing objectives. Furthermore, there is an assumption that all neighborhoods want police intervention (some may prefer the police to go away).

Yet, on the surface, the approach is a commendable example of democratic policing. Legitimacy in policing decisions is maximized as decisions are made by "the community" rather than being dictated by police or government hierarchy. However, there is a potential problem that those consulted may not represent all the multiple communities that live in a neighborhood. Furthermore, they may constitute the "worried well," rather than a group with experience of victimization (Millie 2010). In such cases, the "signal crimes" identified will be based on perception more than actual crime and antisocial behavior (Crawford 2007). The involvement of "hard to reach" or less visible or vocal groups is notoriously difficult (e.g., Skogan and Hartnett 1997). And, as already noted, there is a danger that "usual suspects" – such as young people, street homeless, or other minority and marginalized populations – will become labeled as "signals" and disproportionately policed. According to Loader (2006), if those consulted have expectations for "total security" that cannot be met, then even they may not be reassured. Furthermore, there is a danger that those consulted may suffer consultation fatigue and the police will just assume they know what is required, as Herrington and Millie (2006: 159) have observed:

> . . . we were frequently told that the police knew what the concerns were, the public were tired of being consulted and just wanted something done. This may turn out to be the case, but effective and inclusive consultation is essential if policing is to avoid a "ready, fire, then aim" criticism that is often levelled at them when adopting new initiatives.

Conclusions

The idea of "reassurance policing" was first considered in the USA through the work of psychologist Charles Bahn (1974). However, it was not until the early 2000s in Britain that it was taken forward by Martin Innes and colleagues with the development of the signal crime perspective. A theoretically informed method was developed for delivering a reassurance approach to policing and reassurance policing became a major strand of British policing policy. The approach has also had wider international impact. For instance, reassurance policing has also been considered for policing in Australia, Belgium, the Netherlands, and Sweden.

The evaluation of the NRPP in Britain was largely positive, that reassurance policing has the potential to provide an approach that can improve confidence in the police and improve perceptions of crime and antisocial behavior. There are however obstacles that would need to be negotiated in order to maximize effectiveness:

- Firstly, reassurance would need to be integral to all policing activity, from call handling through to public order policing. Reassurance would be most effective as a consideration for all officers, rather than as a bolt-on extra and only a concern for a smaller number of "community" or "reassurance" officers.
- Secondly, the assumption that more and more visible officers are always better would need to be questioned, especially at a time of fiscal restraint. Other forms of improved visibility could be investigated, such as improved use of police stations and neighborhood bases/shop front offices.
- Thirdly the democratic potential of reassurance policing would need to be taken seriously – that consultation does not focus on the "worried well," but instead the views and experiences of those who have been victimized or have been the targets of police action are actively sought. To be truly inclusive and reassuring to all community members, consultation would need to include young people, the homeless, and other minority and marginalized groups.

Recent Perspectives on the Regression Discontinuity Design

Richard A. Berk
Department of Criminology, University of Pennsylvania, Philadelphia, PA, USA

Overview

The regression discontinuity design was originally proposed in 1960 as a powerful alternative to randomized experiments. It has been little used since. Over the past decade, however, the design has been increasingly and successfully employed by economists in a variety of studies. In this entry, the fundamentals of the regression discontinuity are discussed. Recent advances are emphasized.

Introduction

The regression discontinuity design has a long and complex history. It was originally proposed by psychologists Thistlewaite and Campell in 1960 as an alternative to randomized experiments (Thistlewaite and Campbell 1960). The design became widely known with the publication of the justly famous *Experimental and Quasi-Experimental Designs for Research* by Campbell and Stanley (1963). In 1972, the design was independently rediscovered by econometrician Arthur Goldberger (1972) using a linear regression framework. A bit later, Rubin (1977) provided a formal justification for the regression discontinuity design within a more general conceptualization. That paper is still a very good read. Still later, Trochim (1984, 2001) suggested a range of extensions.

Even in these early formulations, the design was simple and powerful. But there were few applications and apparently only four published studies with significant crime and justice content (Berk and Rauma 1983; Berk and de Leeuw 1999; Chen and Shapiro 2007; Berk et al. 2010a). Over the past 15 years, a number of economists and political scientists have extended the design (Imbens and Lemieux 2008b; Imbens and Kalyanaraman 2009; Green et al. 2009) and applied it in a wide variety of settings (Imbens and Lemieux 2008a; Lee and Lemieux 2009; McCrary 2008; Butler 2009; Caughey and Sekhon 2011). An account of how and why interest in the regression discontinuity design has varied over the years can be found in recent paper by Thomas Cook (2008).

In this entry, the fundamentals of the regression discontinuity design are considered. Some recent advances are highlighted. The discussion begins with a brief introduction to the ways in which statisticians think about causal inference. Then, the classic regression discontinuity design is examined. Newer material follows.

The Fundamental Features of a Regression Discontinuity Design

In early expositions of the regression discontinuity design, there were clear links to conventional regression analysis. The name for the design is no accident. But, reliance on a regression analysis framework is formally unnecessary and can add a statistical layer that confuses matters. We turn, therefore, to a broader nonparametric perspective that at a conceptual level at least is less complicated. In so doing, we are reversing the usual order of didactic treatments. Usually, the historical chronology is employed: parametric linear regression followed by nonparametric approaches.

Imagine an evaluation of probation supervision that compared regular face-to-face meetings between probation officers and probationers with a kiosk check-in system. For the latter, probationers report to a kiosk with a touch computer screen through which they update background information (e.g., address) and enter important changes in their situation (e.g., got a job). A key outcome for the evaluation would be recidivism. Did those individuals assigned to the kiosk system do worse? At this point in the discussion, the outcome could be categorical (e.g., arrested while on probation or not) or quantitative (e.g., the number of failed urine tests).

In the absence of random assignment, agency administrators might decide how to assign probationers to one of the two supervision methods. Suppose they assigned by the risk to public safety. Only low risk probationers would be allowed to satisfy their reporting requirement using the kiosk. Low risk, in turn, would be determined by a threshold on a quantitative measure of risk. Individuals having risk scores below a certain value would be assigned to the kiosk supervision. Individuals with scores at or above that value would be assigned to the usual form of supervision. (See Berk et al. (2010a) for an illustration.)

It would seem that this design builds bias into any estimates a treatment effect. Those assigned to the kiosk already are believed to have a lower risk of recidivism that could falsely make that intervention look more effective than it really was. And this is surely true.

However, suppose the difference in recidivism between the two interventions were measured only for individuals very near and on either side of the risk threshold. For example, assume that the risk score has a probability metric from 0 to 1 with a higher score representing more risk. There is a threshold at .50. Individuals having risk values equal to or less than .50 are placed in the kiosk condition. Those with risk values greater than .50 are placed in the face-to-face condition. But – and this is a key point – the analysis is limited to individuals with risk values between .48 and .52. Given the current state of probation risk assessments, the difference in risk between a probationer with a score of .48 and a score of .52 is likely to be very small and most likely indistinguishable from noise.

In short, one has a near approximation to random assignment for individuals very close to the risk assessment threshold score. Assignment is determined by values that can be much like the product of a random number generator. Insofar as this is really true, differences on either side of the threshold in the average outcome can provide an effectively unbiased estimate of a "local" treatment effect. It is local because the estimate only formally applies to individuals with risk scores between .48 and .52, not to the full range of risk scores. Much of the recent technical work on the regression discontinuity design examines how best to obtain such estimates and what the formal properties of such estimates might be.

One potential weakness with the approach is that there can be relatively few cases close to and on either side of the threshold. With a small sample size, the treatment effect estimate may not be sufficiently precise. Another potential weakness is that an estimated treatment effect only formally applies to probationers close to the threshold. Who is to say whether the estimate applies to probationers far from the threshold? And yet, those probationers may be an important and large subset of the relevant population.

For there and other reasons, it can be important to consider treatment effect estimators that use a much large fraction of the observations and ideally all of them. This is where the links to conventional regression analysis can sometimes be exploited. We turn to those now and begin with the way in which the regression discontinuity design was initially introduced by Donald Campbell and Julian Stanley in the early 1960s.

Basic Regression Discontinuity Design: The Linear Regression Overlay

As already noted, the regression discontinuity (RD) design can have many of the assets of a randomized experiment, but can be used when random assignment is not feasible. Typically, the goal is to estimate the causal effect of an intervention such as gate money for prison inmates, anger management for troubled teens, or changes in police patrolling practices. In the simplest case, there is an experimental and comparison group with assignment fully determined by an explicit and observable rule. For example, whether community policing is introduced in a neighborhood depends on whether the crime rate is above a specific threshold. Neighborhoods falling above that threshold get community policing. Other neighborhoods get business as usual. A relatively simple and compelling analysis can follow. In some circles, the RD design is called a "quasi-experiment."

One appeal of the RD design is "political." If the assignment rule represents need, either empirically or morally, one can sometimes more easily garner the support of stakeholders. Cooperation from study subjects can also more easily follow. For example, it might seem to just make good sense to assign a policing innovation to high-crime neighborhoods. The technical complication is that neighborhoods assigned to the treatment condition will not be comparable on the average to neighborhoods assigned to the alternative. Indeed, systematic selection is explicitly built into the design. How the potential biases can be overcome in practice is a key theme in the material that follows.

To best appreciate the underlying machinery of the RD design requires some familiarity with the way causal inference has come to be formulated by most statisticians. The framework was proposed by Neyman in 1923 and later extended by Rubin (1974) and Holland (1986). These days, it is sometimes called the "Rubin Causal Model." Be clear that the Rubin Causal Model allows one to rigorously *define* a causal effect. It is a conceptual apparatus. Data play no role. It is not a causal model for how nature generated the data on hand. The "Rubin Causal Model" would perhaps be better called the "Rubin Causal Framework."

In its most simple form, there are observational units: people, neighborhood, police departments, prisons, or other entities. There is a binary intervention. Some of the units are exposed to the experimental "arm" of the study, and the other units are exposed to the comparison "arm" of the study. There is interest in estimating a causal effect. For example, one might want to learn how intensive probation supervision, compared to conventional probation supervision, affects recidivism.

Each *unit* is assumed to have two *potential* outcomes, one if exposed to the experimental condition and one if exposed to the comparison condition. These outcomes are *hypothetical* and can vary across units. Thus, a given probationer would have one response if placed under kiosk supervision and another response if placed under the usual supervision. Another probationer would also have two potential responses, which could differ from those of the first probationer. For now, assume that the outcome is quantitative and of a form suitable for conventional linear regression. To take a very different example, if the study units were census tracts and the interventions were two different methods of policing, the outcome might be the crime rate for part I crimes.

Following Imbens and Lemieux (2008b), let $Y_i(1)$ denote the potential outcome if unit i is exposed to experimental condition and $Y_i(0)$ denote the potential outcome if unit i is exposed to the comparison condition. Interest centers on a comparison between $Y_i(1)$ and $Y_i(0)$, often their difference. Thus, the difference between $Y_i(1)$ and $Y_i(0)$ can *define* a causal effect. An example is the number of failed urine tests should a given probationer be placed under the usual supervision minus the number of failed unit tests should that same probationer be placed under kiosk supervision.

In practice, however, one can never observe both $Y_i(1)$ and $Y_i(0)$. A given unit will only experience the experimental condition or the comparison condition. Let $W_i = 1$ if unit i is actually exposed to the experimental condition and $W_i = 0$ if unit i is actually exposed to the comparison condition. The *observed* outcome is then

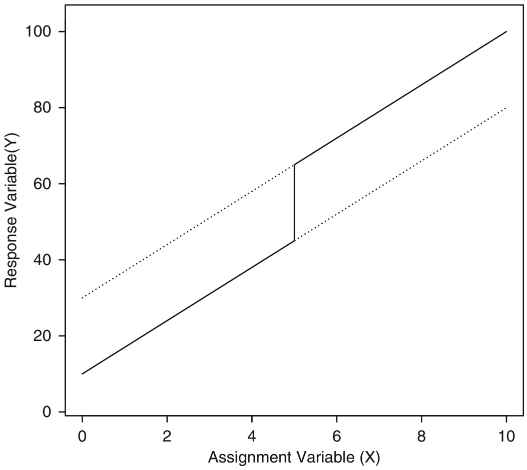
$$Y_i = (1 - W_i) \cdot Y_i(0) + W_i \cdot Y_i(1). \qquad (1)$$

Both Y_i and W_i can be observed. For the basic RD design, one also has a single observed covariate X_i that fully determines whether unit i is exposed to the experimental condition or the comparison condition. In the simplest case, X_i is a continuous covariate with an imposed threshold. A unit that falls on one side of the threshold or right on it is assigned to the experimental condition. A unit that falls on other side of the threshold is assigned to the comparison condition (or vice versa).

X can be associated with the potential outcomes. As in our earlier illustration, X may be a measure of probation risk. A probationer who scores above some threshold is assigned to supervision as usual. If that probationer scores at or below the threshold, assignment is to kiosk supervision. The risk measure is by design associated with the potential outcome of re-offending.

There can be other observed covariates Z. In some cases, they are used to define a multivariate assignment rule. For example, probationers who are younger than 21 and who have more than two prior convictions for a violent crime may be assigned to intensive supervision. In other cases, the Z plays no role in the assignment, but is related to the potential outcomes. For now, there is no need to consider either complication.

Because by definition a causal effect, $[Y_i(1)-Y_i(0)]$, is unobservable in practice, there is a shift to the group level. (The same applies if the ratio rather than the difference is used.) Interest centers on the observed *average* response of the units exposed to the experiential condition compared to the observed *average* response of the units exposed to the comparison condition. We are seeking the average treatment effect. Given the assignment rule, however, there is the possibility that the units exposed to the experimental condition will differ systematically from the units exposed to the comparison condition. And those systematic differences can be related to the potential outcomes. There is the risk of building in selection bias.



Recent Perspectives on the Regression Discontinuity Design, Fig. 1 Conventional linear case

Under certain assumptions, there is a regression-based solution. Consider Fig. 1. On the horizontal axis is the assignment variable X. On the vertical axis is a quantitative response (outcome) variable Y. Units scoring above 5 on X are exposed to the experimental condition. Units scoring at or below 5 on X are exposed to the control condition.

The higher line (dotted below the threshold of 5 and solid on or above the threshold of 5) represents the potential response for different values of the assignment variable when a unit is exposed to the experimental condition. The lower line (solid below the threshold of 5 and dotted on or above the threshold of 5) represents the potential response for different values of the assignment variable when a unit is exposed to the comparison condition. The solid parts of each response function represent the potential responses actually observed under the assignment rule. The vertical solid line at $X = 5$ represents the causal effect. In this illustration, the average value of the response increases above the threshold. One could have as easily had the average value of the response decrease or show no change at all.

Figure 1 shows the theory required for the basic RD design, and there is a lot going on. For both groups, the relationship between X and Y is positive. The larger the value of X, the larger the value of Y tends to be. If one just compared the observed mean of the group receiving the experimental condition (i.e., with $X > 5$) with the observed mean of the group receiving the comparison condition (i.e., with $X < 5$), as one might do in a randomized experiment, an estimate of the average treatment effect could be substantially biased. In this illustration, the group exposed to the experimental condition has by design larger values for X, which implies larger values of Y regardless of the intervention. Analogous results follow if the relationship between X and Y is negative.

However, note that the relationship between the assignment variable and the response variable is for both groups assumed to be linear. This is true for potential responses that are observed (i.e., the solid lines) and potential responses that are not observed (i.e., the dotted lines). The linearity is very restrictive but very convenient. Note also that the linear relationships are assumed to be parallel. This too is very restrictive but very convenient. One has a strong two-part theory about how the assignment variable is related to the response: the two response functions can differ only by a constant. That constant is the treatment effect.

If the relationships shown in Fig. 1 are a good approximation of reality, a very simple and effective analysis can follow. The difference between the vertical placement of the linear relationship for the units exposed to the experimental condition and the vertical placement of the linear relationship for the units exposed to the comparison condition can provide an estimate the average treatment effect.

More specifically, let

$$Y_i = \beta_0 + \beta_1 W_i + \beta_2 X_i + \varepsilon_i. \qquad (2)$$

Equation 2 is a conventional regression expression representing how the values of the response variable are generated. All of the observables are defined as before, and ε_i is the usual regression disturbance. When $W_i = 0$, the conditional expectation of Eq. 2 gives the linear relationship between X and Y for the group exposed to the comparison condition. When $W_i = 1$, the conditional expectation of

Eq. 2 gives the linear relationship between X and Y for the group exposed to the experimental condition. β_2 is the common slope of the two response functions. β_0 is the intercept of the response function for the group exposed to the comparison condition. β_1 is the vertical distance between the two estimated response functions, which quantifies how much the response function for the experimental group is shifted up (i.e., $\beta_1 > 0$) or down (i.e., $\beta_1 < 0$) because of the experimental condition. In Fig. 1, the length of the vertical line at $X = 5$ is equal to the value of β_1. If the experimental intervention has no effect, $\beta_1 = 0$, and the two lines collapse into one.

It is important to appreciate that Eq. 2 is *not* a causal model. Although the intent is to estimate an average treatment effect, no claims are made that the two regressors can account for all of the systematic variation in the response or that if the assignment variable is manipulated; β_2 shows how the response will be altered. Equation 2 is no more than a method to estimate the average treatment effect. It is rather like the difference between the mean of the experimental group and the mean of the control group in a randomized experiment. There is no causal model there either. But random assignment insures that on the average, all omitted predictors are unrelated to the intervention.

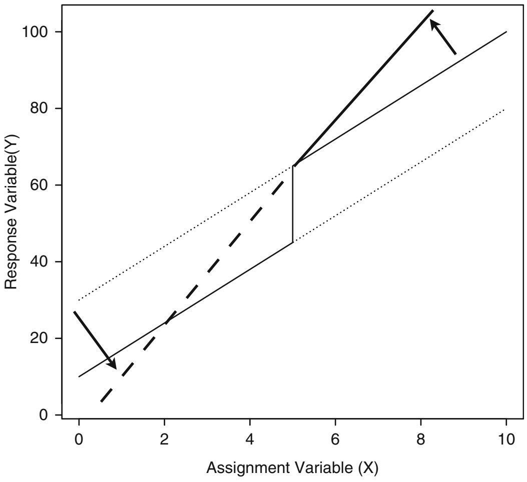
There is an analogous condition for the regression discontinuity design resting on a key assumption: conditional on assignment variable, $E(\varepsilon_i) = 0$. Conditional on the assignment variable, nature conducts the equivalent of a randomized experiment. This can be a credible formulation if assignment to the treatment or comparison condition is solely by the assignment variable threshold and the linear model is correct (Rubin 1977).

In practice, one can use the data on hand and ordinary least squares to estimate the parameters of Eq. 2. Consistent with the design's assumptions, if the two linear relationships are at least nearly linear and parallel, $\hat{\beta}_1$ is an effectively unbiased estimate of the average treatment effect. Likewise, a key to proper estimation is that the true selection mechanism is known and can be accurately represented by a threshold on X. The usual hypothesis test is that $\beta_1 = 0$; there is no treatment effect.

An obvious question is how one would determine in practice whether the two relationships are linear and parallel. A good way to start is to construct a scatterplot of Y against X. On each side of the threshold, one should see a truncated version of the idealized elliptical scatterplot. If there is a treatment effect, the plotted points should be shifted up or down in the region to the right of the threshold (where the units are exposed to the experimental condition). An example is discussed later.

A useful second step is to examine a scatterplot constructed from the residuals and fitted values of Eq. 2. When the residuals are plotted against the fitted values, one should see with no dramatic patterns. In particular, there should be no evidence that the assumed linear and parallel regression response functions are something else. It can also be useful to consider whether the usual assumption of a constant residual variance is credible. In short, one should examine the results from Eq. 2 as one would examine the results from any regression analysis. Graphical methods can be especially instructive and are less constrained by the untestable assumptions that test-based diagnostic methods require (Freedman 2008). An excellent discussion of a number of useful diagnostic methods can be found in the text by Cook and Weisberg (1999).

What can go wrong if proper diagnostic methods are not employed? Figure 2 provides a simple illustration. The two response functions for the potential outcomes are not parallel. The response function for the experimental group is much steeper. (The solid part of the line is observed and the dashed part of the line is unobserved.) In this particularly perverse example, the gap at the threshold between the observed outcomes for the group exposed to the experimental condition and the observed outcomes for the group exposed to the comparison condition just happens to be the same as the treatment effect when the assumption of parallel response functions is met. But this gap is not caused by a discontinuity. There is no evidence of a treatment effect.



Recent Perspectives on the Regression Discontinuity Design, Fig. 2 The conventional linear case gone wrong

It is certainly possible to alter Eq. 2 allowing for linear response functions that are not parallel. Looking again at Fig. 2, however, one would have to know about the nonparallel response functions in advance. One cannot determine from the data alone whether the response functions are not parallel or whether the intervention altered the slope and intercept of the treatment group.

This can lead to an identification problem. Suppose one was prepared to bet that the two response functions were linear but not parallel. Then, β_1 combines the intercept of the response function for the experimental group in the absence of the experimental intervention with a new intercept for the experimental group should the intervention shift that group's response function. Because there are no observations for the experimental group in the absence of the experimental intervention, the confounding cannot be disentangled, and the basic regression discontinuity design fails.

Suppose that one was prepared to assume that the two response functions are linear and parallel before the intervention but that after the intervention, the slope and intercept are altered. By including the product variable ($W_i \times X_i$) as new regressor in the Eq. 2, the intervention-altered linear relationship for those exposed to the experimental condition can be identified, and the linear relationship for those exposed to the comparison alternative can be identified. One has specified an interaction effect between W_i and X_i for certain values of X_i.

But there is an important complication. The size of the gap between the response function of the experimental group and the response function of the comparison group depends on the value of X. Indeed, the treatment effect may be positive for some values of X and negative for other values of X. Although this is statistically acceptable, constructing a coherent substantive explanation can be challenging. One simplification is to focus only on the estimated average treatment effect in the immediate neighborhood of the threshold although, as already mentioned, important external validity questions can be raised. The estimate only applies to cases in the neighborhood of the threshold. Nevertheless, this is an approach to which we return shortly.

There is nothing in the RD design precluding other kinds of interaction effects that are more easily interpreted. One can subset the data by values of covariates Z_i and consider whether there are different average treatment effects. Or one can respecify Eq. 2 so that interaction effects are represented. For example, an intervention may be more effective for women than for men. One way to explore this would be to do one RD analysis for men and another RD analysis for women. Alterations in Eq. 2 would depend on the precise form the interaction effect takes. For instance, one might include a binary variable for gender and the product of the intervention variable and gender. That would allow for different intercepts and different average treatment effects for men and women.

Some of the lessons from the linear case carry over to the nonlinear case. If the two response functions are nonlinear but parallel, one can in principle estimate a shift resulting from an intervention. However, it is not necessarily clear what a change in slope means if the response functions are not linear. The nonlinear case is discussed a more later.

The Generalized Regression Discontinuity Design

One problem with the basic RD design is that the response is assumed to be quantitative. In many applications, the response is categorical or a count. An example of the former is whether a probationer reoffends. An example of the latter is the number of crimes the probationer commits.

The basic RD design is easily extended to include formulations from the generalized linear model. Logistic regression and Poisson regression are two common illustrations. Consider, for instance, a binary response.

We can proceed initially as before. Equation 3 is the same as Eq. 2 except that the quantitative response Y_i* is now completely unobserved regardless of whether a unit falls above or below the threshold. For example, Y_i* may be the proclivity of a prison inmate to engage in some form of serious misconduct, and no measures of this proclivity are available. As before, we let

$$Y_i^* = \beta_0 + \beta_1 W_i + \beta_2 X_i + \varepsilon_i. \tag{3}$$

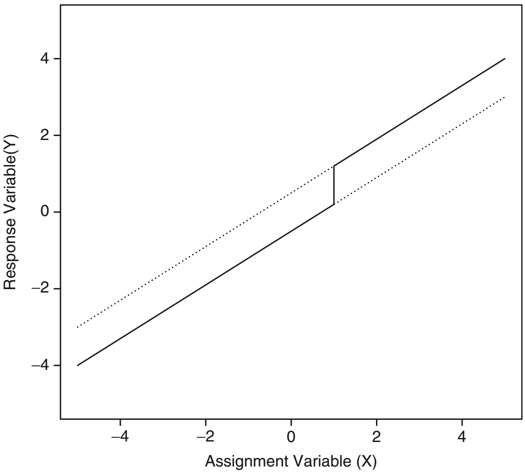
We now hypothesize a second kind of threshold. If an inmate's proclivity toward misconduct exceeds a certain value, an act of misconduct is observed.

If that threshold is not exceeded, no act of misconduct is observed. Suppose this outcome is coded so that "1" denotes an observed act of misconduct and "0" denotes no observed act of misconduct.

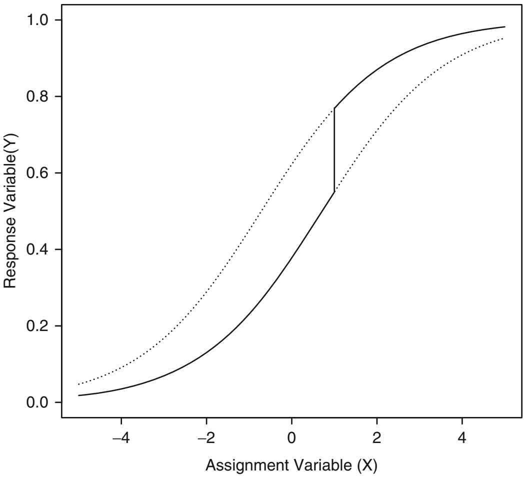
Drawing on a common motivation for logistic regression (Cameron and Trivedi 2005, Section 14.4), the probability P_i of observing a "1" depends on the probability that Y_i* will exceed the misconduct proclivity threshold. If one then assumes that ε_i has a logistic distribution, Eq. 4 can follow directly:

$$\log \frac{P_i}{1 - P_i} = \gamma_0 + \gamma_1 W_i + \gamma_2 X_i, \tag{4}$$

where γ_0 through γ_2 are new regression coefficients. In other words, the systematic part of the formulation is the same as in Eq. 2, but the response is now in units of log-odds (also called "logits"). Figure 3, therefore, is analogous to Fig. 1.



Recent Perspectives on the Regression Discontinuity Design, Fig. 3 The log-odds representation of the logistic case



Recent Perspectives on the Regression Discontinuity Design, Fig. 4 The generalized linear case

If Eq. 4 is solved for P_i, the result is shown in Fig. 4. Note that in Fig. 3, when the response is in logit units, the two response functions are linear and parallel. But when in Fig. 4 the response is in probability units, the two response functions are neither linear nor parallel. This is not a problem as long as, consistent with Eq. 4, the estimated treatment effect is reported in logit units or as an odds multiplier. If stakeholders want the story told in probability units, however, the complications introduced by nonparallel response functions reappear. The good news is that there is no identification problem. The bad news is that the average treatment effect depends on the value of the assignment variable. In addition, any regression diagnostics should be applied to the log-odds form of the model as well. In the logit metric, there are many graphical diagnostic procedures for logistic regression. Again, a good reference is Cook and Weisberg (1999).

Berk and de Leeuw (1999) provide an instructive application. In their study, the outcome was misconduct in prison. Misconduct could include minor but common infractions such as failing to report for a work assignment or rare but serious infractions that would be felonies if committed on the outside. The assignment covariate was a risk score computed for each inmate at intake that was used to forecast prison misconduct. The intervention was prison housing at the highest level security with the alternative any other housing placement. Placement was determined by a threshold on the risk score; scoring about the threshold led to a high security placement. The empirical question was whether a high security placement reduced prison misconduct. It did, but not dramatically.

Analogous issue arises if the response variable is a count. The canonical mean function is not the log of the odds but the natural logarithm. The generalized RD design still applies and can easily be employed.

Matching Strategies

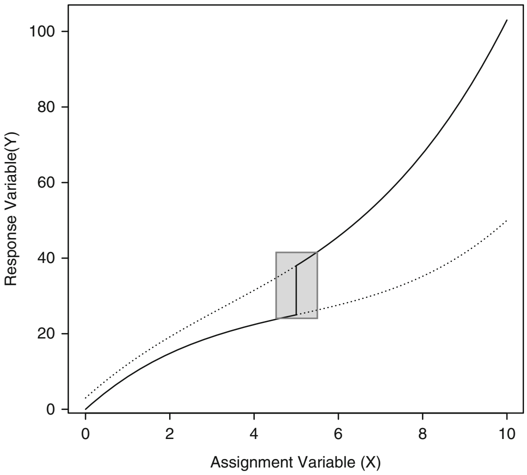
From the issues just discussed, it should be clear that the credibility of the basic and generalized RD design depends on the assumptions one makes about the two response functions linking X to Y. Both designs respond to the same fundamental problem: the observed responses of the group exposed to the treatment and the observed responses of the group exposed to the alternative reside in disjoint regions of the assignment variable. There are no values of X at which one can observe responses for both groups. Therefore, all comparisons necessarily depend on extrapolations, which, in turn, depend on the functional forms assumed.

An alternative strategy introduced earlier is to focus on the observed responses on either side of the threshold and very close to it. If this region, often called a “window,” is sufficiently narrow, the values of X within it are likely to be very similar. Because Y is a function of X, this suggests a matching strategy comparing the average observed response of the units just to the right of the threshold to the average observed response of the units just to the left of the threshold. The difference between the two averages can serve as an estimate of the average treatment effect. The same rationale applies if the response variable is categorical and one is comparing proportions. We now need to consider this approach in more detail.

An important assumption is that the small piece of the response function just to the right of the threshold and the small piece of the response function just to the left of the threshold are linear and parallel to each other. To the degree that this assumption is violated, the size of the possible bias increases. For example, if both are linear and parallel but with a positive or negative slope, the absolute value of the difference between the two averages can be larger than the absolute value of the gap size at the threshold. The hope is that if the window can be made sufficiently narrow, this bias will be negligible. Ideally, therefore, the matching strategy can provide useful estimates of average treatment effects with far less reliance on assumed functional forms over the entire length of the response functions.

Figure 5 illustrates the general idea. The two response functions are neither linear nor parallel. And these would likely be unknown in any case. If within the shaded region the two functions were linear and flat, the difference between the two averages would be the same as the treatment effect at the threshold. In this illustration, the estimated treatment effect would be a bit too large. The gap is larger than had the two functions been linear and flat.

It follows that a critical feature of the window approach is the width of the shaded area (Imbens and Kalyanaraman 2009). How wide should the shaded area be? If the shaded area is more narrow, the true causal effect often can be better



Recent Perspectives on the Regression Discontinuity Design, Fig. 5 Matching within the RD design

approximated. But there will be fewer observations with which to estimate the average treatment effect. With less information, there will be more uncertainty in the estimate. The tension is an example of the well-known bias-variance tradeoff (Hastie and Tibshirani 1990, pp. 40–42). To consider the implications of this tradeoff, we to turn to how one can estimate the average treatment effect. In this context, the terms "bandwidth" or "span" are sometimes used instead of the term "window."

Perhaps the simplest estimator of the average treatment effect within the window is the difference between the mean of the responses to the right of the threshold and mean of the responses to the left of the threshold (Imbens and Lemieux 2009, pp. 623–624). Sometimes, a better approach is to use an explicit kernel function (Hastie and Tibshirani 1990, pp. 18–19), the impact of which can be to weight observations so that those closer to the threshold are given more weight when the means are computed. Values of Y closer to the threshold will often provide more accurate information about the value of Y at the threshold.

Different weighting schemes can be used. For example, when a linear kernel is used, weights decline linearly with distance from the threshold. When a Gaussian kernel is used, the weights decline as a function of the normal distribution centered on the threshold. In practice, all of the common weighting functions that decline with distance from the threshold usually give very similar results. In fact, there is often not much difference between the estimated treatment effect using any of the common weighting functions and the estimated treatment effect using no weighting at all (i.e., all cases get the same weight).

In contrast, the size of the window can have a dramatic effect. Therefore, a criterion is needed that strikes a useful balance between the bias and the variance. A popular theoretical criterion when the response variable is quantitative is the integrated squared prediction error: the mean of the squared disparities between the fitted values $\hat{Y}_i$ and the actual values of Y_i. If a window size could be chosen to minimize the integrated squared prediction error, the sum of the variance and the bias squared will be minimized as well (Hastie et al. 2009, Section 5.5). In this sense, minimizing the integrated squared prediction error provides a good way to define an appropriate balance between the variance and the bias.

Several procedures can be used as an operational stand-in for the theoretical integrated squared prediction error. Cross validation is a useful option and with, modern computers, the calculations can be done very quickly. Other options include the generalized cross-validation statistic, AIC, BIC, and Mallows Cp. Imbens and Kalyanaraman (2009) provide a very interesting advance on this theme. In practice, each of these approaches usually will lead to about the same results, and many work well if the response variable is a count or is categorical. An excellent discussion of the underlying issues can be found in the book by Hastie and his colleagues (2009, Chapter 7).

The comparison between means within the window can be generalized. Suppose that within the window the two unknown response functions are linear, but not necessarily flat or even and parallel. Then, one can often obtain a more accurate estimate of the treatment effect by employing two linear regressions within the window, one on each side of the threshold (Imbens and Lemiux 2009, pp. 624–625). Each is a form of local linear regression. The sole regressor is the distance from the threshold. More specifically, we assume that

$$Y_{iL} = \delta_{0,L} + \delta_{1,L} \cdot (X_{iL} - T) + \varepsilon_{iL}, \qquad (5)$$

and

$$Y_{iR} = \delta_{0,R} + \delta_{1,R} \cdot (X_{iR} - T) + \varepsilon_{iR}, \qquad (6)$$

where within the window, L denotes the left side of the threshold, R denotes the right side of the threshold, T is the value of X at the threshold, X_i is the value of X for given observations, and ε_{iL} and ε_{iR} are conventional regression disturbances. Because $\delta_{1,L} \neq \delta_{1,R}$, the linear response functions do not have the same slope.

At the threshold, $(X_i{-}T) = 0$. Therefore, the average treatment effect at the threshold is $\delta_{0,R} - \delta_{0,L}$. With data for Y and X, one can estimate the values of the parameters from both equations and obtain an estimate of the treatment effect at the threshold by computing the difference between the two intercepts. That is, the estimate of the average treatment effect is $\hat{\delta}_{1,L} - \hat{\delta}_{1,R}$. The same logic can apply for the entire generalized linear model although some of the details will necessarily differ.

Although Eqs. 5 and 6 have much the same structure as Eq. 2, their purpose is rather different. The goal is to estimate the difference between the response functions at the threshold. Therefore, despite the use of regression, the matching logic still prevails. If the regression model is approximately correct, there should be gains by the integrated squared prediction error criterion. In addition, the usual statistical inference undertaken with linear regression can apply although sometimes robust standard errors are desirable (Cameron and Trivedi 2005, Section 4.4.5).

In principle, the regression estimate can be improved upon in two ways. First, one can employ a kernel weighting scheme so that when the regression coefficients are estimated, observations closer to the threshold are given greater weight. In practice, the means squared error gains are usually modest at best. Second, one can assume that $\hat{\delta}_{1,L} = \hat{\delta}_{1,R}$ and reestimate the values of $\hat{\delta}_{0,L}$ and $\hat{\delta}_{0,R}$. In other words, one proceeds as if the two linear response functions are parallel. There can be small but noticeable gains in precision if the equivalence is approximately true. Once again, regression diagnostics can be very instructive.

There can be substantial bias in the estimated average treatment effect at the threshold if regression diagnostics indicate that the response functions are not linear. One possible remedy is to replace the local linear regression with local polynomial regression (Fan and Gijbels 1996) or an even more flexible smoother such as found in the generalized additive model (Hastie and Tibshirani 1990). But, the moment one opens the door to nonparametric regression, there may be no longer a need to stay within the window, and a wide variety of tools are in play. Regression splines and regression smoothers, for instance, can be very effective (Berk 2008a, Chapter 2; Bowman et al. 2004). The task at hand can be reformulated as function estimation problem, with the amount of smoothing replacing the size of the window as a key matter for tuning. The result can be

$$Y_i = \beta_0 + \beta_1 W_i + f(X_i - T) + \varepsilon_i, \qquad (7)$$

where $f(X_i{-}T)$ is determined empirically. Equation 7 is easily extended to the generalized additive model so that binary and count response variables can be analyzed.

One interesting feature of Eq. 7 is that if the fitting procedure for $f\,(X_i{-}T)$ is made sufficiently flexible, there may be no need to include as a regressor. Should there be an important change in the response function in the neighborhood of the threshold, the nonparametric regression procedure is likely to find it. The size of the neighborhood will be determined as well. At the very least, this suggests first using a very flexible nonparametric regression procedure as an exploratory technique to help in the specification of Eq. 7. The risk is that statistical inference can be invalidated (Leeb and Potscher 2006; Berk et al. 2009) and that any findings may be the result of overfitting. Neither problem is unique to the analysis of RD designs, however.

Some Extensions Not Addressed

The RD design may be extended further, but space limitation precludes more than a very brief discussion. One easy and direct extension is to have a deterministic assignment rule constructed from more than one covariate. If there are two such covariates, for example, the threshold is a line, not a point. The various estimation procedures can be altered accordingly. Likewise it is relatively easy to have a proper RD design with more than one intervention, much in the spirit of factorial designs in true experiments.

A more complicated extension addresses the problem of compliance. Just as in randomized experiments, study subjects do not always comply with the treatment or alternative condition assigned. Then, one might be interested in trying to estimate the impact of the intervention assigned (i.e., an "intention-to-treat" analysis) or the impact of the intervention received. The former can be estimated with the procedures we have described. The latter requires more complicated and fragile procedures. A possible approach is using the treatment assigned, conditional on the assignment variable, as an instrumental variable. These and other alternatives are discussed by Imbens and Lemioux (2008b).

External Validity

The results from an RD design raise the same external validity issues as those from a randomized experiment and more. If the study subjects are probability sample from a well-defined population, generalizations to that population can be appropriate. If the study subjects are not selected by probability sampling, generalizations beyond the study subjects must rely on theory or replications. However, any estimates using the matching approach can restrict generalizations further. The relevant units are now only those that fall in the window or for some procedures, only at the threshold. For data that are a proper probability sample, generalizations can now only be to elements in the population that would fall within the window or at the threshold, respectively. When the data are not a proper probability sample, generalizations based on theory or replications must also take these restrictions into account.

In short, the basic and generalized RD designs have the same kinds of external validity constraints as randomized experiments. The external validity constraints can be far more binding if a matching estimation approach is used. The tradeoff is that the matching approach's internal validity may be stronger.

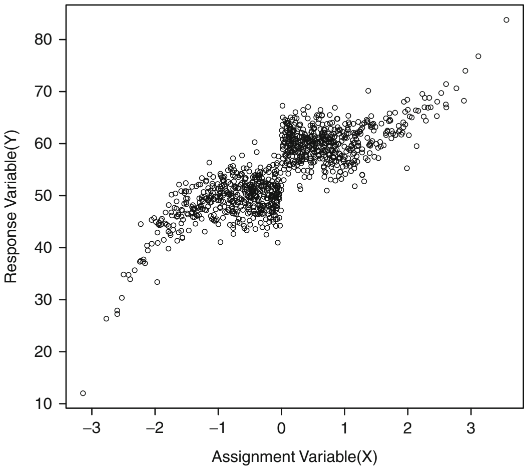
Power

To the degree that the assignment variable is correlated with the treatment indicator, there is, other things equal, a reduction in statistical power. However, other things are not always equal. A possible compensating factor is the strength of the association between the assignment variable and the response. With a larger correlation, there can be an increase in power. It is in practice difficult to determine before the data are collected how strong these two correlations will be. Consequently, conventional power analyses risk being driven very substantially by assumptions that may well prove wrong. The problems are even more serious if one attempts a post hoc power analysis after average treatment effects have been estimated. As a formal matter, post hoc power analyses are difficult to justify (Hoenig and Heisey 2001) and probably should not be taken seriously.

The safest strategy is to work with large samples whenever that is possible (e.g., samples of 500 or more). When the data come from existing datasets or administrative records, the costs of large samples may be no more than the costs of small samples.

An Illustration

We turn now to an illustration. The intent is to provide an overview of how some of the procedures described above can be used in practice.



Recent Perspectives on the Regression Discontinuity Design, Fig. 6 A scatterplot for some fictitious data ($N = 1{,}000$)

Recent Perspectives on the Regression Discontinuity Design, Table 1 Estimates of the RD average treatment effect for fictitious data – true treatment effect = 10.0

Model	Estimate	SE	Fit
Correct model	10.4	.37	.83
Linear model	6.3	.37	.74
Difference in means ($N = 400$)	9.8	.31	.72
Regression splines ($k = 3$)	6.16	.37	.75
Regression splines ($k = 5$)	11.8	.43	.82
Regression splines ($k = 7$)	9.97	.51	.83

Space limitation precludes an in-depth discussion using several different datasets with varying properties.

A good way to begin the analysis of data from any RD design is to examine a scatterplot of the response variable against the assignment variable. Figure 6 is just such a plot for some fictitious data. There are 1,000 observations. The true relationship between X and Y is a fourth degree polynomial. This implies that the relationship on either side of the threshold between the response and the assignment variable is the same. Also by construction, the threshold is at 0.0, and the treatment effect equals 10.0. It is readily apparent that there is a discontinuity at the threshold. For real data, evidence of a treatment effect is usually not so easily discovered.

One would normally not know that the relationship between X and Y was a fourth degree polynomial. But it would likely be empirically apparent that the two response functions were approximately linear and flat over much the range of X, at least where there are data. Except for a few observations at the tails, two linear parallel response functions might seem to be a sufficiently good approximation for the RD analysis.

Table 1 shows some results. Its four columns contain in order the kind of estimator, the average treatment effect estimate, the standard error, and the proportion of the deviance that is accounted for by the estimator. Fit quality was evaluated using the AIC, but the adjusted proportion of deviance accounted for by the model is reported for ease of exposition.

In the first row are the results if the correct relationship between X and Y were known. This is the estimation gold standard. The estimated treatment effect is 10.4, the standard error is .37, and about 83 % of the deviance is accounted for. The estimate is about one standard error from the truth of 10.0. One would not reject the null hypothesis that the treatment effect is 10.0. (The treatment effect estimate is not exactly 10.0 because of random sampling error.)

The second row contains the results if the basic RD design is assumed and the linear model applied. The estimate of the average treatment effect is now 6.3, a reduction of about a third. The standard error has not changed (up to two decimal places), but the fit drops from .83 to .74. In this case, if after looking at the scatterplot a researcher decided that the linear model was good enough, the results would not be grievously wrong. The linear fit is not terribly far from the ideal fit: .83 versus .74 (although the ideal fit would not be known) because, where most of the data are, the linear model is about right. Whether the size of the treatment effect underestimate is large enough to matter would depend on context. In many policy settings, underestimating an average treatment effect by a third can transform a cost-effective intervention into one that is not cost-effective.

The third row shows the results for the difference between means in the region immediately on either side of threshold. The region was defined by the X between -1 and 1. Four hundred observations are contained between these two boundaries. The estimated average treatment effect is 9.8, the standard error is .31, and about 72 % of the deviance for the 400 observations is accounted for. The reduction in the standard error despite the smaller sample size results from a substantial decrease in the variance of the response variable once the more extreme values of X are trimmed. Similar improvements in fit may or may not be found for other data.

Overall, these are all very good results. A key reason is that within the window, the response functions are close to linear and flat. A close look at Fig. 6 makes this clear. Enlarging or shrinking the region by as much as 25 % does not materially change the results. Had the relationship not been approximately flat, a very different causal effect estimate could have resulted.

Rows four through six contain the results for a particular form of nonparametric regression: regression splines. In effect, the procedure seeks to fit the response function inductively (Berk 2008a, Chapter 2). A single functional form with a possible offset is assumed, just as in Eq. 7, and the entire dataset is used.

A key tuning parameter determines the amount of smoothing. Here, that tuning parameter is the number of "knots" (k). The larger the number of knots, the more flexible the fitting function and the less smooth the fitted values will be. Results when $k = 3$ suggest that the fitted values are not flexible enough. The story is about the same as for the linear model. When $k = 5$, the fit improves dramatically, but the estimated average treatment effect is a bit too large. When $k = 7$, the fit of the fourth degree polynomial is improved a bit more, and the estimated average treatment effect is almost perfect. Also, the quality of the fit is virtually the same as for the gold standard in the first row.

From the sequence of results, there are several lessons. To begin, the key to obtaining useful estimates of the average treatment effect is to first arrive at good approximation of the relationship between X and Y. To this end, no single method dominates over the variety of scatterplot patterns one is likely to find in practice. In this illustration, all of the estimates obtained were positive, some very close to the truth. In each case, one would easily reject the null hypothesis that the average treatment effect is zero.

With real data, it will often make sense to proceed in the following steps:

1. Construct and examine a scatterplot of Y against X. The goal is to obtain some initial hunches about how Y is related to X and whether there may be a discontinuity at the threshold.
2. Apply the difference in means estimator with several different window sizes. A key factor will be the number of observations within the window. If there are too few, estimated average treatment effect will be very unstable. But enlarging the window may introduce additional bias. One can use a goodness-of-fit measure such as the generalized cross-validation statistic to help determine the best window size. But new proposals have been appearing with some regularity (e.g., Imbens and Kalyanaraman 2009). The goal is to obtain an instructive initial sense of what impact the intervention may be having.
3. Apply a smoother such as lowess or smoothing splines to the data ignoring the W. Set the tuning parameters so that a very flexible fitting function is applied and then try several different values of these tuning parameters. An overlay of the fitted values on the scatterplot will help to reveal how Y is related to X and what sharp shifts up or down may be apparent for different values of X. Ideally there will be only one, and it will located at the threshold. If there are large discontinuities elsewhere, it may lead to suspicions about the one found at the threshold.
4. Apply a form of nonparametric regression with X and W as predictors. Vary the tuning parameters and use a measure like the cross-validation statistic to pick the best model. If the number of observations is relatively large, any of the common fit measures will likely

lead you to the same models. In addition, examine the usual regression diagnostics to provide additional information about model quality. It will often turn out that two or three models are about equally good. Then, the results for all three should be reported. For example, the last two estimates in Table 1 are reasonable.

Given all of the data "snooping," p-values will likely be biased downward. False power will result. It can make sense, therefore, to discount p-values by the Bonferroni method (Westfall and Young 1993, Section 2.3.1). For example, the .05 level might be represented by a probability .005. However, the problems are actually much deeper (Leeb and Potscher 2006; Berk 2008b), and it can be useful to randomly partition the data into a training dataset and a test dataset (Berk et al. 2009). All of the model building is done with the training dataset. At the end, the model is evaluated with the test dataset. A useful discussion of how to use training data and test data can be found in Haste et al. (2009, pp. 219–223). If the sample is too small to effectively partition, the best advice may be to interpret any tests judiciously and require that large and substantively sensible treatment effect estimates materialize in addition to "statistical significance." There is also some ongoing work on proper statistical inference after model selection that should be available soon (Berk et al. 2013).

Conclusions

When the RD design can be implemented properly, it has the same capacity as randomized experiments to obtain unbiased estimates of an average treatment effect. Why then has it not been more widely use? Perhaps the most important reason is that researchers have too often failed to appreciate that a wide variety of social interventions are delivered conditional on some explicit and deterministic rule. Another reason may be that because of the correlation between X and W, the RD design can sometimes deliver less precise estimates than randomized experiments with the same number of subjects. However, another factor is the relationship between the response and the assignment variable, which in some circumstances may be strong enough to effectively compensate. Moreover, when an RD design is built into the way one or more social interventions are delivered, it is often easy to obtain a very large sample at little additional expense. The bulk of the costs associated with data collection are born by the organization that is responsible for the intervention. In short, the RD design can be a very useful tool that should be far more widely exploited in crime and justice settings.

Overview

Reentry courts are "specialized courts that help reduce recidivism and improve public safety through the use of judicial oversight to apply graduated sanctions and positive reinforcement, to marshal resources to support the prisoner's reintegration, and to promote positive behavior by the returning prisoners (Bureau of Justice Assistance 2010)." An estimated 26 reentry courts and 29 reentry drug courts were in operation as of December 31, 2009 (Huddleston and Marlowe 2011). These courts are intended to address the critical needs of returning prisoners – particularly in the period immediately following release – through the combination of judicial oversight and a collaborative case management process. Reentry courts take many forms, with substantial variation along key dimensions of program design, including the mechanism for jurisdictional authority, target population, whether the court is a standalone model or combined with a drug court, and the point of entry into the program. Because the reentry court model remains a relatively new innovation, very few outcome evaluations have been conducted to provide evidence supporting its effectiveness. Preliminary results from the evaluation of the Harlem Parole Reentry Court are promising; however, additional rigorous evaluation is needed.

Introduction: The Origins of Reentry Courts

Reentry courts are "specialized courts that help reduce recidivism and improve public safety through the use of judicial oversight to apply graduated sanctions and positive reinforcement, to marshal resources to support the prisoner's reintegration, and to promote positive behavior by the returning prisoners (Bureau of Justice Assistance 2010)." These courts are intended to address the critical needs of returning prisoners – particularly in the period immediately following release – through the combination of judicial oversight and a collaborative case management process. The underlying goal of reentry courts is to establish a seamless system of offender accountability and support services throughout the reentry process (Bureau of Justice Assistance 2010). For such a system to be "seamless" requires cooperation between corrections and courts, representing a new form of jurisprudence characterized by these agencies working in partnership in pursuit of the common goal of successful offender reintegration (Wilkinson et al. 2004).

Reentry courts originated as a new strategy for managing prisoner reentry, as policymakers contemplated large numbers of returning prisoners and the myriad problems associated with reintegration. These large numbers were the results of changes in incarceration rates, which, after remaining relatively stable from 1925 to 1973, began to increase steadily starting in 1973 (Travis and Petersilia 2001). Over the next 30 and more years, incarceration rates and prison populations increased dramatically, with the growth only beginning to slow in 2006 (West et al. 2010). By the end of 2009 (the most recent year for which data are available), the number of prisoners under state or federal jurisdiction was just over 1.6 million (West et al. 2010). Because nearly all prisoners are released (West et al. 2010), high incarceration rates result in large numbers of returning prisoners each year. Each year since 2005, more than 700,000 prisoners have been released from federal or state prisons. In 2009, 729,295 sentenced prisoners were released from state or federal jurisdiction (West et al. 2010). This number represented the first decline in the number of prison releases since 2000 (West et al. 2010).

The sheer volume of returning prisoners and the overwhelming obstacles faced by many during reentry have contributed to heightened interest in identifying effective strategies for managing the reentry process. It is well documented that returning prisoners have limited occupational or educational experiences to prepare them for employment, drug and alcohol addictions, mental and physical health problems, strained family relations, and limited opportunities due to the stigma of a criminal record (Petersilia 2003; Travis and Visher 2005; Lattimore and Visher 2009). Thus, it is not surprising that as many as two-thirds of released prisoners are rearrested within 3 years, and over 50 % return to prison or jail (Langan and Levin 2002).

Parole violations play a large role in reincarceration rates. The majority of released prisoners – an estimated 74 % of those released from state prisons in 2009 – are released conditionally, including release to parole, probation, supervised mandatory release, or other conditional release (West et al. 2010). However, many parolees do not complete their term successfully, although the trend toward increasingly high failure rates for parolees appears to have reversed in recent years. In 2000, only 43 % of parolees completed their term successfully or were discharged early (Glaze 2007). This percentage increased to 51 % in 2009, following a trend toward increasing success rates that began in 2006 (Glaze and Bonczar 2010). Among those returned to incarceration, the majority are reincarcerated for technical violations, with only 26 % reincarcerated for a new conviction (Glaze and Bonczar 2010). Additionally, the likelihood of successful completion is lower for parolees who have violated a previous parole term when compared with those who have not. Among state parolees discharged in 1999, only 21 % of parolees with a previous violation successfully completed parole, compared to 63.5 % of first releases (Hughes et al. 2001). Despite a shift toward more positive parole outcomes in recent years, consistently high failure rates among parolees suggest the need for alternative strategies for managing reentry.

In response to the high post-release failure rates and the overwhelming needs of returning prisoners, many reentry programs have been implemented over the past several years to facilitate returning ex-offenders' transition from prison and, ultimately, to reduce recidivism. Several high-profile efforts to promote successful prisoner reintegration by involving a variety of community stakeholders in the design and delivery of rehabilitative services have been implemented, including the Reentry Partnerships Initiative, the Serious and Violent Offender Reentry Initiative (SVORI), the Reintegration of Ex-Offenders program (RExO; formerly the Prisoner Reentry Initiative), and most recently the Second Chance Act.

Reentry courts are distinguished from other approaches to prisoner reentry because they combine rehabilitative services with the power of the courts. Reentry courts began as part of the broader national movement towards specialized "problem-solving courts" to address issues such as drug addiction, mental health problems, driving under the influence, and domestic violence. These problem-solving courts address a wide array of problems but share several elements, including treatment mandates, ongoing judicial supervision, collaboration rather than the traditional adversarial system, direct interaction between defendants and the judge, and community outreach.

Based on the success of the drug court movement, it was thought that a similar model could be applied to support prisoner reintegration. The concept of leveraging judicial authority to manage reentry for returning prisoners through reentry courts was first introduced by Jeremy Travis. Reentry courts recognize that the point of reentry is a critical juncture for intervention and that the judiciary should play a greater role in managing reentry (Travis 2000). Traditional criminal justice policy was thought to constrain the authority and reach of parole agencies and correctional institutions, requiring a new organizational strategy for effectively managing reentry (Travis 2000). Further, court-based reentry management was thought to provide an opportunity for the reentry process to begin at sentencing and continue through the release period (Travis 2000).

Since the conceptualization of this model for managing prisoner reentry, multiple jurisdictions have developed reentry courts. The following section describes the early implementation experiences, including federal efforts to support the application of the reentry court model, and program design characteristics of reentry courts.

Background Description

Federal Efforts to Promote Reentry Courts

Early demonstrations of the reentry court model were promoted by the Office of Justice Programs (OJP) through its national Reentry Court Initiative (RCI). In 2000, OJP identified nine pilot projects (including both adult and juvenile programs) to receive technical assistance for the creation of reentry courts that would provide graduated sanctions in combination with social services (OJP 1999). The goal of the RCI was to "establish a seamless system of offender accountability and support services throughout the reentry process" (OJP 1999). Several core elements were identified among the RCI pilot programs (Lindquist et al. 2004). These components include (1) *assessment and planning*, in which an interagency process was used to identify appropriate candidates and ensure needs assessment and planning prior to release; (2) *active oversight* through public judicial status hearings required regularly throughout participation and involving the reentry court team; (3) *social services*, including the identification and marshalling of necessary resources and a case management approach to ensure their appropriate provision; (4) *community accountability* through an advisory board and the use of restitution and victim involvement; (5) *graduated sanctions* in lieu of revocations, with the swift, predictable, and universal administration of a predetermined range of sanctions; and (6) *incentives for success* to recognize program milestones, ideally administered in a public forum.

Federal interest in reentry courts remained strong, and a decade after the RCI, the Bureau of Justice Assistance solicited applications to fund adult reentry courts under the Second Chance Act of 2007 (Pub. L. 110–199). Several reentry courts were funded under the Bureau of Justice Assistance's FY2010 State, Tribal, and Local Reentry Courts Program and the Bureau of Justice Assistance's FY2009 solicitation for Second Chance Act Adult Demonstration Projects. The framework for establishing a reentry court under the Second Chance Act was based on the RCI and lessons learned from other early reentry courts, with grantees required to include the six RCI components described above. An emphasis on the use of validated assessment tools, tracking of services received by participants, and the use of evidence-based practices distinguished the Bureau of Justice Assistance requirements for reentry courts from those of the RCI (Bureau of Justice Assistance 2010).

Current Estimates of Reentry Courts

The number of reentry courts currently in operation is difficult to estimate. Reentry courts have been established in the federal, state, county, and tribal systems, with some entailing a partnership between government entities. As with drug courts, some programs are subject to statewide oversight for reentry courts, including certification, compliance monitoring, training and technical assistance, and evaluation (Wolf 2011). The National Drug Court Institute reported that 26 reentry courts and 29 reentry drug courts – a common model for reentry courts, as described in more detail below – were in operation as of December 31, 2009 (Huddleston and Marlowe 2011). Including federal reentry courts and programs newly implemented as part of the Bureau of Justice Assistance Second Chance Act reentry grants would increase the estimate. However, although there has been interest in the reentry court concept since its introduction, reentry courts have not witnessed the exponential growth that has been observed for drug courts and other types of problem-solving courts. Instead, implementation of the reentry court concept has been tentative. As described below, implementation challenges – particularly jurisdictional authority and the diverse and overwhelming needs of the target population – are likely responsible for the hesitancy in embracing this model.

Program Design Characteristics

Jurisdictional Authority. The mechanism for judicial authority is a major distinguishing factor among reentry courts and represents an area of complexity for jurisdictions interested in implementing this model. Some reentry courts are administrative courts, in which programmatic authority is maintained by the executive branch. In contrast, others are criminal courts, in which the judicial branch has authority.

Administrative reentry courts are typically part of the corrections system. Under this model, participation is established as a condition of release from prison and an administrative reentry court judge presides over the court hearings. Some states use retired judges or other judicial officers to lead these status hearings (see Tauber 2008).

Reentry court programs run by the judicial branch commonly use split-sentencing jurisdiction, in which an offender is sentenced to prison for a determinate sentence and returned to the jurisdiction of the court for a probationary period after serving the prison sentence, under the active supervision of the reentry court judge. In other jurisdictions, the courts have the statutory authority to sentence offenders to prison with the possibility of early discharge for resentencing after a short term or to sentence offenders to prison to complete a rehabilitation program and then be returned to the sentencing judge after successful completion (see Tauber 2008). With reentry courts operated by the judiciary, the sentencing judge retains jurisdiction over a case during the entire sentence.

Finally, some states are experimenting with collaborative reentry court structures, in which both the courts and correctional authorities are involved in the administration of the program. Such models entail either dual jurisdiction, with the court operated by the county and parole jurisdiction held by the correctional authority, or sole jurisdiction by the correctional authority but with active participation of the reentry court (see Tauber 2008). Regardless of the source of jurisdictional authority, reentry courts are typically mandatory in nature, with eligible participants required to participate.

Target Populations. Risk variability among reentry court participants is a main deviation from the drug court model. Although some reentry courts target a particular population, including narrowly defined offense types or clients with specific treatment needs, such as mental health or addiction issues (Lindquist et al. 2004), most reentry courts do not appear to specialize with regard to client type, resulting in the need to address a variety of client risks and needs. In addition to substance abuse treatment, reentry courts commonly deliver mental health counseling, assistance with housing, transportation, education, vocational training, employment, and other support services oriented toward returning prisoners (Lindquist et al. 2004). This holistic service delivery approach implies a larger network of service providers for reentry courts than for drug courts.

In addition, whereas drug court clients are typically nonviolent, there is a growing trend among reentry courts to focus on individuals assessed at high risk (Wolf 2011). Some reentry courts enroll several "tracks" of participants, including not only newly reentering prisoners but also parole violators assigned to reentry court rather than having their supervision revoked, as well as probationers sentenced to community supervision and reentry court rather than incarceration. However, it is questionable whether serving individuals who are not returning from incarceration is consistent with the original reentry court model; some programs that primarily serve individuals diverted from incarceration are called "pre-entry courts" and seek to keep individuals out of prison (Wolf 2011).

Reentry courts have been designed for both juveniles and adults. In 2005, the National Council of Juvenile and Family Court Judges published a guide for planning, implementing, and operating a juvenile court to manage the reintegration into the community of juveniles who have undergone court-ordered, out-of-home placement.

Reentry Drug Courts. Reflecting the widespread need for substance abuse treatment among returning prisoners, a common model for reentry courts entails the combination of reentry courts with drug courts (i.e., “reentry drug courts”). As noted earlier, slightly more reentry drug courts were in operation in 2009 (n=29) than reentry courts not combined with drug courts (n=26) (Huddleston and Marlowe 2011). Although several models for reentry drug courts have been proposed, the most common model currently in operation appears to entail jail- or prison-based substance using offenders being released from incarceration directly to a drug court. (See Tauber 2009, for a discussion of potential models for diverting prison-bound nonviolent drug-involved offenders to local jails for jail-based reentry drug courts and violent drug-involved offenders to prison-based reentry drug courts.) Importantly, reentry drug courts use the drug court model in facilitating the reintegration of drug-involved offenders into the community upon their release (Huddleston and Marlowe 2011).

Reentry drug court participants receive regular judicial monitoring, intensive treatment, community supervision, drug testing, and ancillary services necessary for successful community reintegration (Tauber and Huddleston 1999). The reentry drug court model can ensure continuity of treatment and accountability for returning prisoners from incarceration through reentry. Furthermore, it can allow jurisdictions with a drug court to capitalize on this existing infrastructure.

Point of Programmatic Entry and Exit. Reentry courts were originally conceptualized so that jurisdictional oversight began at sentencing and continued through the period of release (Travis 2000). Indeed, the calls for a collaborative approach were based on the assumption that the tasks of preparing offenders for release and transitioning them back into the community would be coordinated between courts and corrections (see Wilkinson et al. 2004; Burke 2001).

Some reentry courts do entail this level of coordination and consistent involvement beginning at sentencing. For example, in some courts the sentencing judge makes decisions about where a person is incarcerated, exerts influence over the programming he or she will receive while incarcerated, and stays updated about his or her progress (Wolf 2011). However, other reentry courts do not identify or enroll participants until immediately prior to, or even after, release (Lindquist et al. 2004). The post-release phase appears to be increasingly emphasized. For example, NDCI’s current definition of reentry courts emphasizes court involvement “during the initial phases of. . .community integration” (Huddleston and Marlowe 2011). Although early identification and the ongoing involvement of the sentencing judge offer several advantages, this model may not be possible for all programs. Many courts do not have the capacity to “reach in” to prisons or jails for screening, enrollment, or monitoring of prerelease services. However, some reentry courts transfer participants to transitional housing units in the correctional facility prior to release or to secure residential facilities in the community (Wolf 2011).

The point of exit for reentry court participants, particularly the degree of overlap between reentry court participation and parole (or other post-release supervision), has not been well documented. In some programs, reentry court participation extends throughout the period of post-release supervision. In others, reentry court has a defined duration, such as 6–12 months (Lindquist et al. 2004). According to Huddleston and Marlowe (2011), reentry court graduates are often transferred to traditional parole supervision, at which point they may continue to receive case management services through the reentry court on a voluntary basis. However, very little documentation exists about the duration of reentry court participation relative to participants’ parole sentence (or other post-release supervision mechanism) and the mechanism by which graduates exit reentry court.

Reentry Court Practices

Assessment and planning has been strongly emphasized by the Bureau of Justice Assistance in its oversight of the Second Chance Act Reentry Courts. In particular, the need for using validated assessment tools to identify appropriate candidates for reentry courts, with individuals at high risk of recidivism increasingly recognized as benefitting the most from such programming, has been widely disseminated. The use of needs assessments for planning individualized services (both prior to and after release) and continually reassessing service needs has received less attention. Furthermore, the extent to which best practices in assessment and planning are implemented in the field has not been documented.

Active judicial oversight, which includes public judicial status hearings required regularly throughout participation and involving the reentry court team, has received substantial attention, and several ingredients are thought to be particularly salient (see Hamilton 2010). As with drug courts, reentry courts leverage ▶ judicial authority through formal court proceedings (Travis 2005), with the judge's role expanded beyond traditional criminal court proceeding to include involvement in reentry planning and case management in a collaborative manner. Second, ▶ procedural justice is thought to be a critical output resulting from the use of the public forum (through court hearings). Because the reentry court judge is responsible for openly and publicly explaining program requirements and the purpose of sanctions (Travis 2005), it is thought that under the reentry court model (as with other problem-solving courts), participants develop a greater perception of fairness, which, in turn, increases the likelihood of compliance (Tyler 1988). Furthermore, rather than the closed-door process typically used by traditional parole, the reentry court utilizes a public forum that is thought to contribute to a greater perception of fairness. Finally, consistent with the drug court model, ceremonies or other activities intended to recognize accomplishments are used to incentivize and mark interim compliance and successful participation culminates in a public graduation (Travis 2005).

The remaining core elements, such as graduated sanctions, incentives for success, community accountability, and social services, have not been well documented among the reentry courts currently in operation. While reentry courts do appear to use graduated sanctions and incentives for success, the manner in which they are used has not been well documented. Similarly, little is known about reentry courts' strategies for identifying and marshalling needed social services and incorporating principles of community accountability among such a diverse population.

State of the Art: The Effectiveness of Reentry Courts

Because the reentry court model remains a relatively new innovation, much of the existing research involves only case studies, process evaluations, and documentation of implementation challenges that have arisen in particular programs. Few outcome and impact evaluations have been conducted to provide evidence supporting the effectiveness of the reentry court model. The limited research available to date, most of which has substantial methodological limitations, is summarized below.

In an evaluation of Delaware's Reentry Drug Court, which was implemented in 1993 and is designed to assist offenders who reenter the community following the completion of a residential treatment program, rearrest rates for program graduates were compared to those for the general prison population released between 1981 and 1984. The reentry drug court graduates were less likely to be rearrested for a new felony crime (9 %) than general releases (28 %). Individuals who enrolled in, but did not graduate from, the program were slightly more likely to be arrested (29.1 %) than general releases (Gebelein 2003).

A similar approach was employed in an early evaluation of the Allen County, Indiana Reentry Court. The program was established in 2001 as a complement to the county's Community Transition Program, which accepts selected inmates to a prerelease probation period prior to their anticipated release date. Participation in the project is voluntary and involves 24-h supervision, judicial monitoring and sanctioning, and relevant service referrals by a reentry court team that includes a judge, case managers, treatment professionals, and parole officers. An outcome evaluation was conducted to compare recidivism rates for program participants to national averages. Overall, 3-year rearrest rates for graduates and nongraduates of the program were lower than the national average of 67.5 % (Pearson-Nelson 2009).

The federal reentry court in Oregon (the District of Oregon), which began in 2006 as a strategy to reduce recidivism among drug-involved offenders following their release from a completed term of incarceration, entails judicial supervision through monthly hearings and reentry services that address risk factors including substance abuse, employment, and housing. Participation is voluntary and graduates receive a 1-year reduction of their probation sentence following successful completion (Aubin 2009). An evaluation of the program found that reentry court participants had higher levels of supervision and service receipt than a comparison group, but lower levels of employment and more sanctions (Close et al. 2008).

These three outcome evaluations have significant limitations that make it difficult to draw conclusions about the effectiveness of the reentry court program being evaluated. The most empirically rigorous reentry court evaluation published to date focused on the Harlem Parole Reentry Court and was conducted by the Center for Court Innovation (Hamilton 2010). The Harlem Parole Reentry Court, in operation since 2001, is a collaboration between the Center for Court Innovation and the New York State Division of Criminal Justice Services and Division of Parole. The program provides judicial oversight, supervision, and services to parolees returning to Upper Manhattan in New York City for 6 months following their release from incarceration (Hamilton 2010).

The evaluation used propensity score matching to select a comparison group of parolees released to traditional supervision during the study period. Recidivism outcomes were tracked for all parolees in the sample for 3 years following their release from incarceration (Hamilton 2010). Over the 3-year follow-up period, the reentry court program was found to have a positive impact on preventing new criminal behavior, including rearrest and reconviction for new crimes. Reentry court parolees were less likely to be rearrested and were significantly less likely to be rearrested for a misdemeanor in the first year and drug offenses in the first 2 years. Reentry court parolees were also significantly less likely to be reconvicted than comparison parolees over all 3 years at risk in the community. At 3 years, reentry court participants were 10 % less likely to have been reconvicted than comparison parolees. However, reentry court parolees were found to be significantly more likely to experience revocation after 2–3 years than comparison parolees. Three years following release, reentry court parolees were 18 % more likely to have experienced a revocation, particularly revocations due to technical violations.

These results indicate that the reentry court may have a negative impact on its parolees that may be due to "supervision effects," in which lower caseloads and more intensive supervision lead to increased opportunities for the detection of (and response to) noncompliant behavior. The report suggests the exploration of graduated and alternative sanctions protocols in reentry courts to reduce or avoid supervision effects. Currently, the Center for Court Innovation is implementing a randomized control trial of the Harlem Parole Reentry Court following additional programmatic modifications that will produce an empirically rigorous evaluation of the impact of the reentry court on recidivism and other outcomes important to reintegration, including employment and substance abuse.

In addition to the ongoing experimental evaluation of the Harlem Parole Reentry Court, a multi-site evaluation of the 2010 Second Chance Act Reentry Court grantees is also underway. The evaluation is funded by the National Institute of Justice (NIJ) and led by Northwest Professional Consortium (NPC), in collaboration with Research Triangle Institute (RTI) International and the Center for Court Innovation. The study, known as NIJ's Evaluation of Second Chance Act Adult Reentry Courts (NESCAARC), includes a process evaluation, impact evaluation, and cost-benefit analysis.

In addition, the evaluation will contribute to the development of a true reentry court model by determining the extent to which the sites reveal a common framework. Results are expected to be available beginning in 2015.

Issues and Research Gaps

Awareness of the need to effectively manage prisoner reentry has been heightened in the past several decades. As a result, reentry courts are an innovative strategy for managing the complex problems associated with prisoner reentry. Yet this model remains a fledgling approach, with both implementation strategies and evaluation lagging behind other problem-solving courts.

Part of the hesitancy to embrace the reentry court model may be due to implementation challenges, which can be substantial. Issues such as establishing jurisdictional authority over the target population, developing strategies for the identification and monitoring of participants prior to release, and serving the wide ranging needs of such a diverse population may appear (or be) insurmountable for some jurisdictions. Better documentation is needed from programs that have successfully implemented a reentry court model, including documentation of the challenges that were encountered and the solutions employed to overcome these challenges. Several models of jurisdictional authority have been proposed by Judge Jeffrey Tauber, editor of Reentry Court Solutions. Yet more documentation about the application of these models or barriers associated with each is needed.

Additionally, strategies for courts (particularly programs operated by the judicial branch) to "reach in" to prisons or jails to access participants prior to release have not received as much attention. Many courts do not have the capability to engage in prerelease planning and coordination, leading to a tendency for most reentry courts to focus exclusively on post-release programming. However, an uninterrupted continuum of services, particularly substance abuse, mental health, and healthcare services, is recognized as one of the keys to reentry success following release. A necessary component of the reentry court model is the early identification of participants' needs and the provision of a seamless transition of services from facility to community. An understanding of the necessary steps to establish a continuum of services within reentry court models is necessary to provide maximum substantial benefits for program participants.

Additional attention to develop strategies for adequately meeting the needs of the target population is needed, along with strategies for generating public support for the focus on returning prisoners. It has been observed that the application of the drug court model to returning prisoners may be less successful and have less popular and political support because while drug courts concentrate on the problem of addiction and serve a relatively homogenous group of clients (nonviolent drug addicts), reentering prisoners have numerous, diverse needs and are often at high risk of violence (Maruna and LeBel 2003). Not only are reentry court participants at higher risk, they may have served substantial terms of incarceration. As a result, they may need more services than drug court participants. In addition, it has been argued that more flexibility in response to technical violations and minor offenses is required for returning prisoners, rather than a "heavy handed" approach. Encouragement, incentives, and a sense of community are thought to be particularly important.

Research on operational barriers, such as interagency cooperation, is also needed. Although not documented in the research literature, it is possible that lack of interagency cooperation may be more common with reentry courts than other problem-solving courts because partners may have different visions for the program or agreement on the target population. For example, decisions about whether to include violent or sex offenders have implications for the level of support from prosecutors, acceptance from service providers, intensity of supervision expected from probation or parole officers, and support from the public for the program. Additionally, changing attitudes and agency culture can also be difficult to bring collaborative agency staff in line with the reentry court's mission and goals. Farole (2003) reported that staff cooperation, communication, and turf issues with parole officers were a significant implementation challenge for the Harlem Parole Reentry Court in its initial stages. Without the buy-in and cooperation of all court stakeholders, including outside agency staff, the reentry court model will not achieve the desired levels of program fidelity and therefore, may fail to successfully achieve its goals.

Finally, as noted above, rigorous studies of the effectiveness and cost-effectiveness of reentry courts are needed. Multi-site evaluations and research on approaches to minimize supervision effects are particularly needed, along with the exploration of a broader set of outcomes (in addition to reincarceration) and longer-term follow-up. Importantly, such studies must employ a rigorous strategy for identifying a comparison group that is well matched to the reentry court participants on all eligibility criteria when an experimental design and random assignment are not possible. In addition, evaluations should employ an "intent to treat" approach such that all individuals assigned to the reentry court (not just successful completers) are included in the treatment group. This approach is the most rigorous test of program effectiveness because it does not rely solely on the experiences of clear program "successes."

Very little is known about the cost-effectiveness of reentry courts, and research in this area would be of substantial interest. The issue of which risk levels are targeted by reentry courts may have implications for the cost-benefit ratio of the reentry court. The growing trend is to target offenders assessed as being high risk, typically with regard to risk of violence or serious crime. However, participants in the Bureau of Justice Assistance focus group noted that greater cost savings to the criminal justice system would likely be achieved if risk were defined as risk for reoffending, which is generally higher among low-level drug offenders and the mentally ill (Wolf 2011).

Rehabilitation

Gwen Robinson

Overview

Rehabilitation is a broad but somewhat slippery concept which denotes a wide variety of interventions aimed at promoting desistance from offending, but which can also denote the symbolic restoration of an ex-offender to the status of a law-abiding citizen. This entry presents a critical overview of the ideas, theories, and practices that have been associated with the project(s) of "offender rehabilitation." This entry begins with a discussion of the meaning(s) of rehabilitation in relation to those who break the law, and in relation to broader ideas about the punishment of offenders and the imposition of criminal sanctions. It then moves into a discussion of the various rationales or justifications for offender rehabilitation and some of the key ethical issues associated with rehabilitative practices. Subsequently, this entry considers rehabilitation from an empirical perspective, addressing the thorny issue of whether rehabilitative interventions "work" and the quality of the evidence underpinning claims to effectiveness. The penultimate section analyses the "reaffirmation" of rehabilitation in light of contested ideas about developments in the social and penal spheres which have emphasized the rise of punitive and/or actuarial logics, arguing that the continuing salience of rehabilitative discourses and practices are indicative of their continuing evolution in late-modern contexts. Finally, this entry returns to the practice sphere, and considers some possible future directions for rehabilitation, with reference to some of the contemporary challenges to the "new orthodoxy" of the RNR (risk-need-responsivity) model which has come to dominate practice in many Western jurisdictions.

What Is Rehabilitation?

Rehabilitation is something of a slippery concept, which is surprisingly difficult to pin down (Raynor and Robinson 2009, Chap. 1). General dictionary definitions tend to define rehabilitation with reference to a process of "restoration" – that is, a return to a previous (proper/desirable) condition or status. This certainly makes sense in medical contexts, where rehabilitation refers to a process of regaining or recovering physical strength or cognitive functioning. And in a general sense, we can think of the rehabilitation of offenders in terms of "restoration" – that is, returning to a former, more desirable state. However, as a number of commentators have observed, there are problems with such a conceptualization. These include the fact that the social circumstances of some offenders are such that they have never enjoyed a "desirable" position within society to which they would wish to return, and the related observation that the rehabilitation of offenders often implies a process of *improvement*, by means of the acquisition of new skills, etc.

In the context of offending, rehabilitation usually implies behavioral change: the "rehabilitated offender" is generally regarded as one who has desisted from offending. And although desistance may be achieved with or without the "intervention" of professionals, programs, etc., "offender rehabilitation" commonly conjures up such images, and in much of the literature it is discussed – albeit rarely defined – in these terms. It is important to note, however, that the notion of offender rehabilitation is not confined to the behavioral realm: it also has an important symbolic dimension, although this is often neglected in the literature. Indeed, as Garland (1985) has observed, the concept of rehabilitation actually has its roots in seventeenth-century French law, where it denoted the destruction or "undoing" of a criminal conviction (see also Herzog-Evans 2011). In its fullest sense, then, offender rehabilitation implies not only behavioral change, but also the restoration of the rights of citizenship, and of reputation: or what Braithwaite (1989) has described as the "decertification of deviance."

Rehabilitation and Punishment

In the criminal courts, sentencing decisions are guided by penal philosophies which serve to justify the sanctions imposed upon offenders. Rehabilitation (or "reform") is one of three main *consequentialist* strategies, all of which seek to justify punishment or penal sanctions with reference to the desirability of their future consequences. In common with *deterrence* and *incapacitation*, rehabilitation is oriented to the goal of crime reduction, but it differs from these other consequentialist strategies in that it is usually considered in positive terms. While incapacitation involves physically restraining or removing the offender from society, and deterrence centers on emphasizing the unpleasantness of punishment, "rehabilitative punishment" seeks to reduce the likelihood of an individual reoffending by instituting changes in the offender. Cavadino and Dignan state that:

> Reform (or 'rehabilitation') is the idea that punishment can reduce the incidence of crime by taking a form which will improve the individual offender's character or behaviour and make him or her less likely to reoffend in future. (2007, pp. 41–42)

However, this image of rehabilitation as a positive process is somewhat controversial, especially when it comes to thinking about the means or methods of bringing about offender rehabilitation which have been deployed throughout history – and some in the present day. The fictitious *Ludovico Technique* featured in Anthony Burgess's (1962) novel "A Clockwork Orange" is often held up as a particularly disturbing example of what might potentially pass as a legitimate "rehabilitative" intervention. Indeed, there is nothing in the theory of rehabilitation that guarantees fair or humane treatment, albeit that its advocates have generally seen themselves as well-intentioned "good guys."

Sentencing with a view to achieving the rehabilitation of the offender does not imply a specific penal sanction. Although many of its contemporary advocates emphasize alternatives to incarceration (and indeed diversionary measures, particularly for juveniles) as the best prospect for achieving rehabilitation, early ideas about the reform of offenders centered on finding ways to render prisons rehabilitative. In late eighteenth-century England, the magistrate and penal reformer John Howard proposed that the morals of offenders might be corrected by subjecting them to a regime of "penitentiary discipline" characterized by solitude and silence, substantial doses of religious instruction, and the inculcation of a work ethic through enforced labor (Howard 1929 [1777]). Just a few years later, Jeremy Bentham put forward his infamous "Panopticon" design for a prison modeled on a factory, and his proposed regime centered upon the reformative effects of permanent surveillance and the productive labor of prisoners working in their cells for up to sixteen hours per day. Ever since then, opinion has been divided as to whether custodial institutions can and should aim to be "rehabilitative," what that might mean in practice and whether it is affordable. However, it should be noted that in some European countries (e.g., Germany), "resocialization" (a term which implies the social reintegration of ex-prisoners) continues to be an explicit objective for the implementation of sentences of imprisonment (see Van Zyl Smit and Snacken 2009). In the twentieth century, noncustodial measures (most notably probation) developed in a variety of jurisdictions with an explicitly rehabilitative remit. In some jurisdictions, at least some noncustodial options continue to have the legal status of "alternatives to punishment," but in others (such as England and Wales) contemporary supervisory penalties have evolved into sanctions in their own right.

Today, the idea that punishment or penal sanctions can deliver rehabilitation is contested. Indeed, rehabilitation has been theorized by some as a process that is conceptually divorced from punishment, such that rather than being conceived as an objective of a positive process of punishment, it has been conceived as an *antidote* to punishment (or, to be more precise, the harmful effects of the punishment process) (e.g., Cullen and Gilbert 1982; Rotman 1990). These writers argue that, while punishment may be deserved, the offender should not be unduly damaged by it, and any harm or handicap inflicted upon him or her ought to be mitigated or compensated by rehabilitative measures. According to this perspective, rehabilitation is understood as a process of undoing the harm caused by punishment, not as an objective or type of punishment or sanctioning.

Justifying Rehabilitation

For more than 200 years, rehabilitation has been advocated both as a humanitarian response to crime and as a means of bringing about the humanization (or civilization) of criminal sanctions and punishment. For example, writing in England in the late eighteenth century, John Howard developed his own ideas about the reform of offenders as an alternative to what he saw as the overly harsh and disproportionate deterrent punishments of the time, which centered upon the public rituals of hanging, whipping, and pillory as responses to the full range of offenses (Howard 1929 [1777]). More recently, writers such as Cullen and Gilbert (1982) and Rotman (1990) have continued to promote rehabilitation on similar grounds. For example, Rotman has argued that:

> The rehabilitation of criminal offenders offers the criminal justice system a unique avenue of improvement [and] has enormous potential for humanizing and civilizing social reaction against crime. Modern rehabilitative policies challenge the fantasy that the dark side of society can be forgotten and that deviants can be simply packed off to prison. They propose instead to offer inmates a sound and trustworthy opportunity to remake their lives. (Rotman 1990, p. 1)

During the twentieth century, rehabilitative punishment began increasingly to be justified with reference to positivist criminologies which emphasized the role of forces (biological, psychological, or social/environmental) beyond the control of the individual in the causation of crime. Gradually the notion of the offender as a "sinner" bearing full responsibility for his or her actions came to be displaced by a view of the offender as very much like a person suffering from an illness beyond his or her control. In the context of this emerging "medical model" of crime, it followed that offenders deserved to be helped or treated, in order to remove or ameliorate the factors responsible. It was this set of assumptions which lay behind the so-called individualized treatment model of offender rehabilitation, which dominated penal policies in the USA, the UK, and elsewhere in the middle decades of the twentieth century.

One way to justify rehabilitation, then, is with reference to positivist criminologies, and the general view of offenders as victims (more or less) of forces beyond their control. Some have, however, taken this argument further, positing that there is a case to be made for rehabilitation as a *right* of the offender, or an *obligation* of the state. Cullen and Gilbert (1982), for example, have argued that where social deprivation (e.g., poverty) or other problems which society has failed to properly address (e.g., mental illness) can be shown to have played a role in crime causation, then society arguably has an obligation to help the offender to overcome such obstacles – that is, a right to receive such help or intervention as to enable him or her to avoid offending in the future. A weaker version of the "rights-based" perspective invokes the idea of rehabilitation as an antidote to punishment, considered above, and it is most commonly linked with sentences of imprisonment. If we accept that offenders have a right not be debilitated or harmed (psychologically, socially, economically, etc.) by the process of punishment, then we can justify "rehabilitative" measures as a right of offenders. It is in this spirit that Rotman (1990) advocates the provision of educational and vocational opportunities, psychological and psychiatric treatment services and the maintenance of community and family links for prisoners. He further argues that the offender's right to rehabilitation is consistent with the full restoration of his or her civil and political rights of citizenship following release from prison. This perspective is to be found in the constitutional right to "resocialization" for (ex) prisoners which exists in some European countries (see van Zyl Smit and Snacken 2009).

Rehabilitation can also – and commonly is – justified with reference to *utilitarian* arguments. Utilitarianism is a philosophy which originates in the work of Jeremy Bentham (1748–1832) and it essentially posits that an action is ethically or morally "right" if it produces the best overall consequences, often expressed as "the greatest happiness for the greatest number." Justifying rehabilitation on utilitarian grounds therefore means emphasizing the potential benefits not just for offenders themselves, but more broadly for the communities and societies in which they live. These benefits are usually couched in terms of both maximizing the availability of useful, productive (and tax-paying) members of society, and minimizing future harm by preventing further crime and victimization (see further Raynor and Robinson 2009, Chap. 2). In contemporary discourse, these desirable outcomes are commonly described in terms of "risk management" and "public protection."

Is It Ethical? The Darker Side of Rehabilitation

Rehabilitation is generally represented and understood as a "force for good." However, it is no stranger to problems and controversies. Indeed, as Ward and Maruna (2007) have pointed out, rehabilitation has – some of the time, and to some people – been considered a "dirty word." There are, then, a number of problems and risks associated with the ideas and practices of rehabilitation, and these help to explain why it is that rehabilitation has waxed and waned in popularity across time and space.

The first risk relates specifically to *rehabilitative punishment*, and it concerns issues of justice, proportionality, and equity. Advocates of retributive justice and desert-based sentencing contend that sanctioning with a view to rehabilitating the offender is potentially problematic in that it can invite periods of punishment which are not commensurate with the seriousness of the offense committed. Indeed, this was one of the key criticisms which presaged the demise of the "individualized treatment model" in the 1960s and 1970s. The logic of the "treatment" approach was that individual offenders should be "treated" until such a time that they were considered (by an "expert") to have been "cured" of their criminal tendencies. Because the amount of time or intervention could rarely be specified in advance, rehabilitative sentencing came to be associated with sentences of indeterminate length, and the empowerment of extrajudicial professionals in decision-making. This was a particular issue in the USA, where indeterminate sentencing was more common than it was elsewhere. In the early 1970s, a report prepared by the American Friends Service Committee (1971) was instrumental in exposing the ethical flaws of the treatment model, and in particular the numerous instances in which doctors, social workers, and other "experts" were empowered to make executive decisions which directly affected people's freedom and autonomy, and which were not subject to challenge. Contemporary advocates of rehabilitation tend to accept the risks to justice posed by rehabilitative sentencing and argue that the presumed benefits of rehabilitation should not be used to justify sentences that are longer than commensurate with desert (e.g., Raynor 1997; Rotman 1990).

A second criticism of rehabilitation concerns its coercive potential and the question of whether this can ever be justified. Rotman (1990) draws a useful distinction between two models of rehabilitation – *authoritarian* and *anthropocentric* – which he sees as, respectively, authoritarian/oppressive, and liberty-centered/humanist. Rotman himself advocates only the latter model, arguing that attempts to rehabilitate offenders should be subject to the offender's consent and should invite the active participation of offenders in their own rehabilitation process. Others, however, argue that coercion is not inherently unethical; nor is it entirely avoidable, not least because rehabilitative programs are often a compulsory part of sentences, especially for those who are assessed as posing a high risk of harm to the public (e.g., sex offenders, violent offenders, and substance misusing offenders) (e.g., Carlen 1989; Day et al. 2004). Day et al. have further argued that a degree of coercion can be effective in both getting reluctant offenders into treatment programs and keeping them there.

Of course, whether we are prepared to accept a degree of coercion in efforts to rehabilitate offenders may well depend to a large extent on what it is that we are potentially requiring them to do. While most of us will be unlikely to object to the idea of forcing a reluctant pedophile to undertake a treatment program to reduce the likelihood of further sexual offending, we might be more inclined to object to the idea of compulsory surgical or chemical castration, or Burgess's violent aversion therapy, mentioned above. A third criticism of rehabilitation then concerns its *content*, and the risk of justifying abusive and/or inhumane interventions in the name of "doing good." Even a cursory knowledge of the history of attempts to rehabilitate offenders reveals that the practices for which "rehabilitative effects" have been claimed have included the physically demanding treadmill, through extended periods of solitary confinement, to psychosurgical and pharmacological interventions. Indeed, not all of these examples are confined to history: it is notable, for example, that the "chemical castration" of sexual offenders is currently enjoying something of a revival in a variety of jurisdictions.

A fourth problem with offender rehabilitation concerns the problems associated with making resources and "help" available to offenders, while such assistance may be unavailable to other members of society who have not offended but are experiencing similar or more extreme personal problems or socioeconomic disadvantages. This is a problem which is particularly pertinent in relation to the provision of resources such as employment training, education, and accommodation, which are sometimes referred to as "social rehabilitation" (Robinson and Crow 2009, Chap. 8). Where this occurs, rehabilitation is said to offend the principle of "less eligibility" formulated by Bentham in the eighteenth century. This principle states that those convicted of offenses should not enjoy conditions that are more favorable than those enjoyed (or perhaps endured) by the poorest independent laborer. In contemporary societies, this means that offenders should not obtain advantages over those in the lowest paid employment, who have not offended.

Does It Work? Evaluating Effectiveness

Despite the ethical concerns raised above, by far the most hotly debated issue with respect to rehabilitation – and in particular rehabilitative punishment – relates to its effectiveness in bringing about reductions in recidivism. However, concerns about "what (if anything) works" are a relatively recent phenomenon. Until the 1960s, rehabilitation was a dominant penal narrative in the USA and the UK, the effectiveness of rehabilitative sanctions was widely taken for granted and little research had been undertaken to establish their impact on recidivism. It was not until the 1970s that serious doubts began to emerge about their effectiveness, and these were due in large part (though by no means entirely) to the publication of a now infamous article by Robert Martinson (1974), which summarized the findings of a review of over two hundred studies of prison- and community-based rehabilitative services to offenders. The legacy of Martinson's article was the slogan "nothing works," which came to dominate mainstream penal thought for years to come and dealt a severe blow to faith in the "rehabilitative ideal" (Allen 1959; Garland 2001).

Ever since then, researchers (particularly in North America) have endeavored to demonstrate that "nothing works" was a significant overstatement, and to revive at least some optimism about the potential of penal interventions to rehabilitate offenders (e.g., Palmer 1975; Gendreau and Ross 1980). Efforts to reinstate a "what works?" agenda in the 1980s were accompanied by critiques of the old "treatment model" and the theoretical assumptions which lay behind it, alongside the development of new styles of intervention designed to confront and modify "offending behavior." The late 1980s and early 1990s saw the emergence and proliferation of "offending behavior programs" based upon a predominantly psychological (cognitive-behavioral) model of offending (e.g., Ross et al. 1988; Hollin and Palmer 2006). This period also saw the refinement of evaluative research methodologies, and the adoption (from the medical sciences) of the statistical technique of "meta-analysis." This technique enabled researchers to analyze the findings of large numbers of primary research studies and distil from them not only their impact on reoffending, but also what approaches and methods appeared to be associated with positive outcomes. Throughout the 1990s, summaries of these characteristics or "ingredients" of (apparently) effective rehabilitative interventions, derived from meta-analytic research, began to appear (e.g., Andrews et al. 1990a; McGuire and Priestley 1995) and in some jurisdictions were adopted as the basis for designing and delivering services. Canadian meta-analytic research published by Andrews and colleagues also underpinned a model of offender rehabilitation which came to be known as the "RNR" (risk-need-responsivity) model, which has subsequently had a huge influence on practice across a variety of jurisdictions and is widely regarded as the dominant approach to offender rehabilitation in the early twenty-first century (Andrews et al. 1990b).

England and Wales was one jurisdiction which saw significant investment in the development and evaluation of the so-called new rehabilitation under the auspices of its government's "Crime Reduction Programme," which sought to test the impact on reoffending of a range of programs and interventions for offenders subject to custodial and community sentences. However, the evaluative research commissioned failed to deliver clear-cut results: published studies revealed a catalogue of implementation problems; weaknesses in evaluation design; few completed reconviction studies; and results that were "mixed" and often difficult to interpret because of problems with evaluation methodologies. Far from establishing "what works," then, researchers were left pondering (once again) whether the results of their efforts were best interpreted as failures of theory, implementation, or evaluative research itself, and fearing the implications of a return to the pessimism of "nothing works" (see, e.g., Raynor and Robinson 2009, Chap. 6).

However, the picture is not an entirely bleak one. In a recent review of evidence about "what works" in offender treatment and rehabilitation, Lösel (2012) concludes that:

> various measures from the 'what works' literature are effective. Typical effect sizes range somewhere between 10 and 20 per cent less reoffending in treated than in control groups, but there are also larger or smaller effects. Desirable outcomes have been found for cognitive-behavioural programmes, therapeutic communities, social-therapeutic prisons, milieu therapy, multisystemic treatment, RJ measures, educational and vocational programmes. (Lösel 2012, p. 1006)

This conclusion is supplemented by the important observation that "what works" is rarely reducible to specific programs or interventions that will "work" in any context: there are a variety of "moderators" of program effects that include offender factors (e.g., risk level, motivation, demographic variables), treatment context (e.g., staff skills, continuity of support, institutional climate), and evaluation method (e.g., quality of evaluation design, sample size, length of follow-up period). These are all variables that can have a bearing on the findings of research. An important implication of this is that "what works?" is too crude a question: researchers instead ought to be asking what works, with whom, in what circumstances (etc.).

History has demonstrated, thus, that the apparently straightforward question – "does it work?" – is in fact an extremely complex one, which is difficult to operationalize and has failed to produce clear-cut answers. This is a perennial problem for proponents of rehabilitation who seek to persuade sentencers and policy makers of the potential of rehabilitative sanctions to cut crime, prevent victimization, and protect communities. In the absence of convincing evidence to support such claims, sentencers and policy makers are arguably going to be more inclined to resort to measures that can be shown, or are popularly believed, to impact on crime rates, such as lengthy periods of incapacitation. However, to the extent that research into the effectiveness of rehabilitative interventions continues, it is hoped that we will see more nuanced research designs that reflect some of the lessons of the past.

The Rehabilitation (R)Evolution

The so-called collapse of the rehabilitative ideal in the latter part of the twentieth century is well documented (e.g., Garland 2001). Beginning in the late 1960s and early 1970s, the dominant "treatment model" was subjected to a three-pronged critique which emphasized its theoretical and ethical flaws as well as its apparent ineffectiveness, such that both the legitimacy of rehabilitation as a primary penal objective, and faith in the possibility of rehabilitating offenders were subject to serious doubts. In the wake of rehabilitation's decline in official discourse and policy, analyses of penal transformation proliferated, and in many of these, rehabilitation was consigned to penal history. Whether proclaiming the arrival of a new "postmodern" penology or a "new punitiveness," international penal commentators tended to agree that rehabilitation was dead or at least on its last legs.

More recently, however, it has become clear that claims about the demise of rehabilitation have been overstated. Not only have penal professionals tended to retain at least some optimism about the transformative purposes of their practice, but as we have seen above, research in the "correctional" field has been relentlessly focused on developing new, more effective techniques and interventions and has far from given up the quest to discover "what works." As one of the scholars at the forefront of the "What Works" movement has explained:

> Three decades ago, it was widely believed by criminologists and policymakers that 'nothing works' to reform offenders and that 'rehabilitation is dead' as a guiding correctional philosophy. By contrast, today there is a vibrant movement to reaffirm rehabilitation and to implement programs based on the principles of effective practice. How did that happen? I contend that the saving of rehabilitation was a contingent reality that emerged due to the efforts of a small group of loosely coupled research criminologists. (Cullen 2005, p. 1)

Cullen is correct to point to the important role of the research community in the "reaffirmation" of rehabilitation, which has been evident in (for example) the state of California rebranding its Department of Corrections as the Department of Corrections and Rehabilitation under the leadership of a Republican governor, and in the UK, the Conservative-led coalition government promoting something it is calling a "Rehabilitation Revolution." However, there is arguably more to the story of rehabilitation's reaffirmation than is implied in Cullen's account: it has been argued that we should think of the recent history of rehabilitation in terms of an evolutionary process, whereby it has been successfully transformed and re-marketed in a late-modern context, such that far from going "against the grain" of other currents in penal policy, it has in fact been rendered compatible with them (Robinson 2008). Thus, for example, the "new" rehabilitation has had to adapt to social and political contexts that have become increasingly intolerant of approaches that appear to put the needs and/or interests of offenders above those of victims (actual or potential). In jurisdictions which have been subject to "populist punitiveness," proponents of rehabilitation have had to de-emphasize its humanitarian and welfarist justifications in favor of its utilitarian credentials (Garland 2001; Robinson 2008). Rehabilitation has also had to adapt and reposition itself within increasingly managerial correctional systems dominated by the discourse of "risk." In this process, it has been reframed as one of a number of possible "means" toward the "end" of risk management, as well as being increasingly rationed in line with assessments of risk which determine offenders' eligibility for "rehabilitative" sanctions or interventions.

The adaptation of rehabilitation in late-modern contexts has not however simply entailed putting a new "spin" on an old product (Robinson 2008). We have not witnessed a return to the "old" treatment model, but rather the proliferation of a new breed of "offending behavior programs" underpinned by cognitive-behavioral psychology. This "new orthodoxy" in offender rehabilitation is certainly attributable, in part, to its grounding in research and the promise of measurable reductions in reoffending on the part of program completers. But the dominance of cognitive-behavioral programs may also be attributable to their expressive and communicative qualities, and resonance with "advanced liberal" forms of governance and neoclassical criminologies which emphasize personal responsibility for wrongdoing and rely upon strategies of "responsibilization" as the dominant response to antisocial behavior (e.g., Kendall 2004). Rehabilitation has, thus, adapted and survived into the twenty-first century by transforming itself in important ways: central to its relegitimation in late-modern societies like the USA and the UK has been its successful appeal to three dominant penal narratives, which have been characterized as *utilitarian*, *managerial*, and *expressive* (Robinson 2008).

Challenging the "New Orthodoxy": Future Directions in Rehabilitation

As we have seen, the "What Works?" movement and its key protagonists have played a crucial role in the relegitimation of rehabilitation in the last two decades, and the lessons of that research have spread well beyond North America, such that the "risk-need-responsivity" (RNR) model (associated particularly with the work of Don Andrews and James Bonta) has become the "new orthodoxy" in offender rehabilitation in a host of jurisdictions. The RNR model has had a particularly significant impact on approaches to offender assessment, inspiring actuarial assessment instruments such as the Level of Service Inventory and the British Offender Assessment System, which emphasize the importance of assessing offenders' risks and (criminogenic) needs as a basis for decisions about their suitability for "rehabilitative" interventions. The RNR model has also been intimately associated with the proliferation of cognitive-behavioral offending behavior programs: indeed, the notion of "general responsivity" in the RNR formulation recommends cognitive-behavioral approaches as being the most effective in general terms.

However, both the RNR model and the specific technologies and approaches associated with it have been subject to criticism, from a variety of perspectives. Early critiques focused on the "reification" of "What Works?" (evidenced in a tendency to drop the question mark, thereby implying that the "answer" to the question had now been discovered) and the applicability of theories, assessment instruments, and/or interventions developed on the basis of research with young, white North American male offenders on different groups, such as women, ethnic minorities, and those with substantially different offending profiles. Concerns were also raised about the potentially "authoritarian" (Rotman 1990) characteristics of offending behavior programs, which were seen by some as a worrying return to the bad old days of the "treatment model," proceeding on the basis of predominantly psychological theories of crime causation, and reviving images of offenders as passive recipients of "interventions" delivered by "experts" (e.g., Kendall 2004). Several commentators argued that RNR (and particularly the assessment instruments associated with it) promulgated a *deficit model* which was overly focused on risks, needs, problems, and deficiencies and blind to their potential strengths, achievements, and "protective factors" (e.g., Ward and Maruna 2007).

Drawing on developments in what they call "positive psychology," Tony Ward and colleagues have argued for the development of "strengths-based" approaches to rehabilitation and they have proposed a "Good Lives Model" as a potential alternative to RNR. At the heart of the GLM is a positive perspective: it seeks to equip offenders with the capabilities to secure "primary human goods" (defined as valued aspects of human functioning and living) in socially acceptable and personally meaningful ways. The GLM rests on the assumption that interventions should aim to promote an individual's "goods" as well as to manage or reduce their risk. A major aim of rehabilitative work is to enable an individual to develop a life plan that involves ways of effectively securing primary human goods without harming others. The approach requires an explicit focus on conceptualizing a good life: taking account of strengths, primary goods, and relevant environments and encouraging and respecting individuals' capacities to make choices for themselves. To date, the GLM has been most extensively applied to rehabilitative work with sexual offenders, but its advocates propose that the model (and the theory on which it is based) is relevant for a wide range of offenders (Ward 2010).

Another alternative paradigm for offender rehabilitation builds on research on "naturalistic" processes of desistance – that is, what is known about how and why offenders cease offending. The "desistance paradigm" (e.g., Maruna and LeBel 2010; McNeill 2006) takes issue with the centrality of "interventions" in the RNR model and the notion that achieving desistance is simply a matter of dispensing the right program. This idea, its advocates argue, is at odds with the findings of desistance research, which points to desistance not as an event but a process, characterized by progress and setbacks; hope and despair.

In common with advocates of the GLM, proponents of the desistance paradigm argue that RNR has downplayed the role of offender motivation in the rehabilitation process, in favor of a "one-size-fits-all" model. McNeill has argued that the GLM may offer a promising start in addressing the weakness of the RNR model with respect to motivational issues. However, because both RNR and GLM are models developed by psychologists, both place too much emphasis on the individual and on psychological issues, while de-emphasizing the role of the offender's social context and the importance of developing opportunities and social capital for offenders. McNeill is also critical of the RNR model's underemphasis on the role of relationships in the offender's life (including those between the offender and the "rehabilitative" professionals with whom they engage), which also emerge from desistance research as potentially key in the desistance process.

McNeill is one of a number of commentators who have begun to draw attention to the importance of the relational dimension of, or context for, rehabilitation; that is, the idea that rehabilitation is not best conceived as something which happens to or is "done to" offenders in a social vacuum, but rather it is a process which takes place in the context of – and often seeks to build – relationships of various kinds. The idea of "relational rehabilitation" (Bazemore 1999; Robinson and Crow 2009, Chap. 9) encompasses a variety of "nontreatment" approaches that include restorative justice schemes which bring together offenders and their victims, as well as projects that utilize community members (such as mentoring schemes and "Circles of Support and Accountability" for high-risk sexual offenders). It also encompasses ideas about the potential of sentencers to act as therapeutic agents (often referred to as *Therapeutic Jurisprudence*) which have underpinned the development of specialist, problem-solving courts in the USA and elsewhere.

Finally, recent research and debate about "nontreatment" approaches, relational matters, and (particularly) the role of the law and its agents in processes of rehabilitation has prompted a revival of interest in the symbolic dimension of this concept, and the potential importance of "rehabilitation rituals" to mark the decertification of deviance (Maruna 2011). "Judicial rehabilitation" denotes all of those legal practices and tools which serve to expunge or delete the criminal record, or otherwise recognize or confirm the individual's status as a desister or ex-offender. As Maruna (2011) has noted, jurisdictions differ significantly in their willingness to adopt such mechanisms, and in the extent to which they enable ex-offenders to navigate away from stigmatic labels. In European countries such as France, which traditionally place a high cultural value on privacy, judicial rehabilitation tends to be most developed (see Herzog-Evans 2011). By contrast, in the USA there is a long history of freedom of information (including "naming and shaming" that dates back to the Salem witch trials) which at least partly explains why ex-offenders are particularly disadvantaged when it comes to the protection of their privacy and thus their ability to "live down" their convictions. However, Maruna fears a general trend toward "Americanization" in Europe and elsewhere, as is becoming evident in the practice of making criminal records more widely available, and in community notification schemes with respect to sexual offenders, which tend to prioritize "public protection" over the ex-offender's right to put their past behind them.

Overview

This entry hinges on four nonobvious propositions that, we suggest, largely encapsulate the state of the art in this field. They are that:

1. Most crime is repeat victimization against the same targets, and variation in crime across time and place is often due largely to repeat victimization.
2. One or 2 % of potential targets are the supertargets that experience about half of all crimes.
3. Preventing repeat victimization reduces crime when tactics are properly developed and implemented.
4. A broader-than-usual conception of *near-repeat victimization*, referring to crimes linked by their similarity, may prove a useful foundation for integrating theories of crime concentration.

The evidence and argument underpinning these statements is presented in what follows. References and some further reading are listed at the end, but readers are encouraged to browse the *Oxford Bibliographies Online* (*Criminology*) entry on *repeat victimization* which summarizes around 150 key studies. It documents the growth of studies from the 1970s onwards, the extent and nature of repeats and near repeats in many different countries, theoretical developments, the link to repeat offending, measurement issues, time-course and life-course studies, the link to policy and practice, and crime-specific prevention studies. The study of repeat and near-repeat victimization has become a mainstay of criminology, crime science, and police science in the last two decades, and its contribution was recently assessed as a key area of theory underpinning environmental criminology and crime analysis (Wartell 2010; Wartell and Gallagher 2012).

Definitions and Concepts

People, places, products or services, vehicle, household, business, or systems (including virtual networks) are, once victimized, more likely to be victimized again. Further victimization by the same type of crime is most likely, but polyvictimization involving two or more crime types is also far more likely than would be expected by random chance. One has only to think of hate crime for this to be recognized.

A small proportion of targets are so chronically victimized that they become supertargets. One classic study found that 1 % of people experienced 59 % of all personal crime including violence and that 2 % of households experienced 41 % of all household crime. The supertargets are the 1–2 % of persons and households, respectively, and they represented around one in eight of all persons or households who were victimized (Pease 1998).

Key features of repeats are that they tend to occur sooner rather than later (Daigle et al. 2008; Mele 2009) and are more likely to be by the same prolific offenders, with success breeding repeats. The result is a temporarily elevated risk, greater with each subsequent crime. Similar general patterns of the extent and nature of repeats have been identified for most crime types and places where informed studies have been conducted, though Sidebottom's (2011) study of repeat burglary in Malawi observes that "[t]here is little research on repeat victimization in developing countries" (p. 1).

A growth area for repeat victimization studies has been the area of *victim careers* or *life-course studies* (Gabor and Mata 2004; Buzawa et al. 2006; Averdijk 2010). Another is that of *near-repeat victimization* or *near repeats*, a term coined by Frank Morgan in a study of burglary in Perth, Western Australia (2001). In this entry, the terms repeat victimization or repeats are sometimes used as inclusive of near-repeat victimization.

Spatially, it is well established that crime hot spots are often substantially, and sometimes exclusively, repeats and near repeats. A few hard-hit stores, for example, may account for peaks in crime maps, but this can be obscured by kernel density estimation techniques. Hence, repeat research has been lauded for providing more precise predictions and insight into a real crime patterns than some traditional hot-spot studies. And what is now sometimes termed predictive policing draws on the tradition of the revictimization predictor (Farrell 1995). The significant general expansion of repeat victimization research in recent years is illustrated by a recent study of personal repeat victimization, of potentially major importance, which suggests there is a genetic aspect to the phenomenon (Daigle 2010).

The following four sections cover the propositions that began this entry. They are followed by a short conclusion.

Most Crime is Repeat Victimization Against the Same Targets, and Variation in Crime Over Time and Space is Often Due Largely to Repeat Victimization

In the United States, 75 % of personal crimes over the course of a year are repeats according to the National Crime Victimization Survey, as shown in Table 1. In England and Wales, about half of property crime and two-thirds of personal crimes are repeats (see details below). The Canadian Victimization Survey found that 2 % of the population who were repeat victims of violence experienced 60 % of all violence (Perreault et al. 2010, and Table 2 which is based the work of Nazaretian and Merolla 2013). This sounds like a lot – and it is – but these are conservative estimates. There are various methodological reasons for this. The surveys tend to exclude crimes such as child abuse and victimization of young people or nonhuman animals which have even higher repeat rates. Likewise, robberies, burglaries, and other crimes against commercial establishments (not covered in conventional victimization surveys) tend to have higher repeat rates than equivalent crimes against individuals and households. Because surveys take a time window of 6 months or a year, events within the window which are repeats of pre-window events, or which are precursors of post-window events, are repeats masquerading as one-off crimes!

Repeat rates tend to be lower for property crimes than violent crimes, but, as noted above, repeat property crime rates are disproportionately higher in hot spots and high crime areas, so the potential for focused prevention efforts is greater. Overall, however, the evidence suggests that most crimes are experienced by repeat and near-repeatedly victimized persons, places, and other targets.

Repeat Victimization, Table 1 Personal crimes in the United States

Crime type	Prevalence per 100	Incidence per 100	% Repeats
Rape/sex assault	0.4	2.3	82.6
Robbery	1.3	3.6	63.9
Assault	8.5	37.4	77.3
Personal larceny	0.5	1.2	58.3
Total	10.6	44.6	76.2

Adapted from Planty and Strom (2007, p. 199)

Repeat Victimization, Table 2 Violent crime in Canada

Crime type	Prevalence per 100	Incidence per 100	% Repeats
Sexual assault	1.4	4.2	66.1
Assault	4.0	9.7	58.9
Robbery	0.9	1.3	31.0

Adapted from Nazaretian and Merolla (2013)

Much of the crime trend in England and Wales since 1980 – both increases and decreases – is linked to change in repeats. This is shown in Fig. 1 for household and property crimes measured by the British Crime Survey and draws on the excellent work of Britton et al. (2012). In the United States, a recent study published by the Bureau of Justice Statistics suggests a similar pattern, with a lot of the crime drop being due to declines in repeat victimization (Lauritsen et al. 2012).

The bulk of variation in violence over time in England and Wales was experienced by repeat violence victims (Fig. 2). Such incidents accounted for half to two-thirds of violence, and 68 % in 1995. Repeats also played a disproportionate role in burglary trends. Repeat victims of burglary experienced around a quarter of burglaries in 1981, rising to 40 % in 1995 (Fig. 3). However, while ostensibly one-off incidents doubled between 1981 and 1995, those at repeatedly victimized households more than trebled (a 330 % increase). Between 1995 and 2010, both singles and repeats fell back to their 1981 level.

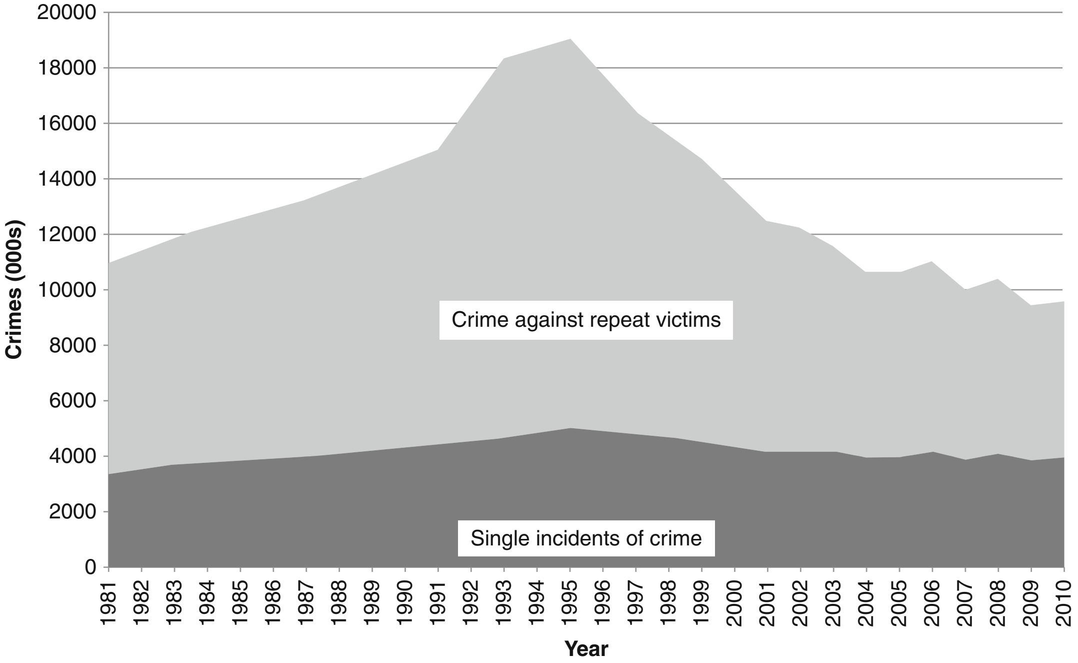
Repeated vehicle-related theft accounted for 40 % of such thefts in 1981, rising to half (49 %) by 1995. However, it accounted for less than one in three by 2010. That is, singles doubled while crimes experienced by repeat victims of car theft trebled from 1981 to 1995, after which repeats declined more rapidly than singles (Fig. 4).

The fall in repeats from 1995 was always greater than the overall fall in any particular type of crime (Fig. 5). This does not necessarily show that declining repeats drove the crime drop, but suggests explanations should certainly consider the role of repeats. Hence, aggregate crime rates seem to go up and down in large part due to variation in repeat victimization. This is consistent with crime increasing or decreasing as the same offenders victimize the same targets more or less often. Note also that these BCS statistics are quite conservative when it comes to the role of repeats because the Britton et al. (2012) analysis, brilliant as it is, stopped counting if a victim experienced more than five similar crimes! In summary, however, most crimes are repeats or nears, and they often underlie spatial, temporal, and other variations in crime.

One or 2 % of Potential Targets are Supertargets that Experience Around Half of Crime

Just as wealth is hugely, perhaps grotesquely, unevenly distributed in society, so too is victimization. Most repeat victims experience two, three, or four crimes in a year, but a few experience many more. The Gini coefficient, which is often used to measure wealth inequality, has also been applied to crime, along with the visually compelling Lorenz curves (Tseloni and Pease 2005). This section outlines some explanations for the existence of such supertargets.

Since a lot of crime is not reported to the police, and reporting rates likely diminish as the number of victimizations increases, a good tactic for police is to ask victims about their recent previous experiences with crime. By this simple means, victims, or the owners or managers of properties or other places where crime clusters,



Repeat Victimization, Fig. 1 Role of repeat victimization in all crime 1981–2010

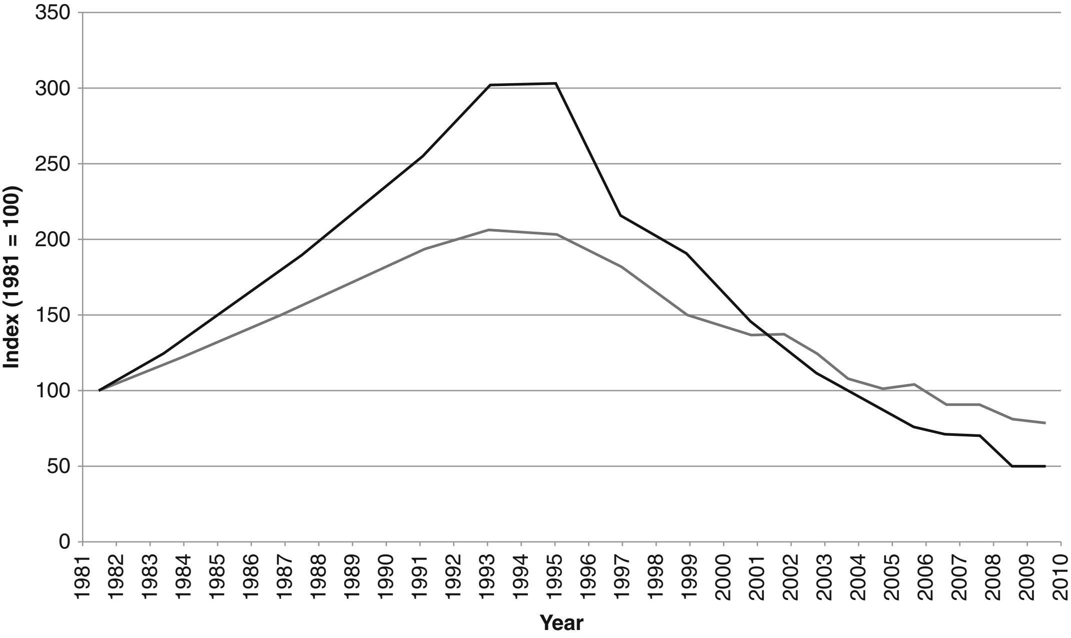
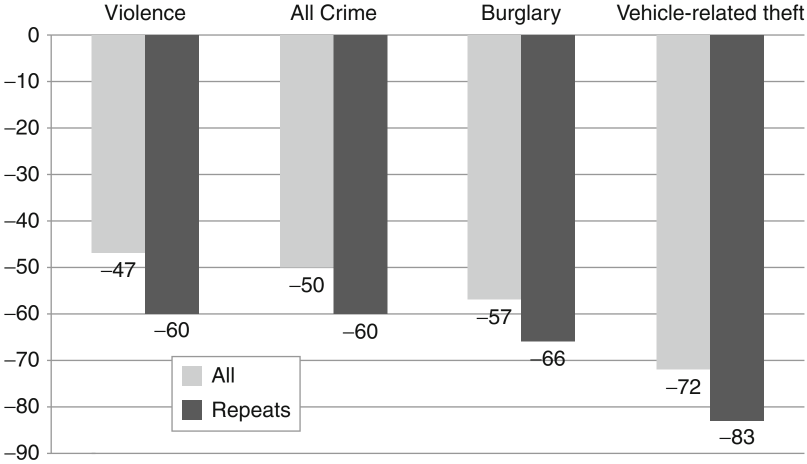
Repeat Victimization, Fig. 3 Single and repeat burglary 1981–2010



Repeat Victimization, Fig. 4 Single and repeat motor vehicle theft 1981–2010

Repeat Victimization, Fig. 5 The crime drop 1995–2010



can reveal patterns of repeat crimes that will not show up in traditional analysis of police records. This is a good means of gathering information about actual crime patterns that can then inform the response that is given by the police, victim services, and others. More specifically, the amount of resources spent on a response can then be tailored to the risk, with greater risk receiving proportional response. This type of model has been termed a graded response or an Olympic response with bronze, silver, and gold responses delivered, depending on risk. Police using this approach should be prepared for an increase in reported crime, as chronic victims become persuaded that such a report has become worthwhile.

There is less skepticism about the existence of supertargets when considering crime types for which high-frequency victimization is well proven. Family violence or incest provides one example, which can produce chronic repeat victims (survivors) of domestic violence, child abuse, and elder abuse. The proximity of victim and offender, perhaps living together and in the same family with emotional or economic reasons for not reporting crime, facilitates unconstrained repetition of the crime. A range of research has established that abuse can occur on a regular and frequent basis. More broadly, those with power or responsibility sometimes exploit their position to repeatedly victimize those in their care.

Crime against businesses is another area where supertargets have been identified. Some types of store represent more attractive targets than others. These include electronic goods stores, pharmacies, convenience stores, and some supermarkets. When such stores are located in high-traffic malls, their crime count rises exponentially. The same commercial establishments are the repeat targets of many shop thieves and the same returners, for example. Particular stores and commercial premises that are perceived as lucrative easy targets are frequently hit by burglars and robbers.

Disputes between neighbors or families in a neighborhood can produce high-frequency victimization. Groups or gangs may become involved in recurring targeting of the same household. A targeted household may experience many crimes of different sorts, including burglary, vandalism of property and vehicles, theft of and from vehicles, and threats and violence of various sorts against residents. Considering such contexts, the existence of chronic victims and polyvictimization by different types of crime should not be surprising.

Stalking and harassment are largely defined by their repetitive nature. Sexual victimization can also manifest itself as different types of crime (assaults, vandalism, cyber-stalking, threats) perhaps by an ex-partner or during a cohabiting or other relationship. Hate crimes, including racial attacks, homophobic crimes, and crimes against the disabled, may result in chronic victimization. A hate crime victim may be identifiable by their appearance, which could prompt victimization by different as well as the same offenders, more so if the location of the victim's household or workplace is known. In schools, the bullying of some victims is frequent and ongoing. A victim may attract victimization from other sources if he or she acquires a reputation as a suitable target.

Some lifestyles appear related to chronic victimization. Some professions, including police, nurses, and other caring professions, are more likely to experience crime. The work can entail regular interaction with likely offenders in risky situations. One study noted that "violent series crimes that occurred in connection with a person's job were usually committed by different offenders who were generally strangers. In contrast, violent crimes committed by spouses or acquaintances were usually perpetrated by the same person who was well known to the victim" (Dodge and Balog 1987).

Repeat offenders are more likely to experience repeat victimization (Fagan and Mazerolle 2008). This may be the result of a lifestyle which includes drug dealing, gang-related violence, ongoing disputes between rivals, or frequent interaction with criminal associates. Offenders are robbed while dealing drugs, fencing stolen goods, because they carry a stash of money and in disputes with co-offenders and rivals. Since offenders are less likely to call the police, their repeat victimization occurs with relative impunity.

A supertarget may emerge due to victimization by different offenders – a *risk-heterogeneity* explanation. High-frequency shoplifting at some stores falls into this category. In many instances, however, one crime boosts the likelihood of another occurring when offenders learn it is an easy and rewarding crime to commit – an *event dependence* explanation. The extreme case is where an offender is "dedicated" to a single target with which they frequently interact and know the likely risk and reward – as may be the situation in family violence, harassment, and stalking. The balance between the two theoretical mechanisms will vary according to the circumstances. The question then becomes why supertargets are under-researched.

Why Are Supertargets Often Overlooked?

It is probably difficult for some people to believe the extent of high-frequency victimization. Or perhaps it is just easier to overlook. Chronic victims are likely those least able to voice their complaint. The NCVS had been running for around 40 years before the Bureau of Justice Statistics began to properly acknowledge the importance of high-frequency victimization in the important study by Janet Lauritsen and colleagues (2012). And even that excellent study used the median frequency of victimization as an upper ceiling on crime counts for all victims. The British Crime Survey was similarly tardy in recognition, and having the issue drawn to the attention of the relevant Ministry excited criticism rather than recognition of the problem.

It is well documented that repeat victimization is generally understated in police data. When it comes to supertargets, this is more extreme, a conservative estimate being a twentyfold undercount (Frank et al. 2012). This is due to conditional probabilities. If the likelihood of a burglary reported to police is 50 %, then the likelihood of two at the same household being reported are 25 % (i.e., .5 ×.5 =.25). It follows that the likelihood that five burglaries at a household are all reported is .5 × .5 × .5 × .5 × .5 = .03125 or 3 %. This is a simplified version, but the basic argument is robust when the initial reporting likelihood and conditional likelihood of reporting of subsequent events are varied.

For crime surveys, the situation is different. If a poly-victim reports assault, burglary, robbery, car theft, and vandalism to a survey, each offence type is typically recorded as a separate, seemingly unrelated, incident or series of incidents. The British Crime Survey does not count as repeat victims those suffering repeated crime where each offense type occurs only once. Likewise, much chronic victimization will not be brought to the attention of the police, so supertargets will be less evident in recorded crime statistics.

Unfortunately, chronic victimization is sometimes swept under the carpet. It is sometimes cut from official crime because it can be “statistically awkward” to handle (Farrell and Pease 2007; Planty and Strom 2007). Crucially, when politicians use victimization surveys to set alongside police recorded crime statistics, to see whether the trends match, allowing chronic victims to be properly counted introduces a degree of sampling variability that is statistically inconvenient. In this way, statistical convenience triumphs over proper accounting of human suffering. Victim advocates may interpret this as institutional discrimination, and the impact is not trivial: If society’s resources in response to crime were apportioned according to risk, then the 2 % of supertargets would likely receive around half.

Preventing Repeat Victimization Reduces Crime When Measures Are Properly Developed and Implemented

Crime has been reduced around 20 % on average, and by greater amounts at victimized households, via targeted prevention efforts. This is the finding of a recent systematic review and meta-analysis of 31 evaluations (Grove et al. 2012; Grove and Farrell 2012). Most of the evaluations were of efforts to prevent residential burglary of which the most successful have two key characteristics:

- Measures that are locally appropriate and prevent repeats by the same *modus operandi*
- Measures that are thoroughly implemented

This makes crime prevention sound simple. Conceptually it is, but it is not always, easy to identify which prevention measures to introduce, to implement them, and to ensure they are used appropriately.

Ensuring that victimized households receive appropriate advice and then implement measures can be difficult. Even ensuring that police officers conduct security surveys at victimized properties has proven tricky in some instances.

The most effective measures tend to be situational. These often physically block opportunities for crime. The obvious tactics include locks and bolts in the case of burglary, but it can also include a range of other measures.

It is clear that there is plenty of scope for research into the prevention of other forms of repeat crime. Efforts to prevent repeat forms of commercial crimes, identity theft, and computer crimes, for example, appear under-developed, even though these may be areas where situational measures could be relatively easily introduced.

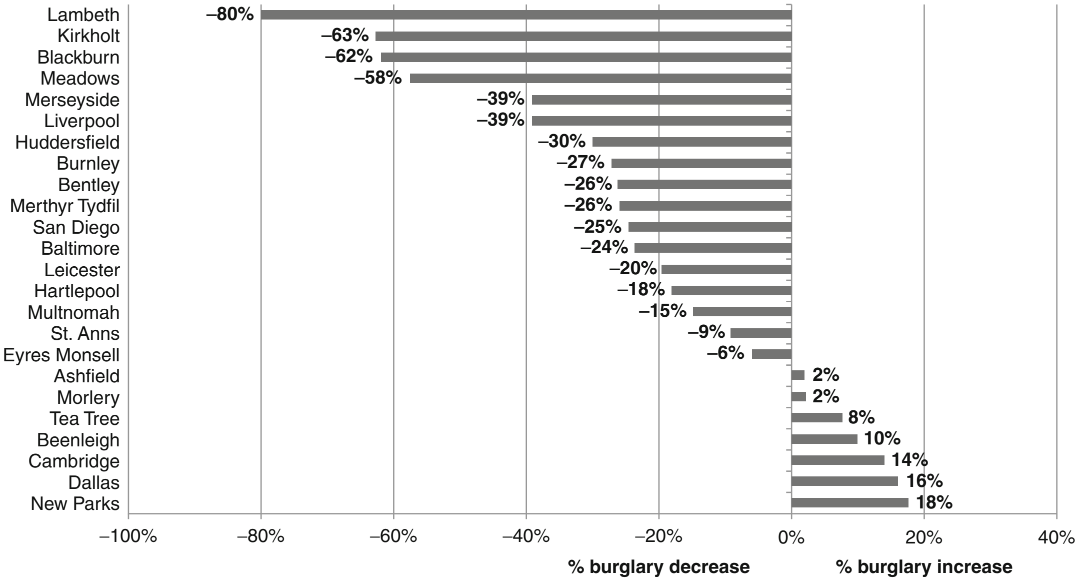
The percentage net change in burglaries for each of the 24 projects included in the systematic review is shown as Fig. 6. The percentage change in repeat burglaries is shown in Fig. 7 for the eight projects where it could be determined.

A Broader-than-Usual Conception of *Near-Repeat Victimization*, Referring to Crimes Linked by Their Similarity, May Prove a Useful Foundation for Integrating Theories of Crime Concentration

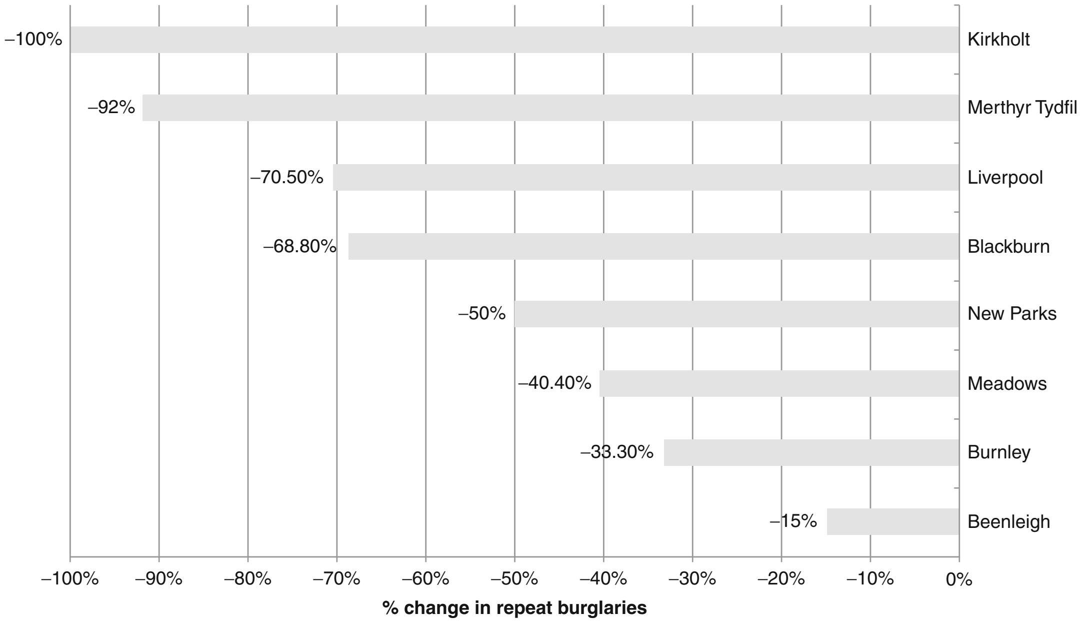
Crimes that are linked to previous crimes but not necessarily against the same target are known as *near repeats*. Spatial nearness is easily conceived, so near-repeat burglaries are of households close to one already victimized, usually fairly soon afterwards. Similar patterns have been found for other crimes (Ratcliffe and Rengert 2008; Wells et al. 2008; Youtsin et al. 2011).

Here, *nearness* refers not only to location and timing but to other characteristics of a crime. Thefts of hot products such as a smartphones often produce near repeats defined by the identical characteristics of the product as well as the similarity of the situation and crime event. The link between repeats and near repeats is the *similarity* of the targets. Similarity is attractive to offenders as the task is easier when the method, risks, and rewards are known. Similarity (or difference) may occur in terms of characteristics of the target, or the time, the location, the offender, the modus operandi, or the crime type.

The dominant theory of hot-spot formation is predicated on the concepts of crime attractors and generators (Brantingham and Brantingham 1995; Kinney et al. 2008). A place with high frequency



Repeat Victimization, Fig. 6 Percent change in burglaries by project



Repeat Victimization, Fig. 7 Change in repeat burglaries by project

of interaction between suitable targets and likely offenders *generates* crime. It may be a train station, a shopping mall, an entertainment district, or another activity node with a high flow of people. That is, even if per capita crime is no higher than elsewhere, a spatial concentration of crime still results. Think of a desert versus an entertainment nightspot. However, certain places then gain a reputation as locations with many suitable targets and *attract* offenders as a result.

The dominant theories of repeat victimization also embody two main components. The first is uneven risk (risk heterogeneity), such that some targets *flag* themselves as better than others. The second is greater ensuing risk (event dependence) wherein offenders learn that a target is worth revisiting, which *boosts* the likelihood they return. They have colloquially become known as flag and boost theories.

The existing theory of supertargets also largely explains why hot spots contain disproportionate repeat victimization. It can be viewed as combining a generator and a boost effect. An area may have high crime because of a generator effect wherein risk heterogeneity produces crime against particular targets. Each time a target in that area is victimized, its risk of revictimization is boosted. That risk increases with each victimization, so that a few targets progress to become supertargets. Other offenders may in turn be attracted. Incorporating near repeats into this model add to its predictive accuracy.

These key concepts – flags, generators, boosters, attractors, and near-repeat difference – may provide the foundation for a unified theory of crime concentration. This, in turn, may provide new impetus and understanding for crime prevention efforts targeting clusters of crime.

Conclusion

In the four decades since frequent returners to the emergency room of a Texan hospital were observed by Johnson et al. (1973), repeat and near-repeat victimization have emerged as a cornerstone of theory and practice in the study of crime. Repeats may often underpin, and perhaps cause, aggregate crime patterns and trends. The suggestion that the major crime drops of the last two decades may be related to reductions in repeat victimization is important when considering the precise mechanisms of change.

Yet while the importance of repeats is established, the intense concentration of crime on a few supertargets is an emerging topic with tremendous potential significance. Directing resources to prevent crime against supertargets would be particularly efficient.

Evidence from a range of studies suggests that it is possible to prevent repeat victimization and that doing so reduces crime. Situational crime prevention tactics tailored to the problem and well implemented seem to work best.

Despite a growing knowledge base, there remains much unexploited potential in repeat victimization research. This should include theory and theory testing, empirical studies, and far greater prevention effort, focused on different crime types.

Overview

This entry reviews what is known about residential burglary. It discusses what burglary is according to legal definitions and survey questions, it enumerates sources of knowledge about residential burglary, and it presents findings about its incidence and about which burglaries are most likely to be reported to police. The entry also describes the characteristics of the neighborhoods, individual dwellings, victims, and items that are the targets of burglary and of the offenders who commit burglaries. Further, the temporal distribution of burglary and patterns of repeat burglary victimization are discussed. The entry ends with a section on the prevention of burglary.

Introduction

A residential burglary is committed when someone enters an inhabited dwelling without permission and with the intent to steal. Although during the past two decades burglary rates have gone down worldwide, burglary is still a common offense. Most people will become a burglary victim during their lifetime. Burglary is listed as a property offense, but for most victims, the illegal entry into their homes has greater impact than the material loss they suffer. Most victims report to the police. The available knowledge about burglary is derived from the police, from victims, and from offenders. Burglars offend in disadvantaged neighborhoods with poor social control. They prefer dwellings that are unoccupied and easily accessible, and they prefer small, valuable, and disposable items (like cash, electronic gadgets, and jewelry). Most burglars are young males who steal to sustain an expensive lifestyle, often including drug use. Juvenile burglars are more likely to co-offend than adult burglars. Many burglaries are repeat burglaries of the same or a nearby address. There is some evidence that situational crime prevention measures are effective in reducing burglary.

Definitions

Residential burglary is the actual or attempted illegal entry into a dwelling with the intent to steal. Definitions vary among law enforcement jurisdictions and among victimization surveys with respect to a variety of details, including whether the entry requires force or destruction and what constitutes a dwelling.

In the United States, the Uniform Crime Reporting (UCR) program defines burglary as the unlawful entry of a structure used as a permanent dwelling to commit a felony or theft. They use three classifications in specifying burglary: forcible entry, unlawful entry where no force is used, and attempted forcible entry. In many jurisdictions, burglary also includes “distraction burglary,” where falsehood, trick, or distraction is used on an occupant to gain access to the property. In many jurisdictions, gradations of burglary are distinguished depending on whether the offender was armed, whether co-offenders were involved, whether it took place at nighttime, and whether the property was occupied when entered.

The nature of the property entered may also play a role of the definition. Some countries exclude theft from a secondary residence or from an attic or basement in multi-dwelling buildings. Some countries include theft from a car (Aebi et al. 2006). Illegal entry and theft from structures not used as a dwelling, such as schools, offices, and shops, are burglaries, but they are not domestic or residential burglaries.

Because surveys have become influential sources of knowledge about burglary, it is important not only to consider legal definitions of burglary but also to understand how burglary is defined in survey questionnaires and to note the differences between these definitions. In the International Crime Victimization Survey (ICVS), these questions are the following (van Dijk et al. 2008: Appendix 8, Q60 and Q65):

> Over the past five years, did anyone actually get into your home/residence without permission, and steal or try to steal something? I am not including here thefts from garages, sheds or lock-ups.

> Apart from this, over the past five years, do you have any evidence that someone tried to get into your home/residence unsuccessfully? For example, damage to locks, doors or windows or scratches around the lock?

The questions in the British Crime Survey (Nicholas et al. 2007, p. 75) are similar but refer to the last 12 months:

> During the last 12 months . . . has anyone GOT INTO this house/flat without permission and STOLEN or TRIED TO STEAL anything?
>
> [Apart from anything you have already mentioned], in that time did anyone GET INTO your house/flat without permission and CAUSE DAMAGE?
>
> [Apart from anything you have already mentioned], in that time have you had any evidence that someone has TRIED to get in without permission to STEAL or to CAUSE DAMAGE?

Those in the US *National Crime Victimization Survey* (*NCVS*) refer to the 6 months that precede the interview. The main burglary question in the NCVS is:

> In the last 6 months, has anyone broken in or ATTEMPTED to break into your home by forcing a door or window, pushing past someone, jimmying a lock, cutting a screen, or entering through an open door or window?
>
> Based on the answers to subsequent follow-up questions (that also cover theft from garages, sheds and hotel rooms), and in line with the UCR classification, the *NCVS* distinguishes between completed burglaries (either "forcible entry" or "unlawful entry without force") and "attempted forcible entries."

Sources of Knowledge

The available knowledge of residential burglary stems from the criminal justice system, from victims, and from offenders. Agent-based computer simulation is a new approach.

Most countries collect and publish statistics on crime recorded by the police and other law enforcement agencies. The European Sourcebook of Crime and Criminal Justice compiles and harmonizes crime and justice data, including burglary statistics, from about 40 European countries (Aebi et al. 2006). In the United States, the Uniform Crime Reports (UCR) are the major source of information at the federal level collected by law enforcement agencies.

The crime victimization survey was developed in the 1970s as an instrument to measure the "dark figure" of crime not reported to or not recorded by the police. In these surveys, a random sample of the population is asked to report their victimization experiences in the period before the survey. In the United States, the *National Crime Victimization Survey* started in 1972. A special methodological feature of the *NCVS* is that it employs a rotating panel design: households remain in the sample for, at most, seven interviews, a feature that affords longitudinal data, albeit over a relatively short period. Another distinctive feature is the use of the first interview as a "bounding interview" to minimize the telescoping effect, that is, the tendency of respondents to report that incidents are more recent than they actually are.

The International Crime Victimization Survey (ICVS), which started in 1987, is the only standardized victimization survey that includes respondents from a large number of countries. There have been five main sweeps of the ICVS (1989, 1992, 1996, 2000, 2004–2005). In the most recent sweep, 38 countries were represented, of which 30 relied on nationwide samples.

Offender accounts are the third source of information used to gain knowledge on burglary. Because the detection rate of burglary is universally low, offender accounts are not useful for estimating the size of the burglary problem. Rather, offender accounts help us understand why and how they commit burglaries. Most offender-based research on burglary has used accounts of detained offenders, but some have sought access to active offenders "out on the street" (Wright and Decker 1994).

Computer simulation, in particular agent-based modeling, is a relatively new approach to understanding phenomena related to burglary (Birks et al. 2012). In agent-based models of burglary, mathematically explicit behavioral theories are formulated by specifying behavioral rules for autonomous "agents" (e.g., burglars, victims, and law enforcement officers). The system-wide implications of their actions (e.g., the burglary rate, the amount of repeat victimization, or the level of spatial clustering of burglaries) are studied and are compared to phenomena in the real world.

Incidence, Prevalence, and Trends

Victimization surveys are generally seen as the best available source for estimating the residential burglary rate. Three related measures have been used to determine burglary victimization quantitatively. *Prevalence* is the number of burglary victims as a percentage of the population, *incidence* (or the burglary rate) is the number of burglaries per person or household, and *concentration* is the number of burglaries per victim. The distinction is important because a substantial number of burglaries have been shown to be repeat burglaries at the same address within a relatively short span of time.

Burglary is a prevalent crime worldwide. For the industrialized countries that took part in the 2004–2005 ICVS, annually there were on average 4.4 completed or attempted burglaries per 100 households. With the exception of Mexico (8.8 burglaries per 100 households), the burglary rate tends to be highest in Anglo-Saxon countries, in particular England and Wales (7.9 %), New Zealand (7.8), the United States (7.5), and Australia (6.1). Countries with a low burglary rate are Japan, Spain, and the northern European countries of Sweden, Finland, Norway, and Germany.

In most countries for which data are available, the ICVS shows that the incidence and prevalence of burglary have been decreasing since the early 1990s (van Dijk et al. 2008, pp. 66–68). The ICVS findings on the long-term trend in burglary rates are supported by data from individual countries, such as the *NCVS* in the United States and the BCS in England and Wales, which may be more reliable because they are updated annually and survey a large within-country sample.

The burglary rate (incidence) in the United States has been decreasing steadily, from 11 burglaries per 100 households in 1973 to fewer than 3 in 2005. In England and Wales, the long-term trend since 1981 is not linear. From 1982 onward, the burglary rate steadily increased until it reached a peak in the early 1990s. Thereafter, however, from 1995 to 2005, the number of burglaries dropped by 59 % (Nicholas et al. 2007, p. 74).

It has been suggested that this continuing long-term decrease in residential burglary is caused by the increased use of antiburglary devices and measures, such as alarm systems, locks and bolts, and improved lighting (van Dijk et al. 2008). The evidence for this claim is reviewed in the section on prevention.

Reporting to the Police

Not all crime victims report to the police. The seriousness of an offense is the best predictor of whether a victim reports to the police (Goudriaan 2006). In the case of burglary, victims of burglary attempts are less likely to report to the police than are victims of completed burglaries, victims of completed burglaries are more likely to report if force was used to gain entry, and victims with (larger) monetary losses are more likely to report than those who lost nothing or little. The reasons victims retrospectively give about their motivations to report or not report to the police vary from perceived moral obligations ("crimes should be reported") to cost-benefit considerations ("to recover property," "to collect insurance").

Burglary reporting rates vary across countries. No less than 90 % of completed burglaries are reported in the Netherlands, Belgium, and Scotland. In the USA, the percentage is 77. The difference between the reporting rates of completed and attempted burglaries is remarkably constant: in most countries covered, completed burglaries are reported about twice as often as attempted burglaries (van Dijk et al. 2008, p. 114).

Targets

The burglary target selection process has been described as a spatially structured hierarchical process, in which the offender first selects a geographic area that fits his or her purposes and subsequently targets a specific street and a specific property on the chosen street. Once the burglar is inside the property, the items to be stolen become the actual targets. Alternatively, in some cases, burglary is a relational offense, for example, when a former husband burglarizes the home of his ex-wife for retaliation, so that the victims rather than their possessions are the real targets. Consequently, a burglary can have multiple "targets." The present section reviews which characteristics of areas, individual premises, and victims are associated with burglary risk and what items tend to be stolen.

Areas

Urbanized areas have higher burglary rates than rural areas, and burglary rates are elevated in deprived areas, in ethnically mixed areas, and in areas with high residential turnover. The relationships between burglary risk and deprivation, ethnic heterogeneity, and residential turnover have been explained as the result of two very different mechanisms.

The first is that all three are associated with a lack of social control among residents. When social control (or social organization or collective efficacy) is lacking, residents are less likely to take notice of crimes taking place in their environment and, if they do, are less likely to intervene personally or call the police to stop it. Thus, where social control is lacking, burglars run lower risks of apprehension, and residents run higher risks of victimization.

The second reason is that most offenders themselves live in deprived, ethnically mixed, and unstable areas and usually offend within their own awareness spaces. Thus, these measures are largely synonymous to being nearby and exposed to concentrations of motivated offenders. This may explain the paradox that although offenders themselves claim that they select prosperous targets, the empirical evidence on actual targets is that burglary is concentrated in deprived areas. Apparently, offenders' preferences for prosperous targets are local preferences: they prefer the most prosperous targets within the (deprived) area they are familiar with. It has indeed been shown that visibly affluent households (e.g., detached and semidetached properties as opposed to terraced properties and flats) in the most deprived areas have the highest risks of burglary victimization.

Premises

A number of physical characteristics of residential units have been associated with burglary risk. Some of these apply to the location of the house or to the design of its immediate environment. Others apply to the structure of the unit itself. Proximity to major thoroughfares increases risk, and being located in a dead-end street or cul-de-sac decreases it, possibly because the former are more and the latter are less likely to become part of many offenders' awareness spaces. The findings are also compatible with a preference on the part of burglars for houses that allow for multiple exit routes. With respect to the units themselves, it has been shown that properties at the corner of a street block have larger burglary risks than properties in the middle of the block and that the burglary risk is elevated in detached and semidetached houses (as compared to terraced properties and flats), especially if they border playgrounds, woods, or other nonresidential area or if parts of the house are not visible from the street.

The three main property selection criteria that burglars use are surveillability, occupancy, and accessibility. Surveillability indicates whether properties can be overseen by other people. It is indicated by distance from the street, the absence of trees or hedges that block sightlines, and the presence of lighting. Occupancy is whether there are people at home. To the prospective burglar, it may be indicated by the presence of noise or light in the house, a car on the driveway, toys in the garden, or the absence of unopened mail. Accessibility indicates how easy it is to break into the property. Open doors and windows are a case in point, although they might also signal occupancy. Dogs and target-hardening devices, such as window locks and alarm systems, restrict accessibility.

Victims

The lifestyles of potential victims play a major role in their victimization risk. Because to commit their offense burglars mostly depend on the times that residents are away from home, a major predictor of burglary victimization is the proportion of time a property is unoccupied. This proportion is directly related to the frequency with which residents go out in the evening and go shopping. It is indirectly related to the composition of the households – single-person households and single-parent families have higher risks – and with age, younger households have higher risks. Renters (as opposed to homeowners) and unemployed residents also have elevated burglary risks, but the reason is unlikely to be related directly to the proportion of time their houses are unoccupied.

Although the issue is not reported extensively in the literature, some results suggest that burglary is not always a crime directed against anonymous victims but one in which victims are targeted who are known to the offender. According to the 1998 British Crime Survey, 41 % of burglary victims were able to say something about the offenders. The offender was a complete stranger to the victims in only 49 % of these cases; in other cases, the offender was casually known (17 %) or even well known (34 %). While the 41 % of cases in which the victim was able to say something about the offender are probably not representative for all burglaries, it emphasizes that burglary offenders and victims quite often know each other. In some cases, for example, those in which a former spouse burglarizes his or her partner's home, it may be the victim who is the burglary target.

Items

If the victim is not the target of a burglary, the item to be stolen is the ultimate focus of acquisitive crime. What do burglars steal? Police records and victim surveys show that the most frequently stolen items are cash, jewelry, and portable electronic gear such as cell phones, cameras, audio and video equipment, computers, game consoles, and televisions. Most of these items are "hot products" that have attractive features for thieves in general and burglars in particular (i.e., they are concealable, removable, available, valuable, enjoyable, and disposable). Cash money is most burglars' favorite item.

Offenders

Burglary is a covert crime. Contemporary knowledge of it is hampered by the fact that the detection (clearance) rates of burglary tend to be low: 12.6 % in the United States in 2006 and generally below 10 % in cities with a population above 500,000, much like those of other covert crime. As a consequence, knowledge of offenders is based on interviews with those who have been arrested or sometimes on observations of and interviews with active burglars in natural settings.

When asked about motives or precipitating factors in the decision to commit a burglary, most offenders mention financial need. Often offenders are driven by the wish to continue a lifestyle they cannot afford without offending. In particular, the continued use of expensive drugs appears to motivate burglars. The influence of others further seems to trigger the involvement in burglaries, and some mention boredom and a need for thrills. Burglaries tend to be committed by young males. Of the burglars arrested in the United States, 86 % are male and half of them are younger than 22.

Among juvenile offenders, burglary tends to be a joint activity. The major reason for this appears to be social rather than practical, as the group setting induces potential offenders for various reasons to join a risky endeavor they would not get involved in on their own. For practical reasons, such as the possibility of carrying stolen items and the usefulness of having one offender act as a lookout, one would expect co-offending to be common in burglary. Offender accounts, however, suggest that adult offenders are solitary burglars most of the time, although one might question whether these accounts are always valid, as interviewed burglars tend to be very reluctant to talk about their accomplices.

Unlike popular images of the persistent burglar, burglary specialization is uncommon. Most offenders are highly versatile, and this appears to be true for burglars as well. There is no evidence that burglars will use violence only when they are unexpectedly confronted with victims or bystanders. Many offenders who commit burglaries also commit violent offenses.

Some authors have proposed a typology of burglars. Maguire and Bennett (1982) distinguish "high-level burglars," "middle-level burglars," and "low-level burglars," a typology that is confirmed by the offense styles described by Bennett and Wright (1984, pp. 43–49), who distinguish between "planners," "searchers," and "opportunists," respectively. Opportunistic offenses occur when a burglary opportunity presents itself and is immediately, without further planning, acted upon. The decision to burglarize, the selection of the target, and the burglary itself take place with little or no time gaps in between. In the searching offense, there is a time gap between the decision to commit a burglary and the selection of a target, but not between the target selection and the act of burglary; in other words, the searcher explicitly searches for a target and attacks when it is found. A planned burglary involves time gaps both between the decision to burglarize and the target selection and between the target selection and the actual burglary; thus, there is forethought and preparation before each phase. As these findings are based on accounts of arrested offenders and because it is possible that offense styles are related to the likelihood of apprehension, it is virtually impossible to estimate how these styles are distributed in the population.

Time

The risk of residential burglary varies across the hours of the day, across the days of the week, and across the weeks of the year. Because burglars tend to avoid confrontations with residents and prefer unoccupied targets, the exact timing of a burglary is often unknown; it is typically discovered when the residents find their place burglarized on returning home. The timing of burglaries is specified in police records using a time window that reflects when residents left their home and when they returned. According to the *NCVS*, in 28 % of the burglaries in the United States in 2005, the victims or the police had no idea what time of day the burglary was committed, although daytime burglaries (between 6 a.m. and 6 p.m.) were slightly more common (53 %) than nighttime burglaries (47 %) in those cases whose timing was known. In England and Wales, 61 % of burglaries occur between 6 a.m. and 6 p.m. (Budd 1999, p. 19). But the patterns display much larger variations, with the least likely burglary hours being those that most residents spend at home.

As about 30 % of burglaries occur during the weekend, from 6 p.m. on Friday evening to 6 a.m. on Monday morning (Budd 1999, p. 19), there is little evidence for a weekly time cycle in burglaries.

Like most types of crime, burglary appears to fluctuate systematically over the seasons of the year. In the United States, burglary rates peak during the summer months and are below average in winter. Interestingly, the pattern is reversed in England and Wales, which are also in the northern hemisphere but where burglaries peak in the winter, especially December and January.

Some, if not all, of the temporal variation in the timing of burglaries is induced by the time use of potential victims or guardians: burglaries usually take place when residents or housekeepers are away from home and sometimes when they are asleep. In addition, offenders themselves have routine activities, such as school or work, that may give rise to burglary opportunities during certain times of the day.

Another part of the (daily and seasonal) temporal variation is induced by burglars' preference to offend under the cover of darkness in order to minimize their risk of being seen and recognized and arrested. As a preference for darkness is not always compatible with a preference for unoccupied homes, burglars' preference for darkness may depend on attributes of the potential targets. For example, it has been found that in daylight, burglars select targets in upmarket low-density residential areas where residents are employed, whereas in darkness, they preferred to target dwellings in deprived high-density areas.

The act of burglary itself is typically short. According to burglar accounts, the majority of burglars spend less than 10 min in the dwelling they burgle.

Repeat Victimization and Risk Communication

Repeat burglary victimization occurs when a property is burglarized more than once within a specified period (e.g., a year). Many studies have demonstrated that prior burglary victimization is associated with an elevated risk of future burglary victimization (Johnson et al. 1997). Repeat burglaries tend to occur swiftly (Polvi et al. 1991) after the initial burglary. Often, revictimization takes place within days or weeks. After a short period, the risk declines rapidly until it reaches its original level. While the data, methodologies, and outcomes differ somewhat across studies, a characteristic exponential decay in the time course of repeat burglary victimization has been confirmed in many studies.

There are two explanations for these findings (Tseloni and Pease 2003). The first is that burglary victimization simply *flags* properties with lasting attributes that attract offenders. According to this explanation, both the initial burglary and the repeated burglary reflect the elevated risk associated with stable attributes of the target. The second mechanism is that the initial victimization *boosts* the likelihood of a repeat. Under this mechanism, the initial burglary alters something about the property or the victim that increases the risk of revictimization.

It has been argued that the temporal pattern of repeat burglaries in particular often suggests the involvement of the same offender or offender group in both offenses (Polvi et al. 1991). Indeed, the boost explanation is compatible with the possibility that a repeat offense against the same premise involves the same offender who committed the initial offense and who returns to collect items not stolen during the initial burglary or that have been replaced since then. On the other hand, in the wake of a burglary, one should expect victims to be extremely vigilant and maybe to install burglary prevention devices, which should logically decrease the risk of repeat victimization. The typical time course of repeat burglary supports the boost explanation of repeat victimization. In particular, it has been viewed as tentative evidence that in a typical repeat burglary, the perpetrators are the same people who were involved in the initial event. Although the exponential decay in the time course itself is not sufficient evidence for this claim, as it may also indicate unobserved risk heterogeneity (Townsley et al. 2000), there is also evidence from interviews and offender accounts that returning to a previously targeted property is a common burglar strategy, especially among prolific offenders.

In the wake of a burglary, properties near the targeted property run heightened burglary risks as well. The phenomenon was first locally established in Australia and England. The ubiquity of such “near repeats” has been demonstrated in no fewer than ten regions around the world (Johnson et al. 2007). Involvement of the same offenders who committed the initial burglary is also likely in near repeats. Near repeats could be displaced repeats, for example, if an offender returns to a previously burglarized property but finds it well secured and subsequently targets an alternative nearby property.

Prevention

What preventive measures have been taken to reduce burglary, and what is known about their effectiveness? Burglary prevention is not typically concerned with changing the attitudes of offenders, partly because efforts to change the delinquent attitudes and behavior of burglars cannot be very specific, as offenders are quite versatile. Another reason is that the burglary detection rate is so low that only a small minority is ever arrested and eligible for rehabilitation. Increases in the burglary detection rate may decrease the number of burglaries, as increased detection will translate into burglary’s being perceived as a much more risky crime for offenders than before. Thus, although improving burglary detection cannot prevent the burglary that has been detected, it may deter the same and other offenders from committing future burglaries.

In this respect, new developments in DNA profiling are interesting, as DNA is most helpful in crimes that are the most difficult to detect. Although DNA samples currently make a relatively small contribution to all detections, they make a powerful contribution when they are available.

Most conventional preventive measures against burglary can be categorized as situational crime prevention, which include measures directed to change the immediate situation in which a burglary could potentially occur. Situational measures against burglary can be taken at various levels. First, target-hardening measures can be taken at the level of the individual property. Data on target-hardening measures of individual properties in the ICVS demonstrate that the penetration of burglar alarms and special door locks is higher in Anglo-American countries (England and Wales, Australia, United States, Canada, Scotland, Northern Ireland) than in Europe and Japan and that it is highest in England and Wales (van Dijk et al. 2008, pp. 135–139). Typically, at country level, the dissemination of target-hardening devices is more or less proportional to the burglary rate. For example, England and Wales and Australia have the highest burglary rates and the highest levels of installed target-hardening devices. The most likely explanation of this finding is that citizens respond to high burglary rates by trying to defend themselves against burglaries.

A considerable number of British householders have installed devices that strengthen the physical barriers against unlawful entry to their property, such as double locks or deadlocks (76 %), window locks (80 %), and security chains on doors (32 %). Further, many have taken measures that draw attention to illegal entries, such as outdoor (40 %) or indoor (24 %) sensor or timer lights and burglar alarm systems (29 %). These home security measures might appear to be a key defense against burglary victimization. Households with no home security measures were almost ten times more likely to have been burgled as households where there were simple security measures such as deadlocks on doors and window locks. Alarm systems only weakly differentiate between households that were victimized and those that were not. That simple security measures such as locks help to keep burglars out is also suggested by the fact that victimized households that experienced an attempted burglary were more likely to have double locks or deadlocks than those where entry was gained (Nicholas et al. 2007, p. 76). This is not the case with respect to alarm systems: an equal percentage of victims of completed burglaries and victims of attempted burglaries has an alarm system. If alarms are not effective, this might be due to their lack of specificity. In Charlotte, North Carolina, it was found that 98 % of alarm activations were false alarms (LeBeau and Vincent 1997).

The simple negative correlations between target-hardening measures and burglary risk may be spurious and may indicate that low-risk households (e.g., homeowners, high-income groups) invest more in burglary prevention than do high-risk households for reasons not directly related to the actual or perceived burglary risk (e.g., because the rich can better afford antiburglary devices or because homeowners can expect longer term benefits).

Some target-hardening measures apply to larger entities than individual premises. Alley-gating, for example, is a successful target-hardening measure that prevents unauthorized entry from the rear of properties of a block of houses. In general, the deterrent effects of individual (property-level) measures are stronger if these measures are also adopted in the wider community.

There is probably no government in the world that has invested as much in reducing burglary as England and Wales, starting with the Safer Cities project in 1988 and more specifically with the Reducing Burglary Initiative that started in 1999. As most of these initiatives are being constantly evaluated (many of them applying quasi-experimental designs with control groups and pre-intervention and post-intervention measurements), this has also generated a host of information on the effectiveness of various prevention methods.

A comprehensive evaluation of nearly 300 antiburglary schemes in England and Wales

(Ekblom et al. 1996, p. 41) found that a combination of target-hardening and community-oriented action (such as fostering Neighborhood Watch, property marking, raising burglary awareness among residents) worked best but that target hardening could also work alone. This is in line with other research on target-hardening interventions, which has concluded that whole-area target hardening can reduce local burglary rates in the short term if continuous publicity is heard or viewed by prospective offenders.

Independently of the prevention tactic chosen, publicity appears to increase the effects of prevention schemes. Apparently, this works because it informs and deters potential offenders from burgling in the area, although publicity may also sensitize potential victims and increase their vigilance. When publicity precedes the implementation, it often reduces burglary in the period before the actual intervention (this may actually undermine the proper evaluation of the effect of the intervention itself, however). It may also reduce crime in a larger geographic area than where the intervention is implemented, and it may prolong the benefits of the intervention.

In general, the largest burglary reductions are obtained by focusing on the areas or on the victims with the highest burglary risks. This explains part of the success of prevention schemes in England that were aimed at preventing repeat burglary victimization by varying means. The Kirkholt and the Huddersfield projects resulted in substantial burglary reductions through multitactic interventions, probably in part because they addressed people who had recently been victimized and thus sensitive to and aware of the emotional and material consequences.

Conclusion

While over the years there has been a lot of continuity in the literature, some important developments may be highlighted. The first is the worldwide drop in burglary. The debate on the causes of the drop is ongoing, but the drop itself cannot be mistaken.

The second development concerns the nature and comprehensiveness of information on burglary. In 1991, the *National Crime Victimization Survey* had been under way in the United States for nearly 20 years, the British Crime Survey had just started in 1982 and did not yet follow an annual cycle, and the International Crime Victimization Survey gained momentum only during the 1990s. Similar developments can be observed with respect to police-reported burglary. In the United States, the Uniform Crime Reports have been reported for decades, yet many other countries have lagged behind. The European Sourcebook is an example of a new initiative to collect and standardize information from various countries and to stimulate international comparison. Noteworthy are a number of authoritative studies based on offender accounts of burglary, either based on prison interviews (e.g., Rengert and Wasilchick 2000) or interviews with active burglars (e.g., Wright and Decker 1994).

A third development to be highlighted is the increasing salience of repeat burglary victimizations in the literature. The success of the repeat burglary prevention programs in the United Kingdom has shown that repeats can be prevented, thereby reducing overall burglary rates substantially. An emerging line of research generalizes repeat victimization by showing that risk of revictimization can be communicated to nearby dwellings.

Some issues require more research. One is the offender-victim nexus. It has been demonstrated repeatedly that offenders are disproportionately likely to be crime victims themselves; another question is whether offenders and victims in the same incident are strangers to each other. Although the issue has not been studied extensively, some findings suggest that quite often victims have an idea of who the offenders are. Ethnographic research shows that offenders quite often know who their victims are, as they tend to select them from a pool of acquaintances.

A second issue that requires more research is the effectiveness of situational crime prevention measures. Although it has been argued that surveys demonstrate strong negative correlations between target-hardening and burglary risk and although trend analyses show that increasing levels of burglary prevention devices are aligned with decreasing burglary rates, the evidence has not always been compelling, and the findings stand in strong contrast to the accounts of offenders, who generally emphasize that target-hardening measures play a minor role in the selection of dwellings.

The detection of burglary should be a third research priority. Worldwide the detection rate of burglary is low and a concern to the police. Possibilities for burglary detection offered by contemporary detection methods and tools (such as DNA matching, CCTV surveillance) have not yet been systematically investigated. The low burglary detection rate should also concern investigators who base their findings on police data or on accounts of arrested burglars. If fewer than 10 % of the burglaries are detected, is there any guarantee that those arrested are representative of the total burglar population? DNA databases may help to solve this puzzle, not by increasing the detection rate but by providing evidence of the behavioral patterns (geographic, temporal, modus operandi) of those offenders who have never been arrested but whose DNA stains have been left at multiple burglary scenes. If the behavioral patterns of these burglars resemble those of arrested offenders, it would increase confidence in present findings that are based on arrested offenders only.

Resistance to State Crime

Elizabeth Stanley[1] and Jude McCulloch[2]
[1]School of Social and Cultural Studies,
Victoria University of Wellington,
Wellington, New Zealand
[2]Arts Faculty, Monash University, Clayton,
Victoria, Australia

Overview

Resistance is an undeveloped aspect of state crime scholarship. Criminologists have been successful in naming state crimes and exposing the violence and harms committed by states but less so in documenting, analyzing, and theorizing the ways individuals and movements challenge, oppose, and even prevent and stop state crimes. State crime scholars are increasingly interested in defining resistance and describing the spectrum of activities that might be considered resistance. Criminologists are also interested in exploring the impact of resistance on state crime and reflecting upon what makes resistance effective in both the short and longer term, along with the factors that might encourage or discourage people to engage in resistance. State crime scholars also need to consciously consider the ways their scholarship might contribute to resistance. This entry sets out criminological contributions to the study of resistance to state crime and maps out some potential future directions for scholarship and research.

Introduction

The capacity of state officials and their contractors to kill, maim, exploit, repress, and cause widespread human suffering is unsurpassed (Green and Ward 2004). The extent and nature of state violence and harm has been successfully exposed in state crime scholarship. Crimes committed by states far outweigh those by individuals and non-state actors. State crime scholars have analyzed how acts including genocide, torture, corruption, escalating militarization, and environmental destruction have been led by the state. They have also developed understandings of how state crimes are managed at individual, societal, institutional, and structural levels; illustrating, for instance, how individual perpetrators are "made"; how bystanders fail to intervene; how state organizations fail to provide justice to victims; and how state violence is typically directed at the least powerful (see, e.g., Cohen 2001; Huggins 2010; Stanley 2009). State crime scholarship has provided significant new approaches in the way criminologists think about crimes, victims, and perpetrators.

One aspect of state crime literature that remains undeveloped is resistance – criminologists have so far paid little attention to the instances where state crime has been challenged or contested and even halted or prevented. Criminologists have tended to present a depressing catalogue of inhumanity and suffering without a corresponding analysis of the humanity and vitality of those who have resisted state violence. Many key historical moments have involved resistance to state crime: the abolition of slavery, the resistance movements of World War Two, the achievements of the civil rights movement in the United States, the implementation of the International Criminal Court, and the 2011 struggles across the Middle East provide just a few examples. Resistance to state crime is ripe for further criminological study.

This entry provides an overview of the criminological insights and debates on resistance to state crime thus far. In addition to exploring what resistance might mean in the context of state crime, it responds to a number of key questions: Who engages in resistance? What might be viewed as "successful" resistance?

And, what might be the role of criminologists in supporting or engaging in efforts to resist state crime? Finally, the entry highlights some directions that criminologists might take in future resistant responses to and analyses of state crime.

Fundamentals

While much of criminology has focused on the support of state policies and practices, even where such policies and practices lead to routine and institutionalized harms, there is a growing literature that focuses on state crime. Criminologists have debated the construction of crime, critiqued the state, and have sought to take control of the definitions attributed to harmful or injurious behaviors. In doing so, scholars have implicitly engaged in or supported resistance to state crime. State crime scholars have been adept in critically analyzing, and refusing to accept, the techniques of denial that frequently accompany acts of state criminality (Cohen 2001). Moreover, in analyzing how the identities of state crime victims are ideologically managed, so that victims are frequently defamed as terrorists or criminals, they have confronted popular conceptions that victims of state crime are deserving of harsh treatment, violation, and even elimination (Stanley 2009; McCulloch and Sentas 2006). State crime scholars have "unpacked" how state crimes come to be made acceptable and justified within complex political processes of neutralization and criminalization. In taking this route, some criminologists have asserted that numerous state actions are unfair, unjust, troubling, damaging, and in many instances crimes of grave magnitude. By their very nature, these analyses are imbued with a sense of resistance.

State crime scholars have attempted to intervene in state crimes by challenging state impunity. For instance, criminologists Hagan et al. (2005) have, through statistical and regression analyses, demonstrated how the Sudanese government directly supported the killings and rapes of Darfurians. In illustrating the racial targeting of African Darfurians by state actors, they bolstered prosecutorial evidence in characterizing these events as state-sponsored genocide. This study, like others of its kind, illustrates that criminological work can play an active role in resisting state crime.

Criminologists have, however, generally failed to consciously consider resistance either as an integral part of state crime scholarship or as a discrete topic to be pursued within state crime studies (see, however, Green and Ward 2000; Pickering 2002). While resistance can be read into state crime scholarship, it is generally embedded in another "story," such as developing a historical context, illustrating techniques of denial, or simply writing against state crime. A "more consciously 'applied' form" of analysis on resistance is needed (Friedrichs 2010, p. 5). This goal underpinned the first symposium on state crime and resistance, convened by Elizabeth Stanley in New Zealand in January 2010. This event propelled new thinking and writing about resistance – including a special edition of *Social Justice* in 2010 as well as a Routledge book edited by this entry's authors (Stanley and McCulloch 2013).

State crime scholars have grappled with defining resistance to state crime. After all, the scope of activities that might be considered as resistance is wide. Resistance is an elastic term that covers various actions. It has multiple dimensions and operates along a continuum. In relation to contesting state crime, Sharon Pickering (2002) and Rob White (2010) argue that resistance could include actions that are passive or active, hidden or overt, peaceful or violent, verbal or physical, ad hoc or strategic, a one-off event or a perpetual happening, concentrated on a limited event or led by a global focus, led by "experts" or by participatory engagement, underpinned by fun or by fear and terror, and small scale or large scale. The motives, contexts, and practices that encompass resistant acts are as varied as the state crimes that they seek to challenge.

Nonetheless, for something to be resistance rather than just a random act, there have to be some defining features. In recent work, Stanley and McCulloch (2011) establish three primary elements of resistance. These elements are intention, communication, and action. First, resistance is about opposition with social, moral, or political intent. The intention is crucial. In this respect, resistance requires some level of consciousness or human agency; it involves a choice. Mohandas Gandhi, seen as the modern father of nonviolent resistance, articulated this view in his idea that resistance was a "conscious option" for resisting injustice (see Urquhart 2011, p. 37). Other scholars, such as Henry Giroux (1983), have argued that opposition is a necessary condition of resistance but that acts of resistance must also be carried out with the aim of emancipation or transformation. The intention to change, or retain a status quo, is a key part of any resistant act.

Second, resistance is a form of communication that constitutes a message or messages. Sometimes, resistant acts can be registered as clear statements directed at dominant powers or the public. A protest march clearly aims to communicate – although, of course, underlying protest messages can sometimes be lost or subverted by state discourses of public order and control. Resistance has the most potential when it reflects the aspiration of a broad range of people. Messages are frequently designed to encourage bystanders to become participants in resistance movements. Sometimes, however, the communicatory nature of resistance may not be understood by or revealed to a wide audience. Quiet, small, or more personal acts of resistance may not be "read" by state agencies or the general public. Nevertheless, they are forms of resistance where there is an element of communication, even when the intended audience is small or intimate. For instance, during the Pinochet-led repression in Chile from 1973 to 1990, female opponents created *arpilleras*, political quilts that represented the pain, injustice, and harm of living under the regime as well as the aspiration of moving beyond repression. These quilts depicting "disappearances," torture, and other forms of violence were private, seen only by trusted family and friends. Nevertheless, they presented a clear and formidable intention to expose state crime and to delegitimize what was happening in the name of counter-terrorism. Acts of resistance can be assessed in terms of how they communicate new ideas and how they challenge dominant, state-centered discourses and generate discourse on state crime, and integral to this is how they subvert popular assumptions about perpetrators, victims, or bystanders, and raise awareness.

A third element of resistance is action towards creating, asserting, or arresting change. Resistance is bound up with the ways in which people understand and act on their capacity to make or oppose changes. These actions can be diverse, for example, they may involve the creation or consolidation of different ways of living or they may involve active or passive opposition to change or in pursuit of change. The following section elaborates upon several key issues in this emerging state crime field.

Key Issues

This section explores some of the central themes that have guided criminological writings on state crime and resistance thus far. In particular, it explores three questions: Who is involved in resistance? What might be viewed as effective resistance? And, how might criminologists resist state crime?

Who Is Involved in Resistance?

State crime scholars have highlighted the fundamental paradox that while states are major perpetrators of crime and active contributors to mass victimization at a global level, they also hold the position as the main protector of people, animals, and environments (Friedrichs 2010; White 2010). Consequently, while those engaged in activism and resistance rally against state actions, they also direct state authorities to defend and protect rights. This unique paradox can make it extremely difficult for resisters to gain truth, redress, or justice on state crime issues. The reason for this is that states will regularly prefer to preserve and protect state institutions rather than protect the people those institutions are purportedly established to serve. Criminologists such as Jamieson and McEvoy (2005) highlight the way that state perpetrators deny their involvement in state crime and engage in elaborate techniques of "othering" to hide their direct participation.

This paradox also impacts on how bystander states challenge criminal states. For instance, notwithstanding the frequent claims made by powerful states about challenging impunity, protecting human rights, and securing justice, "the international political community remains wedded to the practice of *Realpolitik* in terms of applying international criminal law" (Rothe 2010, p. 112). Challenges from bystander states – for instance, to extradite or arrest individual perpetrators – are often hindered and prevented by shifting economic, political, strategic, and military interests. Legal responses to state crimes are regularly quietly dismissed in favor of other considerations, such as developing close economic ties with perpetrating states (Stanley 2009). However, these relationships are not static or impregnable, and, at certain junctures, the constellation of interests may be such that resistance becomes possible, and (continuing the example above) some perpetrators of state crime are arrested, tried, and convicted.

In a global age, those who seek to resist state crimes must engage with multiple targets (Friedrichs 2010). The reason for this is that states are not monolithic and, in an era of globalization, state institutions will frequently operate alongside corporations, international financial institutions, the United Nations, militias, and other bodies in the committal of state-corporate crimes, eco-crimes, crimes of globalization, and finance crimes. Moreover, as Stanley Cohen's (2001) work on denial makes clear, state crimes are sustained by individuals in everyday ways. As consumers, voters, or through other social (in)action, individuals encourage, legitimize, neutralize, or become complicit in state crimes. Consider, for instance, the (media-led) public mandate given to US politicians to engage in torture following the attacks on September 11, 2001; or the usual approach of corporate shareholders not to question how their resources are spent; and popular support for punitive approaches to asylum seekers. It is often difficult to disentangle responsibilities, and criminologists have to be particularly mindful of the ways in which state crimes are operationalized across different networks of power.

Beyond identifying who or what needs to be resisted, criminologists have also begun to pay attention to who engages in resistance and how resistance strategies can cut across diverse groups. The earliest works on state criminality identified that state crime can be censured and sanctioned through a variety of different social audiences: from above, for example, through UN bodies, international courts, or domestic monitoring organizations (such as police complaints authorities); from below, through the withdrawal or erosion of public consent to state authorities (highlighted through protests against state actions); from within, by state workers exerting demands, and making changes, inside their own organizational structures; and, from without, through the work of international nongovernmental organizations (NGOs) who operate to place international pressure on criminal states. In 2009, Green and Ward elaborated upon the mechanisms and processes by which organized civil society groups engage in collaborative actions to challenge and reform criminal states. Working across different power bases at local, national, and international levels, resistant groups frequently take multipronged approaches to resist state crime. These approaches might include a combination of direct action, legal strategies, political lobbying, public relations, and media campaigns all of which are likely to overlap and feed into each other. These different approaches may be calibrated to diverse primary target audiences.

Contemporary practices of resistance transgress conventional political boundaries. The globalization of political spaces has meant that the traditional distinctions between who is a "claims maker" and who is not (at local, national, and global levels) are blurred. In addition, the rise of new technologies – such as camera-mobile phones and the Internet – has meant that state crimes can be documented and circulated across the world with relative ease and at speed. This has, in some circumstances, placed state authorities on the "back foot." Would the United States have been subject to the same level of accountability if the images of the torture and ill-treatment of prisoners at Abu Ghraib and images of hooded detainees at Guantanamo Bay had not been widely circulated? A similar question can be asked about the torture of civilians by Indonesian troops in West Papua. Likewise it has become more difficult for police to deny brutality when such events are captured on video cameras, CCTV, or mobile phones and widely circulated. Changes in technology have made it more difficult for states to claim that acts of violence have not taken place. Nevertheless, states continue to engage in denial by suggesting self-defense in the face of threats posed by criminals and terrorists. Victim-survivors are frequently recast as perpetrators despite visual evidence to the contrary.

The complexity, power, and resilience of states mean that resistance is most effective when it resonates with a community of resisters who have a shared experience and who can support each other and speak with and for each other (Scott 1990). Resisters need to mobilize a movement of concerned others. One element that celebrated resistance leaders such as Mandela, Ghandi, and Martin Luther King share was their ability to mobilize others. This point has not been lost on contemporary human rights groups, trade unions, or religious bodies who seek to develop collective strategies within and across nations in attempts to resist state crime (Stanley and McCulloch 2011). To be effective, resistance requires people to work together to achieve shared goals. In this respect, resistance is a political project in which people morally engage in practical tasks of contestation (Sivanandan 1990).

Of course, mobilizing bystanders is no easy task. Stanley Cohen (2001) has highlighted the way bystanders shut out confronting stories of state crime and distance themselves from any moral imperative to take action. This distancing occurs through various techniques. For example, bystanders can diffuse responsibility (arguing that state crimes are nothing to do with them, and because of this, they should remain uninvolved), they might struggle to identify with state crime victims (particularly if victims have been labeled as criminals or terrorists or denigrated in some other way), and they might feel powerless to help (as they cannot imagine any action that could make a substantial difference). Beyond this, people may consciously or unconsciously feel afraid to identify with or act in solidarity with state crime victims lest they too become victims. Regardless, criminologists are keenly aware that transforming bystanders into participants is crucial to any resistance strategy (Friedrichs 2010). Engaging others, within and without criminal states, is vital to challenging state crimes.

Despite the techniques of denial and the challenges of building movements of resisters, states are often faced with persistent victim-survivors who simply refuse to go away. Victim-survivors, who often have "nothing left to lose" can become "ferocious fighters and tenacious enemies" (White 2010, p. 55). This issue has been demonstrated in criminological writings on transitional justice (see Stanley 2009). In this domain, victim-survivors have been particularly strong in drawing upon international human rights standards and laws and engaging transnational campaigners and support groups to promote their demands over decades.

With fairly limited resources to push for action, victims continually make insistent claims for truth and justice. Part of this, as detailed above, can be attributed to the persistence of victim-survivors; however, it may also emerge as a consequence of the ways in which harms and injuries from state crime develop over time. Some of the crimes or harms resulting from state action may not be fully realized until many years after the initial event. For instance, the impact of depleted uranium in places like Iraq is only now becoming fully apparent in terms of the long-term health effects upon Iraqi citizens who lived on "target" sites, war veterans as well as their descendants (White 2008).

Such events highlight that resistance to state crime often requires a long-term strategy. Nonetheless, many people have shown great resilience in these endeavors. From examples like the Holocaust or the repression in Chile or the Indigenous land rights movement in Australia, it is clear that victims can achieve some "success" – decades after state crimes have occurred, victims can be acknowledged *as* victims, compensation can be paid, and prosecutions can occur (Stanley 2009). These struggles often require great levels of persistence, tenacity, and courage, and their "successful" outcomes are hard won.

What Constitutes "Successful" Resistance?

In responding to state crime, resistant acts may succeed on structural, institutional, social, and personal levels. As Stanley and McCulloch (2011) detail, successful resistance may be momentous or small; it may confront an entire regime or be limited to opposing specific state actions. It might take the form of overthrowing a criminal state, holding the state accountable for its actions, challenging the state's claim to truth, changing the socio-legal landscape to amend unjust laws or provide access to law, "answering back" to colonizing norms and values, reasserting positive values of care or dignity in society, changing the practices and values of state workers, or presenting individuals with an opportunity to take action and move beyond powerlessness.

It is impossible to quantify the multiple acts of resistance that take place all over the world on a daily basis. What is clear, however, is that "successful resistance" or "what works" is varied and depends "very much upon the immediate political struggles and social contexts" (White 2010, p. 50), although there is research to suggest that nonviolent resistance is successful more often than armed campaigns (Stephan and Chenoweth 2008). Resistance requires a recognition of state harms or injuries at a local level. Yet, in contemporary conditions, successful resistance will regularly recognize the global nature of this phenomenon and while dependent upon achieving change at a local level, may often be tied to how individual events might be cast as social problems that have a national or even international resonance. This kind of approach that goes beyond localism and generates allies across the globe can "acknowledge the intrinsic commonalities across borders and a shared moral universe among political activists" (White 2010, p. 52). Resisters do not just deal with "narrow state interests" (White 2010, p. 54) but contest fundamental problems within global structural relations of power.

Effective or successful resistance, however, is difficult to measure. What may initially be regarded as positive advances or real "victories" can turn out to be Pyrrhic, temporary, or have unintended or unforseen consequences. Resistance strategies raise "moral conundrums" (Friedrichs 2010) and may, despite altruistic intentions, adversely impact on people who have few choices and little power. State crime may also prove resilient, continuing, or reemerging in altered forms as the social, political, legal, and cultural landscapes shift (Stanley and McCulloch 2011). Indeed, some state crimes that may be viewed as having ended may continue in different forms. Slavery, for example, is regularly regarded as a historical phenomenon, but it continues unabated in contemporary forms of forced labor, debt bondage, child labor, or trafficking (Bales 2004). Contemporary slavery continues to affect millions of people; however, it often goes "unseen," as it functions as part of an advanced global capitalist system in which labor is outsourced and traded across corporate and contractor networks. In the same vein, slavery and its attendant colonial systems have also changed to fit the demands of contemporary conditions, such that the differential policing and mass incarceration of minority populations within liberal democracies such as Australia, New Zealand, the USA, and the UK have been made acceptable (Stanley and McCulloch 2011). In these instances, it is impossible to argue that substantive equality has been achieved. Instead the progressive eradication of the slave trade through the eighteenth and nineteenth centuries, and an end to formal racial discrimination, has been replaced by new forms of economic, political, and social control.

It is also apparent that what might appear to be a progressive response to resistance strategies can turn out to be merely symbolic. For instance, resisters will often draw upon the rule of law and the judiciary to bring state officials to account. Yet, using state institutions like the judiciary to oppose state crime simultaneously confirms, or shores up, the institutional basis of the state. It can reinforce the parameters of "the law" as well as enhance the legitimacy of the state; such that they present the state as a "protective body" in periods when many state actions suggest otherwise. Sometimes seemingly accommodating state responses to resistance movements or actions can be counter-productive or they can reiterate dominant norms. For example, Bibbings (2009) highlights how new, apparently liberal laws with regard to homosexuality ultimately reinforced hegemonic heterosexual norms (by continuing to advance homosexual activities as being "different" or "deviant" and by increasing the monitoring and control of sexual practices). Nonetheless, the advances in law provided an opportunity for the state to purport "to have moved beyond heteronormativity and homophobia" (Bibbings 2009, p. 42). In addition, legal advances – set against a discourse of progress and equality – made further resistance difficult to pursue as those who continued to complain were labeled as "radicals" or "extremists."

The symbolism of responses to resistant acts is, therefore, an important consideration. Progressive state responses, which might at first glance be regarded as a successful outcome to resistant acts, can just present an opportunity for the state to strengthen legitimacy and highlight that they are governing by consent. It can serve to mystify the state – in that the state (and state actors) can appear as being able to be effectively challenged or changed or "talked back to" (Coleman et al. 2009, p. 15). Where states move to accommodate, incorporate, and adjust to resistance, the solidarity of resistance movements frequently comes under challenge as those within reach different conclusions about the meaning of state actions and the need for continued resistance.

It may, however, be too narrow a frame to consider effective or successful resistance only as collective actions or those that impact discernibly on the state. Successful forms of resistance can also grow unremarked or unnoticed from a whole range of small, quiet "unsuccessful" actions carried out by unknown individuals or small numbers of people (Stanley and McCulloch 2011). This idea of the many small actions over time leading to a more just outcome in the face of state crime is captured in the title of the anthem of the Australian indigenous land rights movement: "from little things big things grow." There are circumstances in which resistance may not be seen, acknowledged, or recognized by a broader audience. It may operate instead as "offstage dissent" (Scott 1990). It may be too dangerous and repressive for individuals and groups to make open claims of victimization and demands for justice. Yet, in such circumstances, individuals and groups often continue to engage in actions that create a "hidden transcript" against the dominant force (Scott 1990). Such "transcripts" may be made up of simple acts – lighting a candle to remember someone killed by state forces or marking a stone where an atrocity occurred. While these acts may not have a broad audience and may even be done in secret, they demonstrate agency within contexts of limited power and may, in ways that are (deliberately) difficult for those not directly involved to comprehend, keep the will towards resistance alive. These struggles against power may, as Milan Kundera (1978, p. 3) maintained, be "the struggle of memory against forgetting."

There are small, as well as significant, victories to be had in resisting state crime. As a final note here, it must also be acknowledged that even if a resistance initiative is seen to have failed overall, that "does not mean that they failed to influence, mitigate or even constrain state policies and actions related to state crime" (Friedrichs 2010, p. 9). While resultant changes may often not meet the expectations of those who resist, they may still have challenged state policies and actions. In addition, the lessons learned through "unsuccessful" campaigns may form the foundation for future "success."

How Might Criminologists Resist State Crime?

From the above discussions, it is clear that state crime scholars have begun to make some progress on the elements and meanings of resistance. Criminologists have also begun to identify, and analyze, the different routes that criminologists might take in progressing a resistant approach. For while a stance on resistance might at first appear to be romantic or naïve, the costs of not challenging state crimes appear to be too high a price to pay (Friedrichs 2010).

To this end, criminologists have ascertained several approaches that might be taken by future scholars. First, state crime academics might participate in a traditional public criminology in which they engage in public education through the remit of their publications and public speaking and work with resistance movements, including with state officials. This approach dovetails with "newsmaking criminology" in which scholars expose state crime issues. This form of public criminology is seen as having limited interactions, as being relatively passive and mainstream (Kramer 2010).

Second, criminologists might engage in an organic public criminology in which they work directly with activist groups or individuals in a process of mutual education. The impetus, here, is to craft political actions and policy choices through more direct activist action. This form of criminology is more visible, thick, and active and may directly challenge public understandings of "crime" and harm (Kramer 2010). This form of criminology also connects with the "idealist critical criminology" proposed by Coleman et al. (2009) who argue that criminologists can be pragmatic and actively influence policy. It is possible to challenge the state (and be outside the ideological terrain of state) and still engage with policy. For example, criminologists can engage with organizations such as Inquest (which campaigns against deaths in custody in the UK), as well as other counter-hegemonic groups, that stand "in opposition to the state's criminal justice agenda but still remain engaged with government in consultations, lobbying and policy work" (Coleman et al. 2009, p. 16).

Within these broad approaches to the state crime issue, criminologists have a number of further concerns and issues to attend to. For instance, there are questions of whether state crime research can ever really be funded or directed by government agencies. After all, such research can be expected to support the imperatives of the state and to consolidate the continued regulation of the powerless (Walters 2009). Alongside this, there remain questions about how criminological literature may be developed to refocus attention to state crime activities. Part of this may involve a substantive reframing of criminological language to include debates on nationalism, sovereignty, universal jurisdiction, legitimacy, human rights, cosmopolitanism, global justice movements, global governance, or sustainability (Friedrichs 2010). For many criminologists, this requires new exploration of crucial ideas and concepts that currently stand outside mainstream attention.

All of these identified routes and concerns revolve around an idea of strengthening the criminological role as "claims makers." It also signifies an academic move from being invisible, passive, or inactive towards being visible and active (Kramer 2010). As academics, paid by the state, criminologists remain capable (with their scholarly privilege) to engage in resistance. Yet, such resistant approaches are not without risks or difficulties. Academics who take such stands may face isolation, attack, or dismissal; they may find that they are negatively portrayed within academic or media circles; and they may struggle to find funding or to access data (Kramer 2010; Walters 2009). In addition, within an environment in which academics face multiple constraints (such that, in many countries, academics are faced with a particularly narrow band of what constitutes "valued knowledge" – in the form of funded research, knowledge disseminated in particular journals, or by particular publishers – and employment or career progression is dependent upon being an academic producing "valued knowledge"), it may be that such academic resistance is becoming increasingly difficult to uphold or engage with (Tombs and Whyte 2003). Even so, it remains the case that western academics usually hold a comfortable position from which to resist from. This places an onus on scholars to engage; as Cohen (2001, p. 40) points out, “Intellectuals who keep silent about what they know, who ignore the crimes that matter by moral standards, are even more morally culpable when society is free and open.” The choice not to speak against state crime in circumstances of freedom and safety is to use a term borrowed from the resistance movements of World War Two, to collaborate with those crimes.

Future Directions

Given the relative dearth of literature on this topic, there are many directions that criminologists might take in the future. Here, five potential aspects of state crime scholarship are explored in relation to resistance. First, as Stanley and McCulloch (2011) note, state crime scholars must be mindful to analyze both the egregious and the mundane. That is, while it is useful and necessary to analyze genocides, such as the Holocaust, it is also important to consider state crime and resistance outside of the most notorious acts of state violence. To understand state crime, as well as resistance, criminologists need to include the study of the everyday harms and violence that are embedded in the fabric of society. Focusing on state crimes and resistance exclusively in the context of the foremost exemplars of state crime, risks overlooking the pervasive state perpetrated violence and harms that occur as normalized, hidden, or denied aspects of society, including in democratic states.

Second, criminologists might also develop analyses of resistance in terms of affirming values, or *becoming* something, rather than acting against. That is, resistant acts may be about sustaining a way of life or invoking a competing claim of universalism (such as affirming and reproducing cultural identities). This idea is illustrated in Harry Blagg’s (2008) recent work on aboriginality and justice. He highlights how difficult it is to imagine “forms of resistance that do not seek to take over the state, or reproduce it, but actively seek to create distance from state structures and recreate traditional forms of order” (Blagg 2008, p. 37). While the state may be viewed, in an Althusserian sense, as the “site and stake” of struggles, some groups want to move beyond the state. In this regard, it is crucial to understand that as a result of history there are divergent meanings attached to state institutions. In addition, some groups hold “radically incommensurate interpretations” (Blagg 2008, p. 47) of past experiences. From this perspective, to celebrate and live by another universality may be a valued form of resistance. Such ways of being move beyond the usual dichotomies of cultural/social/political norms about life, so that ways of being or ways of resisting are called into question rather than being reemphasized and bolstered.

Third, and a related point, is that criminologists may become more mindful of how resistance strategies and practices are differentially experienced across groups. State crime literature has not yet thoroughly engaged with how state crimes are structurally experienced, and the literature on state crime and how it relates to structural relations of gender, “race,” age or class remain relatively undeveloped. Future scholars could therefore be more attentive to how state crimes, and attempts to bring states into line, “will be perceived and experienced differently” (White 2010, p. 57).

Fourth, criminologists could continue to develop analyses on why people and groups become attracted to certain resistance strategies and, simultaneously, how they are also dissuaded from participating. A key question to the latter point might be the following: Why do people not resist more to state crimes? Criminologists (such as Cohen 2001; Stanley 2009; White 2010) have already demonstrated that citizens are dissuaded from resisting as a consequence of many issues, such as compassion fatigue, an acceptance of certain forms of state violence, a culture of individualism such that they are less likely to aid “others,” concerns about their own criminalization or denigration, or a sense that any strategies are doomed to failure. The dangers that resisters and their “communities” might face are worthy of further examination, particularly in terms of how states engage in “counter-resistance” techniques.

Finally, and fifth, there is significant scope to question how resistance strategies impact upon state power. That is, do resistance strategies just embed state power by emboldening states to pursue more authoritarian measures or by providing states with an opportunity to enhance their own institutions, discourses, and status? For instance, as detailed above, while there have been a range of progressive reforms around a whole host of issues, including gender and "race" relations, they have never been secure or adequate (such that essential power relations have remained unchanged). Within such circumstances, it is unclear whether resistance to state crime can be successfully undertaken by strategies that use state institutions and norms – the use of law to ban slavery and the institution of legal regimes of equal opportunity have not dismantled the economic system in which slavery and racialized punishment continue to operate, yet it has emboldened legal and state systems, at international and national levels, to present the appearance that something has been, and is being, done.

Resistance to state crime is emerging as an important aspect of state crime scholarship. Naming, describing, analyzing, and theorizing state crime has contributed to criminology by moving it beyond state-centered notions of harm and security. Harms and violence committed by individuals pale into insignificance compared to those committed by states. Incorporating the study of resistance into state crime studies and into the work of state crime scholars marks an important advance in the field. The challenge of the future is to build on the emerging insights on state crime and resistance so, as state crime scholars, we can confidently claim to have moved beyond being bystanders to participants in the struggle against state crime.

Responses to Domestic Violence in India

Regulate violence

Overview

To understand the formal and informal systems of crime control, including domestic violence, in India, it is important to review the historical, social, political, and cultural perspectives that shaped these systems. The formal system of crime control relies on official agencies and laws to maintain order, deter crime, and respond to criminal activity. Informal crime control depends on families, peers, neighbors, and the communities to settle disputes, maintain peace, and promote lawful behavior. This topic covers domestic violence from historical and contemporary perspectives, specifically focusing on formal and informal methods of addressing the domestic violence in India.

Formal and Informal Systems of Addressing Domestic Violence

During medieval times, formal systems of control were enforced by various dynasties (Unnithan 2005). The kings administered justice under the Hindu religious concept of *dharma* (rules of right conduct), taking into account the circumstances under which the crime was committed. *Dharma* was supposed to sustain society, maintain social order, and ensure well-being and progress of humanity (Hayden 1984). To live in peace, proper education and training must be imparted and individuals must be taught not to transgress the freedom and liberty of others. The religious scripts also included threats of severe punishment for transgressors in their current life and the afterlife. For example, during the Mauryas Dynasty (321–185 B.C.E.) people were sentenced to punishments such as mutilation and the death penalty for minor offenses. In the second and third century C.E., Manu, an important Hindu jurist, drafted the *Dharmasastra* code, which was called *Manusmriti*. The laws of Manu were based on jurisprudence, philosophy, religion, and *varna* (caste), and described how life should be lived by lower caste, priests, kings, women, and men (Doniger and Smith 1991).

In 1500s, the Moguls conquered most of northern India. One of the most influential Mogul emperors, Shah Jahan, ruled India from 1628 to 1658 C.E. During the decline of Mogul Empire, the British East India Company arrived in India as a trading company and slowly gained control. Realizing that the East India Company was becoming a powerful virtual ruler in India, the British Crown took control of India in 1858 and ruled India until 1947. Under the British rule, although formal and informal systems of justice coexisted, the formal mechanisms were strengthened. The British used the approach of “divide and conquer” to rule: they rewarded those who supported them and punished those who sought independence or protested the British rule using the formal system of justice – police, laws, and courts. The formal system was not popular in rural areas because many people either did not understand the laws and procedures of the British or were unwilling to abide by them. Moreover, asking formal criminal justice agencies to settle disputes was not a common phenomenon, because resources such as transportation and access to lawyers were not readily available, especially for poor and disadvantaged populations. In addition, those who failed to seek reconciliation or dispute resolution, whether it was a dispute, a moral issue, or a crime, through informal justice system were shunned by the community. During this time, most of the disputes in rural communities were settled by the traditional caste *panchayats* (village councils).

The *panchayats* consisted of at least five elders, usually from Hindu upper castes, and are often referred to as *caste panchayats*. The caste hierarchy dictated the rules, format, and outcomes of the cases. The four main Hindu castes are *Brahman, Kshatriya, Vaisya*, and *Sudra*. *Brahmins* were at the top of the hierarchy and were considered arbiters of learning, teaching, and religion. The *Kshatriya*s were warriors and administrators. The *Vaisyas* were artisans and known for business ventures. The *Sudras* were farmers and peasants. The fifth class, which does not fall under the caste hierarchy, were once known as *Harijans* (untouchables) or, more recently, *Dalits* (oppressed people). The caste system continues today with many subtypes (*jatis*) in each caste.

After India gained independence from the British rule in 1947, the country moved towards a more formal system of crime control based on the British colonial model and English common law. The traditional (caste) *panchayats*, headed by village elders, were considered out of tune with the democratic processes. The Indian government created a criminal justice system with centralized control and enforcement. Although the police are organized at the state level, the high-ranking police officers (Indian Police Service) are recruited, trained, and appointed by the central (federal) government. In addition to the state-controlled police, the Indian government directed the states to establish elected *nyaya* (justice) *panchayats* as local government units in 1950 (Meschievitz and Galanter 1982).

Hayden (1984) argues that the *caste panchayat* system is different from the court-like *nyaya panchayat*. Unlike the *nyaya panchayats*, the *caste panchayats* take all considerations (e.g., the individual, place, and times) and not base decisions on predetermined rules and laws (Darrett 1978). In *caste panchayat* system, the determination of facts is not essential because the participants are already aware of what occurred. The *caste panchayat* considers known behavior and weighs its propriety (Hayden 1984), rather than labeling the act as criminal or deviant. Unlike the *caste panchayat* who applied indigenous norms, the *nyaya panchayats* relied on statutes, majority ruling, and members are selected by popular elections (Iyengar 2007). By the 1970s, these courts were considered failures due to declining caseloads and client dissatisfaction (Baxi and Galanter 1979). Scholars have asked why attempts to revive the informal justice system after the country's independence failed. Some claim it was due to deficiencies in funding and state control of legislative function, whereas others believe that the Indian elite is comfortable with the formal justice system and does not want a change (Baxi and Galanter 1979). In addition, caste rivalries, class difference, and growing egalitarianism and individualism disrupted communities, and contributed to their failure (Vincentnathan 1992). In order to promote indigenous character within the justice system and to provide an alternative to the Anglo-Saxon model of adjudication, the central government passed an amendment to the Constitution in 1992 giving the elected *panchayats* constitutional status and institutionalized them in a three-tiered system (except in states with a population of fewer than two million people): village level, block level, and district (county) level (*Panchayat* system in India 1995). In addition, because of a backlog of cases in the formal justice system, the government legislated for the establishment of *Lok Adalat* (people's courts) and Family Courts throughout India. The *Lok Adalats* are governed by Legal Services Authorities Act 39 of 1987 and are presided over by retired judges and private legal practitioners. These are court-linked mediation entities, sit on weekends, and hear a large number of gender violence cases (Relis 2011). Their main goal is to encourage parties to settle their disputes through mediation/conciliation. The Family Courts were established to handle the increasing number of marital disputes through speedy process using conciliation (Iyengar 2007).

Historical and Contemporary Views of Women

Some scholars believe that in ancient India women enjoyed equal rights along with men (Mishra 2006), whereas others hold contrasting views (Pruthi et al. 2001). During the early Vedic period (1500–500 B.C.E.), women were allowed to obtain an education. Around 500 B.C.E., following the Islamic invasion and Moghul Empire, the status of women began to change. Women and children faced religious and social restrictions. During medieval times, the practice of child marriages, *Sati* (self-immolation of women following her husband's death), and a ban on widows remarrying became part of social life in some communities. Ancient Hindu religious scriptures (i.e., the code of Manu) illustrate the secondary status of females – they have to be subservient to their fathers in childhood, to their husband after marriage, and to their sons after the death of their husband. With Muslim conquest of India, the practice of wearing a *purdah* (veil) became prevalent among Muslim women. In some parts of India, the *Devadasi* (temple women) were exploited by wealthy, upper-class men. During the colonial era, there was a cultural resurgence. Notable social reformers stood firm against all forms of social bigotry, orthodoxy, idol worship, and encouraged Western/English education. Others brought public awareness of social evils such as child marriages, polygamy, and child widows, and fought for the rights of women. These efforts resulted in widow remarriages, and prohibition of child marriages and bigamy.

Although India's independence has brought some social reforms for women and children, traditional social evils such as dowry and child marriages continue to the present day. According to the United Nations Population Fund Report, many married women in India suffer from domestic violence (Bhat 2006). "Dowry" is a cultural practice in many Indian communities. It involves giving property or valuables to the bridegroom or his family by the bride's family in consideration of marriage.

The traditional definition of domestic violence includes physical, sexual, or psychological abuse, or threats of violence inflicted by an intimate partner related to the victim through marriage, family relationship, or an acquaintanceship (Sahoo and Pradhan, n.d., p. 1). In the Indian context, the definition also includes dowry harassment, dowry death, and economic abuse. The most common causes of domestic violence include dissatisfaction with the dowry, wives refusing to have sex with their husbands, alcoholism of the spouse, the wife's inability to give birth to a male child, to minor acts such as not cooking food properly, not taking care of in-laws, or being too social with male coworkers at workplace (Kumar 2010).

Domestic Violence and Formal Justice System

Beginning in 1980s, women's organizations and other nongovernmental organizations (NGOs) made the public aware of the magnitude of the problem, the ineffectiveness of existing laws, and lack of enforcement. The prevalence of domestic violence and women's fight for equality and social justice prompted the legislators and policy makers to recognize that violence against women is not only a crime but also a violation of human rights. As a result, legislators have revised old laws and drafted new ones to criminalize offenders and provide more protection for women. These include amendments to the Indian Penal Code (IPC), the Indian Evidence Act, and the Dowry Prohibition Act, as well as changes in police procedures (Ranchhoddas and Thakore 1987).

The IPC was amended in 1983 and 1986 to specifically define crimes dealing with marital violence and abuse. Section 498A of IPC recognizes domestic violence as a cognizable (i.e., felony) offense and allows police officers to arrest the perpetrator without a warrant. Under this section, if the victim or the relatives of the victim complain to the police that the victim suffered "cruelty by husband or relatives of husband," the police have no option but to take action. The perpetrator can face imprisonment for a term in prison for a minimum of 3 years, as well as a fine. The definition of "cruelty" is broad and covers not only serious injury or bodily harm, or danger to life, limb, or physical health, but also includes mental health, harassment, and emotional torture through verbal abuse. In India, "harassment" includes such acts as coercing the wife or relatives of the wife, making an unlawful demand regarding property or valuables by the husband or his family members (generally in-laws). The law not only discourages the taking of a dowry but also the giving of a dowry. Both offenses are punishable with imprisonment for a term in prison of 6 months to 2 years, a fine, or the amount of the dowry paid or received. The law also allows women to retrieve their dowries under Section 406 of IPC (Ranchhoddas and Thakore 1987).

More important, section 304B, which was added to the IPC, deals with a new category of crime: "dowry death." This section states that if the death of a woman is caused by burns or bodily injury or occurs under unusual circumstances within 7 years of the marriage, and it is shown that prior to her death she was subjected to cruelty or harassment by her husband or his family, such a death would be considered dowry death. In such cases, the dead woman's husband or his family members would be deemed responsible for her death and shall be punishable with imprisonment for a term in prison of 7 years to "life" (generally 20 years). The inclusion of dowry death in the IPC brought about a change in the evidentiary standards in dowry death cases and a new section (113b) was added to the Indian Evidence Act. The previous section, 113(a), states that when a married woman commits suicide within 7 years of marriage and it is shown that her husband or his family members were cruel to her prior to her death, then it is presumed that her husband or his relatives aided in her suicide. The new section (113b) shifted the burden of proof to the accused, who must show why he should not be charged with the crime (Lawyers Collective Women's Rights Initiative 2010).

In addition to IPC and the Indian Evidence Act, the Dowry Prohibition Act of 1961 was amended in 1984 and 1986. These amendments made giving or receiving dowry a cognizable (felony) offense. Like dowry death cases, the burden of proof is on the person accused of taking or demanding a dowry: he must prove otherwise. A more recent piece of legislation, the Protection of Women from Domestic Violence Act (PWDVA 2005), allows civil remedies, such as a woman's right to reside in her matrimonial home or shared home. The Act recognized domestic violence as a violation of human rights. It required states to appoint regulatory authorities, such as Protection Officers (POs) and NGOs, as service providers. The Act meant that complaints of domestic violence had to be filed with the magistrates. In addition, it prohibited police officers from providing mediation in domestic violence cases (Maya 2006).

To better understand the nature and extent of violence against women, the states are required to document crimes against women under a special category. An annual report is published by the National Crime Records Bureau (NCRB). The report includes IPC offenses such as rape, kidnapping and abduction, dowry deaths, mental and physical torture, sexual molestation, sexual harassment, and trafficking of girls (NCRB 2006). In addition to IPC offenses, the NCRB also documents gender-specific offenses under Special and Local Laws (SLL). These laws include the Immoral Traffic (Prevention) Act (1956); the aforementioned Dowry Prohibition Act (1961); the Child Marriage Restraint (Amendment) Act (1979); the Indecent Representation of Women (Prohibition) Act (1986); and the Commission of *Sati* (Prevention) Act (1987).

Many state governments, by a special order, established All Women Police Stations. These police stations are staffed by women police officers (taken from all level, line staff to supervisory levels). They have the authority to handle both serious and nonserious incidents of domestic violence (e.g., family disputes). AWPS have been established in both urban and rural areas to make police stations "more approachable and less intimidating to women" (Poonacha and Pandey 1999, p. 30). It is presumed that women police officers will have a better understanding of women's needs. The police may register a cognizable (i.e., felony) case either by themselves or on the basis of a victim's complaint. These cases are registered in the First Information Report (FIR). FIR cases include dowry death, cruelty by husband or relatives, rape, intimidation and harassment of women, and demanding or receiving dowry. The noncognizable offenses include less serious offenses that are entered in the Community Service Register (CSR). CSR cases include minor dowry-related cases, drunkenness by husband, adultery, bigamy, family quarrel, seeking the custody of children, false promise of marriage, and desertion by husband. Officers try to resolve CSR cases through counseling or mediation. If the case is not resolved, the police may refer it to a family court or an appropriate court or register a criminal complaint. With the new law (PWDVA 2005), the women police officers must report the case to the magistrate and are not allowed to mediate domestic violence cases.

Formal Court Structure

The court system in India is a unified court structure in which the Supreme Court is the highest court in the country, followed by the high courts (i.e., the highest court at the state level), and other appellate and trial courts at the state level. Under the PWDVA (2005), a woman can avail herself of free legal services. The court of the chief judicial magistrate of the first class or the metropolitan magistrate (lower courts) have jurisdiction over domestic violence cases. The complainant or a protection officer (appointed under the Act) may present an application to the magistrate seeking relief. The order may include payment of compensation or damages for the injuries. A woman may also file for a separate civil suit for such compensation or damages. If the award is given in civil court, then the amount is deducted from the overall damages. The magistrate may also order the parties to receive counseling. The Protection Office must maintain a list of all service providers that offer legal aid or counseling, shelter, and medical assistance within the jurisdiction of the magistrate. A medical report of the injuries must be submitted to the police stations and the magistrate. The courts may also issue a protective order at the request of the woman, which can be modified or revoked if the circumstances of the case changes. The magistrate may also require the respondent to execute a bond with or without sureties. While passing the order, the court may direct the nearest police station to provide protection to the complainant or the person making the complaint on behalf of the victim. The protective provisions enumerated in the Act are comparable to those found in similar laws in the United States.

Those who are seeking redress through the formal justice system are often women from the middle and upper classes. The PWDVA (2005) was hailed as the most important legislation providing protection for women against physical, mental, economic abuse/violence. Some criticized the law as (1) being gender biased, (2) heavily favoring women with the potential for misuse by women, and (3) having too broad a definition of domestic violence. First, the law assumes that only women are victims and only they have rights under the law. A man who is a victim of domestic violence has no rights under the law. Second, such exclusive power will lend itself to misuse by women who want to teach their male relatives a lesson. Such trends were noticed in the case of anti-dowry law (Section 498a). A third flaw is that the definition of domestic violence includes insults and name calling as abuse, which are extremely subjective. Considering these frivolous acts, domestic violence may increase litigation and hurt the foundation of marriages. Those who opposed the law claim that the law in the present form is grossly inadequate (Deshpande 2008).

Recent Innovations in the Informal Justice System

Women in rural India, especially in western and northern states, formed the *nari adalats* (women courts). The nari adalat, an innovation by the Mahila Samakhya, is a grassroot effort by women collectives (Sanghas or groups) to address issues such as violence against women. The Mahila Samakhya is an autonomous program initiated in 1989 by the Ministry of Human Resources Development in 10 states with a primary purpose of empowering women, especially from socially and economically marginalized groups. They operate at the block and village levels and the members are trained on legal issues, discrimination of women, and women's rights. As of 2010, there were 184 nari adalats in 9 states and presided over 6,000 cases (Purushothaman 2011). Because of their popularity and their success, they are often approached by the caste panchayat members if the case involves domestic violence.

These courts consist of a jury of village women and grassroot-level workers who meet regularly to address women's issues, including domestic violence. In some villages, a group of five women, selected by the villagers, sit in a circle as part of the informal court. Many of these women have little education, but they have learned about the law and understand its implications and limitations. Although their caseload concerns women seeking justice, sometimes they hear grievances filed by men as well. Some of the cases they hear include divorce; disputes between women and their in-laws; complaints about husbands' infidelity, domestic violence, rape, dowry harassment, widows, and elderly (Iyengar 2007). They not only mediate cases and propose mutually acceptable decisions, but also serve as a monitoring body to ensure that the decision is implemented. These informal courts have been widely accepted by communities (Sharma 2000, p. 7). This unique form of informal justice is carried out quietly in many villages in states such as Gujarat "through a process of social censure, cajoling, argument and persuasion" (Sharma 2000, 7).

Some examples of cases decided by these courts follow. In one village, the *adalat* (informal court) met on the verandah of the village government office. Although space was offered inside the office, the women preferred to have the court outside so that it would be more visible to the public. An elderly woman announces the start of the sessions. The parties include a young man and a woman with a young girl sitting in a circle facing the members of the *adalat*, which consists of the elderly woman, a facilitator from a local women-empowerment program, and women from various community organizations. The young man asked for divorce because his wife left him 2 years ago to live with her parents and he does not want her back. When the *adalat* women asked why his wife left him to be with her parents, he did not respond. The facilitator states that if he wants a divorce, he must pay his wife INR (Indian Rupees) 500 (about USD$10.50) a month for 7 years, and INR8,000 (USD$170) for his daughter's education, for a total of INR50,000 (USD $1,063). He was told that he has 1 week to decide and, if he is willing to pay, he can get divorce. The second case involved dowry harassment by in-laws. The woman complains that her husband and her in-laws are insisting that her parents should buy an electric fan. Moreover, she states that she brought considerable amount of dowry into her marital home. The court told the husband, "Don't look at other people's palaces and in the process destroy your own house," and "Why don't you earn enough to buy yourself a fan?" (Sharma 2000, p. 16). The husband and his family agreed and provided a written assurance that they will not harass her any more by signing on a legal, stamped paper.

In another village, the *adalat* meets under a tree on the grounds of the government office. In a case heard at this *adalat*, a young woman complains that her husband has been unfaithful and has had affairs with her sister and sister-in-law. Her husband has thrown her out of the house and now wants a divorce. The accused replies that the women came after him. He then shouts at the adalat that it takes the side of the woman and stomps off. After a while, when tempers have cooled off, he returns and tells the court that he changed his mind because he cannot pay maintenance. The wife demands that she will return to him only if he asks for her forgiveness, which he does.

In addition to these traditional courts, recently Oxfam India, in collaboration with its partner organization, FARR (Friends Association for Rural Reconstruction) and other nonprofit organizations, conducted state-level public hearings for survivors of domestic violence in March 2011. The Oxfam India is a right-based organization that fights poverty and injustice in partnership with local NGOs. Among its five aims – the right to a sustainable livelihood, the right to basic social services, the right to life and security, the right to be heard, and the right to equality – the last one addresses gender and diversity issues. In addition, it aims to fulfill its overarching vision, "rights to life with dignity for all," by empowering poor and marginalized populations. Its recent efforts targeted seven states (Assam, Bihar, Chhattisgarh, Jharkhand, Orissa, Uttar Pradesh, and Uttarakhand) and four social groups (*Dalits*, tribals, Muslims, and women) (Oxfam India, n.d.).

The Oxfam India hearings were supported by the Department of Women and Child Development and other civil society organizations. The panel members included lawyers from the State Legal Service Authority, representatives from the State Women's Commission, and distinguished feminists. The organization heard about 50 cases of domestic violence in various locations throughout the state. The primary reason for holding these hearings was to offer a speedy resolution of cases filed under the PWDVA (2005). Moreover, these hearings offered an opportunity for women, especially from tribal villages, who were victims of informal justice systems to be heard. In some instances, an informal justice system may not be favorable to tribal women – it may even be detrimental to them. These hearings provide a voice to the survivors of domestic violence, and the panel of experts can provide a quick resolution to their disputes (Oxfam India, n.d.). An example of a case that was decided by the panel involved a woman requesting that her valuables and dowry be returned to her. Her husband died after 2 months of marriage and her in-laws forced her to leave the marital house. She wanted her valuables and dowry back so that she could start a stationary store. A lawyer from the State Legal Service Authority assisted the victim in getting her valuables and dowry back from her father-in-law. Several other women benefitted from these hearings (Das and Bandi, n.d.).

Discussion

The laws dealing with domestic violence (Section 113[a] of the Indian Evidence Act, Section 498[a] and 304[b] of the IPC, and the Dowry Prohibition Act [1961; as amended in 1986], and the PWDVA [2005]) have had limited impact on the timely disposition of cases. For example, Amnesty International reports that an analysis of court decisions in one particular district of Maharashtra showed that only 2.2 % of cases filed under 498(a) of the IPC during 1990–1996 ended in convictions (Mitra 1999). The PWDVA (2005), which was hailed as a landmark victory for the women's movement in India, faced with problems such as lack of enforcement mechanisms to implement the provisions of the Act. For example, many women who sought protection under the Act were turned away by the courts (Maya 2006) because several states failed to appoint protection officers.

A comprehensive study conducted by Relis (2011) in India covering eight states, and included interviews with victims, the accused, family members, lawyers from both sides, judges, judge-mediators, nonstates justice arbitrators (*panchayats*), court-linked mediators (*lok adalats*) in lower and high court, and nonstate women's courts (*nari adalats*), public interest lawyers, and human rights commission members, found that victims have little to no education regarding human rights. More educated women know about the concept of human rights, but still lacked information about specifics. Her study also found that less educated victims of violence preferred quasi-legal justice systems and wanted to resolve their cases through compromise so that they could return to their joint families. Victims wanted to maintain the honor of their families of origin. She explains that individuals in non-Western cultures define their identity by their membership in a group or community, not as anonymous entities. Her study also found that the quasi-legal arbitrators (e.g., women's courts) used human rights' principles in gender violence cases far more than lower courts. In order to effectively use informal justice mechanisms (e.g., *nari adalat* or women's courts), communities must have similar occupational experiences and common perspectives that bind them together (Vincentnathan 1992). Unlike the traditional *caste panchayats*, the newly emerged *nari adalats* have representatives from different communities. These *adalats* are referred to as "social justice forums largely of women, for women, and by women" (Purushothaman 2011, p. 52). These adalats have been very successful because their goal is to protect the woman's rights and facilitate a change so that she could live a violent-free live.

In order for these informal control mechanisms to work effectively, the people in the communities must have collective orientation through occupation, caste, or religion. In tribal areas of India, NGOs are working with village *panchayats* by providing training to tribal people, including women, about the various issues undertaken by the *panchayats* (Kumar, n.d.). A more effective way to deal with violence against women is to strengthen the informal system of justice mechanisms for less serious offenses, increase awareness of domestic violence, and improve the performance of formal justice systems in serious cases through timely disposal of cases, enforcement of court orders, and other forms of assistance to the victims.

Restitution as a Penal Aim

Michael M. O'Hear
Marquette University Law School,
Milwaukee, WI, USA

Overview

Across the past century, restitution has become an increasingly prominent and formalized aspect of criminal sentencing. When included in a sentence, an award of restitution requires an offender to pay compensation to her victim. Restitution is most commonly justified as a way to provide assistance to victims more quickly and less expensively than would be possible through a civil lawsuit. There are concerns, however, that restitution blurs the line between crimes and torts, and in various practical and symbolic ways may undermine the traditionally recognized objectives of the criminal-justice system.

Restitution advocates have responded in two quite different veins. Some have argued that restitution not only furthers the end of victim compensation, but also serves more conventional criminal-justice objectives, such as offender rehabilitation and atonement. Another, more radical response is that the traditional approaches to criminal punishment are fundamentally flawed, and should be supplanted by victim compensation as the system's overriding objective. The latter response has attracted much interest in the scholarly literature, but has yet to gain much support among policymakers.

As policymakers have sought to enhance victims' restitution rights, a variety of practical problems have emerged. Many of these problems seem to turn on the same basic question: To what extent should restitution rules seek to replicate in the criminal system the same damages awards that could be obtained through tort litigation in the civil system? Different jurisdictions have answered this question in quite different ways, which may reflect underlying uncertainties as to whether and how victim compensation can be reconciled with the traditional processes and purposes of criminal punishment.

Fundamentals

Definition of Restitution

Restitution refers to compensation paid by an offender to a victim. More specifically, as understood here, restitution refers to a payment ordered by a court in connection with the resolution of a criminal case. Functionally, a restitution award has many similarities to a damages award in a civil case. Indeed, the term "restitution" can also be used to refer to a type of civil remedy. Here, however, the term is used only as it relates to criminal litigation.

Restitution differs from other sorts of monetary awards in criminal cases, such as fines and assessments of court costs, inasmuch as restitution is designed to compensate a victim for an injury. The amount of the payment is determined by reference to what is necessary to repair or offset some or all of the victim's losses, and the intended beneficiary is the victim herself.

Although restitution normally involves a discrete victim or set of victims with individualized injuries, it is also possible to conceptualize an award of restitution based on a more diffuse, shared injury, such as the psychological distress experienced by all of the members of a community when a frightening crime occurs in their middle. Likewise, although restitution normally involves an award of money or other property, it is also possible to imagine a restitutionary payment in the form of services. Court-ordered community service might thus be seen as having a restitutionary character.

Formalization of Restitution as an Aspect of American Criminal Procedure

Since the late nineteenth century, restitution has become a progressively more routine and formalized aspect of criminal procedure in the United States. The rise of restitution was initially linked to the rise of probation and suspended sentences (Harland 1982). Endowed with wide discretion in setting conditions for probation, judges often found it appropriate to require probationers to pay compensation to their victims as a condition of avoiding prison. For much of the twentieth century, restitution was awarded in such cases with little or no express statutory guidance.

In the latter decades of the twentieth century, American legislatures became increasingly active in promoting restitution. This resulted from a confluence of factors. The most important was likely the appearance of a politically powerful victims' rights movement. Reflecting a growing sensitivity to the situation of crime victims, most American states adopted victim-compensation laws between the 1960s and 1980s (Harland 1982). These compensation statutes, however, were not true restitution laws, as they contemplated a nonjudicial process administered by an administrative board, from which victims could obtain compensation even if their victimizers had not been apprehended and convicted. In any event, the laws varied widely in their eligibility limitations and maximum awards Holezel (1980)). Perhaps reflecting a sense of dissatisfaction with these compensation schemes, the victims' rights movement shifted its attention to achieving various reforms in court procedures, including establishing clearer rights to restitution.

Complementing the pro-restitution advocacy of the victims' rights movement, the 1970s and 1980s saw a breakdown of the rehabilitative paradigm in criminal justice and a new emphasis on holding offenders accountable for their crimes. This emphasis on accountability, in lieu of treatment, often took the form of longer, harsher prison sentences. To some, however, accountability implied not harshness per se, but rather the performance of certain apologetic or reparative actions by the offender through which he or she might achieve a measure of atonement and reconciliation with a victim or the wider community (Garvey 1999). This view of accountability, which found effective expression in many communities through the restorative-justice movement, was quite amenable to restitution

(Umbreit et al. 2005). Of course, advocates of greater harshness might also welcome greater use of restitution, so long as restitution serves as an *additional* imposition on the offender, and not as a substitute for other forms of hard treatment.

Reflecting these various considerations, by the early 2000s, about one-third of American states and the federal government had adopted mandatory restitution laws (American Bar Association 2004). For instance, the federal Mandatory Victims Restitution Act of 1996 (MVRA) requires judges to order restitution as part of the sentence imposed for most federal offenses in which there is a victim. The law specifies, moreover, that a restitution order must cover the full amount of the victim's injuries, regardless of the offender's ability to pay. Reflecting the change from permissive to mandatory restitution, the amount of "federal criminal debt" in the United States increased from about $6 billion to more than $50 billion in the first decade after the MVRA's enactment, with about $1.8 billion in restitution collected in 2007 alone (Dickman 2009).

The growing popularity of such laws in the United States might also be understood against the backdrop of the nation's "politics of mistrust" in the latter decades of the twentieth century and related legislative efforts to curtail judicial sentencing discretion (Zimring et al. 2001). Despite increasing legislative emphasis on restitution, however, concerns remain that judges and other criminal-justice professionals have not given sufficient priority to imposing and enforcing restitutionary obligations (American Bar Association 2004).

International Developments

The United States has hardly been alone in enhancing the role of restitution in criminal procedure in recent years, or more generally in displaying greater concern for the situation of crime victims. For instance, in 1985, the United Nations General Assembly adopted a "Declaration of Basic Principles of Justice for Victims of Crime and Abuse of Power," which, among other things, encouraged restitution and recommended that governments "should review their practices, regulations and laws to consider restitution as an available sentencing option in criminal cases."

Similarly, a 2004 directive from the Council of the European Union mandates that all member states "shall ensure that their national rules provide for the existence of a scheme on compensation to victims of violent intentional crimes committed in their respective territories, which guarantees fair and appropriate compensation to victims." Indeed, even before then, most members already had systems in place for victim compensation by the state (European Commission 2001). However, despite a 1985 recommendation by the Council of Europe's Committee of Ministers that criminal courts be given the authority to order restitution, the EU has stopped short of mandating this of its members. Rather, a 2001 "Framework Decision on the Standing of Victims in Criminal Proceedings" only requires that any compensation decisions in criminal proceedings be made within reasonable time limits.

Many individual nations do, in fact, incorporate restitution into their criminal processes, although this is far from universal. In England and Wales, for instance, the Powers of Criminal Courts (Sentencing) Act of 2000 requires courts to consider ordering compensation and to provide reasons when they do not do so (Doak 2008). Germany permits restitution as a condition of probation, and also makes available a hybrid process in which victims can attach a civil tort claim to criminal proceedings (Loffelmann 2006). As a final example, France also permits victims to claim compensation as part of the criminal proceedings, and has facilitated their ability to do so by, for instance, excusing them from having to appear in court in order to make a claim (Hodgson 2002).

Key Issues and Controversies

Justification of Restitution

Since crime victims typically have civil remedies available as a means to obtain compensation from offenders (at least as a theoretical matter), the creation of an additional compensation mechanism through the criminal process seems to require some justification beyond simply a desire to shift losses from victims to offenders. The most obvious such justification would be convenience for victims. If restitution is available, then the victim may be spared the trouble and expense of initiating her own civil proceeding, and instead take advantage of what may be a speedier award through procedures that may be less formal, less costly, and more favorable in a number of other respects than conventional civil procedures. Moreover, the court system, too, may reduce its costs by folding what would have been a separate civil case into the criminal proceeding. Indeed, even some defendants might have cause to welcome the apparent efficiencies.

Yet, there may be problems with viewing restitution as simply a more efficient way to effectuate recoveries that could have been had in the civil system. Liability standards for restitution may be structured differently than tort liability standards, or may be understood differently by criminal lawyers and judges than civil lawyers and judges. Different procedural rules (e.g., with respect to rules of evidence and right to a jury trial) may produce different results in restitution litigation than in civil tort litigation. Moreover, the prosecutor and criminal judge have an extraordinary source of leverage over many criminal defendants that is generally not available in civil litigation: If the prosecutor or judge takes a real interest in ensuring a certain level of restitution, the defendant who declines to cooperate may find herself facing a threat of increased incarceration. The restitution defendant may thus feel considerably more pressure than the civil defendant to “settle” the dispute on terms favorable to the victim. (On the other side, however, if the victim relies on a prosecutor to press her claim in a restitution proceeding, the victim may receive less zealous advocacy than a civil lawyer would provide, depending on how the prosecutor prioritizes restitution among the other disparate objectives of criminal prosecution.) More generally, the incarceration-related decisions that must be made in many criminal cases may overshadow restitution decisions and lead to more careless handling of claims than would be provided in a civil lawsuit. All of these considerations suggest that restitution outcomes may often deviate from civil litigation outcomes.

To the extent that victims fare worse in restitution, the outcomes may perhaps be justified on the basis of greater speed in recovery, reduced transaction costs, and the victim’s freedom to press claims in civil court in addition to or in lieu of restitution claims. It is not immediately clear, however, on what basis *greater* awards in restitution proceedings would be justified. This might require a theory to explain why conventional civil remedies are *substantively* inadequate for some types of crime victims, as opposed merely to being slower or more costly to obtain. In any event, it appears that the defense of restitution as simply an expedited form of civil recovery may be a bit more complicated than some proponents of restitution have made out.

If one line of criticism of restitution would focus on its potential to upset the balance struck in the *civil* system between the rights and interests of injurers and the injured, another line of criticism would highlight the potential of restitution to undermine the established priorities of the *criminal* system. The imposition of large financial burdens on some offenders, especially those whose economic situation is already precarious, may impair their prospects for rehabilitation and successful reintegration into the community. To the extent that incarceration time is traded off against restitution in plea negotiations or at sentencing, it is possible that the deterrence or incapacitation aims of criminal law may be compromised. (To be sure, the same trade-offs might occur even if restitution were not a formal part of the criminal process – e.g., a judge might, as a matter of discretion, treat voluntary reparations as a mitigating factor at sentencing – but the endorsement of restitution as an express objective of the criminal process might make such trade-offs more common.) The time and resources expended in litigating and adjudicating restitution claims in some cases might mean that offenders in other cases are able to avoid punishment or receive inadequate punishment. More generally, the increasing prominence of restitution in criminal litigation might create an impression that the criminal-justice system has been co-opted by private interests, which may undermine the ability of the system to pronounce condemnation on behalf of the community in a credible fashion. The system's credibility may also suffer if victims are commonly awarded large sums in restitution that offenders are not realistically able to pay.

In light of all of these concerns, a persuasive justification for restitution might have to show an organic connection between restitution and the particular ends of the criminal-justice system; simply providing a more convenient forum for advancing the ends of the civil-justice system may not be sufficient. Moreover, having a clearer sense of how restitution is capable of contributing to the purposes of punishment might help policymakers to sort out some of the difficult design questions, such as whether ability to pay should be taken into account in making a restitution award.

Proponents have indeed argued that restitution does serve conventional criminal-justice ends. For instance, while restitution obligations may in some respects impede rehabilitation, restitution may also be seen as "an effective rehabilitative penalty because it forces the defendant to confront, in concrete terms, the harm his or her actions have caused. Such a penalty will affect the defendant differently from a traditional fine, paid to the state as an abstract and impersonal entity, and often calculated without regard to the harm the defendant has caused" (*People v. Moser*, 50 Cal. App. 4th 130 (1996)). To be sure, this view of restitution as rehabilitative seems to rest on a very different sense of the rehabilitative project than the social-service model of earlier generations; here, we seem closer in spirit to atonement-based approaches, about which more will be said below.

Likewise, in the abstract, restitution seems capable of producing helpful deterrent effects, at least in the lower-level sorts of cases in which there is little risk of lengthy incarceration (the fear of which would presumably overshadow the threat of monetary penalties). On the other hand, even in lower-level cases, it is not immediately clear that restitution offers any marginal deterrence benefits when it is simply layered on top of civil remedies and criminal fines and forfeiture; for the added threat to matter, one would seemingly need a prospective offender who has both an ability to pay the full set of potential penalties and a nuanced understanding of law and legal process – not to mention a sufficient fear of getting caught such that the person's estimation of potential financial penalties would matter.

At first blush, restitution might also be seen as advancing the ends of retributive proportionality. And, indeed, it is hard to deny the "eye for an eye" appeal of imposing on an offender a sanction that is financially equivalent to the victim's losses. Yet, the thrust of modern retributive theory has generally been to emphasize *intended* (or at least culpably risked) harm, rather than *actual* harm, as the central determinant of desert (Moore 1997). Then, too, modern retributive theory has also tended to focus on *ordinal*, rather than *cardinal*, proportionality, that is, seeking to ensure that relatively more blameworthy offenders receive relatively harsher punishments, rather than striving for some absolute moral equivalence between the crime and the sentence (Von Hirsch 1998). Restitution may thus operate in ways that are significantly out of step with some views of retributive proportionality. For instance, a person convicted of a minor, unintentional traffic violation might find herself facing a ruinous restitution award if her violation by some unhappy chance resulted in a catastrophic accident – an award that might make her total punishment exceed those of other, more blameworthy offenders who intended serious harm but did not succeed in bringing it about. On the other hand, it may be easier to imagine such hypotheticals than it is to find them in practice. Moreover, concerns may be mitigated by limiting restitution recoveries to those harms for which the offender had some minimally required level of culpability. Yet, even at that, restitution may introduce some undesirable administrative complexity if one's basic approach to punishment focuses more on the *severity* of a sentence than on the *form* that it takes; a system of fines pursuant to standard guidelines, for instance, may be a much more straightforward manner of ensuring that the severity of each offender's sentence is precisely calibrated to the relative blameworthiness of her conduct.

Atonement-oriented approaches may be even more amenable to restitution. Advocates of such approaches tend to see proportionality in relatively flexible terms (Duff 2001). The aim of punishment on this view is not proportionality per se, but rather the communication of moral condemnation of the offense in the hope that the offender will come to repent what she has done, undertake reparative actions, and achieve reconciliation with the victim and the wider community. Punishment should thus take the form of a sort of secular penance, which will serve to focus the offender's attention on the offense and provide an opportunity to make reparations. (This approach to punishment overlaps considerably with restorative justice, although they might be distinguished to the extent that restorative justice – a label applied to a diverse set of approaches to crime and social conflict – is seen as an *alternative* to community condemnation, or as merely a set of procedures to be employed without regard to the character of the outcome (Duff 2005)).

Restitution would seem a quite appropriate – perhaps even a necessary – aspect of an atonement-oriented criminal process. The presentation and adjudication of restitution claims may serve to focus the offender's attention on the consequences of her conduct and why that conduct is viewed as blameworthy by the community. Moreover, the payment of restitution affords the offender with an opportunity to take responsibility for the offense and to establish conditions that may facilitate reconciliation. Indeed, on this view, it may be easier to see why restitution is superior to fines, for fines may appear confusingly similar in form to taxes or even licensing fees, and thereby detract from a sentence's ability to communicate moral condemnation (Duff 2001). To be sure, as with other retributive approaches, it might be necessary to limit restitution to culpably caused harms to the extent that harms without culpability are not fit for condemnation.

In sum, it does seem possible to justify restitution based on various familiar purposes of punishment. How persuasive the justification is may depend both on the specifics of the restitution law or practice at issue and on one's views about which purpose or purposes of punishment ought to receive greatest emphasis. Additionally, the foregoing discussion should make clear that there may be significant practical tensions between the conventional purposes of punishment and the hope that restitution may serve as a speedier and less costly alternative to civil litigation. For instance, the strict liability and simple negligence standards that govern some civil tort claims may be difficult to reconcile with at least some versions of retributivism. Incorporating these approaches to liability into the criminal process risks undermining the project of moral condemnation that many see as a central animating principle of the criminal-justice system.

Restitution as a "New Paradigm"

The previous discussion considered how restitution might be justified as one part of a criminal-justice system that maintains the conventionally recognized aims and penal options of Western criminal law in the modern period. Restitution, however, may instead be seen more radically as an alternative, fundamentally different approach to criminal justice – one that might wholly displace important aspects of current practice, such as the use of incarceration as a standard punishment for serious crime.

Perhaps most notably in this vein, the American legal scholar Randy Barnett proposed restitution as a "new paradigm of criminal justice" in a much discussed 1977 article. At the center of his proposal lay a privatized vision of criminal justice:

> The idea of restitution is actually quite simple. It views crime as an offense by one individual against the rights of another. The victim has suffered a loss. Justice consists of the culpable offender making good the loss he has caused. It calls for a complete refocusing of our image of crime. . . . Where once we saw an offense against society, we now see an offense against an individual victim. In a way, it is a common sense view of crime. *The robber did not rob society; he robbed the victim.* His debt, therefore, is not to society; it is to the victim. (Barnett 1977, pp. 287–88)

Barnett's proposal contemplated a radically reformed criminal process. Following conviction of a crime, an offender would be sentenced to a restitution period. The amount of the award would be determined in light of civil tort principles. If the offender were not able to make immediate payment in full, then the victim would have a legal claim against the offender's future wages. If the offender is unable to gain employment or is found to be "untrustworthy," the offender would be confined to an employment project. "This would be an industrial enterprise, preferably run by a private concern, which would produce actual goods or services" (289). Here, the offender would earn wages, and would secure her release upon satisfaction of the restitution award.

Barnett identified several advantages to his reform, which he termed "pure restitution." These included that victims would receive assistance, victims would have greater incentives to report crimes and appear at trial, offenders would have a mechanism for relieving their "guilt and anxiety," and taxpayers would be spared the expense of supporting idle prison inmates.

Barnett's proposal has much in common with various restorative-justice approaches, which are also often presented as a radical alternative, and not merely a supplement, to conventional criminal justice. Like Barnett, some restorativists seek to privatize our understanding of crime and punishment (Christie 1978). Many also share Barnett's prioritization of victim compensation and his distaste for straight incarceration as a useless, possibly even counterproductive, form of punishment. Additionally, Barnett contemplates routine, direct negotiation between offenders and victims, which is a centerpiece of many restorative-justice programs. Restorativists, however, would not be so narrowly focused on financial compensation as the subject of negotiation, but might instead emphasize to an equal or even greater extent apology, dialogue for its own sake, community service or service to the victim, ceremonial shaming and reintegration, and treatment. More generally, Barnett's approach runs counter to the communitarian and moralistic tendencies of many restorativists, who might object to the extent to which Barnett would marginalize the wider community, create a two-track penal system based on ability to pay, and monetize and commodify wrongdoing. (In addition to the presumably for-profit "employment projects" that will enforce restitution obligations, Barnett envisions the development of crime insurance markets and participation by insurance companies in the criminal process.)

Thus, despite some similarities with restorative justice, Barnett's proposal is better thought of as an expression of libertarian political values, and as being related to neoclassical law and economics, the proponents of which have also urged the substitution of monetary penalties over imprisonment on efficiency grounds (Posner 1980).

In any event, Barnett's proposal has been subject to considerable criticism. It is said that Barnett fails to appreciate the condemnatory aspect of punishment, which serves an important role in reinforcing collective moral norms (Miller 1978). Likewise, Barnett's emphasis on monetary penalties fails to address the particular dignitary harms suffered by the victims of intentional crimes (as contrasted with the qualitatively different harms suffered as a result of accidental torts) (Pilon 1978). Indeed, monetary awards for serious crimes against life or bodily integrity, such as murder or rape, might be seen as degrading and morally offensive (Miller 2009). More generally, restitution "sends the wrong message": "Punishment is not something you can buy your way out of, as if you could simply purchase a license to commit a crime" (Flanders 2006).

Critics wonder, moreover, how punishment would be available in Barnett's system for such crimes as cruelty to animals, harm to public institutions, attempts, and driving recklessly or while intoxicated (Miller 1978). Similarly, consensual transactions like drug distribution and prostitution would seemingly lie beyond punishment, notwithstanding views that these acts are inherently immoral (Miller 2009).

Critics also contend that Barnett faces a dilemma in how to handle restitution for unforeseeable injuries. Miller (2009) gives the example of two thieves who steal two identical jewelry boxes. It turns out, however, that one victim's jewelry box had great sentimental value because it was a gift from her deceased mother; to the other victim, the value of the jewelry box is simply the market price. If Barnett wishes to emphasize victim compensation, then it would seem that the two thieves should be subject to quite different restitution orders (assuming that the stolen items themselves cannot be returned). Yet, from the thieves' perspective, precisely the same crime has been committed against each victim. Differential punishment would thus violate the principle that equal punishments should be imposed for equally blameworthy conduct. Similar objections might be made to pure restitution's inability to recognize distinctions between intentional and accidental harms (Miller 2009).

Finally, critics argue also argue that Barnett has failed to address numerous practical difficulties with his proposal in a convincing fashion. For instance, Miller (2009) contends that no satisfactory mechanism is available for translating emotional harms into awards of money damages, particularly in view of the way that such valuations may be influenced by the sex, race, and class of the victim and of the person doing the valuation. For his part, Hershenov (1999) focuses on the challenge posed by unskilled or disabled offenders who cannot provide labor of sufficient value to offset the costs of their confinement, let alone to compensate victims. Additionally, there are concerns that a pure restitution system would not adequately deter crime, because no "premium" is added to the punishment to offset the likelihood that a prospective criminal will avoid apprehension or conviction (Barnett 1998).

To a considerable extent, the debate over pure restitution turns on deep questions of political philosophy and punishment theory. Barnett's proposal is likely to resonate with those who are especially distrustful of the state's use of coercive power against individual citizens, who reject the enforcement of paternalistic moral norms, and who find victim compensation a more legitimate or attractive project for the courts than enhancing social solidarity. Thus, the fact that pure restitution has not had much apparent influence among policymakers may, in part, reflect the continuing strength of communitarian impulses in defining and responding to crime.

But, as a practical matter, perhaps the greatest difficulty for pure restitution has been perceptions that it is not up to the task of protecting public safety – what Barnett himself characterizes as the "most obvious objection" to his proposal (Barnett 1998, p. 216). Barnett responds, however, that existing systems of deterrence, incapacitation, and rehabilitation are dysfunctional in various ways and perhaps even counterproductive to the objective of crime control. He notes, too, that his proposal may carry greater deterrence benefits than first appears. This is because compensation must be paid not merely for direct victim injuries, but also for the costs of detection, apprehension, and prosecution of the crime, and because these financial incentives will cause victims and law-enforcement agencies to put more effort into ensuring that offenders are caught and punished. Finally, Barnett notes that pure restitution is not incompatible with robust rights of self-defense and some limited use of preventive detention by the state, both of which may also serve crime-control ends.

Greater acceptance of pure restitution in the political system may have to wait for more widespread agreement that incarceration-oriented approaches are as ineffective as Barnett claims. Even at that, it is not clear that pure restitution would be a more appealing alternative than, say, restorative justice or a revival of treatment-oriented rehabilitation.

Design and Implementation Questions

In designing and implementing restitution programs, legislatures and court personnel have confronted a multitude of difficult questions. A few are briefly described below.

First, restitution orders may be limited to injuries caused by the formal offense of conviction or may reach out to embrace harms caused by any related criminal conduct. For instance, imagine that a burglar is caught in the act by police. A search of the burglar's home then uncovers evidence that she was also responsible for nine other burglaries. The prosecutor initially charges the offender with all ten burglaries, but then agrees to drop five of the charges in exchange for the offender's guilty plea to the remaining crimes. Should the victims of the dropped charges be able to obtain restitution at the offender's sentencing? If restitution is conceptualized purely as an alternative device for obtaining what would otherwise be available through a civil judgment, then ordering compensation for all victims seems a sensible enough answer – this would likely further the aim of providing victims with compensation in the most efficient and prompt manner. On the other hand, Boldt (1986) argues that going beyond the offense of conviction undermines the integrity of the criminal adjudication process, rendering adjudication an empty formality and diminishing the ability of punishment to serve its central function of strengthening social cohesion by reinforcing shared views of moral responsibility. (To be sure, commentators have for many years recognized an erosion of the "tort-crime distinction" as a result of the multiplication of no- and low-culpability regulatory crimes (Coffee 1991). Perhaps there is no "integrity" left to preserve on the criminal side.)

Second, whether or not the offender's relevant conduct is limited to the offense of conviction, there are questions regarding what categories of harm are compensable and how close the causal connection must be between the conduct and the harm. Courts often borrow the doctrine of proximate causation from civil tort law in order to impose some minimal limitation on recoveries, which seems quite consistent with the idea of restitution as an alternative to civil recoveries. Beyond this rather imprecise limitation, different jurisdictions impose a diverse array of additional limitations (Harland 1982). For instance, some limit recoveries to economic losses, while others specifically preclude "pain and suffering." Still others provide that victims may receive the full amount that they could obtain in a civil action. Likewise, there are different approaches to the possibility of recovery by the family members of deceased victims and others who might be thought of as secondary or vicarious victims (American Bar Association 2004). All such questions again put into issue the question of how important it is that restitution liability track conventional civil liability. As against the benefits of close tracking, the more inclusive approaches to restitution liability not only risk undermining the integrity of the criminal process (as Boldt might caution), but might also entangle criminal lawyers and judges in complex and unfamiliar sorts of loss calculations that could be more capably handled by civil practitioners.

Third, legislators, prosecutors, and judges must sort out the relative priority of restitution and competing sentencing alternatives. For instance, if a defendant is unable to pay restitution, court costs, and a fine, which should be paid first? Also, to what extent should it be a priority in fashioning a plea deal or a sentence to ensure that an offender is able to maintain or obtain employment? An extended period of incarceration will make full payment of restitution highly unlikely in many cases. More subtly, certain sorts of convictions may disqualify the offender from working in some professions (e.g., a lawyer may lose her license to practice law), which may also impede the payment of restitution. Yet, selecting the disposition that maximizes the likelihood of prompt, complete restitution may frustrate other legitimate objectives of the criminal-justice system, including the objective of obtaining funds from offenders to support system operations.

Finally, there is the question of whether ability to pay should be taken into account in setting a restitution award. US jurisdictions are split on this question (American Bar Association 2004). An emphasis on replicating civil judgments would point against taking ability to pay into account. This ability-blind approach might also be seen as accountability-reinforcing by formally making the offender fully responsible for all compensable harms that she has caused. Yet, a number of arguments might be made against this approach. For instance, a large financial obligation may create economic pressures that interfere with an offender's rehabilitation. Moreover, if the offender is unable to keep up with required payments, then the court and/or other responsible agencies must bear the administrative burdens of responding to the noncompliance, which may involve readjustments to the payment schedule or the imposition of sanctions, possibly including incarceration for offenders who had been released on probation. Victims may find the process of repeated sanctions and readjustments no less frustrating than offenders, and might even prefer a more modest restitution award that is more reliably paid.

Although setting awards on the basis of ability to pay might seem to lead to unequal treatment for offenders of different economic classes who commit the same crime, it may be that the severity of a financial sanction is more properly assessed by reference to its *relative* effect on the offender's wealth or income, rather than its *absolute* monetary value. This is, of course, the premise of day-fines. Thus, from an atonement-oriented perspective, an ability-blind award that will take many years for an offender to pay off (during which time the offender will likely have to remain under supervision) may communicate an inappropriately harsh message regarding the severity of the offense and the prospects for the offender to be restored to full membership in the community. Conversely, an award that takes ability to pay into account may be more precisely calibrated to serve communicative ends.

Future Directions

To the extent that policymakers and court officials continue to respond favorably to victim demands for restitution, a multitude of practical and theoretical problems will become increasingly urgent. This section briefly surveys a few of the emerging questions.

First, a prioritization of restitution as a routine, central component of criminal sentences may increase the demand for a variety of structural reforms to the criminal-justice system. Because few offenders have substantial reserves of wealth, the satisfaction of a restitution award in cases of serious injury normally requires that an offender have a steady source of income, a portion of which may be set aside for restitution payments over an extended period of time. Yet, a criminal conviction and the nonrestitution aspects of a sentence are apt to diminish or even entirely eliminate the offender's income-earning potential. Structural reforms that might be considered so as to minimize the economic effects of a conviction include: the elimination of employment-related "collateral consequences" of convictions (e.g., categorical bars on felons working in certain trades or obtaining government-subsidized loans for higher education); recognition of stronger confidentiality rights regarding convictions (e.g., through liberalized expungement laws or "ban the box" laws that prohibit employers from inquiring about prior convictions); greater use of deferred prosecution agreements, pursuant to which criminal charges might be greatly reduced or dropped entirely if an offender satisfies certain conditions (which might include entry into a legally enforceable victim-compensation agreement); more generous provision of social services to offenders so as to enhance their income-earning potential; diminished use of incarceration; greater availability of employment-friendly "intermediate sanctions" as an alternative to straight incarceration (e.g., community-based detention centers with work-release opportunities); diminished use of pretrial detention, which may result in job loss while an offender's case is pending in court; and diminished use of pre- and post-conviction release conditions that are employment-impairing (e.g., travel and residency restrictions). Of course, structural reforms such as these would not only support restitution, but would also address growing concerns regarding prisoner reentry and recidivism.

On the other hand, such structural reforms are also objectionable on a number of grounds. The stigmatization and socioeconomic marginalization of offenders might be seen as useful or necessary from the standpoint of deterrence or retribution. It might thus be regarded as morally offensive or insulting to victims if a person who commits a serious crime is able to proceed with her career as if nothing had happened, especially if the career is in a high-status profession. Likewise, offenders might be seen as undeserving recipients of social services, especially in a society in which many poor people who have not committed crimes are unable to obtain all of the services that they would find beneficial. Moreover, public safety might be compromised if there is less offender detention or reduced public access to criminal-history information. In light of such concerns, victim compensation might be better handled through expanded social insurance, rather than through structural reforms that are intended to facilitate restitution payments. Yet, expanded social insurance would not generate the atonement-type benefits that are said to accompany restitution.

Second, much as has occurred in tort law, collectively caused or experienced harms may put pressure on traditional notions of individualized proximate causation as a limitation on restitution liability. For instance, tort causation requirements have been relaxed in some jurisdictions in cases of "toxic torts" so that an injured plaintiff may recover from any of the manufacturers of a particular type of hazardous substance, even though the plaintiff may not be able to prove which manufacturer caused her specific injury. Likewise, tort law has devised various solutions to the problem of long latency periods for toxic exposure, which may leave it uncertain at the time of a lawsuit which individuals exposed to a tortfeasor's hazardous substances will eventually fall ill as a result. Environmental crimes present obviously analogous problems for restitution law. Drug trafficking offenses may present similar challenges. For instance, should narcotics wholesalers in a given market be liable for restitution to overdose victims in that market in proportion to their volumetric share of the market? And how about child pornography? Many subjects of child pornography experience significant psychological injuries as a result of the fear that their images are being widely circulated to strangers on the Internet. Some have sought, thus far unsuccessfully, to recover under federal restitution law from those convicted of possessing their images (Jacques 2011). Their claims raise questions about whether individual participants in the child-pornography market should be required to pay restitution for their role as consumers in sustaining a market whose very existence is said to harm victims.

In such circumstances of diffuse or uncertain causation, the question of whether to make restitution available presents familiar tensions between victim-compensation objectives, on the one hand, and, on the other, the goals of avoiding complex new adjudicatory responsibilities for the criminal-justice system and maintaining the system's traditional focus on individual moral responsibility. Additionally, in cases in which there are both identified and unidentified victims (as is frequently the situation in child-pornography cases), there are questions about whether and how assets should be preserved for victims who emerge in the future. It may be fairest and most efficient in such cases for restitution to be paid to a victim-assistance organization, rather than to individual victims.

Finally, there is the question of legal representation for victims in restitution proceedings. There may be a natural tendency to regard prosecutors as advocates for victims, and some prosecutors doubtlessly welcome such a role. Other prosecutors, however, may find that such a role presents awkward conflicts of interest, for instance, in the question of whether to drop certain charges in plea-bargaining when doing so would it be harder for some victims to recover. (Consider, for instance, the example given above of the prosecutor who drops five burglary charges in order to secure a guilty plea to five others.) Still other prosecutors may feel that they lack the time and resources to litigate restitution questions on victims' behalf.

In the face of prosecutorial disinterest, a restitution claimant may engage her own counsel, of course, but many victims will lack the resources to do so. These considerations might seem to support the court appointment of lawyers for victims at public expense (at least to the extent that the cost cannot, as a practical or legal matter, be shifted to the offender as part of the restitution award). Yet, such appointments might seem inappropriate if public funding is already inadequate for the legal representation of indigent *defendants*, as seems to be the case in many jurisdictions; it seems misguided to fund a process that will likely increase the level of punishment in a system when there are reasons to doubt the reliability of the underlying guilt determinations. The difficulties may supply yet an additional reason to narrow the scope of restitution liability relative to tort, confining restitution to the sorts of direct, easily monetizable injuries so as to which victims are least likely to require legal representation in order to prove.

Restorative Justice and Practice

Jonathan Doak[1] and David O'Mahony[2]

Overview

In recent times the promulgation of restorative justice has come to exert an increasingly strong influence in criminal justice policymaking. The restorative paradigm conceptualizes criminal behavior in a very different manner from orthodox models of criminal justice and aims to give "ownership" of the dispute to the primary stakeholders: the victim, the offender, and the community. There are many different forms of restorative justice practice, though they are frequently classified under four main heads: victim-offender mediation, panel-based interventions, police-led restorative cautioning, and family group conferencing. Overall, research shows that both victims and offenders are more likely to express satisfaction with restorative schemes than with court-based processes. There is also evidence to show that restorative interventions can have an impact in reducing recidivism.

Introduction

Restorative justice has developed as victim-centered approach which conceptualizes criminal behavior in a very different manner from which it has been traditionally conceived within orthodox models of criminal justice. In recent years, it has come to exert an increasingly strong influence over juvenile justice systems as policymakers have become increasingly concerned about the capacity of the traditional criminal justice system to deliver participatory processes and fair outcomes that are capable of benefiting victims, offenders, and society at large.

Proponents of restorative justice conceptualize criminal behavior in a very different way from orthodox criminal law theory. Crime is viewed first and foremost a violation of people and relationships, and the restorative process aims to repair the harm that has been caused to victims, offenders, and communities (Zehr 2005). The retributive focus of the traditional justice system and the prioritization of punishment and just deserts are thus not the primary goals of restorative justice. The normative frameworks of the traditional criminal justice system are thus viewed as being largely ineffective and even undesirable insofar as they can be counterproductive in their failure to meet the needs of those most affected by crime (Zehr 2005). By contrast, the restorative process looks to the needs of the individual parties. It seeks to repair the injuries caused, restoring relationships, repairing harm, and addressing the needs of the offender. In turn, restorative approaches are said to promote greater community protection and safety by promoting offender responsibility, restoring and reintegrating the key stakeholders, providing empathy and understanding for participants, and ultimately (hopefully) reducing the likelihood of reoffending (Braithwaite 1989; Zehr 2005).

Defining Restorative Justice

In spite of its growing popularity, restorative justice remains a contested concept, which has proved difficult to define in concise terms. One of the most widely accepted definitions is that provided by Marshall (1999 p. 5), who described it as "a process whereby all the parties with a stake in a particular offence come together to resolve collectively how to deal with the aftermath of the offence and its implications for the future." However, other commentators have argued that as an alternative to associating the with a specific archetypal process, the term should be instead thought of as encapsulating a body of core practices which aim to maximize the role of those most affected by crime: the victim, the offender, and potentially the wider community (Dignan 2005).

The potential fluidity of the concept underscores the risk that it may come to mean "all things to all people" (McCold 2000). Such a danger is highlighted by the fact that restorative justice programs worldwide vary considerably in terms of what they do and how they achieve their outcomes – let alone the level of actual "restorativeness" in terms of what is done. Practice often differs according to the situation and the manner in which programs have developed in local areas. For instance, not all schemes accept all restorative principles in equal measure, and there is also considerable divergence on the extent to which schemes may be integrated into existing criminal justice structures. As such, there is no single "prototype" format for practices that adopt the "restorative" label. While the best-known restorative schemes often operate in relation to youth or lower-level offending, there are now programs covering a diverse range of issues including corporate crime, conflicts in prisons and schools, domestic violence, serious violent crime, and political violence (see further Johnstone and Van Ness 2006).

Schemes may also differ in relation to the degree of formality or legality. Some schemes are based in statute and require that offenders be dealt with through a strict legislative (restorative) framework. In such instances, considerable resources are often invested across a range of statutory agencies, and widespread training and a change in working culture of the police, prosecutor, and courts are required. By contrast, other schemes may be practice led and "voluntary" and are much more informal. Typically, such schemes will lie on the fringes of the criminal justice system and may experience problems with resources and logistics.

Even where restorative programs become integrated within the formal criminal justice system, the conditions for referring a young person may vary considerably, with some schemes taking referrals as diversionary interventions or as a form of police caution, while others may be referred by the prosecutor or by the courts as an official form of disposal (Dünkel et al. 2011). Programs can be led by different agencies, such as the police, an independent conferencing service, or even local community mediation organizations. Programs also differ according to the level of victim involvement, with some using face-to-face meetings, while others use indirect mediation or those that rarely involve victims. Even the nature of the offence and type of offender differ, with some schemes only taking first-time offenders who have committed relatively minor offences, to others that consider a whole range of offences and individuals who have offended in the past. In essence, restorative practice is highly divergent and in considering how programs operate, one needs to be aware of their scope, range, and intentions (Doak and O'Mahony 2011).

Restorative Justice in Practice

Although restorative justice has permeate both law and criminal justice practice in around the world, there are clear differences in how these interventions are delivered and what they are designed to achieve. The following describes the main types of interventions, which include mediation, panel-based interventions, police-led restorative cautioning, and family group conferencing models.

Victim-Offender Mediation

Victim-offender mediation programs were first developed in Ontario, Canada, in the mid-1970s. They were promoted by the Christian Mennonite movement to promote personal reconciliation between victims and offenders. As such, they seek to bring together victims and offenders with a facilitator or mediator, who is usually professionally trained. Mediation aims to give victims and offenders a safe environment in which they are able to discuss the crime, its impact, and the harm it may have caused and to allow an opportunity to put right the harm caused.

Victim-offender mediation has proved very popular and is currently the most common form of restorative practice used across the United States and Canada (Dignan 2005). The technique is also widely used as a form of dispute resolution used to deal with conflicts within communities, especially where there has been a history of tension between the parties that has not been resolved by other forms of intervention. Mediation has also gained in popularity across many parts of Europe where it is currently one of the most dominant forms of restorative practice (Miers et al. 2001).

Most mediation projects are used to divert minor juvenile or adult offenders away from criminal sanctioning. Often prosecutors act as the gatekeepers to such programs and refer cases to mediation before they reach court. There is considerable variation in the types of programs available and some – particularly in cases involving young people – are based on an extension of welfare legislation, rather than being used as a penal measure.

The use of mediation is relatively a commonplace in Austria as a means of diversion for both juvenile and adult offenders. The process is designed to ensure that a much more comprehensive form of restitution is delivered which is more constructive for victims of crime than just a court-imposed sanction. The mediation process has three possible components which provide compensation for personal injury, loss, or damage; reconciliation talks which provide apologies and may help the victim; and in exceptional cases community service or payments to public welfare institutions or "symbolic restitution" (Miers et al. 2001).

Mediation services are generally delivered by organizations linked to the Probation Service. The mediation usually takes place directly with the victim, offender, and mediator in the same room. Unlike conferencing, supporters and representatives of the wider community are not generally permitted unless juveniles are involved. Occasionally indirect or "shuttle mediation" is also arranged, where the parties are reluctant to meet in person. Mediators meet regularly with members of the judiciary and representatives of the public prosecutor's office to share experiences and discuss difficult cases.

Similarly, Norway makes considerable use of mediation and the services are run directly by the central Ministry of Justice. Mediation referrals are usually made by the police or prosecutor, though they can also be ordered by courts as part of a community sentence or as a condition of a suspended sentence. The process only takes place after an admission or finding of guilt and the prosecutor usually decides whether the case is suitable for referral to mediation. Providing the parties agree on the facts of the case and consent to the process, mediation will be offered as an alternative to a formal penal sanction. The prosecutor will also take into account whether there is a personal victim, as well as considerations relating to individual deterrence. Thus, despite mediation being well developed throughout the country, it is still generally confined to less serious offences and retains its diversionary character (Kemény 2005).

The mediation process in Norway usually involves face-to-face meetings between victims and offenders. The mediation event may be brief, as is typically the case with offences against property, or prolonged, as is the case with neighbor disputes or violence (Miers et al. 2001). Services are normally provided by trained volunteers, who receive a nominal fee. Volunteers are trained through a national accreditation program, and are accountable to a coordinator based within the Ministry of Justice. In addition, the Ministry of Justice arranges annual conferences and publishes a regular journal for mediators to inform and generate exchange and good practice (Miers et al. 2001). The vast majority of mediated cases reach an agreement in Norway and nearly all of these agreements are fulfilled. The major forms of disposals include compensation, work, and reconciliation.

In the United Kingdom, there have been a number of victim-offender mediation projects; however, these have mostly developed on an ad hoc basis. Generally, they have been relatively small scale and have been local initiatives, rather than being "mainstream" projects. This has largely been the result of a lack specific legislation to formally establish them and the provision of little or no central funding, which has obviously impeded their development (Dignan 2005). Although the Home Office funded a number of pilot projects in the 1980s, funding was not continued beyond the pilot phase. Most of the schemes that operate today have been developed at a local level, through good working partnerships between criminal justice agencies such as probation, the police, and social services. However, they continue to experience considerable logistical and resourcing difficulties, concerning which agencies should fund them and where their referrals come from.

Recently, the government undertook to fund a number of these voluntary schemes and offered financial backing and an evaluation as part of its Crime Reduction Programme (Shapland et al. 2011). These schemes were established primarily to concentrate on cases involving adult offenders at different stages of the criminal justice process, from presentence through to release from prison. They are largely typical of those operating on a local level around the country, although they cover offenders convicted of serious crimes, including assaults, robberies, and burglaries.

Panel-Based Interventions

Panel-based interventions such as community reparation boards have been commonly used in the United States. While these are primarily used for adult offenders convicted of nonviolent offences, more recently their use has been extended to cover juvenile offenders. Such boards are typically composed of a small number of community representatives who hold face-to-face meeting with offenders, who have been referred by the courts. The board, with the offender, decides the sanction that should be imposed for the offence, monitor compliance, and report back to the court on its completion. The main goal of the boards is to promote community involvement and empowerment in relation to offending and to promote offender responsibility and victim reparation (Bazemore and Umbreit 2002).

In the United Kingdom, panel-based interventions are used as part of the referral order. It is a mandatory court disposal for first-time low-level juvenile offenders between the ages of 10 and 17. The referral order operates by diverting a young person away from court to a Youth Offender Panel. The panel then decides how the offence should be dealt with and what form of action is necessary. If the victim wishes, they may attend the meeting and can describe how the offence affected them. Parents are required to attend the panel meeting (if the young person is under the age of 16) and meetings are usually held in community venues.

The panel offers a discussion forum, and in theory, it gives the young person an opportunity to make reparation to the victim and community, take responsibility for their actions, and achieve reintegration into society. Although similar mechanisms in certain North American jurisdictions require the young person to consent to taking part in such a program, this is not the case with the English system of referral orders. However, the disposal is the result of a contract that must be negotiated and agreed and not simply imposed on a young person. Usually, a contract will contain specific offender-orientated interventions such as family counselling, mentoring, victim awareness sessions, and drugs or alcohol programs, which may be complemented by reparative measures, like a verbal or written apology, or an offer to repair damaged property. The amount of reparation and length of the plan have to be proportionate to the seriousness of the offence, and the young person must agree to the plan. In the event that there is no agreed outcome, the Youth Offending Panel will report back to the court, who will then reconsider how to deal with the young person.

Referral orders allow young people to play more of a role in how they are treated and they may find their plan or contract "useful," especially compared to the experience receiving a punitive sentence by the Youth Court. However, concerns have been raised about referral orders, especially where young people and parents may feel forced into agreeing plans. Some panels have experienced difficulty devising suitable plans because of a lack of local resources, and there have been ongoing difficulties of involving victims in the process (Crawford and Newburn 2003). The low level of victim participation in these panels arguably places a significant limitation on their overall restorative potential.

Police-Led Restorative Cautioning

Police-led restorative cautioning schemes were developed in the early 1990s, mostly as an alternative approach to the traditional formal police caution. The approach spread and was taken up and used in various forms in New Zealand and America, particularly in Minnesota and Pennsylvania in the mid-1990s.

The approach is largely based around Braithwaite's ideas of "reintegrative shaming" (Braithwaite 1989). In essence this approach deals with crime and its aftermath by attempting to make offenders ashamed of their behavior but in a way which promotes their reintegration into the community. It is different to the traditional police caution, which has been described by Lee (1998) as a "degrading ceremony" in which the young person, most often a first-time and minor offender, is given a "dressing-down" and good talking by a senior police officer.

The process is achieved by firstly attempting to get the young person to realize the harm caused by their actions to the victim, their family, and themselves. The focus is placed on the wrongfulness of the action or behavior, rather than the wrongfulness of the individual. The process attempts to reintegrate the young person, after they have admitted what they did was wrong, by focusing on how they can put the incident behind them, for example, by repairing the harm through such things as apology and reparation. It thereby allows the young person to move forward and reintegrate back into their community and family. The whole process is usually facilitated by a trained police officer and involves the use of a script or agenda that is followed in the conferencing process. The victim is encouraged to play a part in the process, particularly to reinforce upon the young person the impact of the offence on them, but as Dignan (2005) notes, restorative cautioning schemes have typically placed a greater emphasis on the offender and issues of crime control than on their ability to meet the needs of victims.

Despite these concerns, it has generally been found that the police are enthusiastic and committed to the restorative process. They are usually well trained and young people and their parents often place a high degree of confidence and support for the scheme. There is also evidence that restorative cautioning schemes can have other beneficial effects especially in terms of helping improve police/community relations (O'Mahony and Doak 2004; Doak and O'Mahony 2011).

Restorative Conferencing

Perhaps the best-known restorative conferencing scheme is the family group conferencing model, first developed in New Zealand. The model was devised as part of a more general initiative to address difficulties in the way young people were being treated in the criminal justice and welfare systems in New Zealand – particularly minority group offenders. The model sought to develop a more culturally sensitive approach to offending that emphasizes inclusive participation and collective decision making, bringing together young people, their families, and the broader community to determine appropriate means of redress for victims (Maxwell and Morris 1993).

The family group conferencing scheme was brought into New Zealand under a reform agenda that emphasized diverting young people away from criminal justice interventions through police cautions or informal resolutions. The legislation made conferencing the main avenue of disposal for all but the few most serious offences like murder and manslaughter. In effect, family group conferencing became the main statutory method of disposal for young offenders being prosecuted. Young people can only be prosecuted if they have been arrested and referred by the police. The courts are required to send offenders for family group conferences and they have to consider the recommendations of the conference and usually do not deal with cases until they have had a conference recommendation (Maxwell and Morris 1993).

Northern Ireland has also adopted a fully mainstreamed statutory-based restorative conferencing model for young offenders. The measures provide for two types of disposal, diversionary and court-ordered conferences. Both types of conference take place to provide a plan to the prosecutor or court on how the young person should be dealt with for their offence. For the diversionary conference, which is usually for less serious offences, the successful completion of a conference plan will avoid a court appearance and criminal conviction. Court-ordered conferences, on the other hand, are referred for conferencing by the court. An important feature of the legislation is that the courts *must* refer all young persons for youth conferences, except for offences carrying a mandatory life sentence. The court *may* refer cases that are triable by indictment only or scheduled offences under terrorism legislation. In effect, the legislation makes conferencing mandatory except for a small number of very serious offences. However, for conferencing process to take place, the young person must agree to the process and they must either admit guilt or have been found guilty in court.

The format of the youth conference itself bears much similarity to the general model used in New Zealand, though the Northern Ireland model places the victim much more at the center of the process. It normally involves a meeting, chaired by an independent and trained youth conference facilitator (employed by a Youth Conferencing Service), where the young persons will be provided with the opportunity to reflect upon their actions and offer some form of reparation to the victim. The victims, who are actively encouraged to attend, are allowed to explain to the offender how the offence affected them, in theory giving the offender an understanding of their actions and allowing the victim to separate the offender from the offence. Following a dialogue a "youth conference plan" or "action plan" will be devised which takes into consideration the offence, the needs of the victim, and the needs of the young person. The young person must give their free consent for a plan to be used. Plans can run for a period of not more than 1 year and usually involve some form of reparation or apology to the victim. Ideally the plan will include elements that address the needs of the victim, the offender, and the wider community, so as to achieve a restorative outcome (O'Mahony and Campbell 2006). Plans may include restrictions and requirements of the young person, including curfews. They may even recommend a custodial sentence.

The direct involvement of offenders and victims in conferencing and their ability to engage in dialogue contrast starkly with the conventional court process. In court, offenders are afforded a passive role – generally they do not speak other than to confirm their name, plea, and understanding of the charges – and are normally represented and spoken for by legal counsel throughout proceedings. Similarly, victims are able to actively participate in the conferencing process and many report the experience as valuable, in terms of understanding why the offence has been committed and in gaining some sort of apology and/or restitution.

The vast majority of conference plans are agreed by participants and victims and offenders usually report being happy with the content of the plans. Interestingly, plans often center on elements designed to help the young person and victim, such as reparation to the victim or attendance at programs to help the young person. The most positive aspects of conferencing for participants often relate to its ability to provide a means of moving forward for both parties, beyond simply punishing the offender. Both victims and offenders who have been through conferencing express a strong preference for it, as opposed to going to court, and they see conferencing as offering a more meaningful environment for them.

Research and Evaluation

The vast majority of research studies on restorative programs to date report high levels of satisfaction among participating victims irrespective of the seriousness of the offence or cultural or geographical variations. Satisfaction rates are particularly high where comparative research has evaluated the experiences of victims who went through a restorative process compared with those who went through conventional processes. Umbreit and Coates (1993) noted that 79 % of victims who participated in mediation schemes in the USA were satisfied with the way in which their cases had been handled, compared with only 57 % of those whose cases were dealt with in a non-restorative manner. McCold and Watchell (1998) reported statistics of 97 %

satisfaction for the restorative process compared with 81 % for the non-restorative process, and Sherman et al. (2005) reported that 70 % of victims who had participated in a restorative conference were satisfied, in comparison with 42 % whose cases where dealt with by a court. These findings are reflected in Latimer et al.'s meta-analysis (2001), where participation in a restorative scheme was found to result in higher victim satisfaction ratings when compared with comparison groups in all but one of the 13 programs examined. More recently, similar findings have been reported by Poulson (2003), who found that victims who had participated in restorative programs were half as likely to feel upset about the offence afterwards compared with those victims who attended court.

One of the more significant research evaluations to date has been the Canberra-based Reintegrative Shaming Experiments (RISE), which randomly assigned cases to a police-led conference or a court hearing and sought to compare the effectiveness of each procedure. The researchers arrived at the "inescapable" conclusion that "both victims and offenders can name many ways in which they prefer conferences to court" (Sherman et al. 1998: 165). Perceptions of fairness among victims and offenders were higher and observations reported greater participation, emotional intensity, procedural justice, apologies, forgiveness, and time and effort given to justice in conferences than in court (Sherman et al. 1998). Furthermore, conferences were said to increase offenders' respect for the law and the police, and over 70 % of contractual obligations were fulfilled by offenders (Sherman and Strang 2007). Similar positive data relating to stakeholder satisfaction have been collected in evaluations of police-led projects in the United States (see, e.g., McCold and Watchell 1998).

More mixed evaluation results have been found in relation to police-led restorative cautioning. The Thames Valley scheme evaluated by Hoyle et al. (2002) found most offenders and victims were generally satisfied and felt they had been treated fairly. But a significant minority felt they had not been adequately prepared for the process or said had been pressured into it.

Most evaluations report that victims gain a strong sense of procedural justice. Mediators/facilitators have been widely regarded as fair and objective (see, e.g., Shapland et al. 2011; Campbell et al. 2005), with victims feeling that they had adequate opportunity to express themselves (see, e.g., Trimboli 2000; Hayes and Daly 2004; Campbell et al. 2005; Shapland et al. 2011). Typically, victims place particular value on the ability to explain the effect the crime has had on them, put a face to the offender, and to have questions such as "why me?" answered (Hayes and Daly 2004; Campbell et al. 2005; Shapland et al. 2011). In relation to outcomes, satisfaction levels are similarly high (Campbell et al. 2005; Shapland et al. 2011).

Research also indicates that offenders are generally satisfied with their experience of the restorative process. In Northern Ireland, 92% of the young offenders felt the conference had helped them realize the harm they had caused and 93 % felt the conference plan was fair (Campbell et al. 2005). Similarly, 71 % of the young offenders were satisfied with their conference. In New Zealand, 84 % of offenders and 80 % of parents said that they were satisfied with the outcome of the family group conference. By contrast offender perceptions of their involvement in the process were much lower: 34 % of young people felt involved and only 9 % felt that they ultimately decided the outcome (Maxwell and Morris 1993). Results from more recent research suggest some level of improvement with around half of the sample of young people reporting that they felt involved in the conference process (Maxwell et al. 2004). Arguably, the inclusion and active participation of the offender is vital to the restorative process and the extent to which it is achieved may impact upon their perception of fairness and justice.

The perceived success or failure of restorative programs is often linked to their impact on recidivism rates. An overview of 14 different studies conducted by Nugent et al. (2003) found that those who participated in mediation had a statistically significant lower rate of recidivism. A broadly similar study conducted by the Canadian government (Latimer et al. 2001) found that restorative programs including mediation and group conferencing yielded reductions in recidivism compared with other non-restorative approaches. For programs involving group conferencing and sentencing circles, Umbreit et al. (2006) found somewhat mixed results. For the majority of the studies, the results were generally positive and showed that those who had gone through a conferencing process were less likely to reoffend than those who were traditionally processed. However, some of the studies reported differing results for different types of offenders. They note the RISE experiments from Australia showed a reduction in reoffending for violent crimes, but not a statistically significant reduction for the other categories of offences studied (mostly property offences). The research conducted by McCold and Watchell (1998) similarly found in their study of police-led conferencing that conferences had a more positive impact on recidivism rates for participants whose offences were relatively more violent.

A comprehensive meta-analysis of research looking at restorative interventions and their impact on reconviction was completed by James Bonta and his colleagues (Bonta et al. 2008). This meta-analysis was based on a wide review of differing programs that had a restorative basis and included court-imposed family group conferences and a range of community-based forums. Their analysis included studies with a comparison sample and recidivism data. Some 39 studies were used and nearly half were situated within a court setting, covering a range of restorative based programs. Overall, the researchers found the restorative programs produced a statistically significant 7 % reduction in recidivism rates over an average 17-month follow-up period (Bonta et al. 2008). In the case of violent offenders, the effect of the restorative intervention was stronger, with a reduction in recidivism of about 15 % (Bonta et al. 2008). However, the research suggests that the restorative interventions may be less effective with repeat, high-risk offenders – who by definition have a much higher rate of recidivism. These research findings are generally supported by other similar research, especially more recent studies (e.g., Shapland et al. 2011; Sherman and Strang 2007). In sum, therefore, it appears that restorative interventions have the ability to deliver lower levels of recidivism, especially compared with other criminal justice interventions. They also appear to work better with offenders who have committed more serious types of offences than petty offences.

Overview

Despite the continuing decline in the number of violent conflicts in recent years, the post-World War II period can be marked as one of the most violent periods in human history. The gross majority of the conflicts were intrastate conflicts involving flagrant and massive human rights violations. It is estimated that in the period 1945–1996 alone, 220 conflicts (not including international conflicts) resulted in 87 million deaths and many more millions of people stripped of their fundamental rights, property, and dignity (Balint 1996). In the final decades of the last century, various mechanisms for dealing with violent conflicts have come to light, in order to call the offenders to account and to provide compensation to the victims. The mechanisms that were put in place range from national and international tribunals or courts to nonjudicial forums like truth commissions. The emphasis on the development of more victim-oriented mechanisms is a logical continuation of the growing interest in the fate of victims in favor of the victors of conflicts. Some explain this profound shift as the progressive consolidation of the democratic model. At the same time, criminology and the understanding of crime have gone through the same paradigm shift – the social criminal as a survivor in poor communities has made room for the suffering victims.

The conflicts and crimes listed as prime examples of international crimes, that is, crimes incorporated in the Rome Statute of 1998 establishing the International Criminal Court, are as follows: (a) war crimes, (b) crimes against humanity, and (c) genocide. It should be noted that the large majority of these violent crimes are committed by states and their agents (e.g., police forces, army personnel, and intelligence services) and can therefore be considered state crimes (Rothe and Mullins 2010). However, the concept of state crimes is also wider, as it involves behavior that is not traditionally regarded as violent, such as instances of espionage or corruption.

This contribution largely equates state crimes with international crimes and leaves out the particular instances of treason, espionage, and corruption, which would merit a separate analysis. Its objectives are twofold: the first is to understand the recent developments that are gradually leading away from situations of impunity of international crimes toward situations of post-conflict justice into the face of a democratic transition; the second is to integrate the idea of restorative justice in the framework of post-conflict justice. The main argument is that the restorative justice theory, as an emerging discourse within the criminological sciences, may offer a promising approach toward the victims and perpetrators of mass violence. Moreover, it is suggested that it could contribute to broadening the object of criminology by shifting the attention from common crimes to political crimes and to deepening our theoretical understanding of the phenomenon of mass violence (Fig. 1).

The text takes the following structure. It first looks at the dominant approach to deal with international crimes, namely, retributive justice as evidenced through the criminal prosecutions of such crimes. It then shifts to a restorative justice approach and highlights its main features in the context of international crimes, by looking at truth commissions as the primary example of restorative justice. And, finally, it attempts to assess the relationship between these two very different models of justice in the case of violent conflicts and international crimes.

Retributive Justice Mechanisms and Their Shortcomings

The end of the twentieth century has witnessed the revival of international criminal justice in response to mass atrocities. The establishment of the International Criminal Court symbolizes this development. This first permanent international court will have the competency to judge individuals for having committed international crimes. It has been heralded by many as the start of a new era of justice. This era was already prepared by the establishment in 1993 and 1994 of two international ad hoc tribunals to deal with the gross human rights violations committed in the former Yugoslavia (ICTY) and in Rwanda (ICTR). Furthermore, the world has witnessed the prosecution and conviction of four Rwandans in a Belgian court, charged with complicity in genocide in Rwanda. Perpetrators of international crimes can be prosecuted outside their home country, in a "third country," on the basis of universal jurisdiction. It goes beyond the scope of this entry to describe all the existing retributive justice mechanisms that are available to post-conflict states when dealing with gross human rights violations. Instead, it focuses on the basic features of criminal prosecutions at the national and the international level.

Restorative Justice and State Crime, Fig. 1 Restorative justice typology (Source: McCold and Wachtel 2002)

As argued elsewhere (Parmentier et al. 2008), the classical way to deal with international crimes has been to punish them and to use the criminal justice system for this purpose. This route fits into a retributive justice approach, according to which punishment is considered a justified response to crime because those who commit offenses deserve punishment. Much more than in the case of common crimes, criminal prosecutions for international crimes may take place at various levels, national and international. From the outset it should be clear that retribution is not the monopoly of criminal prosecutions, as also civil damages to victims, or the lustration of persons having worked for a former authoritarian regime, constitute illustrations of retribution. For the sake of the argument, however, the next paragraphs discuss retributive justice in terms of criminal law and criminal justice only.

Strengths and Weaknesses of Criminal Prosecutions

Calls to bring the presumed offenders to a criminal court usually ring loud after a regime change has taken place, and the old authoritarian leaders have been replaced by a more or less democratic form of government. At that time, the political context tends to be more conducive to the necessary freedom of speech and of action. Moreover, the case of Pinochet has clearly illustrated that such calls for prosecution can be made long after the crimes have taken place. The former Chilean president and dictator was arrested in London in 1998 on charges of torturing political opponents during the early years of his dictatorship that ran between 1973 and 1990 but ultimately released by the British government on humanitarian grounds (old age and weak health).

The strong points of criminal prosecution for international crimes have been well documented. Huyse (1996) has listed two main arguments in these debates. The first is related to the reconstruction of the moral order, that is, the general idea that “justice be done” to satisfy the desire for justice of a society as a whole and of specific groups in particular. This moral argument is frequently coupled with a political one, in the sense that prosecution can also strengthen the fragile democracy, by confirming the principle of the “rule of law" and by thus providing the firm foundation on which to construct a human rights awareness and culture in the country. In such manner, criminal prosecutions serve the role of breaking through the thick walls of impunity and engage countries on the road to accountability. Closely linked to the reinforcement of the rule of law is the issue of deterrence, often voiced as a third argument. In this line of thought, to prosecute and punish perpetrators of international crimes will also serve to deter people from committing similar or other crimes in the future, both the perpetrator himself/herself but also the population at large.

On top of these two arguments that primarily pertain to the issue of the desirability of criminal prosecution, there are also aspects of legality involved. Orentlicher (2007) has argued in strong terms that there exists "a duty to prosecute in international human rights law" for serious human rights violations, founding her arguments on the various human rights treaties that contain passages to this effect and on the ensuing case law. Nevertheless, she also accepts the distinction between the "global norm" (criminal prosecution for the most responsible perpetrators) and the "local agency" of enforcing and interpreting this norm (including non-prosecution for many low-level offenders). In general legal terms, criminal prosecutions and convictions have the advantage of establishing a "legal or judicial truth," that is, an account of the acts and the facts that stands beyond doubt for the parties involved as well as for future generations. In the words of the South African Truth and Reconciliation Commission, this truth is mostly "forensic" or "factual" (TRC Report 1998), and it is of course focused on individual perpetrators and victims.

In a large number of cases, the calls for criminal prosecution are voiced by the direct victims of the violations or crimes, those who directly suffered from arrests, torture, convictions, and other forms of repression. Also their relatives, and their surviving family members, who have witnessed the crimes and have felt their consequences from close by, tend to be staunch defenders of criminal prosecutions. They usually wish to know what has happened to their beloved ones and to see the offenders be called to account. The examples of the survivors of the Holocaust or the Madres de la Plaza de Mayo in Argentina (the so-called Crazy Mothers who for 30 years demanded clarifications from the successive governments for the disappearances of their relatives during the years of the military junta between 1976 and 1983) speak for themselves. In other cases, victims conduct their activities with the support of human rights groups and committees, local but also international, such as Amnesty International, Human Rights Watch, and the Fédération Internationale des Droits de l'Homme.

It should be noted, however, that criminal prosecution is not without problems or even risks. Huyse (1996) has listed some of these risks. Contradictory as it may sound, criminal prosecutions of perpetrators may also undermine the "rule of law" of the new state. Some regimes may incur contradictions with the principle of nonretroactivity of criminal law, notably if they wish to prosecute crimes that were not prescribed or that were not punishable under the former regime. Another problem for the new state is to guarantee the independence and the impartiality of the criminal justice system. This is not always easy, because the criminal justice systems may still be populated by the same police offers and judges appointed by the former regime and still adhering to its values. The examples of Germany after World War II and South Africa after apartheid are telling in this respect. But also when the police officers and the judges are new to the system, problems may occur in that they may want to make a clear rupture with the past by adopting very repressive policies without due diligence for the rights of the accused. The reality of postwar repression in Western European countries has clearly illustrated the possible risks associated with such approach, which can lead to many controversies and tensions in the long run. And of course it is problematic to prosecute the offenders in the case of an amnesty rule that shields them off from further legal action, criminal and civil.

Another category of risks is less of a legal but more of a political nature. Many new democracies are fragile, as the old political and military elites can be resisting and actively opposing the transitional government. Prosecuting well-known offenders, or even the threat thereof, can provoke the old elites and even seduce them to seizing power again. The examples of Chile and Argentina are telling in demonstrating the power of the old elites and the caution with which the new government has proceeded. Another problem relates to the capacity of the system. In long-term autocratic regimes, only a small minority tends to possess the knowledge and the skills required to govern a country in political and economic terms. To call to account the members of this elite may lead to growing uncertainty about the future of the elites in general and may even push them to emigrate from the country, a scenario not unknown to countries from Central Europe in the early 1990s and to South Africa in the late 1990s.

Furthermore, there are problems with the logistics of criminal justice systems that are confronted with the legacy of mass violence. In some cases, the sheer numbers of offenders and potential suspects are so large that the system would become completely clogged if too many prosecutions were to take place. The example of Rwanda, where almost a decade after the genocide still over 100,000 persons were imprisoned, speaks for itself, and it has prompted the Rwandan government to look for new solutions and to revive the old conflict resolution model of Gacaca and to adjust it to dealing with the crimes of genocide (Penal Reform International 2002). Even in situations less extreme, it is unavoidable to be very selective and to only bring some perpetrators to the criminal court. Then a number of tough questions arise, namely, whether the prosecutorial agencies should aim at the heads and the planners of the crimes, who have ordered the crimes or were aware of them taking place, or whether they should target those who executed the orders and those who assisted them. And what about the so-called bystanders, who did not actively participate in committing the crimes but nevertheless witnessed them and in some cases may have benefited from the consequences?

Finally, criminal trials by their very nature are mostly focused on the offenders and on the rights of the accused and pay far less attention to the victims and to the harm inflicted upon them (Zehr 1990). This is the case with ordinary criminal trials, and it is by and large the same with international crimes and crimes of mass violence. This is not to say that victims are completely neglected but that their role in the criminal process is often reduced to that of witnesses or in other ways.

Given the many difficulties associated with criminal prosecution, many choices have to be made. Therefore, it does not come as a surprise that in practice criminal prosecution has often proved more the exception than the standard. Between the aspirations of criminal prosecutions and their realities, there exist many law and legal regulations, as well as several practical objections.

The Triptych of Criminal Prosecutions

States are traditionally well equipped to conduct criminal prosecutions against suspects of regular crimes, through the various institutions of their criminal justice systems (notably the police, the Public Prosecutor's Service, the trial courts, and the prison system or other measures for the execution of criminal sanctions). However, crimes of mass violence bring with them new challenges (Parmentier and Weitekamp 2007). One of the challenges lies in the political nature of the crimes, meaning that either the intent of the offenders or the object and context of their crimes relate to politics. Another distinctive criterion between common crimes and international crimes lies in the massive numbers of victims of the latter and sometimes in the large numbers of perpetrators as well. Therefore, criminal justice systems in many countries, particularly if poorly equipped, tend to be reluctant to engage in widespread prosecutions.

While in the past criminal prosecutions for international crimes were limited to the country where the crimes had been committed, the last two decades have witnessed two important shifts in this regard (Parmentier et al. 2008). The first shift relates to the development of so-called universal jurisdiction legislation in a number of countries. This allows third countries to prosecute and to try international crimes, without the existence of a link between the third country and the place where the crimes have been committed, the nationality of the offender, or the nationality of the victim. The main rationale lies in the fact that international crimes are considered so heinous that they not only affect the victims and the criminal justice system of the country where they took place but that they also affect humanity as such, for which reason also third countries put their criminal justice system at the disposal of the world community. Such cases of "pure" universal jurisdiction are in fact rare in today's world, the actual Spanish legislation and the former Belgian legislation (until 2003) being among the exceptions. In fact, a number of countries – mostly European – have a limited form of universal jurisdiction and require at least one specific link with the crime in order to prosecute and try it. While welcomed by some as an ethical triumph for humanity, recent events in Western Europe suggest that the efforts to establish genuine systems of universal jurisdiction are often subject to the *Realpolitik* of international relations.

The second major shift to respond to mass atrocity lies in the establishment of criminal justice mechanisms at the international level. The forerunners of this tendency were the two ad hoc tribunals, for ex-Yugoslavia (ICTY) and for Rwanda (ICTR), set up by the Security Council of the United Nations in 1993 and 1994, respectively, for a limited period of time and with a limited territorial jurisdiction. They have been followed by the establishment of a permanent International Criminal Court, entering into operation in 2002 and dealing with three main categories of international crimes, genocide, crimes against humanity, and war crimes. While the two ad hoc tribunals have a primary competence to deal with serious human rights violations, the ICC has a complementary task to prosecute and try international crimes when States Parties are "unwilling or unable" to do so, thus leaving the prime locus at the national level. It was followed by a number of mixed international-national tribunals, for Sierra Leone, East Timor, Kosovo, and Cambodia. The rapid development of international criminal justice mechanisms has been heralded by many as the final start of a new era of justice. Others, like Drumbl (2000), have argued that the practice of punishment by international tribunals is foremost an example of "legal mimicry," whereby every new institution tries to build on the experience of the previous one, despite the many different crime situations they are facing and despite the often "confusing, disparate, inconsistent, and erratic" sanctions they have applied thus far. He raises very serious questions about the fact that international criminal justice has been strongly imbued with a western conception of justice, which is liberal and legalistic, and may not be the only model to deal with these "extraordinary" crimes that involve many victims, many perpetrators, and a large group of bystanders – and all of these within a political context. Moreover, some mechanisms run the risk to be driven by economic and political motives and lack the credibility to engage in the restoration of broken relationships in the society.

Restorative Justice Mechanisms and Their Promises

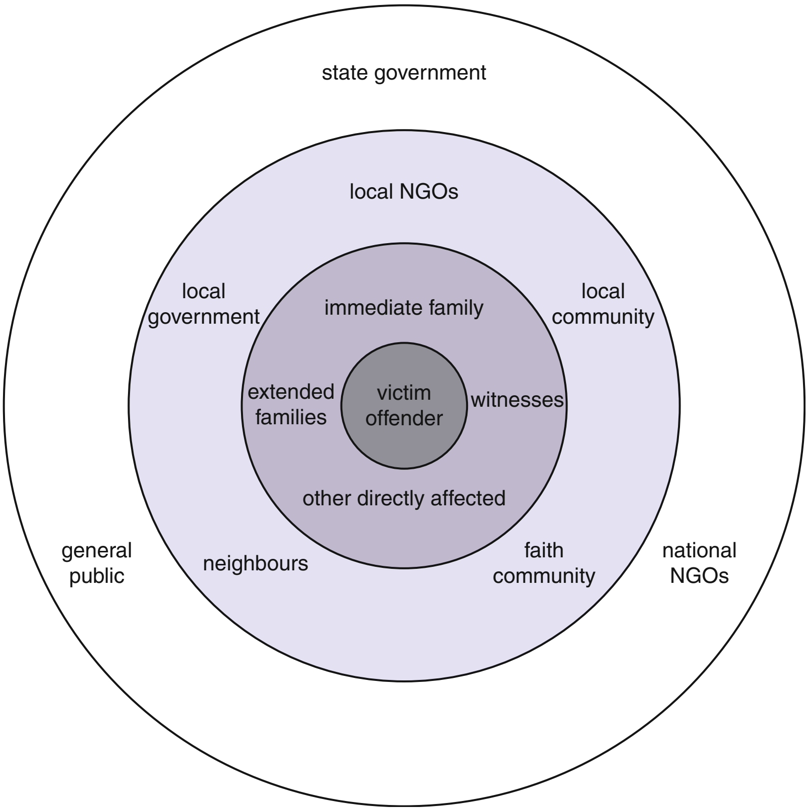
While the revival of the (international) criminal justice is often regarded as the starting point of a new era for justice in the case of mass violence, the preceding section exposed some of the major problems and shortcomings of the retributive approach to post-conflict justice. Moreover, retributive justice objectives will continue to represent only one side of the "coin of justice." Given the many problems with prosecutions and retributive justice in general, recent years have arguably seen an increasing interest for other institutions and other models to deal with serious human rights violations and international crimes (Parmentier et al. 2008). The more than 40 truth commissions that have been established since the last quarter of the twentieth century are the best known examples of "second-best" solutions (Hayner 2011). Truth commissions have become strongly associated with restorative justice principles, and some like the South African one are among the few transitional justice mechanisms to be explicitly labeled as a restorative justice mechanism (Villa-Vicencio 2001). As a result there is increasing attention for the model of restorative justice and particularly for the applicability of restorative justice in situations of mass victimization and post-conflict justice (Weitekamp et al. 2006). Such approach requires "changing lenses," as aptly put by Zehr (1990) in his seminal work on restorative justice for common crimes.

In this second part, it is argued that the road to post-conflict justice requires further steps that move beyond the limits of retributive justice. By prosecuting and punishing perpetrators of mass violence, many aspects of the phenomenon of mass victimization – such as its societal, victimological, and especially its criminological relevance – are overlooked. To reach some of the key goals of post-conflict justice, namely, to prevent the reoccurrence of the violent conflict and to repair the harm that was suffered during the conflict, it is crucial to consider a number of questions that are criminological par excellence: What are the causes of mass violence? What were the conditions that made this violent conflict happen? What are the sociological and psychological reasons that could explain people's involvement in committing these atrocities? Here follows a short overview of how a restorative justice approach to post-conflict situations can offer a meaningful answer to these questions.

At this point, an important problem arises. Few concepts have been quoted more frequently in criminology during the last decade than the concept of restorative justice. At the same time, few concepts cover a more diversified meaning that this one, which is sometimes considered vague and fluid. The bottom line of restorative justice is to view crime as a violation of people and relations, thereby creating an obligation to make things right. This process should be facilitated by bringing victims and offenders together on a voluntary basis, such as in victim-offender mediation programs, and possibly also with the other stakeholders, for example, in restorative justice conferences. In these forums, room is made for dialogue and for creating an opportunity, with the help of a mediator, to restore the harm done and to reconcile the relation. For restorative justice scholars, crime is fundamentally a violation of people and interpersonal relationships, and restorative justice seeks to heal and put right the wrongs committed. In other words, restorative justice constitutes a different way of thinking about crime and our response to it. It focuses on the harm caused by crime and repairing the harm done to victims and reducing future harm by preventing crime. Therefore, need offenders assume responsibility for their actions and the harm they have caused? Restorative justice seeks redress for the victim, recompense by offenders, and reintegration of both within communities. This is achieved through cooperation by communities and the government. For Dignan and Marsh (2001), restorative justice has the following characteristics: the offenders' personal accountability to those harmed by an offense, an inclusive decision-making process incorporating the key players, and the goal of putting right the harm caused by an offense. However, looking for a meaning that is widely accepted and that can serve as the starting base for our analysis is obviously no sinecure. At least four approaches can be identified to come to terms with restorative justice: (1) looking at definitions, (2) studying criteria, (3) identifying basic principles, and (4) developing models (Fig. 2).

It is striking that developments in restorative justice are almost exclusively focused on less serious property crimes and on juvenile crime, with a limited number of isolated examples of victim-offender programs for serious interpersonal crimes (e.g., Umbreit et al. 2003). But thus far very little attention has been paid to restorative justice for crimes of a political nature, sometimes reaching the level of mass violence and mass victimization (Christie 2001). However, viewing restorative justice in such a way that it may complement retributive mechanisms in dealing with mass violence allows for an extension of the concept of governance of international crimes. Before addressing the question if and how it can be used in the case of

Restorative Justice and State Crime,
Fig. 2 Stakeholders needs (Source: McCold and Wachtel 2002)



international crimes and state crimes, the meaning of restorative justice as developed in the area of criminology for common crimes has to be studied.

Definitions of Restorative Justice

Although no commonly accepted definition seems to exist, the literature makes frequent reference to two types of definitions. Marshall defines restorative justice as "a process whereby parties with a stake in a specific offence resolve collectively how to deal with the aftermath of the offence and its implications for the future" (Marshall 1996, p. 37), whereas Bazemore and Walgrave are goal-oriented as they formulate restorative justice as "every action that is primarily oriented towards doing justice by repairing the harm that has been caused by the crime" (Bazemore and Walgrave 1999, p. 48). Additional definitions abound in the broad and rapidly growing field of restorative justice.

Criteria of Restorative Justice

Definitions provided in the previous section remain somewhat general, and some would say quite vague. One way to make them more concrete is to enumerate specific criteria for restorative justice. The international community, personified by the United Nations Economic and Social Council (ECOSOC), has subscribed to the idea of restorative justice by adopting in 2002 a resolution encouraging countries to use Basic Principles on the Use of Restorative Justice Programmes in Criminal Matters to develop and implement restorative justice in their countries (www.restorativejustice.org).

The Basic Principles do not contain any formal definition of restorative justice, probably due to the fact that the text does not address the theory of restorative justice but is explicitly directed to particular programmatic expressions of restorative justice (Parmentier 2001). The text refers to "restorative justice programs," meaning a program that uses restorative processes or aims to achieve restorative outcomes, two pillars that are clearly distinguished. "Restorative processes" imply those whereby all parties "affected by a crime actively participate together in the resolution of matters arising from the crime, often with the help of a fair and impartial third party," as exemplified by mediation, conferencing, and sentencing circles. The second pillar, restorative outcomes, comprises agreements reached as the result thereof and explicitly includes restitution, community service, and other programs with an objective of reparation for victims and the community and reintegration of victims and offenders.

Rather than defining restorative justice, the Basic Principles enumerate various conditions under which restorative justice programs can and should actually work. These include, i.a., the availability of restorative justice programs at all stages of the criminal justice process, the voluntary character of restorative justice processes, the establishment of clear guidelines and standards governing the use of restorative justice programs, the importance of procedural safeguards in such processes, the issue of confidentiality, the importance of follow-up and implementation of agreements, the skills required for facilitators, and the importance of evaluation research. Through this focus on the working conditions of restorative justice programs, this text may be seen to mark the start of a more "conditional" approach to the problem of a common understanding of restorative justice.

Principles of Restorative Justice

A third way to understand the meaning of restorative justice is to identify the key principles that are underlying. By way of example, Roche in his important book (2003) has identified four such principles: (1) personalism – crime is a violation of people and their relationships rather than a violation of (criminal) law; (2) reparation – the primary goal is to repair the harm of the victim rather than to punish the perpetrator; (3) reintegration – the aim is to finally reintegrate the perpetrator into society rather than to alienate and isolate him/her from society; and (4) participation – the objective is to encourage the involvement of all direct and possibly also indirect stakeholders to deal with the crime collectively. These principles allow for a close study of the restorative character of procedures and institutions.

Models of Restorative Justice

Finally, it can be argued that restorative justice can be conceptualized by developing various models. One very useful typology was developed by McCold and Wachtel (2002) who talk about three "degrees of restorativeness," namely, "fully," "mostly," and "partly" restorative justice practices. These degrees depend on the degree of involvement of three actors, victims, perpetrators, and communities. As can be seen from the figure below, the authors consider family group conferences, peace circles, and community conferencing to be fully restorative while all other practices are only mostly or partly restorative.

The Relevance of Restorative Justice for International Crimes: Looking Through the Lens of Truth Commissions

Having sketched various approaches to restorative justice for so-called ordinary or common crimes, this contribution moves to indicating how restorative justice can be understood in the domain of international crimes, most of which are committed by states and their agencies. Rather than looking at all sorts of mechanisms that display some restorative features in dealing with international crimes, it is justified to focus on one specific mechanism, namely, truth commissions. In the following paragraphs, truth commissions will be looked upon, and it will be indicated how the principles and the models of restorative justice can be applied to them. At the same time, it should be noted that not all truth commissions share exactly the same features and therefore not all live up to the criteria of restorative justice (Villa-Vicencio 2001).

According to Hayner (2011), the following elements have to be present to speak of a truth commission: (1) it has to be set up with public (meaning state or government) support and cannot be the result of private initiatives only;

(2) its objective is not to focus on individual cases but to sketch an overall pattern of human rights violations; (3) its major focus is on the victims who are provided ample opportunities to share their experiences of the crimes committed; (4) it finishes its work by a final report that is given publicity; and (5) the report contains recommendations about how to deal with the legacy of a dark past and how to avoid similar conflicts and crimes in the future. From the above it follows that a truth commission is quintessentially a nonjudicial body, set up for a limited duration, and without the intent to establish the guilt or innocence of individual persons but more to contribute to a form of conflict settlement between parties and at the level of society.

Such commissions of inquiry are increasingly considered as a valuable and a complementary practice to civil or criminal courts because of their strong emphasis on truth, reparation, and reconciliation (Christie 2001). The restorative dimension is particularly present at two levels: first, at the institutional level of the commission, as it provides a public forum for victims and offenders to voice and share their experiences, and secondly, at the interpersonal level where individual victims and offenders can meet during or after the process of the truth commission with a view to dialogue, personal healing, or restoration on the long term. Again, not all truth commissions adhere to the same operational rules, and there it is important to conduct specific case studies to reveal in which way and to which degree truth commissions fulfill their promise of providing restorative justice (Parmentier 2001). The South African Truth and Reconciliation Commission (TRC) provides an interesting example of how such commissions may contribute to restorative justice, in this case through the work of its three separate committees (TRC 1998): first, by providing a forum to victims during the public hearings organized throughout the country as part of the Human Rights Violations Committee, which in limited cases have led to an encounter between victims and suspects or representatives of the apartheid regime; second, through actual encounters between offenders applying for amnesty to the Amnesty Committee and therefore being obliged to disclose all relevant facts, which in some instances led to a dialogue with the victims or survivors; and third, through the recommendations of the Reparation and Rehabilitation Committee that issued recommendations to the government on matters of reparation and rehabilitation.

Other examples of mechanisms with restorative justice aspects include customary mechanisms, also called community-based mechanisms, such as the Gacaca tribunals in Rwanda, set up to process the high numbers of alleged perpetrators of genocide in detention and with the objective to strike a balance between justice and reconciliation (Penal Reform International 2002).

Principles of Restorative Justice and Truth Commissions

Roche's four principles of restorative justice can easily be applied to truth commissions and particularly to the one in South Africa (Parmentier et al. 2008).

First of all, the principle of personalism, meaning that crime is a violation of people and their relationships rather than a violation of (criminal) law, finds application. This principle refers to the social dimension of "emotional involvement" that enables the conflicting parties to restore the broken relationships. Crimes of mass violence are first of all violations of people rather than violations of law. Truth commissions do bear the promise of being a "fully restorative justice process" if they stress the importance of encounters between victims and offenders and are also able to live up to these expectations (Weitekamp et al. 2006). One of the implications of such encounter is to organize victim-offender dialogues, either as part of the truth commission process or outside of its direct ambit. In that case, the key issue of "encounter" should be included as a new element in future truth commissions. To date no single truth commission has gone as far as bringing perpetrators and victims together to deal collectively with the aftermath of the violent conflict, with the possible exception of some amnesty hearings in the South African TRC. In the South African case, and presumably in other post-conflict nations as well, there is quite a lack of information on how and, more importantly, to what extent victims' expectations were effectively met through the TRC process, and very little is known about their backgrounds, expectations, and motivations. As to the offenders, it is already shown that if they are brought around the table, it might help to reverse the process of dehumanization of the perpetrator (Drakulic 2004). On a more general level, van der Merwe has illustrated how the national plan for reconciliation in post-apartheid South Africa has led to efforts to obstruct and to hamper the individual process of reconciliation for many victims (van der Merwe 2001). Finally, it should be noted that there exist many more legitimate responses to mass victimization after violent state conflict that are culturally and socially appropriate responses attempting to bring people together in some way. One of the examples could be the Gacaca tribunals in Rwanda (Penal Reform International 2002). Responses could also include a blend of mechanisms that form an integrated response to deal with the past.

The second principle of reparation, the primary goal of which is to repair the harm of the victim rather than to punish the perpetrator, is more difficult to apply straightforwardly. Reparation is becoming increasingly important to address, and even undo, the injustices of the past, and the last decade has witnessed an enormous increase of the awareness in this regard. According to the UN resolution of 2005 holding the Basic Principles and Guidelines on Reparation, reparation is to be understood as a very wide concept, including restitution of goods, financial compensation, rehabilitation through social and medical measures, symbolic measures, and guarantees of non-repetition of the alleged acts. All of these measures can be individual or collective. While the principle is now firmly established in international law (Sarkin 2004), many questions do remain (Du Plessis and Peté 2007). Although it is generally accepted that the beneficiaries of reparation are the victims, it is less clear how far to stretch this category and whether also indirect victims or society as a whole can be included. Another issue is how to enforce the right to reparation, through a general government policy or through individual administrative or judicial action? Apart from preventing conflicts to reoccur the restorative justice principle of reparation is a primary goal of transitional justice. For a long time in the debates on transitional justice, reparation was promulgated as a necessary mechanism, but only a few examples have shown a successful outcome. In the years to come, reparation is expected to rise high on the transitional justice agenda. In the context of the South African TRC, reparations were present at various levels (TRC Report 1998): the Reparation and Rehabilitation Committee awarded urgent and interim reparations to those victims who had provided written or oral testimony to the TRC and were in need of medical, psychological, or material help; it also recommended to the government to take measures of various nature, including individual reparations, symbolic reparations, and legal and administrative matters, community rehabilitation programs, and institutional reforms. It has to be said that the recommendations have not led to the expected results on the part of the government, and many victims have tried to force the government to implement these recommendations by bringing their claims to the collective level of victim support groups, direct lobbying, and even court cases. It remains to be seen what the concrete outcomes of such actions have been (Fig. 3).

The principle of reintegration, meaning that the aim is to finally reintegrate the perpetrator into society rather than to alienate and isolate him/her from society, poses another set of difficult problems. In retributive justice the focus is on the accountability of offenders, namely, calling to account those who have committed gross violations of human rights that sometimes amount to international crimes. In contrast to common understanding, accountability is far from a straightforward reality. One of the main problems relates to the type of offenders to be called to account, the heads and the planners of the violations or those who executed the orders and those who assisted them, and what to do with the "bystanders" who did not actively participate in committing the crimes but may have benefited from the consequences? On top of that, it should be clear that international crimes only constitute

fully restorative

the symptoms of a violent conflict. Dealing with the most serious crimes without dealing with the underlying conflict itself is merely touching the tip of the iceberg. A restorative justice approach to accountability is necessarily different, particularly when coupled with the key principle of reintegration. This principle demands from a society that it aims to hold perpetrators accountable for their wrongdoings in a supportive way, taking into account all the needed measures to work toward their reintegration into the same society. The merely punitive approach of trials leaves little room for future reintegration, and this same argument applies to states that choose not to face their violent past and decide to live in a permanent state of denial (Cohen 2001) or amnesia. A restorative justice approach to the issue of accountability is geared toward cooperation with the perpetrator, to resolve problems and to reintegrate rather than to alienate or isolate the perpetrator from his/her society. Providing a high level of support to perpetrators while not minimizing the control over the accountability process could arguably provide the most sustainable and durable response to dealing with perpetrators of serious human rights violations. Another aspect going to the heart of reintegration relates to the beneficiaries of international crimes and serious human rights violations. There is a great deal of controversy around the issue of involving the benefiting parties in the process of accountability and reparation. The experiences of the South African TRC on the (lack of) involvement of beneficiaries show the sensitive character of this matter. The amnesty hearings of the TRC focused only on individual perpetrators, and the institutional hearings with large sectors of society (e.g., business, media, and medical and legal profession) were purely voluntary. In this way, the structural evil of apartheid as a system was largely downplayed in favor of the misdeeds committed by some individuals. According to some, the beneficiaries of apartheid were let off the hook without being obliged to confront their past in a direct way (Mamdani 2000) (Fig. 4).

other directly affected

And fourthly, the principle of participation, whereby the objective is to encourage the involvement of all direct and possibly also indirect stakeholders to deal with the crime collectively, is applied. This principle refers to the dimension of empowerment and stresses that those affected by the crime need to regain their sense of autonomy. This can only be achieved when the stakeholders are actively involved in the process, and we distinguish two categories of stakeholders: those directly affected by the crime and those indirectly involved but not emotionally affected. In post-conflict situations, it is an enormous task to clarify the different roles and stakeholders that were affected either directly or indirectly and either personally or structurally by a violent past whereby gross violations of human rights were committed by the state on the one hand and by groups of the society (e.g., liberation movements, activists, minorities) on the other hand. Very few people will appear to be not affected at all, so that dealing with mass victimization in post-conflict situations will seem to be an insurmountable task to fulfill. Overall, restorative justice pays a lot of attention to victims and their needs, but a problem may arise when the group of victims is systematically narrowed. In the process of the South African TRC, for example, many victims could not be taken into account because they were not "victimized enough" according to the mandate. Only victims of gross human rights violations were defined as victims in the TRC Act. For a huge number of victims, there seems not to have been a feeling of justice at all, notably the victims of structural apartheid and the victims who suffered from the everyday apartheid policy. A lot of victims were disappointed and embittered after the proceedings of the TRC and felt that their rights and feelings had been neglected and justice was not gained. In this respect, it is also important to consider the distinction between individual and collective victims, direct and indirect victims, and see to what extent we can broaden up the definition of what victims are so that they can all have their place they deserve in the process of transition. In other words, while the process of truth seeking in the TRC has gone far beyond forensic forms of truth in individual cases and has involved narrative and social truth in a collective framework, it has still fallen short of allowing the participation of a wide range of victims of apartheid. Not all stakeholders were present in all parts of the procedures. They were mostly present in the hearings of the amnesty committee (AC), which always involved the amnesty applicants and the public and sometimes also the victims or their relatives. In the Human Rights Violations Committee hearing, the same three parties were sometimes present but sometimes not (only victims and the public). The picture is therefore mixed, moreover so because at the end of the day, only 22,000 victims in one way or another participated in the TRC's work, which in light of the many millions only constitutes a tiny fraction.

Models of Restorative Justice and Truth Commissions

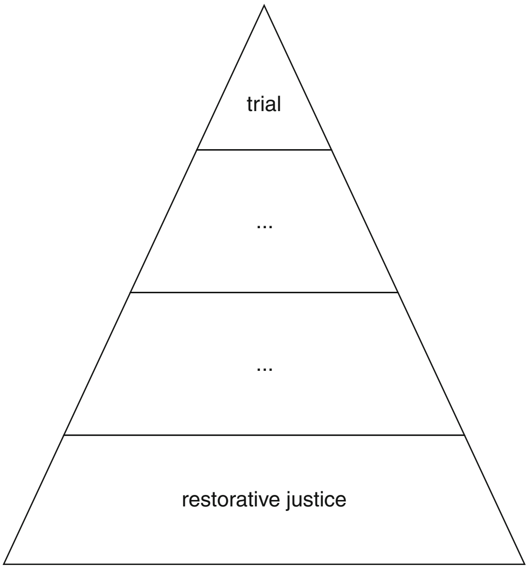
Another way to assess the restorative justice aspects of truth commissions is to apply the model of restorativeness as developed by McCold and Wachtel. Using the three basic actors, perpetrators, victims, and communities, it is possible to reinvent their model into a "restorative transitional typology" to fit the purposes of international crimes and post-conflict justice (Parmentier et al. 2008). As a result, six practices could be considered as fully restorative, including truth commissions (under the condition they allow encounters between offenders and victims), community peace programs (if they allow sufficient space for victims and offenders), Gacaca tribunals (provided they reserve a proper place to the community), the mediation model applied in Bougainville (Braithwaite 2002; see infra), the practice of Sulha (the middle eastern model of doing justice), and healing through remembering programs in various parts of the world. It goes without saying that much more research is needed, particularly in the countries concerned, to find out all the details of these practices.

Toward an Integrated Approach of Retributive and Restorative Justice in Post-conflict Situations

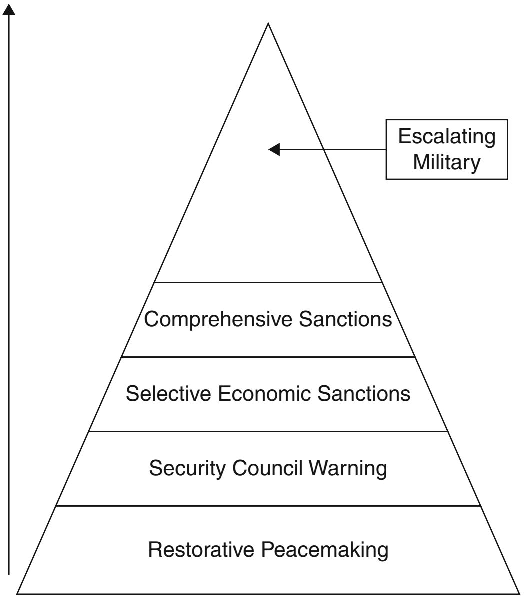
Having sketched the strengths and weaknesses of retributive justice models in relation to international and state crimes, and having indicated the features of restorative justice and its potential to be applied for such crimes, one crucial question comes up consistently: how to understand the relationship between both models of justice in the case of international crimes and in the context of post-conflict justice?

Much has been written about this one-million-euro question, and it would go far beyond the limits of this entry to deal with all possible answers in the literature. Instead, it is focused on the theoretical work of the very influential work of Australian criminologist John Braithwaite (2002). He has consistently argued that it is always feasible (and preferable) to adopt a restorative justice approach at the start and try to uphold it as long as possible. At the same time, the level of pressure and coercion can be gradually increased, and if nothing convinces the stakeholders to enter into a restorative practice, it is possible to go back to the retributive approach. In other words, while restorative justice is the preferred model to deal with conflicts and crimes, a certain degree of coercion may be unavoidable. For Braithwaite, this theory works both in the case of common crimes (the "restorative regulation pyramid" below) as in the case of violent conflicts involving international and state crimes (the "responsive regulatory pyramid of international diplomacy" below) (Figs. 5 and 6).

The theory provides a very useful and promising framework to conceptualize the relationships between retributive justice and restorative justice. In the context of international crimes and post-conflict justice, it provides a better understanding of how both models of justice could work together and even complement



Restorative Justice and State Crime, Fig. 5 Restorative regulation pyramid (Source: Braithwaite 2002)



Restorative Justice and State Crime, Fig. 6 Responsive regulatory pyramid of international diplomacy (Source: Braithwaite 2002)

one another. But of course, much more research is needed, both of a theoretical and an empirical nature, to grasp the full details of such complex relationship.

Others have tried to gain further insight into this matter by developing two models of post-conflict justice. The first analyzes the building blocks of post-conflict justice and identifies seven key issues for any government to deal with in the aftermath of violent conflicts: truth, accountability, reparation, reconciliation, trauma, trust, and dialogue (Parmentier and Weitekamp 2007; Weitekamp and Parmentier 2012). The second model relates to the interplay between retributive and restorative justice instruments that can be used in national and international interventions after violent conflicts have come to an end (Weitekamp et al. 2006). The interested reader is referred to the literature contained therein.

Conclusion

In the aftermath of violent conflicts and the commission of international crimes, often by state agencies, the dominant approach is to start criminal prosecutions against the alleged perpetrators. While prosecutions take place at the national and the international level, many problems continue to abound in terms of capacity, impartiality, and the like. Moreover, little if any attention is paid to a restorative justice approach in dealing with international and state crimes. One of the reasons is the multiple understanding of what restorative justice really means and implies.

This contribution has highlighted various ways of viewing restorative justice and has applied some of these to the field of international crimes, by looking through the lens of truth commissions that have emerged in international relations over the last 30 years. It can be argued that restorative justice is a useful approach to consider in cases of international crimes. At the same time, the relationship between retributive and restorative justice is far from clear and in fact very complex. More research is needed, theoretical and empirical, to develop sound models for understanding and for intervening during and after violent conflicts.

Overview

This entry looks at recent retributivist theories that draw on denunciation and the expression of moral emotions in order to justify punishment. After setting out some of the canonical sources of the retributivist tradition, and explaining some of the most serious objections to this tradition, it looks at how these recent developments seek to overcome the objections while preserving what seems most of value in retributive ideas. The entry identifies work by P. F. Strawson and Patrick Devlin as the starting-point of these developments. In different ways, Strawson and Devlin seek to vindicate the idea that punishment should express our sense of the moral seriousness of crime as wrongdoing. Furthermore, they imply that punishment is necessary to do justice to the moral seriousness of wrongdoing. The entry considers to what extent this line of argument, if more fully developed, might offer a successful defense of retributivism. It also gives a survey of some of the major recent contributions to this field, including Jeffrie Murphy, Andrew von Hirsch, and R. A. Duff.

Introduction

Three important developments in recent thinking about the justification for punishment are: the rise of communicative theories of punishment; renewed interest in the moral emotions; and the return of retribution. This entry concerns the way the first two have informed the third. After a long period of neglect, during which it was thought to be a barbaric remnant of superstitious thought that more rational forms of society would sweep away, retribution has, over the past 40 years, returned to the fore as a rationale for punishment. There are, of course, various social and political factors that have contributed to this change. But a full explanation of the trend would surely have to refer to the fact that theorists over the past 40 years have discovered new and prima facie attractive ways of construing retributive ideas. One claim, associated with early work by Herbert Morris (1968) and Jeffrie Murphy (1973) among others, is that retributive punishment is necessary to restore the fair balance of benefits and burdens in a system of social cooperation. However, this approach has always faced the charge that it reduces all retributive action to action aimed at rectifying unfair advantage, and therefore cannot capture the sense that there is something about wrongs such as murder, rape assault, and willful neglect that call for retributive responses. A different strand of the new thinking about retributivism, on the other hand, has concentrated on the connections between retribution, moral condemnation, and the moral emotions. Wrongdoing is something that we often feel strongly about – and such feelings can, it is said, (sometimes at least) be justifiable. It is this latter strand of retributivism that is the subject of this entry.

What Is Retributivism?

Whether there is something yet living in the retributive tradition depends on whether, on due reflection, at least some of its canonical ideas continue to strike us, under a certain interpretation, as moral insight rather than illusion.

One central source for this tradition is the idea, common to Judaism, Christianity, and Islam, that there is one perfectly just God who will, at some ultimate point of judgment, reward the virtuous with perfect happiness and punish the vicious with eternal suffering. Immanuel Kant captures this thought by claiming that the highest conceivable or possible good is the "distribution of happiness in exact proportion to morality [i.e. to the goodness of one's will]" (Kant 1996, p. 135). On this view, the purpose of retributive action is to help bring about a perfectly just state of affairs. Such action may be seen, in the final analysis, as the business of the Deity. However, it is important to recognize that this is not the only way to think about retribution.

Another source of the retributive tradition is deontic or act-focused, and thinks of justice as requiring that transgression of authoritative limits on conduct must be answered by a like, or at any rate commensurate, infringement inflicted on the transgressor. For instance the claim, from the Book of Exodus, that a wrongdoer should give "life for life, eye for eye, tooth for tooth, hand for hand, foot for foot, burning for burning, wound, for wound, stripe for stripe" (often called the lex talionis) can be interpreted in this light. A similar idea can be found in Pre-Socratic Ancient Greek thought (for some discussion, see Nussbaum 1993).

Thirdly, the retributive tradition contains ideas about moral contamination or pollution. For instance, we might think of the forbidding claim made by Immanuel Kant that, were a civil society to disband, it would be necessary for the last murderer in prison to be executed before the disbandment should take place, to prevent "blood-guilt" from infecting each of the departing members (Kant 1991, p. 142). The blood-guilt presumably affects the murderer most directly. But, secondly, the contamination can be passed on to otherwise innocent parties if they do not do their duty in visiting proper justice on the murderer. Again, a similar conception is present in Ancient Greek thought, where the failure of Thebes to take action against their king Oedipus has dreadful consequences for all.

Fourthly, the retributivist can lay claim to the ideas of repentance and atonement common again to a number of religious traditions (Etzioni and Carney 1997). The idea of at-one-ment suggests a moral fracture in the offender, a separation from God or the Good, that is brought about by sin or wrongdoing. The wrongdoer needs to be made whole again, to overcome her separation from what is most important in her life (i.e., God or the Good) through sincere repentance and atonement. One prominent development of this set of ideas is the Roman Catholic sacrament of penance, in which penitents undertake something otherwise harmful or onerous in order to make amends for sin.

What each of these sources has in common is the view that it is inherently right or good that something negative should be suffered by those who do wrong. One feature commonly said to be distinctive of retributivism is that it is a backward-looking theory: It takes the importance of the wrong committed to be the central reason for punitive action. We can understand better what is meant by this if we contrast it with forward-looking approaches such as deterrence. According to a deterrent theory, the reason we punish is, not the moral nature of the crime itself, but rather the need to prevent future crimes: Punishment is necessary because (and insofar as) it produces some future good. The forward-looking view gives a clear explanation of why punishment is important, but also makes its justification derivative and conditional. Whether punishment is justified depends on whether it really is an effective means for the production of the future good we have in mind. On the backward-looking view, however, there is something about punishment that is inherently fitting for answering, or annulling, or avenging, etc., the wrong. Thus, an aspect of the retributive view is that some acts derive their importance and necessity, not from the future benefits that they bring about, but rather from their role in doing justice to what has gone before.

In addition to its backward-looking focus, another distinctive feature of retributivism is that it places some importance on harm suffered by the offender as a result of the wrongdoing. Thus, according to one prominent recent characterization, retributivism centers on “the Desert Thesis”: “that when a person has done something that is morally wrong it is morally better that he or she should suffer some loss in consequence” (Scanlon 1999, p. 274). If we put these two features of retributivism together, we come to the distinctive retributivist claim that it is morally important or necessary that wrongdoing or evil should lead to some response that involves the offender suffering in some way.

Serious Objections to Retributivism

The shape of any contemporary retributivist theory will be dictated by the need to preserve what seems most attractive in the retributive tradition, while at the same time avoiding or answering the main objections that have been raised to retributive action. We turn to look at some of these main objections now.

First of all, critics often object to retribution as a rationale on the grounds that it does not bring about any good. This is connected with its backward-looking orientation. It might be claimed that retributive action does not actually achieve anything. Indeed, the situation is worse than this, because retribution involves glorying in suffering that seems to be inflicted for its own sake. Therefore retribution can look redundant at best, and at worst, downright sadistic.

In response to this, however, the retributivist should deny that nothing is achieved by retribution (Murphy 1971). The retributivist thinks that sometimes, it is necessary to take action to do justice to a past act, independently of future benefit. Actions of gratitude, or reward, or mourning seem to share this feature. What such actions achieve is an appropriate response to that past action. Therefore, the retributivist should resist the claim that retributive action is redundant. And if the suffering of the offender is part of such appropriate response, satisfaction at suffering is not mere sadism.

Nevertheless, there is clearly an important question to be answered as to what makes the suffering of the offender the appropriate response to wrongdoing. The suspicion will be that the retributivist is influenced by ideas about moral pollution. But those ideas might be said to be part of a world view that we have long outgrown (see, e.g., Smart in Smart and Williams 1973 on guilt as a stain on the soul).

A second major line of criticism looks at the problem of free will. For retributive responses to be appropriate, it would have to be the case that perpetrators of wrongdoing acted freely. If the apparent wrongdoing was not really the wrongdoer’s fault, then they cannot deserve to suffer punishment in response. But, the objection goes: Our understanding of the basis of human action is now sufficiently advanced that we can see that no action is entirely freely chosen. Human beings are complex biological mechanisms; they act in social conditions they have not chosen, on the basis of culturally constructed understandings. Where is the room for free will in all this?

We will look in more detail at responses to this criticism below. However, it is worth saying at this point that empirical evidence about the basis of human action will not by itself refute moral responsibility. In order to assess the justice of this criticism of retributivism, we would have to look first of all at which forms of freedom are necessary for moral responsibility. This is not an empirical question, but a philosophical and moral question about the conditions under which it is fair and right to hold someone to account for what she has done. The absence of some sorts of freedom does indeed excuse or exempt from blame. But which? Only once we have answered that question can we turn to the empirical evidence and look at whether, given everything we know about human beings, it is plausible to think that we are free in the ways moral responsibility requires. Therefore, an assessment of the free will criticism depends on some understanding of what is going on in retributive action, and what forms of unfreedom make retributive action invalid.

Some other common criticisms of retributivism are worth mentioning at the moment. For instance, if we are committed to retribution, to what extent should we take into account the extent to which someone has already suffered in their life in assessing how much they presently deserve? More broadly, and leading on from this, is it not the case that the goal of apportioning happiness to personal virtue (and suffering to personal evil) requires a degree of knowledge of people's character and motivation that we routinely lack (perhaps it is no accident that the task of doing justice is often allotted to an all-knowing God). One way to respond to these problems is for the retributivist to reject a character-based concern with personal virtue and vice as a whole (the first source considered above), and argue instead for an act-focused form of retribution as a response to transgression (the second source). However, even the act-focused form of retributivism will have to address the question of how much suffering is proportionate to which crime. Once we reject the notion of literal equivalence between punishment and crime – for instance, on the grounds that it would have us raping rapists or torturing torturers – the notion of proportionality becomes more mysterious.

Another type of criticism asks whether retribution is an important, or even legitimate, state purpose. This is compatible with allowing that some form of retributivism may be morally important. But if we think of how much money is spent on criminal justice, we have to ask whether retribution gives good value for that money. If prison is necessary to bring about security of person and property, it may be money well spent. But why is it important to spend the money on something backward-looking? A related criticism is that if retributivism were the rationale for state punishment, then the state would be committed to punishing for all moral wrongdoing. So, for instance, lying, adultery, sexual perversions etc.: If any of these are moral wrongs then, the objection claims, the retributive state would punish for them. Yet this would be illiberal: It is characteristic of the value given to freedom by the liberal state that at least some moral wrongs are viewed as private and irrelevant to the legitimate concerns of law. In short, retributivism seems allied to legal moralism – the claim that law should sanction immorality as such – whereas the liberal position, it might be said, rejects this approach.

Retribution, Denunciation, and Emotion

Having looked at some of the sources of the retributive tradition, and some of its most serious objections, we can now turn to recent developments that seek to show how retributivism might yet have the resources to answer these concerns. It is central to the approach to retributivism that we will look at here that retribution is not only a rationale for punishment, but also a feature of our emotional life in a range of interpersonal relationships. Thus, according to this line of thought, there is a deep connection between retributivism in punishment and our intuitive ways of dealing with one another in everyday life. In one way, this represents a strength of retributivism over, e.g., the view that punishment is justified as deterrence or incapacitation. After all, one of the reasons why people maintain and support an institution of punishment might well be that it reflects something important about the way they think wrongdoers should be treated in nonlegal cases, for instance, when one person betrays or lies to or steals from or unjustifiably harms another. On the other hand, retributivists may be vulnerable to the criticism that they fail to recognize the extent to which legal punishment in a diverse modern society differs from blame in intimate relationships.

We can begin by identifying two interventions that helped to initiate the current revival in thinking about retributivism, condemnation, and the emotions: P. F. Strawson's "Freedom and Resentment" (1962) and Patrick Devlin's "The Enforcement of Morals" (1959). The latter initiated a debate with H.L.A. Hart (1963), one result of which was the publication of Joel Feinberg's highly influential "The Expressive Function of Punishment" (1965; see also Moberly 1968). The argument of neither, of course, has been universally accepted. Yet both operate by identifying something missing in the then-prevailing liberal-utilitarian consensus on criminal justice, with its emphasis on the efficient management of social behavior, and both suggest that the "barbaric" retributivism opposed by utilitarianism has more to be said in its favor than previously thought.

Devlin argued for retaining the criminalization of homosexuality in the UK on the basis that it was quite proper for the criminal law to target immorality or sin that arouses repugnance in "the reasonable man." Now there are many points in the Hart-Devlin debate in which the reasonable reader may find Devlin to be in the wrong. For instance, many people will find his views on homosexuality repellent, and his view that criminal law should be explicitly recognized as having a basis in Christianity is hard to reconcile with the multicultural nature of many modern democracies. Furthermore, it is often unclear whether he is arguing that criminal law should be based on what is justifiably regarded as immorality, or rather what the "common man" finds repugnant. We may share Hart's view, in *Law, Liberty and Morality*, that the criminal law ought to be shaped by the moral ideas that best survive critical reflection, rather than our gut feelings. Nevertheless, when Devlin argues that "no society can do without intolerance, indignation and disgust; they are the forces behind the moral law" – and makes it clear that he is talking about disgust "that is deeply felt and not manufactured," the presence of which "is a good indication that the bounds of toleration have been reached" – he touches upon an important aspect of the function of criminal law that is ignored if we see punishment merely as a technique for behavior control. This is a point picked up by Feinberg in his discussion of the expressive aspect of punishment. Punishment is not merely, as the utilitarian might regard it, an incentive against antisocial behavior; rather, it is a vehicle of symbolic collective condemnation, expressing the anger, indignation, or repugnance that an act arouses in the "right-thinking person." What is missing in purely forward-looking accounts of the criminal sanction is something that connects punishment with our sense of the seriousness of the wrongdoing.

Strawson's argument, on the other hand, is addressed most directly to the debate over free will and moral responsibility. As I explained above, any argument about whether we have free will depends on some conception of the kind of free will necessary for moral responsibility. Strawson gives us an account of what we are doing when we hold people morally responsible, from which he then adduces an account of the freedom we need to be morally responsible. He argues that our sense of moral responsibility and retributive justice is found in the operation of moral emotions such as resentment and indignation, which lead us to withdraw goodwill from, and inflict harm on, those to whom they are directed. Strawson defends retribution and responsibility by arguing that the tendency to have such emotions is inextricably intertwined with accountability in interpersonal relationships. The interpersonal relationships that Strawson has in mind are those grounded in mutual expectations of some level of goodwill: relationships that are based on trust rather than mere containment and accommodation. Such relationships are an important part of the value of human life, and do not seem to be a merely illusory ideal. But when we enter into such relationships, we adopt a certain practical perspective on human behavior, according to which participants are reasonably subject to certain demands for good will. Of course, this perspective on human action is not the only one that it is theoretically possible to adopt. We can also see human action, not as a response, adequate or inadequate, to legitimate expectations, but rather as the deterministic behavioral output of a number of personal, subpersonal, and environmental inputs. This is what we do when we note that human beings are biological mechanisms, that their action is the result of social forces, etc. It is also the perspective we adopt when dealing with the very young, or the insane. But human life would be barren – perhaps even impossible – if this perspective (which Strawson calls the objective attitude) were the only one we ever took up. Therefore, we should reject the abandonment of moral responsibility; there is no reason to think that our practices of accountability are in bad order.

Strawson's arguments, and the outcome of the Devlin-Hart-Feinberg debate, altered the way in which it was possible to understand the significance of retribution. We can see this if we think about how the viewpoint they developed might be used to help us address some of the criticisms of retribution we considered above. One of the main criticisms of retribution was that its backward-looking nature makes retributive action redundant, and its desire for the suffering of the offender makes it cruel. Another problem concerns free will, while another argues that apportioning virtue to happiness, even if desirable, is a pointless task for limited human beings. Yet another criticism is that retributivism is tied to outdated ideas of moral pollution. The Devlin-Strawson approach, in response, sees punishment or blame in deontic fashion as a necessary part of recognizing the significance of responsible wrongdoing in the context of relationships that are based on trust. Being subject to these retributive reactions for wrongdoing is simply a condition of being included in such relationships.

Strawson and Devlin enable the retributivist to argue that the value of retributive responses lies in the fact that they (a) recognize the seriousness of the wrongdoing, and (b) recognize the agent who did the wrong as a human being who could and should have done better, and can thus justly be held to the relevant moral demands. When a person is punished, in other words, it involves being treated harshly, but it also involves being included rather than excluded from the terms of the relationship.

This line of thinking might also allow the retributivist to turn the tables on the deterrence theorist, charging that the deterrence theorist advocates merely threatening the offender, treating her as a mere means to a social end, whereas retribution is directed at the offender as an individual, a responsible moral agent. This criticism is made most forcefully by R. A. Duff, who quotes approvingly Hegel's damning remark that, according to the deterrence theory, punishment is like raising a stick to a dog (Duff 1986, p. 180). Even if this seems too strong, a more modest point can be made. Strawson reminds us that mere deterrence is not what we are engaged in when we experience emotional correlates of punishment like resentment and indignation. This raises the question whether punishment itself could not be made more like an interpersonal interaction. Deterrence theory sees punishment as an interaction between an individual and a bureaucratic state agency motivated by an overview of social welfare. A potential strength of the retributive approach is that it envisages the criminal justice process as – ideally – something more like an interpersonal interaction.

Two Cheers for Devlin and Strawson?

In order to understand more recent developments, we turn now to evaluate how far these arguments take us. They may have convinced us that offenders should be held to account for what they have done, and that their actions deserve criticism or moral disapproval. Furthermore, we might be persuaded that condemnation of at least a certain range of wrongful actions is a legitimate state purpose. Perhaps the state has no business condemning people for adultery, or for sexually perverted behavior. But we might agree that it should condemn those who, say, violate the legal rights of others, or who rape, murder, and assault. This view of punishment provides an important alternative to the view that the function of criminal justice is simply as an effective means to protect life, liberty, and property, and has been explored by writers such as Andrew von Hirsch (1985, 1993) and R. A. Duff (1986, 2001).

However, the argument so far seems to suffer from an important gap. Serious wrongdoers may deserve condemnation, perhaps even by the state. But why, we might ask, do offenders deserve to suffer in addition to being criticized? Feinberg himself advances this criticism (Feinberg 1965). He argues that punishment is merely a conventional symbol of moral disapproval, and asks whether we could not find less harmful symbols to do that work for us. This question requires an answer, and, in response, censure theorists find themselves in two camps: those who argue that there can be no meaningful condemnation without hard treatment, and those who agree with Feinberg that the goal of censure does not by itself require hard treatment. In the latter camp lies the influential version of the censure conception of punishment put forward by von Hirsch. Von Hirsch argues that censure is an important function of punishment because it addresses the crime as a wrongful action, does justice to the victim, and conveys to the offender that some response is required to the offense (von Hirsch 1993, pp. 9–10). However, he argues that the hard treatment element of punishment is only necessary for preventive purposes: If punishment had no deterrent effect, there would be no need for hard treatment. A similar view is put forward by Matt Matravers (2000). A prominent writer in the opposed camp is Igor Primoratz (1989; see also Moberly 1968), for whom punishment is analogous to language. If we change the symbols, according to Primoratz, we change what is said or done by punishment, so the symbolism of punishment is not conventional in the sense that we can arbitrarily choose what symbols to use without change in meaning. If we aim to condemn, then we must use a vehicle that is symbolically adequate.

This raises a question about the nature of symbolic or expressive action in general and as such takes us into deep waters beyond the philosophy of criminal law and punishment. To what extent can we alter the symbolic action we use to convey, e.g., gratitude or grief or outrage while still preserving a meaningful connection to these attitudes? The retributivist – who wishes to argue for some infliction of hard treatment as the privileged symbolism for expressing outrage – requires some view on which symbols are more or less resistant to alteration. Thus, in response to the objection that we might respond to wrongdoing by turning the other cheek, or simply communicating disapproval in a calm and measured way, the retributivist will want to argue that these responses, insofar as they avoid inflicting proportionate hard treatment, fail to do justice to the seriousness of the wrongdoing involved. One way to defend such a view, which can be seen in recent work by Jeffrie Murphy and Jean Hampton (1988), is to follow Strawson and Devlin in referring to the emotions. On the basis of phenomenological investigation, we can say that the experience of being in the grip of an emotion provides a subject with a deep sense of fit between some feature of her situation and the behavior that expresses that emotion, such that that feature appears to "call for" that behavior. For instance, if I have cause for pride I might find myself "walking tall," and in that situation walking tall feels right. Or if I perceive myself as having done something shameful, then covering my face or hiding away feels right. With respect to retribution, we might point to something to do with the fact that the emotions of outrage, indignation, and resentment are expressed through aggressive action taken against the offender, such that it appears to us that the situation of wrongdoing calls for such a response. This might explain our sense that the symbolism of punishment is at least in part invariable: In order to express condemnation symbolically, we must do something that connects with the behavior we find satisfying as an expression of the emotions aroused by wrongdoing.

Morality, Retribution, and the Emotions

Given the history of hostility to the emotions in Western philosophical thought, however, this turn to the emotions to inform our thinking about punishment is likely to provoke strong criticism. Thus, a critic might ask whether the retributivist is right to give such weight to the emotions in normative theorizing – theorizing that may, after all, end up with some people (offenders) being seriously harmed. In particular, we might wonder whether, from the fact that something feels right when in the grip of an emotion, we can conclude anything about the nature of right or permissible action. This objection need not deny that there can be some value in the expression of emotion. Perhaps, in spontaneous interpersonal interactions, we cannot help expressing our emotions. And perhaps we should not always try to restrict such expression: maybe there is a value in spontaneity. But the spontaneous expression of retributive emotions leads to suffering, and the institutionalized expression of those emotions through state punishment can blight whole lives. The suspicion will be that our emotionally-driven sense of fitting response is too slender a thread on which to hang such weighty matters. Indeed, criminal justice policy, according to this challenge, may be better seen as containing rather than releasing such emotions (e.g., see Gardner 1998 on the "displacement function" of punishment).

In exploring how the retributivist might answer this criticism, we will need to say something about recent developments in the philosophy of emotion and moral epistemology. But briefly, the retributivist might attempt to argue three points. First of all, that emotions are not brute psychological states, but are what Scanlon calls "judgment-sensitive attitudes" (Scanlon 1999), attitudes in principle responsive to justificatory reasons. Secondly, the reason that emotions are judgment-sensitive attitudes is that they present a subject with an evaluatively loaded (cognitive) representation of the situation under consideration, the plausibility of which can be assessed by the subject for its coherence with her other factual and evaluative beliefs. Thirdly, because the emotions can be understood as intelligent, cognitive evaluations of our environment, and not merely automatic responses to it, we have a default epistemic entitlement to trust the way they represent our situation, in the absence, that is, of strong reason to doubt that representation. If those three points could be established, then the retributivist and the critic might agree on the following possibility: The way a situation is presented to us in the grip of an emotion could be our best way of understanding the evaluative nature of that situation and the response it demands of us. The argument with respect to retributivism would then come down to whether we have strong reason to mistrust those experiences in which it appears to us that taking wrongdoing seriously requires some type of hard treatment of the offender.

The retributivist's line of argument might start by following Nussbaum and Kahan in distinguishing a mechanical from an evaluative conception of the emotions (Nussbaum and Kahan 1996). The mechanical view sees emotions as strong sensations, immune from thought and rationality, that are triggered by certain stimuli and drive us to certain actions. One of the key developments in the philosophy of emotion in the twentieth century has been the observation that, at least in some respects, and for what might be called the "higher emotions" (Griffiths 1997), this view is too simple. The emotion of fear is not a simple sensation like the feeling of stepping into a warm bath. Fear is a state with intentional content, it is directed toward something (i.e., it is "fear of" or "fear about" or "fear that") in a way that simple sensation is not. Therefore, fear could be said to be a state that represents the world in a certain way. It is a way of seeing or understanding (according to Roberts (1988), "construing") a situation rather than just simple feeling triggered by the situation. (This is one of the main arguments against the James-Lange hypothesis that emotions are simply the effects in consciousness of bodily changes brought about by external stimuli.) Nussbaum and Kahan use this as evidence that emotion is more like a cognitive or evaluative state than the mechanical view allows (though for criticism, see, e.g., Deigh (2008)).

We could also point to the fact that it is often possible to judge emotions according to rational standards of adequacy to the facts: If I am afraid of a noise that turns out to be only the wind rattling the door-knob, then normally speaking my fear will abate; this suggests that fear is at least sometimes sensitive to reasons for that fear, that it can be justified or unjustified. Hence, the claim that emotions are "judgment-sensitive."

Any proponent of the cognitive or evaluative view of the emotions needs to recognize, however, that there is a partial truth in the mechanical view: Some emotions in particular are capable of getting out of proportion quite easily, and they can grip our attention to the extent that we find it difficult to get other things into proportion. But while the existence of irrational and disproportionate emotion is clear, this should not blind us to the fact that it is often possible to bring our emotions into line with our considered evaluative beliefs. In other words, some emotions can be justified in the sense that they embody our considered values. Furthermore, if this is allowed, it may open up the possibility that sometimes the direction of revision goes the other way round, and that it is our evaluative beliefs that have to change to accommodate the epistemic deliverances of an emotional experience that appears authentic and compelling. This is a possibility famously defended by Bernard Williams (Smart and Williams 1973; Williams 1976): Although Williams does not put it quite like this, we might say that it is the idea that justified and proportionate emotion might involve seeing the world in the right light (cf. McDowell 1985). If this is at least a possibility, then we might argue that we have a default entitlement to trust our emotions (or moral intuitions) unless we have reason to think that they cannot be made coherent with our other justified evaluative or factual beliefs (though the proper role of intuition in moral theory is the subject of great controversy: see Sinnott-Armstrong et al. (2010)). Applied to retribution, this would mean that we have a default entitlement to trust our feeling that the retributive response is fitting unless we have reason to think that this response cannot be made coherent with the demands of those other values in the validity of which we have great confidence (Moore 1988).

Nevertheless, the most we have established thus far is the possibility of justifying retribution on the basis that we might have an undefeated entitlement to trust the way our emotions present the situation of wrongdoing. In order to determine the success of this strategy for justifying retribution, we would need to investigate whether the purported validity of retributive experience in informing us of the demands of the situation has to be regarded as illusion because it conflicts with the other things we know about what the situation demands. And the reader might be forgiven for being underwhelmed by this result. For it might appear that it simply returns us to the realm of normative argument between the retributivist and her opponents about whether retributive responses are compatible or incompatible with what we know about our obligations, e.g., not to impose suffering. However, if the "retributive emotions" strategy is successful, then this reaction would be unjustified for three reasons. First of all, the success of the strategy would make it clear that the burden of justification lies with the opponent of retributivism. Retributive reactions could not be written off as mere "gut reactions." Secondly, it would provide a way of understanding ideas such as moral pollution or contamination that does not involve a commitment to unwanted metaphysical baggage. "Moral contamination" would simply be that quality that, when we are in the grip of (let us suppose) justified retributive emotion, seems to us to call for that reaction. It would not be a property of the universe with the power to cause famine, pestilence, etc. Thirdly, it would affect our view of how to conduct moral inquiry. In order to evaluate retributive reactions, what we would need to look at is, in part, whether we can understand our experience of those reactions as inauthentic and illusory, or whether it is rather our conflicting beliefs that need to change. This introduces an essentially phenomenological Gestalt-like element into moral inquiry.

The likelihood that we will conclude that retributive reactions are authentic or illusory no doubt depends on which emotions we focus on.

The relevant emotions are often taken to be those felt by third parties toward offenders, such as in Jean Hampton and Jeffrie Murphy's discussions (1988). But many readers may find that it is easier to feel comfortable with the claim that offenders should feel bad toward themselves than it is with the claim that "we" should endorse aggressive feelings toward "them." For this reason, another important line of work for retributivists is to be found in the conceptions of guilt and remorse put forward by Herbert Morris (1981), Gabriele Taylor (1985), R. A. Duff (1986), and Raimond Gaita (1991).

Emotion and Punishment

By way of conclusion, we can now distinguish three ways in which punishment might be related to the expression of the emotions.

- Firstly, state punishment might be carried out in order to displace aggressive retributive action motivated by strong feeling on the part of individual citizens.
- Secondly, punishment might be carried out in order to maintain the perception of the legitimacy of the state among the populace, a perception that might be strengthened if state action is carried out in line with the strong feelings of the citizens.

What we need to notice about these first two suggestions is that their motivation comes, not from the endorsement of the emotions involved, but rather from the desire for social stability: The policy is driven by the need to contain or accommodate strong emotion that might disrupt social relations. The justifiability or unjustifiability of those emotions is not relevant to the social need to contain them. However, the result of this is that a theory that gives this kind of role to the emotions is not distinctively retributive. For the need for punishment derives in the end from the need for social stability, not the retributive concern with doing justice.

For a distinctively retributive view, we need to consider a third possibility, which comes about if, after due reflection, we can endorse the way the situation of wrongdoing appears to us when we are in the grip of retributive emotions. If state punishment is a vehicle for treating the offender as those emotions prompt us to treat him, then we might say the following:

- Thirdly, state punishment is carried out because the way of seeing the significance of wrongdoing that is involved in the retributive emotions – namely, that it calls for hard treatment in response – is our best understanding of what the situation demands.

The retributive emotions present wrongdoing as mattering in a certain way, specifically as being impermissible or transgressive, and they present the situation as one that calls for a certain kind of response directed at the wrongdoer. The strand of retributivism in which we are interested here argues that we have reason to allow this phenomenology to inform our normative judgments, broadly endorsing our tendency to act on retributive emotions, and deploying state punishment as a vehicle for the condemnation of the offender. The reason for expressing the emotion is not a desire to release emotional pressure – as though the emotion were just a psychological force – but rather because retributive responses are our best understanding of what the situation demands.

Risk Assessment, Classification, and Prediction

Edward J. Latessa and Brian Lovins
School of Criminal Justice, University of Cincinnati, Cincinnati, OH, USA

Overview

Over the years, the assessment of offenders has evolved from using one's "gut feeling" to decide who is likely to reoffend, to instruments that have focused on past behavior (static indicators), and to what are now called fourth generation assessments. These instruments combine static and dynamic (changeable) factors to more accurately predict risk of recidivism. They identify the crime-producing needs that should be targeted for change, and produce results that can be fully integrated into case plans used to manage what programs and services offenders receive as well as gauge progress (Andrews Bonta and Wormith 2006).

One of the foundations of developing effective correctional practices and programs is adoption of a validated risk assessment. Once focused primarily on the seriousness of the offense, the criminal justice system is now speaking in terms of risk and need factors. Hence, the risk level of the offender becomes the primary consideration for treatment and supervision over the offender's felony level. As departments adopt a risk, need, and responsivity (RNR) framework, the importance of assessing for risk has been elevated. In fact, many of the leading professional correctional organizations fully endorse the use of risk assessment in assisting in classification decisions and delivery of evidence-based practices (American Association of Community Justice Professionals, American Probation and Parole Association, and the International Community Corrections Association). To understand the impact risk assessment has had on corrections, this entry reviews the history of risk assessment, provides a framework for understanding the context in which assessment should be adopted, and discusses the current controversies surrounding the development of 3rd and 4th generation risk assessments. Finally, this entry provides recommendations for the field in regard to adopting risk assessment and using the results to best inform correctional practices.

What Do Risk Assessments Measure?

This seems to be a straightforward question. However, people have different concepts of "risk" and different instruments measure "risk" for different types of behavior. For some, "risk" is a concept associated with the seriousness of the crime. For example, a felon must be higher risk than a misdemeanant. Even though a felon has been convicted of a more serious offense than a misdemeanant, his or her relative risk of reoffending may have nothing to do with the seriousness of the crime. For most, "risk" refers to the probability of reoffending. A low-risk offender is one with a relatively low probability of committing a new offense (i.e., relatively prosocial people with few risk factors), while a high-risk offender has a much greater probability of future engagement in crime (i.e., more antisocial with several risk factors). While many in the criminal justice system are interested in the likelihood of reoffending, there are also assessments used in corrections that assist in determining if an offender is suicidal or likely to commit a violent act, be a victim of violence, engage in future sex offenses, engage in misconducts while incarcerated, etc. The purpose of the assessment dictates the outcome it measures. For example, a pretrial tool is likely to predict failure to appear in court and short-term behavior, while an institutional classification system will provide staff with a prediction of institutional misconducts. The focus in this entry is on the use of risk assessments to predict future criminality among offenders.

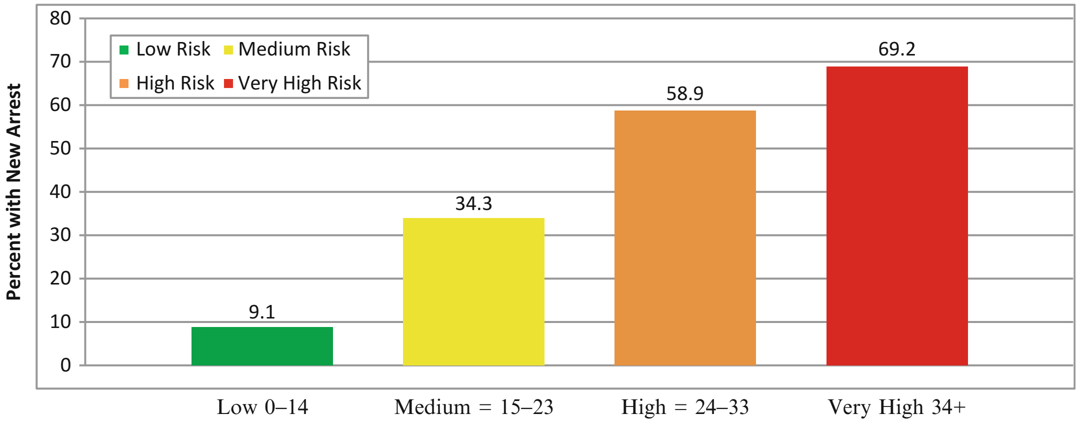
History of Risk Assessment

From the early beginning of community corrections, there has been an attempt to predict who will reoffend. Even prior to the use of actuarial tools, corrections professionals have tried to determine the likelihood that offenders would engage in future criminal behavior (Monahan 1977). Without the assistance of empirically based assessments, correctional workers have been forced to use a wide array of clinical assessments to draw on their professional experiences to make prognoses regarding offenders' likelihood of reoffending. The problem is that professional judgment alone is not very accurate. Dawes et al. (1989) found that clinical judgment was not accurate compared to statistical prediction for a range of outcomes. Ultimately, they concluded that humans take into account factors that are not predictive, weigh characteristics that are less predictive, and even when given additional training, do not outperform statistical models. Without a structured assessment process using validated and objective measures, corrections will be limited in what it can do to reduce recidivism (Latessa 2004). Adopting a risk assessment can help the criminal justice system identify the offenders who are at highest risk for recidivating, assist in enhancing public safety by ensuring that those higher-risk offenders receive appropriate supervision and interventions, help reduce bias in making decisions, and improve placement and utilization or resources.

Clinical Judgment, Structured Professional Judgment, and Actuarial Assessments

Three primary ways to assess offenders are clinical judgment, structured professional judgment, and actuarial (also called statistical) methods. As discussed in the previous section, clinical judgment is the process in which a staff person collects information and makes a decision about risk based on "gut feelings" or intuition. Clinical judgment relies on the skills, knowledge, and ability of individual staff to gather appropriate information and then to make a decision based on the totality of the information. In contrast, structured professional judgment combines clinical judgment and theoretically relevant measures into a single assessment – putting limits on the evaluators' biases while still tapping into their professional knowledge (Borum and Douglas 2003). Tools based on structured professional judgment are designed to help staff determine what they can do to disrupt future recidivism, not necessarily predict who will reoffend. The tools based on structured professional judgment are not scored per se; there are no cutoffs produced or a final composite risk score; instead specific areas in which the evaluator will rate the offender based on low-, moderate-, and high-risk levels are provided. These tools consider static and dynamic factors, protective factors, and contextual factors to assist correctional professionals to guide decisions regarding risk management (Vincent et al. 2009). One example is the Structured Assessment of Violence Risk in Youth (SAVRY), which is based on structured professional judgment along with standardized risk factors. With this tool an evaluator assesses a youth on 24 items and determines if the youth presents as low, moderate, or high risk for each indicator. Upon identifying the level of risk for each item, the assessor will make a final determination of the youth's overall level of risk. The SAVRY has demonstrated intraclass correlation coefficients of 0.81 and produced correlations with recidivism that range from 0.25 to 0.70.

A third method in conducting risk assessment is the actuarial method. Actuarial risk assessment is similar to what insurance companies use to calculate insurance rates. Actuarial instruments are based on statistical analysis of records and other information that result in the development of probability tables: if you score X you have an X chance of reoffending. The foundation of statistical risk assessments in corrections is similar to that in most actuarial sciences. For example, life insurance is cheaper for a nonsmoker in his 40s than a smoker of the same age. The reason insurance costs more for the smoker is that smokers have a risk factor that is significantly correlated with health problems – which runs a greater risk that the insurance company will have to pay out a claim before



Risk Assessment, Classification, and Prediction, Fig. 1 Risk level by recidivism for community supervision sample

they recoup their money. Similarly, an offender who uses drugs and is unemployed has a higher chance of reoffending than someone who does not use drugs and has steady employment. Figure 1 shows how a distribution of offenders might be classified according to risk. Note that the probability of someone in the low-risk category reoffending is less than 10 %, moderate risk is 34 %, high risk is nearly 60 %, and very high risk is about 70 %.

Types of Assessment Tools

In addition to the methods by which assessments are designed, there are three unique types of risk assessments. Screening instruments are designed to assess a large population (usually at intake) to predict a specific outcome by sorting offenders into risk categories quickly. Screening tools are usually comprised of static items (e.g., criminal history) and can be completed by either a file review or a brief interview. They are typically used to separate low-risk from moderate- and high-risk offenders but have little utility beyond identifying levels of risk due to a limited number of dynamic items.

Beyond screening tools, comprehensive risk/need assessments are designed to gather more complete data to assist in determining levels of risk. They typically are longer to administer, require training, and can be used to identify targets for treatment. These instruments include a range of dynamic factors that can be used to reassess the offender. Furthermore, composite risk assessments can be used to develop case plans to ensure that programming targets criminogenic needs of the offender (Latessa and Lowenkamp 2005a).

Once a comprehensive risk assessment is completed, specialized assessments can be used to assess specific domains (like substance abuse) or special populations (i.e., sex offenders, mentally ill offenders, psychopaths). Specialized assessments can be completed on offenders who are flagged as risky on composite risk/needs tools. These instruments usually require additional training, while some tools require special licensures to conduct.

In many instances jurisdictions adopt all three types of assessments. A screening instrument might be used at pretrial or to assess offenders at intake to determine who needs further assessment. For those offenders who continue deeper into the system, a more comprehensive assessment tool would be used. Once assessed on a composite risk tool, specialized assessment should be prescribed on an as-needed basis. Following this approach can increase efficiency, since not all offenders will be thoroughly assessed, but those offenders who appear to pose the greatest risk to reoffend will be examined much more closely (Flores Russell Latessa and Travis 2005).

Risk, Need, and Responsivity

As agencies become more familiar with risk assessments and incorporate risk assessments across multiple decision points, it is important to understand how the results can be used to guide decisions in the field of corrections. The risk, need, and responsivity principles provide the context in which the results can be used to best serve the corrections population.

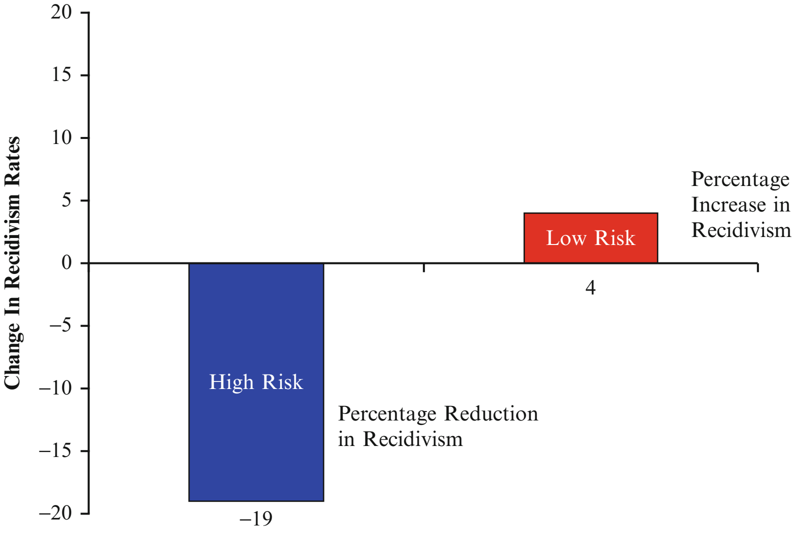
Risk Principle

The risk principle offers guidelines to correctional workers on which offenders are best served and under what conditions. Andrews Bonta and Hoge (1990) suggest that corrections should target those offenders with a higher probability of recidivism, provide the most intensive treatment to higher-risk offenders, and refrain from disrupting the lives of low-risk offenders. Although often ignored, correctional interventions that adhere to the risk principle demonstrate significantly greater reductions in recidivism (Latessa Brusman and Smith 2010). Consider a program that serves 100 low-risk offenders. Without intervention, approximately ten of the 100 offenders will reoffend. For the program to be effective, it would have to reduce recidivism for a portion of the ten offenders while not increasing recidivism for the other 90. In contrast, a program that serves 100 high-risk offenders would expect a recidivism rate of 60 %. For the program to be effective, it would have to reduce recidivism for a portion of the 60 offenders – resulting in a greater chance of reducing recidivism while reducing the chance of disrupting those that would not reoffend. The more troubling aspect to the risk principle is the fact that providing intensive interventions for low-risk offenders can actually increase failure rates (Lowenkamp and Latessa 2004). This effect is illustrated in Fig. 2, which shows the average changes in recidivism rates when we target high- and low-risk offenders.

While it makes sense that programs can have an impact on higher-risk offenders, it is not as evident why programs would increase recidivism for low-risk offenders. First, when low-risk offenders are placed in more intensive settings, they are more likely to be exposed to higher-risk offenders – increasing the likelihood of an iatrogenic effect. Considering the number of settings where lower-risk offenders are potentially mixed with higher risk – community service, treatment programs, jail, and prison – it is not surprising that lower-risk offenders are often more risky upon completion. Second, for low-risk offenders, residential programs, jails, and prisons actually disrupt what makes them low risk, causing the likelihood of recidivism to increase. For example, if you placed your low-risk child in a residential program for six months due to a substance abuse problem that child would miss out on education programming, he or she would experience family disruption, the youth's prosocial attitudes and friends would be replaced with antisocial thoughts and antisocial peers, and his or her friends' parents would likely not be interested in exposing their child to yours once released. In other words, risk would be increased, not reduced due to placement of the youth. Third, low-risk offenders are often victimized, taken advantage of, and pressured into engaging in antisocial behavior by more sophisticated offenders (Lowenkamp Latessa and Holsinger, 2006).

Grounded in the risk principle, the system should identify lower-risk offenders and provide alternative services to them without disrupting what makes them low risk. As a general rule, low-risk offenders should be excluded from intensive correctional programs. In order for the criminal justice system to adhere to the risk principle, offenders must be assessed and decisions must be made regarding the appropriate placement of lower risk offenders. If ignored, the results can be alarming. This was seen in a 2010 study conducted in Ohio that examined the effect of placing offenders in a halfway house versus regular supervision (Latessa Brusman and Smith 2010). Placing a low-risk offender in a halfway house led to an average 3 % increase in failure rates, while placing a high-risk offender in the same program resulted in an average 14 % reduction in recidivism.

Risk Assessment, Classification, and Prediction, Fig. 2 The risk principle & correctional intervention results from meta analysis (Source: Andrews and Dowden (2007))



Need Principle

The need principle suggests that there are specific targets that should be addressed if the system is expecting to reduce recidivism. Research by Andrews, Bonta, Gendreau and others have identified seven dynamic areas associated with criminal conduct:

1. Antisocial/procriminal attitudes, values, and beliefs
2. Criminal peers and the lack of prosocial others
3. Antisocial temperament
4. Family
5. Education, employment, and finances
6. Limited prosocial leisure activities
7. Substance abuse

While the risk principle suggests that higher-risk offenders should be targeted for more intensive services, the need principle points to which needs should be addressed. Although most third and fourth generation risk assessments include both static and dynamic factors, the need principle is more concerned with those that can change (dynamic). Dynamic items include factors like who an offender chooses to hang around with, his or her attitudes and values towards crime, a lack of problem solving skills, substance use, and employment status. All these factors are derived from several decades of research and are correlated with recidivism. These dynamic factors are also called *criminogenic needs*: crime-producing factors that are strongly correlated with the risk of reoffending. Combining static and dynamic factors together gives the best picture of overall risk of recidivism and the most effective way to target criminogenic needs (Latessa and Lowenkamp 2005b). For example, people who are at risk for a heart attack usually have some common characteristics: over 50 years old, male, a family history of heart problems, high blood pressure, excessive weight, smoking, stress, and high cholesterol. While some of these are historical or static factors, others are dynamic. The benefit of assessing the dynamic factors is that if addressed, the high-risk patient can actually decrease his or her risk of having a heart attack. Similarly, dynamic items on a criminogenic risk assessment can provide malleable targets for risk to reoffend.

The need principle provides a roadmap to programs to ensure that appropriate criminogenic needs are targeted. Programs would benefit from targeting crime-producing needs, such as antisocial attitudes, antisocial peer associations, substance abuse, lack of problem solving and self-control skills, and other factors that are highly correlated with criminal conduct (Dowden and Andrews 1999). Identifying criminogenic needs is an important part of offender risk assessment; since it tells us “what” to focus on to reduce risk.

Responsivity Principle

The responsivity principle suggests that we should match the style and mode of service delivery based on key offender characteristics, such as culture, gender, mental health, or learning ability. This may not decrease risk, but will increase the likelihood of success in correctional interventions. One of the limitations of corrections is its ability to deliver services based on individual needs of the offender. The criminal justice system's reliance on group interventions has made it very difficult to ensure that interventions are individualized. For example, offenders who have cognitive delays may not respond well to group treatment focused on insight-oriented processes. There are often personal characteristics of an individual that should be assessed, since these factors can effect their engagement in treatment. These would include areas like mental and emotional problems, cognitive functioning, and level of motivation or readiness to change. Assessment of these areas can often improve the placement of offenders, assist with case planning, and impact the overall effectiveness of correctional treatment.

Controversies in Risk Assessment

Although the criminal justice field has moved beyond "gut feelings" as its primary form of assessment, there still remain several questions regarding the implementation of risk assessments. The first question relates to the applicability of risk assessments at the time of sentencing. From 1975 to 2002 incarceration rates increased by more than 300 % (Stemen et al. 2005). As the "get tough" movement took hold, many jurisdictions moved to determinate sentencing, stricter sentencing guidelines, and abolition of post-release supervision – resulting in massive numbers of offenders committed to state institutions. As a result, many have been calling for the implementation of risk reduction efforts at sentencing (Pew Center 2009). In fact, the Pew Center has identified the adoption of a risk assessment at sentencing as one of their top ten recommendations to control escalating prison populations. Of course, adopting a risk assessment at sentencing is not supported by all. Singer (1979) suggests that prison is not intended to address recidivism; the point of prison is to mete out a punishment commensurate with the harm to the victim. Others suggest that risk assessment should be used to develop appropriate targets for change post-sentence. In 2010, the Indiana Supreme Court upheld a decision by a trial judge to use the results of a risk assessment to inform the overall manner in which a sentence was to be served (Malenchik v State 2010).

A second question that has been raised regarding risk assessment is whether a single composite score comprised of risk and need factors should be used or should risk and needs be separated into two unique tools. Baird (2009) argues that risk assessment should be split into separate risk and needs assessments, suggesting that the risk index should be reserved for a fewer set of items that have moderate to high correlation. Limiting risk assessments to fewer, more highly correlated items will allow for greater parsimony, increase prediction, and ensure that staff can score the items accurately. The need assessment should be separately scored and based more on clinical judgment or instruments designed to determine why people commit crime – suggesting that composite risk tools cannot accurately measure individual level needs. In contrast, Bonta (2002) recommends that risk assessment should include items that are theoretically relevant, have multiple measures or items per domain, incorporate a combination of static and dynamic factors, and employ a multi-method approach to understanding risk. Risk assessments designed using Bonta's approach will typically hold more items, will measure risk using theoretically derived measures, and will focus more on the utility of the tool than parsimony.

The third question is whether third and fourth generation tools can meet acceptable levels of inter-rater reliability – that is, can different assessors come to the same decision based on the same information. Austin et al. (2003) suggests that measures of inter-rater reliability should reach a minimum of 0.70 for a risk assessment to be deemed reliable. The argument regarding third and fourth generation tools is that they typically include a significant number of dynamic items – which, in turn, are difficult to accurately rate. While Austin et al. (2003) and Baird (2009) point to third and fourth generation tools lacking reliability, there are many studies that have demonstrated that these tools can achieve acceptable levels of reliability with training. In fact, Austin found significant increases in reliability for the LSI-R when staff was provided with training on the instrument.

The fourth area in which there are questions regarding the use of fourth generation tools is in regard to using the results to develop individualized case plans. Can fourth generation risk assessments be used to identify treatment targets for individual offenders? The answer is mixed. Fourth generation tools typically identify levels of need by domain. For example, the Ohio Risk Assessment System-Community Supervision Tool (ORAS-CST) provides low, moderate, and high levels of need by each of the seven domains. These cutoffs assist staff in readily identifying areas that are riskier for offenders and help to form appropriate treatment targets. These domains are used to "flag" areas of need. Once an offender is identified as having moderate to high need in an area, the worker will want to explore each domain in greater detail to determine the individualized needs of the offender. For example, offenders that present a high risk of substance abuse may have different reasons for being high-risk substance abusers. For example, one offender may be physiologically or psychologically addicted to drugs. A second person may use drugs not because she or he is addicted, but because the offender spends significant amounts of time with peers that use drugs. A third person might use drugs to mask an underlying mental illness. All three offenders are high risk in regard to substance use, but present with uniquely different targets for treatment. Traditional drug treatment may work for the offender who is addicted, but that type of intervention may not be very effective for an offender who uses due to peer networks. In fact, sending an offender to a substance abuse group or AA/NA may not be appropriate given the treatment target is really antisocial peers. For the third group, if the underlying issue is mental health, helping an offender reduce substance use will have no impact on the symptoms of mental illness – again resulting in an intervention that has little impact on the presenting problem. To address the fact that any one need domain has a number of potential treatment targets, an offender who has a moderate to high level of need in a domain-specific area should receive additional need specific assessments to determine the individual level treatment targets.

The fifth question is in regard to the ability of risk assessments to measure change over time. Several studies have been conducted to examine the impact of a change in composite risk score on the LSI-R. Andrews et al. (2006) argues that offenders can change and that risk assessments should reflect the ability to measure these changes. Andrews and Robinson (1984) have found support for the ability of the LSI-R to predict change over time. In contrast, Baird argues that the use of third and fourth generation tools have significant limitations in measuring change over time. Moreover, he suggests that risk tools should be modified between intake and reassessment – shifting emphasis from prior history items to current behaviors.

These instruments use dynamic risk factors to measure initial risk and then reassess on these items to determine if the offender has made any significant changes in the risk he/she poses to society. In addition to targets of change, the fourth generation tools allow departments to focus their resources on those domains (broad area of need) that are moderate to high risk. Ultimately, if the criminal justice system can significantly reduce the recidivism rates for offenders, this will result in increased public safety. The fourth generation tools provide agents of change with a specific "road map" to address the needs of the offenders, manage limited resources, and protect public safety.

Obstacles to Good Practice

Here are some of the more common obstacles that exist with regard to offender assessment:

1. Offenders are assessed, but the process ignores important factors. Sometimes this is

because the tool selected is comprised mainly of static predictors, or the assessment process focuses on one or two domains (like substance abuse) to the exclusion of other important risk factors.

2. Offenders are assessed, but the process does not distinguish quantifiably determined levels (i.e., high, moderate, low). This is common with narrative assessments, and the result is often that the summaries all read the same: "offender is at risk to reoffend unless they get substance abuse treatment." This type of information tell us little about the actual risk the offender poses to reoffend or the level of need in specific areas. This is common with clinical assessment processes.
3. Even when offenders are comprehensively assessed, the results are not used – everyone gets the same treatment. As we will discuss below, adopting a risk assessment tool is only one step in the process. If the information is not going to be used then why assess?
4. Staff members often are not adequately trained in the use of the instruments, or they are only trained when the new instrument is selected. Usually, when a decision to use a new instrument is made, everyone is trained, but as time goes on and new employees are hired, little refresher training may be done, and the new staff simply learn how to use the tools by watching the older staff. The result is that reliability and validity suffer, and stakeholders lose confidence in the results of the assessment.
5. Staff resistance is one of the most persistent obstacles to overcome. Some of the common refrains that are heard by a staff include "I just need to talk to them for 5 minutes to determine their level of risk," "we don't have time to conduct an assessment," "they are all high risk," and "they all get the same treatment anyway so why assess them?" While staff resistance can be a challenge, it is not insurmountable, and as Jones Johnson Latessa and Travis (1999) found, most community correctional agencies understand the importance and value of using a valid and reliable risk assessment tool.

To avoid these and other mistakes and to derive the full value from assessments, there are some points to consider (Latessa and Lowenkamp 2005b; Latessa (2004)):

- There is no "one size fits all" assessment tool. Some domains or types of offenders will require specialized assessments, such as sex offenders or mentally disturbed individuals. In addition, the use or purpose will vary. For example, the assessment tool for making a decision about whether to grant pretrial release may be different from one for making a decision about whether to grant probation.
- Actuarial assessment is more accurate than clinical assessment, but remember, no process is perfect and there will always be false positives and false negatives – sometimes low-risk offenders reoffend, and sometimes high-risk offenders are successful.
- Assessment is usually not a "one-time" event, especially if the offender is under some form of community control. Offender risk and need factors change, so it is important to consider assessment as an ongoing process.
- Assessments help guide decisions, but they do not make them – professional discretion is part of good assessment-aided decision-making.
- While the new dynamic assessment tools can produce more useful information, they require more effort to insure reliability – they require staff training and continual monitoring of the assessment process. Fidelity and quality assurance make a difference.
- Good risk assessment serves a number of functions and helps guide decisions by providing reliable information in a systematic and objective manner. It can be the cornerstone of a more effective, efficient, and just system.
- A flexible process should be developed that expands as needed – higher-risk offenders need more assessment.
- Processes and instruments should be standardized so that everyone is speaking the same language with regard to risk assessment.
- Regardless of the assessment tool used, staff should be thoroughly trained on the rationale and use of a risk assessment tool. Proper training will ensure that the staff understand

the advantages of risk assessment and that they use the tool in an appropriate and consistent manner. The level and amount of staff "buy in" can drastically affect the level of success in implementing a risk assessment process or tool (Lowenkamp Holsinger Latessa 2004).

- Following training, agency administrators should establish quality assurance processes such as periodic audits of assessments, refresher training, or even certification of assessors.
- Assessment results should be used to develop case supervision and treatment plans and to assign offenders to programs.
- Information should be shared with service providers so that they understand the risk of the offender they are involved with as well as the criminogenic factors that need to be targeted.
- An assessment tool should be validated on the population for which it is being used. There are several widely used actuarial instruments that have been validated in numerous settings and across several subgroups (i.e., males, females, different racial, and ethnic groups). Nonetheless, agencies should still analyze assessment results based on the population for which the tool is being used.

Juvenile sex offenders

Overview

According to the FBI's Uniform Crime Report, 16 % of arrests for rape and 19 % of arrests for other sexual offenses are committed by youth under the age of 18 (United States Department of Justice 2001). Moreover, many adult sex offenders admit committing their first sexual offense before the age of 18. Indeed, Knight and Prentky (1993) found that half of the 1,025 adult sex offenders in their sample began sexually offending as adolescents. Because many sexual offenses are not reported, the prevalence of adolescent sexual offending is higher than official statistics indicate. Given these facts, it is not surprising that adolescent sexual offenders (ASOs) have become a major societal concern.

An etiological understanding of adolescent sexual offending is needed to refine assessment and intervention strategies. One area of research that would be particularly helpful is identifying if adolescent sexual offending can be explained by a generalist model of criminal behavior or if ASOs should be considered specialist offenders, with special factors that explain the onset and/or maintenance of their crimes. If ASOs are generalists, then existing risk and need assessment measures and interventions would likely be useful with this population. However, if ASOs are specialists, with distinct etiological factors, then different risk/need measures and interventions may be required.

ASOs have commonly been considered a distinct subtype of adolescent offender, with different developmental trajectories and criminogenic needs. Indeed, the National Adolescent Perpetrator Network, an organization of professionals involved with ASOs, concluded in an influential task force report that "…sexually abusive youth require a specialized response from the justice system which is different from other delinquent populations" (1993, p. 86). However, some empirical literature does suggest that the crimes committed by ASOs are a manifestation of general delinquency risk factors, including antisocial personality traits such as impulsivity and callousness, antisocial attitudes and beliefs, delinquent peers, early conduct problems, and substance abuse. Indeed, on average about half of ASOs would qualify for a diagnosis of conduct disorder, which by definition requires involvement in a range of antisocial behaviors (e.g., Elliott 1994).

The purpose of this entry is to summarize the theoretical literature concerning the models of adolescent sexual offending and the evidence for and against the generalist and specialist perspectives. The results of a recent meta-analysis conducted by Seto and Lalumière (2010), examining 59 studies comparing adolescent sex and nonsex offenders, will be discussed in detail to highlight where there are similarities and differences between ASOs and other adolescent offenders and to provide insight into the generalist versus specialist debate.

Key Issues/Controversies

The General Delinquency Explanation. The general delinquency explanation suggests that ASOs share etiological factors with other adolescent offenders. In a series of studies conducted by Lewis et al. (1981), the authors compared 17 ASOs and 61 other violent adolescent offenders on psychiatric, neurological, and psychoeducational variables. The authors concluded that the similarities between violent adolescent offenders and ASOs indicate these groups have similar therapeutic needs. While ASOs do warrant some specialized treatment options, general antisocial and violent tendencies must be addressed in treatment as well. Awad et al. (1984) found that the similarities between ASOs and other adolescent offenders outweighed the differences. These similarities included psychiatric history, inadequate parenting, past delinquency, violence, school misconduct, and parent-child attachment.

Recidivism studies are also consistent with a generalist model of adolescent sexual offending. Relatively few adolescent offenders commit only sexual crimes; most commit nonsexual offenses as well, though the extent of involvement in nonsexual offending varies greatly. In a meta-analysis conducted by Caldwell (2002), ASOs were six times more likely to be rearrested for nonsexual offenses than sexual offenses, and only a small proportion (10–15 %) of ASOs go on to commit sexual offenses as adults. Next, the majority of the factors that have been shown to predict recidivism among delinquents in general (criminal history, early behavior problems, antisocial personality traits, attitudes, etc.) also predict sexual recidivism in ASOs (Hanson and Morton-Bourgon 2005). Lastly, sexual offenses committed by adolescents tend to occur in an escalating pattern, starting with minor nonsexual offenses such as theft to more serious nonsexual crimes such as assaults, and eventually leading to serious sexual crimes (Elliott 1994).

Based on these findings, it is plausible to suggest that ASOs would display similar scores to that of other adolescent offenders on general delinquency risk factors. Findings of this nature would suggest that ASOs are not a distinct subtype of adolescent offender. If this were the case, current assessment tools, treatment options, and theories that are applied to adolescent offenders could be used in the study and treatment of ASOs without diminishing the reliability and validity of such options.

Specialist Explanations. Specialist explanations of ASOs suggest that these offenders have different etiological factors than other adolescent offenders. If this perspective is correct, then assessment and treatment methods developed for adolescent offenders in general will be less effective with ASOs, as they only address any common factors the two populations share. Theories describing the etiology of ASOs have focused on factors such as poor childhood attachment, heterosocial incompetence, atypical sexual experiences, psychopathology, cognitive abilities, atypical sexual interests, and sexual abuse history. Each of these factors will be briefly described below.

Poor Childhood Attachment. The ability to form mutually rewarding relationships is thought to stem from the parent-child relationship. Studies conducted with adult sex offenders have found that they are more likely than other offenders to have insecure childhood attachments that develop into insecure adult attachment styles (for a review see Marshall and Barbaree 1990). Awad et al. (1984) found that the vast majority of ASOs in their sample had been separated from their parents for an extended period of time and just over half of the youth showed serious problems in their family system, including parental abuse and neglect, witnessing violence within the home, and parental rejection. Marshall and Barbaree (1990) suggested that insecure childhood attachments increase the likelihood of sexual offending in adolescents by hindering the development of healthy emotional regulation, empathy, and social skills. Indeed, ASOs seem to be characterized by a pattern of poor social relationships. Fagan and Wexler (1988) found that ASOs were significantly more socially isolated than other violent adolescent offenders. If poor childhood attachment is a risk factor specific to ASOs, it is expected that ASOs would differ from other adolescent offenders by having more childhood attachment problems, especially insecure attachment.

Psychopathology. Studies have often found high levels of anxiety, depression, and personality problems in both adolescent and adult sex offenders. Among 22 ASOs, Galli et al. (1999) found that 82 % had a diagnosable mood disorder such as depression, 55 % had an anxiety disorder, 50 % had a substance abuse disorder, 55 % had an impulse control disorder, and 71 % had attention-deficit/hyperactivity disorder. Indeed, many participants in this small clinical study had substantial psychiatric comorbidity. The authors also reported that some participants in their study stated that their sexual impulses and sexually aggressive behavior increased when they were experiencing mood symptoms.

There are theories that postulate that sexual offending is associated with affect regulation and personality problems. For example, Hall and Hirschman's (1991) quadripartite model suggests there are four subtypes of sexual aggressors, each differing in the primacy of physiological, cognitive, affective, and personality problems. The third subtype emphasizes episodic affective dyscontrol, suggesting that ASOs are more likely to engage in sexually aggressive behavior when they are angry or sad. The fourth subtype is characterized by developmental personality problems such as neuroticism. If increased psychopathology is an etiological factor specific to ASOs, these offenders should score higher on measures of psychological problems compared to other adolescent offenders.

Cognitive Abilities. Theories that focus on cognitive deficits in ASOs suggest that offenders who have lower intellectual functioning have poorer impulse control and thus are more likely to sexually offend opportunistically against children. At the same time, youth who are of lower intellectual or cognitive functioning may be more likely to be sexually rejected by similar-aged peers and thus feel the need to turn to children or engage in sexually coercive behavior to satisfy their emotional and sexual needs. In a meta-analysis conducted by Cantor et al. (2005), the authors found that adult sex offenders scored significantly lower on measures of intelligence compared to adult nonsex offenders. However, though ASOs tended to have a lower mean intelligence score than other adolescent nonsex offenders, these results were not statistically significant. A limitation of this meta-analysis is that the authors included all available samples of sex offenders with all available samples of nonsex offenders. The samples were not matched on possible confounding variables such as how they were selected for study. Therefore, these groups may have differed in a way that influenced their intelligence scores and explains why this study did not confirm previous findings of lower intelligence in ASOs. In a direct comparison of groups recruited in the same settings using the same procedures, one would expect that ASOs would score significantly lower on measures of intellectual and cognitive functioning than other adolescent offenders.

Heterosocial Incompetence. Heterosocial incompetence refers to the lack of social skills necessary to function in a heterosexual relationship, given that most ASOs are male and sexually prefer females. Explanations that focus on this factor suggest that ASOs seek relations with younger children or use sexual coercion against peers or adults because they do not have the necessary social skills to maintain an age-appropriate relationship that satisfies their emotional and sexual needs (e.g., Marshall and Barbaree 1990). Adolescent child molesters have been found to score significantly lower than other adolescent offenders in regard to heterosocial competence (Katz 1990). Lastly, in a meta-analysis conducted by Hanson and Morton-Bourgon (2005), intimacy deficits (composed of poor social skills, negative social influences, conflicts in intimate relationships, emotional identification with children, and/or loneliness) were a significant predictor of sexual recidivism in adult and ASOs. If heterosocial incompetence is a correct explanation, one would expect that ASOs would score lower on measures of heterosocial competence compared to other adolescent offenders.

Psychosexual Development. Researchers have speculated that ASOs differ from other adolescent offenders in their psychosexual development (Marshall and Barbaree 1990). One common finding is that ASOs experience earlier and more frequent exposure to sex as children. Some studies suggest adult sex offenders are characterized by more frequent use of pornography in childhood compared to nonsex offenders, but in a meta-analysis of the adult literature, Allen et al. (2000) compared criminal sex offenders with the general population and found that the two groups did not differ in their frequency of pornography use as well as age at first exposure to pornography. However, the authors did find that criminal sex offenders were more likely than the general population to perform consensual and/or nonconsensual sexual acts following pornography viewing. If this explanation were correct, it is expected that ASOs would score higher than other adolescent offenders on measures of atypical sexual experiences such as sexually inappropriate family environments and early exposure to pornography or sex.

Atypical Sexual Interests. Atypical sexual interests usually refer to relatively strong sexual arousal to depictions of children or sexual coercion, compared to consenting sex with same-aged peers. Research has confirmed that adult sex offenders show levels of increased sexual arousal to these atypical stimuli compared to either nonsex offenders or non-offenders (see Seto 2008). Additionally, measures of these atypical sexual interests have been shown to be significant predictors of sexual recidivism in adult and ASOs (Hanson and Morton-Bourgon 2005).

Seto et al. (2000) found that as a whole, their group of 40 adolescent child molesters displayed more sexual arousal to depictions of children and coercive sex compared to young adult nonsex offenders. The difference was driven by those who had offended against boys; those who had offended against girls did not differ from the comparison group. Seto et al. (2003) found that phallometrically assessed sexual arousal to children was correlated with sexual victim history in an expected fashion, such that adolescents who had offended against boys, multiple child victims, younger child victims, or unrelated victims were more likely to show a preference for children than those who offended against only girls, a single child victim, older child victims, or related victims. Given all of these results, it is expected that ASOs will show significantly more arousal to children or coercive sex when compared to nonsex adolescent offenders.

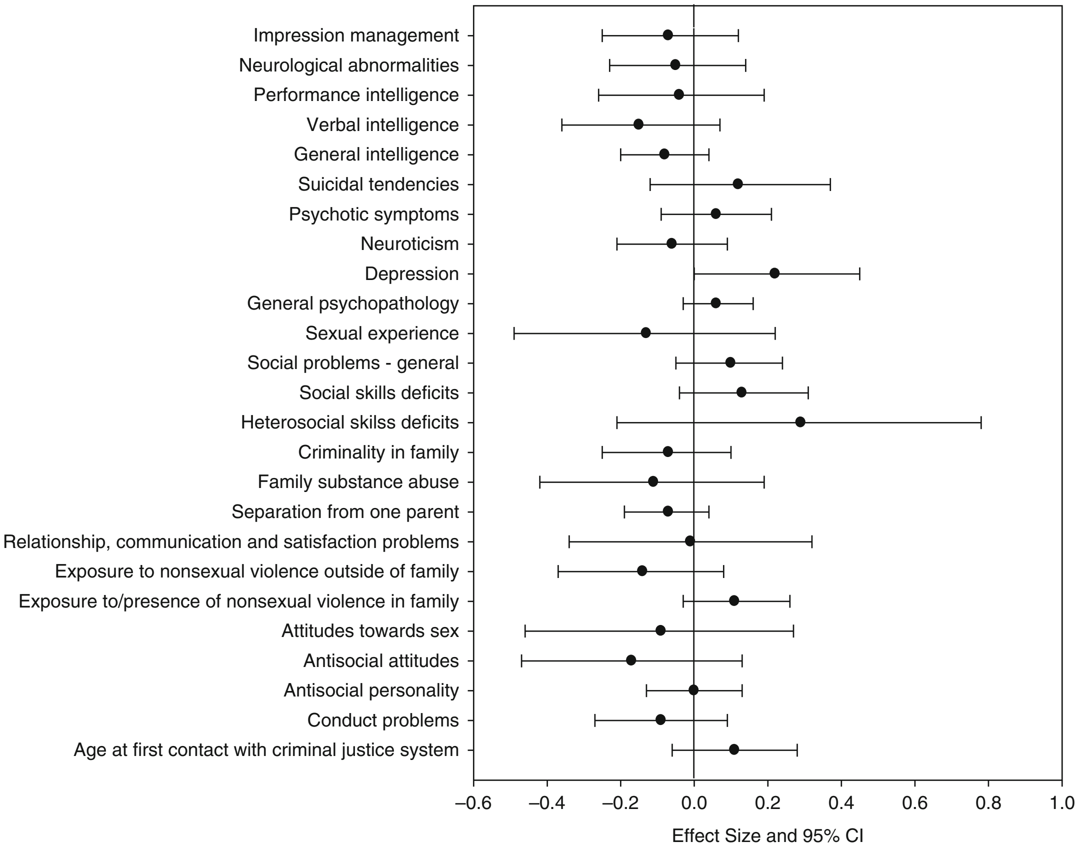
Sexual Abuse. The most common etiological explanation of sexual offending in adults or adolescents is sexual abuse history. These theorists suggest that children and adolescents who are sexually abused are more likely to commit sexual offenses later on in life (Marshall and Barbaree 1990). In a meta-analysis conducted by Jespersen et al. (2009) comparing 1,037 adult sex offenders and 1,762 adult nonsex offenders, there was a significantly higher prevalence of sexual abuse history in adult sex offenders compared to other nonsex offenders. In fact, adult sex offenders had 3.36 times greater odds of having a sexual abuse history than their nonsex offender counterparts.

For ASOs, Johnson (1988) found that the earlier the sexually abusive behavior in ASOs begins, the more likely the youth is to have been sexually abused themselves. In the authors' sample, 72 % of the youth who began committing sexually abusive behavior before the age of 6 had been sexually abused themselves, whereas 42 % of the youth who began committing sexual abusive behavior between the ages of 7 and 11 had this history. In another study, Worling (1995) found that of the 1,268 ASOs included in his sample, 30 % had a history of sexual abuse. These explanations would suggest that ASOs should have a higher prevalence of sexual abuse history compared to other adolescent offenders. Because the explanation posits a specific link between sexual abuse history and sexual offending, any difference for sexual abuse should be greater than for physical abuse or other forms of maltreatment.

Meta-analysis. A meta-analysis is a statistical procedure that integrates the results of independent studies to produce a more reliable estimate of the actual size of the effect for the variable in question. A systematic review first identifies all relevant studies in an effort to minimize publication and other related biases. After the systematic review, the meta-analysis can be conducted to calculate a weighted statistic to give a more reliable calculation of effect size. Additionally, meta-analysis allows for the examination of moderators. Moderators are variables that affect the strength of the relationship between a predictor variable and an independent variable. Lastly, meta-analysis techniques allow for the development of more homogenous groups, which subsequently allows for the ability to compare subsets of samples found in different studies.

Seto and Lalumière (2010) examined 59 direct comparison studies, with a total sample of 3,855 male ASOs and 13,393 male adolescent nonsex offenders, on theoretically derived variables. These included offender age, criminal involvement, conduct problems, antisocial tendencies, substance abuse, childhood abuse and exposure to violence, interpersonal problems, family problems, cognitive abilities, sexuality, psychopathology, and impression management. Figures 1 and 2 summarize the results of this meta-analysis, which provided an empirical test of the generalist and specialist explanations previously discussed.

The factors suggestive of a generalist model (Fig. 1) include variables that have been identified as risk factors for general delinquency, including antisocial personality, behavior and attitudes, as well as family characteristics including family criminality, violence, and substance use. The factors suggestive of a specialist model (Fig. 2) include variables theoretically identified as special to adolescent sexual offending, including sexual abuse history, atypical sexual interests, heterosocial incompetence (poor social

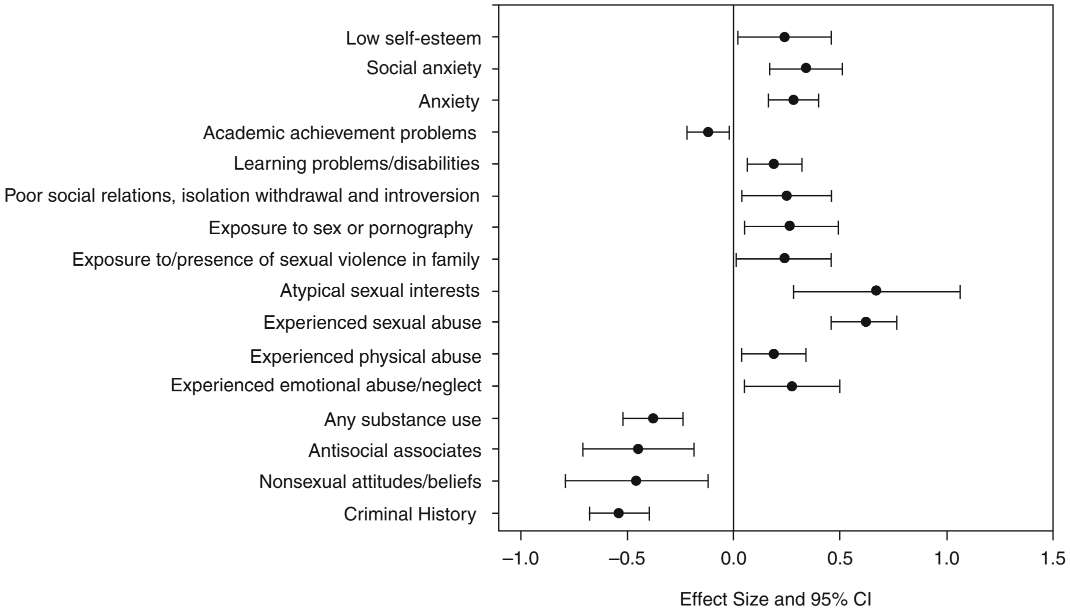


Risk Factors for Adolescent Sexual Offending, Fig. 1 Factors suggestive of a generalist model

relations), atypical sexual experiences (exposure to sex or pornography), psychopathology (anxiety and low self esteem), as well as cognitive deficits (learning problems/disabilities). The largest specialist-anticipated differences between ASOs and other adolescent offenders were found for atypical sexual interests and then sexual abuse history.

There are two main conclusions that can be drawn from the Seto and Lalumière (2010) meta-analysis. The first would be that, on average, ASOs share many of the same risk factors as other adolescent offenders, including antisocial attitudes and personality traits, which helps explain why ASOs are involved in criminal behavior. But in order to explain why a particular adolescent commits a sexual crime rather than a nonsexual crime, factors associated with psychosexual development, including sexual abuse history, exposure to sex or pornography, and atypical sexual interests, also need to be considered. The second conclusion that can be drawn from the meta-analytic results is that neither the generalist explanation nor the specialist explanations can fully explain adolescent sexual offending.

Offender Typologies. The results of Seto and Lalumière's (2010) meta-analysis need to be considered in conjunction with other research. ASOs are heterogeneous, and it is expected that there are different types of ASOs. The generalist and specialist explanations are not mutually exclusive. Both could be true: Some ASOs could be generalists, with similar risk factors and treatment needs as other adolescent offenders, whereas other ASOs could be specialists, with special factors that require other assessment or treatment methods.



Risk Factors for Adolescent Sexual Offending, Fig. 2 Factors suggestive of a specialist model

Additional support for the specialist/generalist distinction comes from studies examining the performance of actuarial risk assessment measures. The Juvenile Sex Offender Assessment Protocol II (JSOAP-II) is a 28-item scale of theoretically derived static and dynamic risk factors for ASOs (Prentky and Righthand 2003). The items are organized into four subscales: Sexual Drive/Preoccupation, Impulsive/Antisocial Behavior, Intervention, and Community Stability/Adjustment. Rajlic and Gretton (2010) confirmed the predictive validity of the JSOAP-II using a sample of 286 male ASOs. The authors found that as a whole, the scale significantly predicted sexual as well as nonsexual recidivism. Specifically, the Sexual Drive/Preoccupation subscale predicted sexual but not nonsexual recidivism, while the Impulsive/Antisocial Behavior subscale predicted nonsexual but not sexual recidivism. The Intervention subscale and the Community Stability/Adjustment subscales predicted both sexual and nonsexual recidivism. These findings are important because it suggests that ASOs who have more risk factors in the Impulsive/Antisocial Behavior subscale (who are more likely to be generalist offenders) are more likely to reoffend nonsexually, while offenders who have higher scores in the Sexual Drive/Preoccupation subscale (who are more likely to be specialist offenders) are more likely to reoffend sexually.

The generalist/specialist distinction has been examined in ASOs as well. Butler and Seto (2002) found that 22 sex-only ASOs (adolescents who had only committed sexual offenses) and 10 sex-plus ASOs (adolescents who had committed sexual as well as nonsexual crimes) were different in many ways. Sex-plus offenders had more conduct problems as children, more antisocial attitudes and beliefs, higher risk for future delinquency, as well as a more extensive criminal history, substance abuse, and peer and family problems. All of these factors are related to general delinquency, indicating that sex-plus offenders have much in common with other adolescent nonsex offenders who were included in the study as a comparison group. These sex-plus offenders would be considered generalist ASOs. Conversely, sex-only offenders were characterized by less criminal history and conduct problems, less substance abuse, fewer peer relation problems, and fewer psychological problems.

Risk Factors for Adolescent Sexual Offending, Table 1 Overlap between typological clusters in adolescent sex offenders

Model						
	Adolescent types					
Butler and Seto (2002)	Sex-only	Sex-plus				
Chu and Thomas (2010)	Specialist	Generalist				
Oxnam and Vess (2006)		Antisocial	Normal			Inadequate
Worling (2001)		Antisocial/ impulsive		Overcontrolled/ reserved	Confident/ aggressive	Unusual/isolated

Note: Rows represent individual models while columns represent conceptual overlap between proposed types. The labels used in this table come from the original authors

The sex-only offenders, as specialists, had less in common with other adolescent offenders on these variables. Using the same generalist/specialist distinction, Chu and Thomas (2010) created a classification model for ASOs based on risk of recidivism. While there was not a significant difference in the rate of sexual recidivism between generalists and specialists (14.3 % versus 9.9 %, respectively), generalist offenders were significantly more likely to recidivate violently and nonviolently.

Oxnam and Vess (2006) used hierarchical cluster analysis to distinguish three groups of ASOs. The first group was described as "antisocial" and was characterized by youth who were prone to aggression and unpredictable. These youth lacked close bonds with others and had a propensity for substance abuse. The second group was described as "inadequate" and was characterized by severe psychopathology. This group was more likely to have a history of abuse and more likely to be negative and self-degrading. The last group of ASOs was described as being in the "normal range" and did not have extreme scores on any of the personality/risk scales.

Lastly, Worling (2001) conducted a cluster analysis of ASOs based on personality characteristics. This analysis revealed four types. The first, "antisocial/impulsive," was characterized by a propensity for rule violations that included sexual and nonsexual offenses. The second, "unusual/isolated," was characterized as emotionally disturbed and socially isolated. The third, "overcontrolled/reserved," was shy, reserved, and relatively weak at forming intimate, age-appropriate relationships. The last, "confident/aggressive," was characterized by overt aggression and narcissistic personality traits. The authors found that the "antisocial/impulsive" and the "unusual/isolated" groups were both at a higher risk to reoffend, whether violently (including sexually) or nonviolently, compared to the other two groups.

Table 1 displays the extent of overlap between these different typological clusters proposed by the above studies. While typologies may be useful in the classification and treatment of offenders, they do not provide suggestions for the etiology of the different proposed types. To develop an integrated theory of adolescent sexual offending, the origins of these different types of ASOs must be examined. Of particular interest are the developmental trajectories underlying the different types. In the following section, focus is placed on the developmental trajectories of generalist and specialist offenders.

Developmental Trajectories. Seto and Barbaree (1997) introduced a model of sexual offending in which they describe at least two developmental trajectories. The first trajectory (antisocial) is characterized by an early onset of problem behaviors and general delinquency risk factors. These offenders may show an early onset of sexual activity, have affect regulation problems, and can be manipulative and callous. The origin of this trajectory lies in the interactions between neuropsychological predispositions and criminogenic environments, consistent with Moffitt's (1993) description of the developmental trajectories of life course-persistent offenders. The second trajectory is characterized by opportunistic sexual offending. Though individuals in this trajectory may engage in nonsexual antisocial behavior as well, it is not early onset, varied, or persistent, consistent with Moffitt's (1993) description of adolescence-limited offenders.

Sexual deviance factors may be present in either trajectory; their presence increases their risk of sexual recidivism (Hanson and Morton-Bourgon 2005). Crossing the presence or absence of sexual deviance with the developmental trajectories creates four hypothetical groups of offenders: *persistent generalists*, *limited generalists*, *persistent specialists*, and *limited specialists*. *Persistent generalists* are high in delinquency risk factors, show problems early in life, and are likely to continue to nonsexually or, to a lesser extent, sexually offend in the future (they are life course persistent). Sexual offending for them would be part of a general pattern of antisocial behavior, and thus they would be more likely to engage in opportunistic sexual offenses, usually against peers/adults but sometimes against older children, particularly those showing some signs of puberty. *Limited generalists* are not expected to have sexual deviance risk factors but do have some delinquency risk factors. These offenders are expected to offend as a result of lack of sexual opportunities with peers and access to potential victims. *Persistent specialists* are high in delinquency risk factors but are also high on atypical sexual interests and thus are likely to continue to both sexually and nonsexually reoffend. They are expected to be more likely to offend against children than persistent generalists and are more likely to plan their sexual offenses. This group would pose the greatest risk of sexual recidivism. Lastly, *limited specialists* are low in delinquency risk factors and likely low to moderate in sexual deviance risk factors. Their sexual and nonsexual offending is expected to be limited to adolescence. Their sexual offenses may be attributed to their reactions to perturbations in their psychosexual development as a result of sexual abuse, early exposure to sex or pornography, social isolation, and lack of sexual opportunities with peers.

Future Directions

The results of the Seto and Lalumière (2010) meta-analysis can only indicate that both generalist and specialist explanations (but not all specialist explanations) contribute to an understanding of adolescent sexual offending. There are many unanswered questions. Of primary interest is the proportion of ASOs who can be characterized as generalists or specialists and whether these broad distinctions encompass more specific types on the basis of antisocial behavior, sexual behavior, and offense/victim characteristics. This question could be addressed by using cluster analysis or similar techniques on a large sample of ASOs with data on relevant measures. Ideally, the data would include information about developmental and historical variables to explore the developmental trajectories leading to the different empirically validated types. The different trajectories for antisocial behavior in terms of disposition, environmental interactions, age of onset, and life course are relatively understood, but the same is not true for the trajectories of sexual behavior and sexual deviance. Also of interest would be follow-up studies to determine if different ASO types respond differently to treatment or other interventions and to determine if they differ in their risk to sexually and/or nonsexually reoffend. Studies of this nature would go far in explaining the etiology of adolescent sexual offending and would have important implications for assessment and intervention practices.

Predictors of gang membership

Overview

The question "Why do people join gangs?" has been of particular interest to those hoping to prevent gang membership. There are a number of potential methods to gain insight into the people who join gangs and the conditions or factors that lead to membership. These methods include the descriptive approach (a descriptive account of the characteristics of gang members), the direct approach (asking gang members why they joined), and the risk factor approach (identifying predictors of gang joining). Each approach is accompanied by limitations and benefits. The risk factor approach offers a number of methodological benefits and has significantly moved the gang literature forward in the most recent decades. A summary of gang risk factor studies and their theoretical contributions is offered here. While great strides have been made in the gang risk factor area, much work remains. A discussion of needed areas of research and potential hurdles is included.

Introduction

Gangs have historically been a complicated phenomenon to understand. They form, they change, some disappear, some reappear, and some show amazing stability. People join, and some stay, but many leave quickly. In short, gangs and gang members come in so many shapes and sizes it has been difficult to define with confidence, let alone identify them all and study the extent and nature of the problem. But, there is a great desire to do so. One major reason for a preoccupation with gangs and their members is the strong link between gang membership and delinquency.

Gang members commit more delinquency than nongang members. This robust finding has been replicated over time, samples, and place (both across the United States and around the world). The rate of delinquency and violence has been so noteworthy that much public attention (media, research, policy, policing) on gangs has been in an attempt to address this issue. However, the history of concentrated gang suppression efforts has shown that gangs can be quite resilient. There is, in fact, evidence to suggest that attempting to force a gang to disband may actually increase their cohesion and group bond, thus actually making them stronger entities and less likely to dissipate. Therefore, *prevention* efforts (i.e., keeping gangs from forming or keeping people from joining) have become particularly important options for this type of social problem. For prevention to be feasible, however, the impetus for gang membership must be well understood. In other words, we must ask "Why do people join gangs?" If there is a greater understanding about the reasons for gang joining, there may be better venues to combat the problem before it starts.

Background Description

Gang studies have been challenged with definition and identification issues. There has not been a universal consensus (among practitioners, policy makers, or researchers) on exactly what constitutes a gang or a gang member. Therefore, efforts to identify, classify, or study gangs have always been fraught with questions of validity, comparability, and generalizability (for a review, see Klein and Maxson 2006). While this limitation has not hindered the ability to produce quality research studies, it must always be considered when interpreting gang findings.

The history of gang research has spanned both macro- and micro-level inquiry and has included both qualitative and quantitative methodologies. The earliest gang studies were generally qualitative studies that focused on a specific area or particular gang. These primarily descriptive studies were central in providing a rich understanding of gangs and their behaviors. A number of these studies reveal the conditions under which gangs form, and some implicated reasons why gang members joined their gangs. Quantitative studies soon followed. Many of these studies cast a wider sampling net by including both gang and nongang youth. These types of studies have been critical in assessing differences between gang and nongang members, the factors led some to join and others to resist, as well as a plethora of other subjects.

The quality of the quantitative, individual-level studies has improved substantially as gang research began to adopt both the use of cross-sectional methods and the more methodologically rigorous longitudinal data collection efforts. The expansion of knowledge in the area of risk factors for gang membership has benefited tremendously from data produced by prospective, quantitative, and longitudinal studies like the Denver Youth Survey (Esbensen et al. 1993), the Rochester Youth Development Study (Thornberry et al. 2003), the Pittsburgh Youth Study (Lahey et al. 1999), the Montreal Longitudinal Experimental Study (Craig et al. 2002), and the Seattle Social Development Project (Hill et al. 1999). These studies have been used to test and validate conclusions of cross-sectional studies and to provide firm, temporal ordering for predictors of gang membership. Longitudinal research efforts are integral to the study of risk factors (see Thornberry et al. 2004 for overview). They are, however, incredibly costly, time intensive, difficult to conduct, and therefore rare. As such, we are limited to only a handful of these types of studies. It is difficult to make sweeping generalizations regarding the importance of specific factors with such few studies. Cross-sectional studies help to bolster confidence in results, but they suffer from temporal ordering problems and cannot be given as much weight. Therefore, while much progress has been made in area of gang risk factor research, conclusions are still limited and many of our conclusions are still inconclusive.

Fundamentals

There are a few ways in which to answer the question “Why do people join gangs?” The first method would be to describe the types of people that are gang members and infer that these characteristics were important determinants in why they joined a gang. This approach is often used in media or law enforcement depiction of gangs. These methods examine a group, neighborhood, city, state, or country and identify the gang members and describe them. Using this approach, results might suggest that gang members are often minority, males from highly impoverished areas. The implication for the question “Why do people join gangs?” then becomes that something about a person’s status as a minority, male, or resident of an impoverished area leads to gang membership. Generally, the descriptors available are superficial (sex, race/ethnicity, socioeconomic status, location, age) because the data being collected are from an outside observer’s determination of gang membership. In other words, this method does not include surveying every resident of a community about their gang status and then presenting descriptive information. This approach is limited to the observer’s ability to determine *gang membership* and the quality of the data that can be collected (usually) from afar. This approach is also limited in that it does not offer a good context for comparison. Even if a majority of gang members are minority, male, and residents of an impoverished area (which is debatable), it is not true that a majority of all minority, male, residents of impoverished areas are gang members.

The second way to find out why people join gangs is to ask them directly. Both qualitative and quantitative researchers have used this approach to gain insight into gang joining. This is a very direct and valuable approach. It is also limited in certain ways. First, usually, the sample captured in the direct method is more limited than the observational method due to the work intensity. Second, this approach requires finding gang members that are willing to disclose sensitive information. Self-report will always raise questions about recall and honesty. Finally, gang members can either be asked to offer their reasons for gang joining with or without prompts (i.e., answer choices). If gang members are allowed to answer without prompting the gamut of responses can be infinite and difficult to classify and generalize. If they are probed with specific responses, then an argument can be made that their responses are not as genuine. Regardless, the direct approach provides unique insight into the cognition of gang members.

Finally, there is a risk factor approach to determining who joins gangs and why. Risk factors are conditions (either individual or environmental) that increase a person's likelihood of developing some negative condition. Risk factors precede the outcome of interest and, therefore, should be measured at an earlier period than the outcome. This requires the use of at least two observational points (i.e., a longitudinal study). In addition, the risk factor approach requires a comparison group (in this case, nongang members) to identify characteristics that distinguish gang members as a special group. In order to obtain this information from gang and comparison groups, a larger sampling net must be cast. This method often relies on respondent's assessment or admittance that they are gang involved, which can assist in identifying gang members that may not be as "obvious" in the observational approach first described (but also suffers from the same limitations as the direct method described above). Usually in the study, a broad range of questions and statuses can be asked. One benefit to this method is that, unlike directly asking a respondent why they joined a gang, the predictors of gang joining need not be known to the respondent.

The Descriptive Approach

The descriptive approach uses the characteristics of gang members to understand "who joins a gang." If a status is overrepresented in a gang sample than what would be expected in the general population, one could infer that status is related to gang membership. Official data (i.e., arrest statistics, incarceration rates) is one example of data that can offer a descriptive account of gang members. These data are collected when gang members come to the attention of the justice system. These data are often limited to whatever characteristics are collected by law enforcement (i.e., mostly superficial like sex, race, age). Using official data and the descriptive approach, gang members are often described as older, male, racially/ethnically minority, and from impoverished areas.

It is important to note that the descriptive picture of gang members differs depending on the use of self-report versus official data. Conducting a similar descriptive analysis of gang members using self-report data can yield a different depiction of what a "gang member" is. Self-report data collection efforts find that the peak age of gang joining is much younger than official data would offer. Self-report also shows that though males are more likely to be gang members, females make up a more significant proportion of gang members than official data would indicate. Self-report studies have identified gang members in both high-risk communities and low-risk communities. Though official data may suggest that gang members are usually racial/ethnic minorities, self-report studies identify substantial proportions of white gang members.

From Gang Members Themselves

A number of cross-sectional and longitudinal studies have asked gang members why they joined gangs. The most common response pro-offered by gang members varies by study. Many of these studies collect these data by offering choices that gang members can select as the reasons they joined; therefore, if an answer is *not* supported by a study, it may be because it was not offered as a choice or because it was never selected by a gang member.

Many studies report that *protection* is a common reason for gang joining as suggested by members. This answer is both commonly asked by many studies and is a commonly reported reason offered by gang members. Another common reason for gang membership is that family or friends are involved in the gang. Studies that looked specifically at differences between girls' and boys' responses to gang joining found that girls were more likely to say that they joined because friends and family were in the gang than boys (though it was a common response for boys as well). Gang members also cite a desire for respect or a reputation, to feel like they are a part of their neighborhood, and to fit in better or to feel like they belong. It is also quite clear that the sheer fun and excitement of gang membership is an attractive feature for gang members.

This method has been very useful in debunking certain myths associated with gang joining. Gangs are often depicted as being organized, disciplined groups that are brought together for profit making in illicit business – in particular, drug selling. Studies show that it is actually rare for youth to report that they joined the gang for instrumental purposes like drug selling. Gang members identified by Esbensen and colleagues (1999) from a national sample of American youth, however, did often state that the general notion of "for money" was an important impetus for joining. Another commonly hypothesized cause of gang membership is that youth are forced to join gangs. A national survey of youth found that youth (boys and girls) rarely reported that they joined a gang because they were forced.

Risk Factor Approach

The risk factor approach requires both temporal ordering and a comparison group in order to truly identify the characteristics that *lead* to gang membership. As such, risk factor studies are generally far more labor intensive and costly than a cross-sectional descriptive study or even an interview study with gang members. Thus, the number of "true" risk factor studies is quite low. More cross-sectional studies (no temporal ordering) have been conducted that identify differences between gang and nongang members. These studies are useful and informative but will always suffer the lack of temporal ordering. However, longitudinal studies have generally supported the results of cross-sectional studies which lend greater confidence to the results. For the purposes of this review, the results of both longitudinal and cross-sectional studies will be included, though any result based solely on cross-sectional studies will be viewed with more caution.

Drawing from the more general literature on juvenile delinquency, gang risk factors are often presented in five domains: individual, family, school, peers, and community. Studies have shown that gang risk factors span all five domains. Therefore, no domain should be ignored. Previous work on risk factors for juvenile delinquency, more generally, shows that the importance of any of the five domains varies by social development. In other words, during some periods of the life course, certain domains may be more important than at others. It has been strongly argued that the causes of gang membership are unlikely to be set at the earliest stages of the life course. There is no evidence of an innate predisposition for gang membership. This makes intuitive sense because gang joining necessitates a gang to join – which is strongly influenced by life and environmental circumstance. This suggests that infant gang risk factor studies may not be a top priority, but starting early is still of serious consideration. Longitudinal research shows that important risk factors are present at relatively early ages. For example, using the Seattle Development Study, (Hill et al. 1999) measured risk factors at ages 10–12 that predicted gang joining at ages 13–18.

It has been repeatedly shown that risk factors for gang joining have a cumulative effect. In other words, the more risk factors present, the greater the likelihood of gang involvement. In the Seattle Study, youth with seven or more risk factors were 13 times more likely to join a gang than those with no risk factors or only one. The cumulative effect of risk factors has been shown both cross-sectionally and longitudinally. And this pattern has also been frequently demonstrated for juvenile delinquency more generally. It also appears that individuals with risk factors across multiple domains are at an increased likelihood for gang membership.

In reviewing the risk factor literature, it is important to keep measurement issues in mind. For ease of generalization and an overview, the intended spirit of measures needs to be grouped together, but the specific wording of each measure varies from study to study. And, as with any interpretation of quantitative data analysis, the determination of what constitutes "significant" is important. Bivariate relationships are the easiest types of analyses to detect any relationship between an independent and dependent variable. These types of relationships may not "hold up" in multivariate models. Does that make them irrelevant? In some cases, these same factors may be included in other multivariate models specified with other measures and be significant. Does that make them relevant? Clearly, model specification matters to the ability to detect significance. For better or for worse, this review mostly relies on the results of the most sophisticated statistical model presented by the researchers.

Individual Domain

Of all risk factor domains, the testing of the "individual factors" domain is the most expansive. Individual factors include demographic features, individual attitudes and beliefs, as well as behavioral characteristics. The ability of demographic features to predict the likelihood of gang joining has certainly depended on the sample under consideration and the type of analysis being conducted. As stated prior, males are more often thought to be gang members especially by media or law enforcement estimates, but self-report shows that a significant proportion of gang members are female. Similarly, the overrepresentation of minorities as gang members is less dramatic in self-report studies. Still, sex and race/ethnicity as significant risk factors of gang membership vary tremendously by study and the samples under investigation. Numerous school-based, self-report studies fail to find differences by sex and racial/ethnic propensity for gang membership, and other youth studies find differences. A handful of studies have examined the role of ethnic identity on an individual's propensity to join a gang. These studies consider the role of ethnic identity separately for different racial/ethnic groups under the theoretical assumption that gang membership may be related to the level of integration that youth feel within their racial or ethnic group. Studies testing ethnic identity have failed to find a significant relationship between identification within their ethnic group and gang joining.

It has been hypothesized that one factor that leads to an increased likelihood to participate in gangs are internalizing or externalizing disorders or affective states. Factors that have been examined in this category include disruptive behavior, conduct disorder, impulsivity or hyperactivity, risk seeking, low self-esteem/self-derogation, or the lack of guilt. Self-esteem is one of the most commonly tested factors and not commonly found to be associated with gang joining in either cross-sectional or longitudinal studies. Non-delinquency problem behaviors like conduct disorder, disruptive behaviors, or oppositional defiant disorder are more often available for consideration in longitudinal studies and have been consistently supported as a significant risk factor for gang membership. Impulsivity, risk seeking, and guilt have been less frequently tested (and mostly by cross-sectional studies) and have, thus far, garnered preliminary support.

Scholars have also examined whether pro-crime or pro-gang attitudes increase the likelihood of gang joining. There is some cross-sectional support that pro-gang attitudes are associated with increased gang joining, but there has not been support for the notion that youth who perceive more benefits to gang joining are more likely to join (or that youth who perceive many cons to gangs will not join). There is cross-sectional and, more limited, longitudinal support for the notion that youth with higher tolerance toward deviance, antisocial beliefs, more extensive use of techniques of neutralization for crime, or more supportive attitudes for alcohol and drugs are more likely to join gangs. Related to this, youth who hold more conventional beliefs or a stronger belief in rules have been more often shown to refrain from gang activity.

Numerous theories posit that gang membership is a response to blocked opportunities, status frustration, or other negative life events. Generally, there is consistent support that exposure to negative life events is associated with gang joining, but perceived (future) opportunities have not shown the same pattern. Experienced barriers to success or strain have been a strong basis for theories of gang membership in qualitative studies. Support for this notion in quantitative studies, both cross-sectionally and longitudinally, suggests that it may matter for male gang joining, but not for females.

Finally, gang joining may also be predicted by an individual's behaviors. As stated prior, the link between gang membership and increased rates of offending (e.g., general delinquency, violent offending and aggressive behavior, graffiti, official contact with justice system agencies, loitering/ hanging out/cruising, drug sales) has been well established. Much of this research is based on correlational studies where causal ordering could not be definitively established (i.e., which came first, the gang joining or the offending). However, cross-sectional studies that incorporate nondelinquent, problem behaviors and longitudinal studies that establish temporal ordering can be used to assess the degree to which behavior predicts gang joining. Sexual promiscuity or early sexual experiences, for example, have been found to predict gang joining. Alcohol use and drug use (both legal and illicit) and additionally, early alcohol or drug use have predicted gang joining.

Longitudinal studies have supported the notion that youth with delinquent histories may be more likely to join gangs, but the amplification effect of gang membership on the rate of delinquency (post-gang joining) has a very strong grounding. In other words, some studies show that gang members are more likely to have committed certain types of crimes before they joined gangs (e.g., violent, total delinquency), but it is also clear that the rate of offending significantly increases after youth are a part of the gang and then falls off after leaving. There has been very little support for the notion that involvement in prosocial activities decreases the likelihood of gang joining in either cross-sectional or longitudinal studies. Researchers have examined the role of religion (e.g., religious service attendance, "religiosity," or bonds to religion), employment (during school year and during the summer), and community-based activities like sports or events without noteworthy results.

Family Domain

There is some cross-sectional and longitudinal evidence that youth in families of lower socioeconomic status are more likely to become gang members. There are, however, more studies that fail to find the connection. The same can be said of research on family structure. There is inconsistent support for the role of nuclear family structure versus single parent households (or other family structures) on the likelihood of gang joining. Scholars have suggested that what is more important than the structure of the family is the quality of the parenting within the family. Risk factor studies often test the degree or quality of parental monitoring or control on youth. There is strong cross-sectional and longitudinal support for the idea that more parental monitoring decreases the likelihood of gang joining. The same has not been shown of the level of familial attachment. There is limited cross-sectional and longitudinal support that youth that are less attached to his/her parent or family are more likely to join a gang.

Many alternative family domain factors have been identified and proposed, but strong statements regarding generalization cannot yet be made. In a review of major risk factor studies, Klein and Maxson (2006) declare some results as "inconclusive" because an equal number of studies find support, fail to find support, or are inconclusive. There are also a number of factors that have not been extensively tested or exclusively tested in cross-sectional studies, and therefore, definitive conclusions would be premature. The role of familial deviance is still unclear. There is some support that the lack of parental role models, the presence of parents with prodeviant norms, or antisocial family members like siblings may increase the likelihood of gang joining. However, studies have also failed to show a link between actual familial deviance/violence and gang joining. There is preliminary evidence that familial or parental conflict, family bonding, and familial involvement and support are not as strongly associated, but these factors have had limited scrutiny. Other conceptually appealing factors like the effect of relatives in a gang have been presented as important in numerous qualitative studies (e.g., Vigil 1988), but have had limited quantitative testing.

School Domain

Most school domain risk factors are still considered "inconclusive." That is not to say that various factors have not been examined, but inconsistent results across studies and only a handful of longitudinal studies make it hard to generalize conclusions. While no variable can be argued as having "overwhelming" support, the factors with the most support at this point are educational aspirations, school achievement (as measured by grades at various times or testing), and attachment to school. These factors have been tested more often than others. The implication of these results is that the more strongly a youth is tied to school, the less likely he/she would become gang involved. There is preliminary cross-sectional and longitudinal support for the effect of negative labeling by teachers and schools on the likelihood of gang involvement. Studies have found that negative labels like "bad," "disturbed," and "disabled" are associated with gang involvement. The opposite effect was not shown. Being labeled as a "good student" did not buffer gang joining. Safety in schools has been tested less often and generally without much support.

Other factors that have been investigated in just a few studies and require more evidence before trends can be discerned are features like attachment to teachers, self-esteem about school, educational marginality, school environment, educational frustration, winning awards in school, truancy/absenteeism, participation in school sanctioned activities, and having gang members in the classroom.

Peer Domain

The peer domain seems particularly important given that gangs are a peer group. This is why temporal ordering is of particular concern to this domain of risk factors. Cross-sectional studies that report peer group characteristics at the same time as an individual reports gang membership could very well be reported on the qualities of the gang – which is interesting and informative but not predictive. Only longitudinal studies can decisively establish whether the characteristics of or commitment to certain peer group types increases the likelihood of future dealings with gangs.

While the wording of questions or scales can differ from study to study, peer domain variables have generally clustered around two types of measures: the quality of the peers present and the level of attachment to peers. In measuring the quality of the peers that are present, scholars generally attempt to capture whether youth surround themselves with delinquent and/or prosocial peers. Delinquent peers would be a risk factor, whereas the presence of many prosocial peers would indicate a potential buffer for gang joining. Cross-sectional studies often find that gang members are more likely to be surrounded by delinquent peers, but due to the lack of temporal ordering, it is not clear whether this is because their delinquent peers are, in fact, their fellow gang members. There is, however, also longitudinal support for the effect of delinquent peers to lead to gang membership. Fewer studies have looked at the buffering effect of having prosocial or *good* peers on the risk of gang joining. There is preliminary support that the presence of more prosocial peers is important though more work is certainly needed.

The second cluster of peer domain factors has been the extent of an individual's commitment to their peers. These measures have been tested less often and generally with weaker methodology, but the pattern generally follows that of the quality of peers present. Youth that are more strongly committed to their negative/delinquent peers or who have low commitment to prosocial peers are more likely to be in gangs. Youth that are more strongly committed to conventional or prosocial peers are less likely to join gangs.

Other factors that have had limited examination, but show some promise as risk factors, include the presence of or ability to resist peer pressure, the experience of being approached by a gang, and the time spent unsupervised or "hanging around." Future studies should begin to examine some of these factors more directly related to socialization with peers.

Community Domain

Despite being one of the first domains to emerge in the gang literature (mostly from qualitative studies), the community domain is one of the least often tested in the quantitative work on gang risk factors. In qualitative studies about gangs, the structural features of the community are quite prominent. Decades of research show that gangs often form in highly disadvantaged and disorganized communities that lack effective social controls. Therefore, it is known that community level factors should not be neglected as important predictors for individual-level gang membership. However, risk factor data are most commonly collected at the individual level (i.e., people are asked questions about themselves and their lives). These measures often capture an individual's perceptions of their community characteristics. These perceptions may or may not be consistent with the actual state of their neighborhood condition. Therefore, the most common method for testing community factors may not be sufficient measures of the actual phenomenon and may fail to find support even if it does exist.

Two common community measures are the level of (1) crime and (2) disorganization or disorder in a neighborhood. Studies have shown mixed results in regard to the effects of these two characteristics on the likelihood of gang joining for youth. There are longitudinal studies that show that community arrest rate and neighborhood disorganization predict later gang joining, though other studies (longitudinal and cross-sectional) do not. Other community related factors have been investigated, but not extensively. There is at least some support to suggest that perceived access to drugs in the neighborhood, attachment to a neighborhood, availability of firearms in the community, drug use in neighborhood, degree of poverty of the community, and the presence of gangs in the community should be considered.

Risk Factor Theories of Gang Membership

There are a number of theories of gang formation and gang membership. Many of the most popular theories are based on early qualitative studies on gang groups and their dynamics. Most of these theories fit under the broader umbrella of other major criminological theories. For example, many theories of gang formation have their roots in macro-crime theories like social disorganization, strain, and subculture of violence. Learning theories have also been widely cited as the mechanism to explain shared norms and their transmission among gang members.

More recently, however, the rise of longitudinal risk factor research has spurred developmental theories of gang membership. The risk factor approach assumes that there are multiple paths to the same outcome. The timing, order of risk factors, and cumulative nature play a dynamic role in the likelihood of gang joining in youth. These theories would not be possible (nor testable) without these multiple-wave, longitudinal studies that can capture stimuli at various points during development. Arguably, the most well-known theory and documented risk factor theory is Thornberry and colleagues' (2003) Interactional Theory of Gang Membership.

As the name suggests, this theory stresses that interactions between variables and bidirectional causality are important. According to this theory, it is not the case that exposure to every type of risk factor directly influences gang members. Factors like the neighborhood and family are predictive of gang membership indirectly because they loosen prosocial bonds. The decline of the bonds increases the chances for antisocial influences or values. A culmination of risk factors and disadvantage increases stress, delinquency, and general problem behaviors. Engaging in these behaviors then increases the perceived benefits of gangs (e.g., excitement, protection) and, hence, increases the odds of gang joining.

Thornberry and colleagues found support for their model using the Rochester Survey of Youth. Their theory focuses mostly on late childhood and early adolescent predictors of mid-adolescent gang membership. Since their work, other proponents of a developmental framework to explain gang membership have argued that the theory should incorporate earlier risk factors like at preschool or upon school entry (see Howell and Egley 2005) because a number of longitudinal studies (using gang and delinquency in general) have shown risk factors measured at earlier ages to be important. Regardless, risk factor research has made it possible for the understanding of gang joining and membership to be placed within a developmental context.

Future Directions

Risk Factors for Gangs vs. Other Serious Offenders

One important aspect of the gang risk factor literature that is still up for debate is the difference between gang members and nongang serious offenders. The studies reviewed here compared gang members with nongang youth. In this direct comparison, a number of significant differences can be found. The most noteworthy and consistent difference between gang and nongang members is involvement in delinquency and other problem behaviors. Gang members commit significantly more offenses than their nongang counterparts, and, as shown here, there are a number of risk factors that distinguish these two groups.

When gang members are compared to nongang, but *deviant* peer group members, their behavior is also shown to be significantly more delinquent. A number of gang scholars contend that gangs are substantively different than even nongang deviant peer groups. If this is the case, one would expect that there are unique risk factors that significantly distinguish gang members from these other serious offenders. There are a limited number of studies that have attempted to address this issue. In one study using the Denver Youth Survey (a longitudinal study of over 1,500 youth), the researchers found that while many factors distinguished gang members from the non-offending youth, few differences existed between the gang members and nongang street offenders. A separate study using a national sample of youth (n = 5,935) used the same 18 predictors on violent offenders and gang members. Of the 18 factors, 6 of them predicted both violent offending and gang membership in multivariate models (i.e., low guilt, neutralizations, delinquent peers, delinquent peer commitment, time spent with drugs and alcohol, and negative school environment). Four additional variables predicted violent offending but not gang membership (i.e., impulsivity, risk seeking, few prosocial peers, and time spent without adults). No factors independently predicted gang membership.

Scholars have struggled to predict gang membership above and beyond what we already know about delinquency more generally. Risk factors for gang members are very similar to those for violent and/or serious offenders (despite differences in level of behavior). This leads to the question of whether there is reason to study gangs as separate entities from other highly delinquent youth groups. The study using a national sample of youth also found that gang members, on average, had more cumulative risk factors than even violent offenders. This may be an important point of inquiry that requires further investigation. Perhaps, it is not specific risk factors that predict gang versus nongang serious offenders, but the sheer magnitude of cumulative risk factors that makes the difference. Gang risk factor research needs more investigation into the mechanisms or factors that lead gang members to gang groups as compared to other deviant peer groups.

Longitudinal Studies Are Needed to Move the Field Forward

True risk factor studies need to be longitudinal. Cross-sectional studies are informative, often more feasible to execute, and can be used to add support to longitudinal findings. However, they will never be able to definitively establish causal ordering and, thus, can never identify a true “risk factor” or predictor of future behavior. With newer theories like Thornberry and colleagues (2003) interactional framework for gang membership, more attention has been focused on pathway models as explanations for behavior. This makes intuitive sense. Human behavior is a very complicated thing to predict. It is highly unlikely that all factors simply work in a unidirectional fashion. The progress that the gang risk factor literature and theory building has made in recent decades has come from a handful of well-executed, longitudinal studies.

Unfortunately, there have been a limited number of these types of data collection efforts. They are costly, time-consuming, and labor intensive to conduct. The data available from these established studies have also been used quite extensively to study gang risk factors. No data collection effort can provide an infinite number of gang studies. The major longitudinal study efforts currently available also represent a limited geographic section of America, and especially with regard to gang research, diversity in location and population is an important consideration. Therefore, without more longitudinal data collection efforts, new information would not be available and gang risk factor work will not move forward. To complicate matters, tests of interactional theories (as opposed to simply direct effects of risk factors) require analysis with sufficient statistical power (i.e., lots of people to study). This requires studies with even more resources and time commitment. These types of studies are a monumental undertaking, but without more efforts, this area of work cannot make forward progress.

Risk Factors for Prison Recidivism

Rearrest; Recidivism versus reoffending; Return to prison

Overview

One of the most frequently used measures to gauge the effectiveness and impact of criminal sentencing and correctional programs is the recidivism of those processed through the justice system and released from community corrections programs or prisons. Broadly defined, recidivism is the return to criminal behavior following some type of intervention by the criminal justice system; however, in practice and research, how recidivism is measured varies dramatically, and as a result, so too do rates of recidivism. Based on one definition that has been used for those released from prison – whether or not the former inmate was rearrested for a new crime within 3 years following release – the recidivism rate of a nationally representative sample of released inmates in the United States was 68 %; however, when defined as returned to prison as a result of a new conviction, the recidivism rate was 25 % (Langan and Levin 2002). In addition to recidivism rates varying depending what definition of recidivism is used, the likelihood of recidivism also varies depending on a variety of individual-level and community-level risk factors, as well as state and local criminal justice practices and policies. Over the past four decades, risk factors for prisoner recidivism have increasingly been used to guide criminal justice practice and policy, and the understanding within the field of criminal justice and criminology as to the factors associated with prisoner recidivism have increased in depth and sophistication. This knowledge has helped improve the targeting of limited criminal justice resources to those who pose the highest risk of recidivism and those who can benefit most from rehabilitative interventions that can reduce risk of recidivism. These advances in understanding of the risk factors associated with prisoner recidivism have also improved the designs of evaluations of program and policy interventions intended to reduce recidivism.

Definitions and Measures of Recidivism

The broad definition of recidivism is the return to criminal behavior following some type of intervention by the criminal justice system, such as following an individual's conviction and placement on probation or following their release from prison. Although there are a number of purposes or goals when it comes to sentencing those convicted of crimes, including individual and general deterrence, retribution/punishment, incapacitation, and rehabilitation, only two of these goals actually seek to reduce criminal behavior following the completion of a criminal sentence: individual deterrence and rehabilitation. Thus, the concept of recidivism within this context can be seen as a measure of the degree to which these interventions were effective. "High" recidivism rates can be used to draw the attention of public policy makers and practitioners to interventions that may need to change or are used to illustrate the difficulty of deterring or rehabilitating specific types of offenders. Varying levels of recidivism rates across programs or services, or among specific types of offenders, can also be used by practitioners and policy makers to invest more, or refer more offenders, to those interventions that seem to be "working" to reduce recidivism.

However, as important as recidivism is as a measure of the effectiveness of criminal justice interventions, the definition of what constitutes "recidivism" in the domains of both criminal justice researchers and practitioners varies considerably. While the conceptual definition of recidivism is the return to criminal behavior, how exactly have researchers and practitioners operationalized this concept so that it can be measured in the real world? The operational definitions and methods of measurement have ranged from researchers interviewing former prison inmates and asking them to self-disclose new criminal behavior, such as illegal drug use or theft, to state departments of corrections determining how many of the inmates they released from prison have been readmitted to prison. Because the specific measure used to gauge recidivism has such a significant impact on the level of recidivism that will be detected, it is important here to briefly describe the measures of recidivism that have been most frequently used in examining those released from prison and their relative strengths and weaknesses.

In addition, the amount of time following an inmate's release from prison during which recidivism is measured also varies considerably from study to study, ranging from relatively short periods of time at risk to much longer postprison follow-up periods. Generally, recidivism research has found that if a prison release is going to recidivate, it tends to happen relatively soon after their release and as the longer they survive without recidivating, the lower the likelihood that it will occur.

As a result of these different methods of operationalizing and measuring recidivism, recidivism rates can vary considerably and also have varying levels of reliability and validity. For example, many practitioners and policy makers would question the truthfulness (i.e., reliability) of former inmates reporting new criminal behavior to a researcher, regardless of assurances of anonymity or confidentiality that may be used to improve the reliability of the responses. In addition to the concerns regarding the reliability of self-reported information about the participation of former inmates in new criminal activity, one of the biggest limitations to the use of self-reported information as a means of gauging postprison recidivism is the enormous amount of time and resources needed to collect this information from sufficiently large samples of former inmates.

Because of the costs and concerns with the reliability of obtaining self-reported information to gauge recidivism, most researchers, agency administrators, and policy analysts examining prisoner recidivism utilize “official” records of recorded events, such as new arrests, convictions, or admissions to prison. However, while relatively easy to access and obtain, operationalizing and measuring recidivism using official records of arrests, convictions, or returns to prison also have their own limitations, and recidivism rates vary dramatically depending on which of these measures is selected. Illustrative of this is recidivism analyses performed on a nationally representative sample of prison releasees by the US Department of Justice’s Bureau of Justice Statistics which utilized four different measures of recidivism (Langan and Levin 2002). Specifically, the recidivism of a cohort of inmates released from state prisons in 1994 was examined using rates of rearrest, reconviction, return to prison for any reason (a new conviction or a technical parole violation), and return to prison as a result of a new conviction, all within 3 years of release. While somewhat dated, the results from that study are illustrative and useful for revealing the differences in recidivism rates across different definitions of recidivism. For example, when the operational definition of recidivism was rearrest for a new crime, 68 % of prison releasees recidivated, compared to a recidivism rate of 52 % when defined as being returned to prison for a new crime or a technical violation of their release conditions, 47 % when recidivism was defined as being reconvicted for a new crime, and, lastly, a recidivism rate of 25 % when defined as being resentenced to prison for a new crime (Langan and Levin 2002). Thus, depending on the operational definition of recidivism selected, the overall rates of recidivism will vary considerably, but, again, there are concerns regarding the validity of these measures. For example, some would not feel as though being convicted, or returned to prison as a result of a new conviction, is a sufficiently broad (i.e., valid) definition of recidivism, and it is likely that if it were possible to obtain reliable self-reported information regarding involvement in crime that the recidivism rate would be considerably higher. Similarly, many have pointed out that simply being arrested for a new crime does not necessarily provide a valid measure of recidivism, but merely that police had probable cause that the individual had committed a crime, and it is also obvious that not all criminal behaviors come to the attention of the police or result in arrests.

Fundamentals of Risk Factors for Prison Recidivism

While the operational definition used to measure recidivism results in different recidivism rates, regardless of the specific measures of prison recidivism used, a number of risk factors have been identified as having a consistent relationship to recidivism and have played a significant role in criminal justice policy and practice. Indeed, one of the oldest and most fundamental decision-making processes in community corrections, including the supervision of those released from prison, is the assessment of offender risk (Holsinger et al. 2001). The problem of predicting offender risk is paramount to decision making at various stages of the criminal justice system and is integral to several decisions regarding the release of those from prison, including decisions as to whether or not they should be released and, if released, the level and conditions of parole supervision. Over the past 30 years, the tools and approaches to risk assessment of prison releasees and probationers have evolved dramatically, and experts in the field of community corrections have identified three generations of risk assessment: subjective or clinical judgments, actuarial or case classification approaches, and criminogenic/dynamic evaluations (Bonta 1996). From the development of these risk assessment instruments, and extensive research on recidivism of those released from prison, a number of general conclusions regarding risk of prisoner recidivism have now become widely accepted within the field of criminal justice and criminology, while other risk factors are either evolving in terms of better understanding prisoner recidivism, and still others are the subject of considerable debate among scholars, practitioners, and policy makers. These risk factors associated with prisoner recidivism can be grouped, generally, into three main categories: (1) individual-level risk factors, (2) community-level risk factors, and (3) criminal justice policies and practices that influence the likelihood of recidivism.

Individual-Level Risk Factors of Prisoner Recidivism

The first category of risk factors for prisoner recidivism include the characteristics or traits of the individual prison releasee and have been characterized by Andrews and Bonta (1994) as falling into one of two subcategories of individual risk: individual static characteristics and individual dynamic characteristics. Static risk factors are those that cannot be changed as a result of correctional interventions and include traits such as age at first arrest, prior arrests, current age, current conviction offense, and gender. Dynamic risk factors, on the other hand, are characteristics of the offender that can be changed, either through clinical interventions or by changes in the former prison inmate's circumstances, such as antisocial thinking patterns and cognition, drug use patterns, employment status, and having antisocial or criminal peer groups and associates.

As a result of numerous individual studies and meta-analyses examining prison inmate recidivism, a number of individual-level, static characteristics have been consistently found to be associated with postprison recidivism. For example, a meta-analysis conducted by Gendreau et al. (1996) found the offender's criminal history, history of other antisocial behaviors, age, the environment within which the inmate was raised as a child (family criminality, family structure, and family-rearing practices), race, and gender were all related to the risk of recidivism. Two of the strongest individual-level, static predictors of recidivism in the Gendreau et al. (1996) study, as well across numerous individual studies examining offender populations (i.e., prison releasees and probationers), were the individual's age and the extent of their criminal history.

Generally, the older the individual when discharged from their correctional programming (i.e., prison or probation), the lower the risk of recidivism, regardless of how recidivism has been operationalized and regardless of what other risk factors are statistically controlled. While the general criminology literature has found a strong association between age and involvement in crime, or desistence from crime, even among those who are known offenders (i.e., those released from prison), this pattern also holds. Similarly, those released from prison with more extensive criminal histories, whether operationalized as prior arrests, prior convictions, prior prison sentences, or other measures of previous antisocial behavior, have a higher risk of continued involvement in crime (i.e., recidivism) independent of other risk factors or characteristics. Males released from prison also tend to have higher rates of recidivism than females, even after the influence of other characteristics have been accounted for or statistically controlled. The current conviction offense has also been found to be associated with recidivism of those released from prison, with those released from prison after having served a sentence for a property crime or a drug-law violation having a higher risk of recidivism than those who had served a sentence for a violent crime. However, the magnitude of effect for this risk factor tends to lessen after other risk factors are controlled for, such as age at release from prison, prior criminal and substance abuse history, and education level. In fact, the static, individual-level risk factors of age, criminal history, gender, and current conviction offense are even consistent predictors of prisoner recidivism in the few studies of inmate recidivism that have been performed in nonindustrialized Western nations, such as in Malta, a small republic in the Mediterranean Sea (Baumer 1997).

The Gendreau et al. (1996) meta-analysis also found the race of the offender to be related to recidivism in the small number of studies that included this as a variable, with minorities having a higher likelihood of recidivism, and some more recent studies have also found that minorities have significantly higher odds of recidivating than white offenders (DeComo 1998; Strom 2000). However, some studies suggest that in fact there is *no* statistically significant difference in the recidivism rates of minority and white juveniles (Mbuba 2005), particularly after other risk factors are taken into consideration. Thus, while some studies have found race to be predictive of recidivism for those released from prison, others have found the magnitude of the race effect on recidivism to vary or be neutral depending on what other variables are statistically accounted for in the analyses. There are also a large number of recidivism studies that have not included race as an individual-level risk factor in the analyses.

However, from the standpoint of criminal justice policy and practice, one of the biggest limitations of these static risk factors is that, by definition, they cannot be changed. Thus, while they can be used to aid in predicting the risk of recidivism, and as a result subject the individual to a higher level of supervision, they cannot always be effectively used to reduce the risk of recidivism. Therefore, it is critical to point out that there are also numerous individual-level risk factors that are considered dynamic or malleable and, if changed, can be viewed as assets or protective factors. For example, while an individual's history of drug use is predictive of their likelihood of recidivism, their current drug use patterns, their cognitive views on the appropriateness of drug use, and their completion of substance abuse treatment while in prison can reduce the likelihood of recidivism. Although the efficacy of prison-based treatment as a means of reducing the risk of recidivism was challenged in the 1970s, leading to a number of policy shifts that reduced the availability and emphasis on rehabilitation for prison inmates, there is currently agreement among most criminologists that treatment addressing dynamic criminogenic needs and utilizing evidence-based practices can reduce the risk of recidivism, which has led to a revival of rehabilitative efforts both within prisons and following release from prison.

Again, a number of meta-analyses have identified the individual-level, dynamic risk factors associated with recidivism among those released from prison, including antisocial personalities; socialization with other offenders; antisocial attitudes related to behavior, employment, and education; conflict with family; personal distress, such as anxiety and low self-esteem; social achievement, such as employment, marital status, and education; and drug use patterns (Gendreau et al. 1996). Thus, interventions that seek to alter a prison inmate's or a parolee's antisocial attitudes, teach them to more effectively handle anxiety or interpersonal conflict in noncriminal ways (i.e., without the use of drugs or violence), or improve their educational achievement or employability can change these dynamic risk factors and, as a result, reduce the risk of recidivism. Evidence regarding the impact these types of interventions can have on recidivism is also quite plentiful. For example, Wilson et al. (2000) found in a meta-analysis of corrections-based education, vocational and work programs that participants generally had lower rates of recidivism, although the existing literature is still limited in terms of fully understanding the causal relationship of these programs versus issues of selection bias regarding who participates in these types of programs. Another intervention used within prisons to addresses individual-level, dynamic risk is cognitive-behavioral therapy (CBT), which views an offender's cognitive processes related to crime as something that can be changed. "Cognitive-behavior therapy is based on the assumption that cognitive deficits and distortions characteristic of offenders are learned rather than inherent. Programs for offenders, therefore, emphasize individual accountability and attempt to teach offenders to understand the thinking processes and choices that immediately preceded their criminal behavior" (Lispy et al. 2007). In their meta-analysis of CBT programs, Lipsy et al. (2007) found that, overall, CBT interventions were effective at reducing recidivism and that some specific characteristics of programs generated greater recidivism reductions, including how well the programs were implemented (i.e., fidelity to program design), targeting of higher risk offenders, and the incorporation of specific CBT elements related to anger management and interpersonal problem solving.

Prison-based programs that seek to address issues related to an inmate's substance abuse patterns, also an individual-level dynamic risk factor, are another means by which the risk of recidivism can be reduced upon an inmate's release back to the community. One of the most effective modalities of providing prison-based substance abuse treatment to inmates is through the use of Therapeutic Communities (TCs). TCs are "residential [programs] that use a hierarchical model with treatment strategies that reflect increased levels of personal and social responsibility. Peer influence, mediated through a variety of group processes, is used to help individuals learn and assimilate social norms and develop more effective social skills" (National Institute on Drug Abuse 2002). Also, because TCs are one of the most common and widely studied drug treatment modalities for prison inmates (Lurigio 2000), their efficacy in reducing the risk of recidivism among prison releasees has been well documented and established. Mitchell et al. (2006) is one of the most recent, comprehensive, and rigorous meta-analyses published on the effectiveness of incarceration-based drug treatment. In general, most of the research on prison-based TCs, including Mitchell et al. (2006), has documented recidivism reductions for those inmates who participated, although the magnitude of the reduction varied, depending on the length of stay, the population served, the inclusion of educational and vocational programming, and the provision of access to aftercare following release from prison.

Although not generally considered among the individual-level, dynamic risk factors for recidivism, the amount of time spent in prison is certainly a factor that can be modified and altered by criminal justice practitioners and policy makers if it were found to influence recidivism. Yet despite the fact that longer prison sentences have consistently been argued as an effective crime control policy based on the belief that longer sentences would generate individual deterrence and thus reduce subsequent recidivism, much of the research that has sought to examine this question is dated, suffers from methodological limitations, and has produced inconsistent and, at times, contradictory findings. For example, a meta-analysis by Gendreau, Goggin, and Cullen (1999) found that longer prison sentences were associated with an increased likelihood of recidivism, contrary to what would be expected through the lens of individual deterrence; however, Snodgrass et al. (2011) points out that this meta-analysis was based primarily on research conducted in the 1970s, when sentence lengths among prison inmates were dramatically different than they are today. In their recent examination of the question as to whether or not length of time in prison reduces recidivism among prison releasees in the Netherlands, Snodgrass et al. (2011) found there to be no effect of time served on subsequent recidivism. More generally than just length of time served, a meta-analysis examining the relationship of harsh penalties and recidivism found that harsher punishments were related to a slight increase in recidivism, but when it came to sentence lengths, sentences under six months showed no impact on recidivism while sentences were found to increase the risk of recidivism (Smith et al. 2002). Thus, while the research literature regarding the impact of length of stay in prison on subsequent recidivism appears to suggest that it either has no effect or increases the risk of recidivism, many would also argue that the reduction of recidivism is only one goal in the sentencing of convicted offenders to prison, and thus longer sentences would be justified on the basis of retribution and incapacitation.

The Universal Nature of Individual-Level Risk Factors

It is important to note that many of the individual-level risk factors for recidivism, including both static and dynamic risks, may not be consistent or have the same magnitude of effect to all subpopulations of prison releasees. For example, since the majority of prison releasees are accounted for by males, and therefore much of what is known about risk factors for prison recidivism has been based on research predominantly of male offenders, concern regarding the generalizability of risk factors specifically to female prison releasees has been raised. Similarly, the degree to which risk factors are consistently predictive of "general" recidivism versus recidivism for specific types of crimes, such as violent offenses, also varies. For example, while under supervision or during reentry from prison, unemployment or job dissatisfaction – an individual-level dynamic risk factor – is related more to men's recidivism than to women's (Benda 2005). On the other hand, greater educational achievement significantly lowers women's risk of recidivism, but has less effect on men's recidivism (Uggen and Kruttschnitt 1998). Similarly, research has produced inconsistent findings on whether having friends who engage in criminal lifestyle – which has been identified in meta-analyses of increasing the risk of recidivism – increases the risk of recidivism for both men and women (Uggen and Kruttschnitt 1998; Benda 2005).

In addition to factors that increase or decrease the overall likelihood of recidivism, practitioners and policy makers are often concerned with recidivism for very specific types of crimes. For example, it is of greater concern from the standpoint of public safety when the recidivism involves crimes of violence against a victim than when the recidivism involves minor property crimes or drug-law violations. Similarly, for offenders sentenced to prison for sexual assault, upon their release from prison one of the biggest concerns among practitioners and policy makers is their likelihood of committing another sexual assault. However, because violent recidivism, and even more specifically sexually violent recidivism, is much less prevalent than more general recidivism, it tends to be more difficult to accurately predict. Still, a review of research on the accuracy of standardized risk assessment scales of predicting violent recidivism indicates that scales containing individual-level dynamic risk factors have higher predictive accuracy than scales that contain only individual-level static risk factors (Campbell et al. 2009).

Community-Level Risk Factors

While there is a fairly extensive body of literature and significant agreement on the individual-level risk factors that contribute to recidivism among those released from prison, as a result of the growing interest among researchers and policy makers in the area of prisoner reentry, it has increasingly been recognized that the characteristics of the community the offender is released back into may also influence the likelihood of recidivism. Moreover, these environmental conditions may modify the predictive accuracy of certain individual-level risk factors. For example, offenders who have a history of substance abuse are more likely to relapse and use illicit drugs (i.e., recidivate) in high-poverty areas than in neighborhoods with low poverty rates (Galea et al. 2003). Thus, the risk assessment field has recently recognized the importance of incorporating risk factors that relate also to the criminogenic aspects of an offender's surrounding environment in assessing offenders' risk of recidivism. The recognition of this issue by policy makers and practitioners, coupled with the application of more sophisticated statistical techniques to examine recidivism (i.e., hierarchical linear modeling), has produced a small but growing body of scientific literature that has examined the influence of community-level characteristics on prisoner recidivism.

In the limited number of studies that have been published, there appears to be some confirmation that community or neighborhood characteristics related to poverty, crime and disorder, economic opportunity, and the availability of social services does influence, independent of individual-level risk factors, the risk of recidivism among prison releasees. For example, Kubrin and Stewart (2006) incorporated Massey's (2001) Index of Concentration at the Extremes (ICE), a community-level measure of the degree of concentrated affluence relative to the concentration of poverty, in their analyses of recidivism among individuals released from prison and found that inmates released into neighborhoods with higher concentrations of affluence had a lower risk of recidivism independent of their individual-level risk factors. Similarly, Hipp et al. (2010) found that inmates released to communities with high levels of concentrated disadvantage and disorder had a higher risk of recidivism, independent of their individual-level risk factors, but communities where social service providers were not in close proximity to the released inmate also increased the risk of recidivism after controlling for the influence of other factors. A similar pattern was found by Olson et al. (2009), which suggested that inmates released back to communities where aftercare services for inmates are more readily available, and more varied, had higher rates of aftercare participation and completion, which reduced the likelihood of both parole violations and recidivism. Thus, while the Urban Institute's research on reentry across a number of states has documented that the communities many inmates are released to have high levels of social and economic disadvantage (LaVigne et al. 2004), the increased risk that this poses regarding recidivism may be mitigated if there are higher levels of social service programs available. As the research regarding the independent influence of community-level risk factors for prison recidivism increases and evolves, it will be possible to better isolate the relative influences that individual-level versus community-level risk factors play in prisoner recidivism.

The Influence of Criminal Justice Practice and Policy on Prison Recidivism

The last of the three general areas that can change the risk of recidivism has to do with changes and differences in criminal justice practice and policy. Among all of the risk factors presented, the degree to which criminal justice practice and policy impacts recidivism had more to do with how recidivism is operationalized and interpreted. For example, if return to prison within three years is the definition of recidivism, and one of the ways that a former inmate can be returned to prison is the result of violating the conditions of their release, then it is obvious that policies related to the extent and nature of post-release conditions of supervision, staffing levels, and practices of parole agents, and the policies regarding how violations of release conditions are handled, will all influence the rate at which individuals released from prison are returned to prison (i.e., "recidivism"). Generally, those released from prison that are subject to a higher frequency of supervision contacts and more intensive monitoring have higher rates of violations of release conditions being detected and, as a result, higher rates of being returned to prison. The level and intensity of postprison supervision can change over time within a specific state and also varies considerably across states.

For example, in some states, such as California, those returned to prison for parole violations accounted for 65 % of all prison admissions in 2010, while at the other end of the spectrum were the states of Florida, Virginia, North Carolina, Idaho, Ohio, and Nebraska, where parole violators accounted for less than 10 % of all prison admissions (Guerino et al. 2011). Generally, the larger the proportion of prison releasees who are subject to supervision and other conditions of release, the larger the proportion of admissions accounted for by parole violators and the higher the "recidivism" rate if measured by rates of return to prison. If only a small proportion of prison releasees are supervised and have conditions, it follows that only a small number of prison releasees can be returned to parole violations. Also, some of these changes in practice and policy can be gradual, whereas other changes can be implemented quickly and dramatically. Thus, it is important to note that policies related to whether or not those released from prison are subject to supervision, what other conditions of release are required and monitored, and how long that supervision lasts vary from state to state and, as a result, can produce different rates of "recidivism" when measured as return to prison. Further, before one can conclude that recidivism rates based on return to prison in a state have changed or are higher or lower than another state, changes or differences in postprison supervision policies and practices need to be considered and accounted for in analyses.

However, it is not only correctional or parole policy and practice that can influence and impact recidivism rates of those released from prison but those of police departments and the courts as well. For example, if individuals are released from prison during a period when police departments are cracking down or focusing on specific types of crimes or offenders, such as drug delivery offenses or parolees in specific neighborhoods, then inmates released from prison during that period of time may be more likely to be arrested than those released from prison when police officers were being deployed for other purposes or periods when police presence was lower. Thus, if the definition of recidivism is rearrest for a new crime, then obviously changes or differences in police policy and practice over time and across place can have an influence on this measure of recidivism. The same can be said for measures or recidivism that rely on reconviction as the operationalized definition of recidivism: changes in the practices and policies of prosecutor's offices regarding what types of offenses they will file charges for, take to trial, or plea bargain can potentially influence the likelihood of a prison releasee being reconvicted of a crime or a felony offense following their release. Importantly, all of these changes in policy and practice – parole supervision intensity, police department activities, and prosecutorial decision making – can impact each other and have differential impacts on the different measures of "recidivism" (i.e., rearrest, reconviction, return to prison for any reason or specifically as a result of a new conviction).

Conclusions and Directions for Future Research

The body of research and knowledge on the risk factors of prison recidivism has increased and improved dramatically over the past 40 years and is increasingly being used by criminal justice practitioners and policy makers. This knowledge of risk factors for prison recidivism is increasingly being used by clinicians working with prison inmates to better identify and target the individual-level dynamic risk factors that need to be addressed, by parole boards in deciding which inmates can be released from prison due to their lower risk of recidivism, and by policy makers as they seek to allocate resources to programs, interventions, and community-based services that can reduce recidivism among those released from prison. Still, it must be recognized that while the use of more sophisticated approaches to identifying and classifying the risk of prison recidivism has improved predictive accuracy and guided case management strategies and practices, the science is not perfect and is continually evolving and improving. When tasked with the challenge of predicting human behavior (i.e., recidivism), even when we can take into consideration individual-level static and dynamic risk factors, coupled with community-level risk factors, there are bound to be false positives and false negatives: there will be individuals who are low risk based on all of these factors that will reoffend, as well as individuals who are high risk based on their risk factors who end up not reoffending. The latter is unlikely to be a concern for criminal justice practitioners or policy makers, but the former will be of considerable concern and oftentimes results in the questioning of using actuarial risk to determine if an inmate should be released from prison and how they should be supervised. However, generally speaking, the criminal justice system can identify and utilize risk factors for recidivism much more effectively than in the past to address individual-level risks, reduce recidivism, and ultimately, improve public safety. Future research that improves the understanding in the field of the interactions of individual- and community-level risk factors, and can effectively articulate how this knowledge and information can be used within the applied setting of criminal justice practice and policy, will go a long way towards continuing to improve public safety and reduced risk of recidivism for prison releasees.

Risk Management in Policing

Carol A. Archbold
Department of Criminal Justice and Political Science, North Dakota State University, Fargo, ND, USA

Introduction

Police officers are exposed to risk every time that they put their uniforms on. This exposure can result in them being named in citizen complaints, liability claims and lawsuits. Liability claims and lawsuits can have a significant financial impact on police agencies. For example, New York City paid out $500 million in settlements and judgments as a result of police actions from 2005 to 2010 (Lui 2011). From 2000 to 2007 the city of Chicago paid out approximately $126 million as a result of litigation involving the Chicago Police Department (Midwest Human Rights 2011). Litigation costs for American police agencies have increased significantly since the late 1960s. Some police executives have recognized this increase and have started to take proactive measures to reduce officer exposure to risk. Risk management is one of the latest proactive measures being used by some police executives to manage liability.

Fundamentals

Risk management is a tool that can help identify and manage potential risks and liability problems within organizations. Organizations adopt risk management because of increasing costs associated with liability claims and litigation, to reduce the risk of harm to their clients and their employees, and to provide a higher quality of service to their clientele (Wong and Rakestraw 1991).

In the past, some people believed that the principles and practices associated with risk management were not applicable to public agencies. This perception is inaccurate as most public agencies can function better if they have the maximum amount of resources available to them. In addition, it could be argued that public organizations are held to a higher level of accountability than private organizations because they are entrusted with budgets that largely come from the community (i.e., taxpayers) (Vincent 1996). If public agencies use risk management to identify risks that often lead to organizational loss, and then make changes with the hope of reducing future loss, they will be able to spend more resources on services to the community instead of settlements for liability claims and litigation. Today, the public sector is among the fastest growing segments of the risk management profession (Vincent 1996).

There are five basic steps in the risk management process that apply to most types of organizations (Ashley and Pearson 1993; Wong and Rakestraw 1991):

1. ***Identify risks, frequency of exposure to risks, and the severity of losses resulting from exposure to risks.*** To do this, organization members can use data on the history of organizational loss including past litigation and monetary payouts resulting from liability claims. There are three general categories of assets that organizations are responsible for managing including: physical, human and financial assets (Young 2000). Vehicles, buildings, computer equipment and other technological equipment are considered **physical assets**. If this type of asset is damaged or lost, organizations face costs associated with replacing the item and also any time that is lost during the replacement of the item. **Human assets** include all employees that work within an organization. Employees are at risk for both physical harm and financial difficulties if injured while on the job. It also costs organizations money to retrain new employees when they need to replace employees that are killed or injured while on the job. **Financial assets** include any financial resources that are available to organizations that have a direct impact on how organizations are able to function. In public organizations this could include annual budgets and any external grants that can be acquired by an organization.
2. ***Explore methods to manage exposure to identified risks***. This step requires a thorough review of an organization's policies and procedures, training, and the supervision and accountability of employees.
3. ***Choose an appropriate response to manage exposure to identified risks.*** This might require making changes to policies, employee training, and/or supervision in order to reduce exposure to identified risks.
4. ***Execute the response that was chosen to manage exposure to risks***.
5. ***Evaluate the impact that the response has on exposure to identified risks.***

The risk management process is not over once the first four steps are completed; this process is ongoing because organizational risks can change over time.

The use of risk management by police agencies seems logical as most of the basic duties associated with police work expose officers to risk (Gallagher 1990b; Wennerholm 1985). Some of those duties include making arrests, pursuing fleeing suspects using patrol cars, using both lethal and non-lethal force on citizens, and serving felony warrants. There are three general benefits of using risk management as part of a police liability management strategy: (1) increase the safety of police officers and the citizens that they serve; (2) increase the quality of police service provided to the public; and (3) financial management of the costs associated with police-involved liability incidents that often result in payouts for liability claims or settlements for lawsuits (Young 2000).

The authorization of the use of force is an aspect of police work that makes it unique to all other professions. This distinctive aspect of police work also contributes greatly to police officer exposure to high levels of risk, which in turn, can lead to litigation, liability claims or citizen complaints. Improper use of lethal and non-lethal force by police officers during arrests, and improper service of due process are two incidents where damages are commonly sought and that settlements are paid out to citizens (del Carmen 1991). Liability Assessment and Awareness International (LAAW) asserts that liability related to police officer use of force can be managed by close supervision (Ashley and Pearson 1993). This group also suggests that department policies should be restrictive when identifying situations where use of force is deemed appropriate in order to keep this type of officer behavior under control. In addition, keeping standards high while reviewing all cases of alleged misuse or abuse of force will allow police executives to get a handle on this type of incident (Ashley and Pearson 1993). These suggestions made by LAAW mirror the findings of research on the use of force, which suggest that restrictive policies and enforced mandatory reporting of use of force incidents can harness this particular police officer behavior (Alpert and Fridell 1992; Pate and Fridell 1995).

Another common police activity that exposes police officers to risk is arrest (Kappeler 2006). In some cases, citizens make claims that police officers made a “false arrest.” False arrest can be defined as “the unlawful seizure and detention of a person” by a police officer (Kappeler 2006). False arrest claims consist of those cases where individuals believe that police officers did not have probable cause to stop or question them or unlawfully detained them. To avoid liability resulting from allegations of false arrest, police officers can obtain a warrant prior to making arrests (when possible). Securing a search warrant prior to arrest takes the authority of determining probable cause away from police officers and places the responsibility on judges. Because making arrests is such a common police action, it is not always possible to obtain a warrant prior to making an arrest. It would also be beneficial if police officers receive thorough training on when it is and is not appropriate to make arrests.

Another high-risk liability incident that often results in organizational loss is the operation of police vehicles. Typical liability incidents involving police vehicles include participation in high speed pursuits, the use of emergency lights and equipment when police vehicles are parked, the placement of people and vehicles during traffic stops and the investigation of traffic accidents, and the failure to use or misuse police vehicle occupant restraints (Ashley and Pearson 1993). Geoffrey Alpert and his colleagues discuss some of the ways to identify and respond to exposure to risks related to police vehicle operations in their book, *Police Pursuits: What We Know*. Alpert and his colleagues suggest that police executives scrutinize the history of their organization’s losses, review both past and pending lawsuits filed against their organization, and then survey police personnel to measure their knowledge of policies and liability issues associated with the operation of police vehicles (Alpert et al. 2000). Since the operation of police vehicles is an essential and required part of policing, the identification and management of the risks associated with vehicle operation becomes a necessary task for police executives. Similar to the research on police officer use of force, the research on police pursuits has found that clarification of pursuit policies, enforced mandatory reporting, and constant monitoring of pursuit activities will reduce the frequency of pursuits, as well as injuries and accidents that can result from this activity (Alpert and Fridell 1992).

Police agencies become exposed to risk when police services are not conducted within defined jurisdictional boundaries. Roughly 10 % of police-involved litigation is related to jurisdictional issues (Liability Assessment and Awareness International Inc. 2001). Police actions such as vehicular pursuits, surveillance or investigation of crimes require that police officers involved in those incidents understand jurisdictional boundaries.

Canine units can also be a source of liability for police agencies (American Civil Liberties Union of Southern California 1992). Some jurisdictions, such as Los Angeles, rely heavily on canine units to help them find and then capture fleeing suspects. As a result, the number of dog bites has also increased. It has been reported "that an average of nearly one person per day is bitten by Los Angeles Police Department canines" and that "more than 900 men, women, and children have been attacked and mauled by these dogs in a 3 year period (American Civil Liberties Union of Southern California 1992)." There is also evidence that the LAPD uses canine units in predominantly minority-populated neighborhoods of Los Angeles more frequently than other neighborhoods (Los Angeles County Sheriff's Department 2000). With police agencies of all sizes beginning to utilize canines in their daily operations, liability could become more of a concern in the future.

Several professional groups and national publications have recognized the potential benefits of using risk management in police organizations and have provided some guidance for the implementation of risk management. The Public Risk Management Association – PRIMA (a professional trade association of risk managers) published a police liability assessment guide that outlines the police activities that pose the greatest liability risks for police officers. PRIMA's liability guide identifies the use of firearms and other non-lethal weapons, police pursuits, defensive tactics, and hostage situations as some of the activities that pose a high level of risk to police organizations. The PRIMA guide notes that adequate training in high-risk incidents, along with department policies that clearly define procedures in high-risk incidents is critical in the control of police liability (PRIMAFILE 2000).

The Police Chief (a magazine geared toward police practitioners) has also featured articles focused on the importance of risk management as it relates to police liability. In addition to highlighting the importance of implementing risk management programs in police organizations, these articles suggest that risk management can potentially bolster the level of police professionalism (Gallagher 1990b). Several articles on the use of risk management by police agencies have been featured in *Business Insurance* magazine, *National Underwriter* magazine, and *Public Risk* magazine, which are publications geared toward risk managers and insurance professionals. These articles highlight the fact that very few police agencies actually have in-house risk management divisions, and that risk management programs can help police executives identify problematic officer behaviors that can lead to litigation and liability claims (Ceniceros 1998; Heazeltine 1986; Wojcik 1994). It is important to point out that all of these articles appearing in these publications are based on professional experiences of risk managers and other insurance professionals, and not based on empirical research.

The implementation of risk management could also provide non-monetary benefits to police agencies. Police executives need to consider the extent to which integrity violations by police officers impact individual officer careers, other police officers working within the same organization, the police organization as whole, and ultimately, the relationship between the police and the community. After non-monetary costs have been identified by risk managers, changes could be made to include information in education and training programs to teach police officers that their decisions and actions cost their departments far more than settlements or liability claim payouts.

Research on the use of risk management by police agencies in the United States can best be described as very limited. Most of the published literature on this topic has been written by professionals that have experience working with police agencies that use risk management, but is not based on empirical research (Gallagher 1990a). Only within the last decade has any discussion of risk management emerged in the academic literature. In his book, *Police Accountability: The Role of Citizen Oversight*, Samuel Walker reports that "One of the most notable failures of both police departments and other city officials has been their neglect of modern concepts of risk management and in particular their refusal to examine incidents that result in litigation and seek to correct the underlying problems (Walker 2001)." He also provides a thorough discussion on the potential benefits that can result from using risk management, early warning systems, and citizen oversight as police accountability mechanisms.

Geoffrey Alpert and his colleagues devote a chapter to risk management and police liability in their book, *Police Pursuits: What We Know* (Alpert et al. 2000). In this chapter, risk management is discussed in the context of a "plan of action" to prevent costly payouts and injuries associated with vehicular police pursuits. The authors discuss risk management in terms of police agencies taking a proactive or "front-end" approach instead of a reactive approach to the implementation of risk management. The "front-end" approach is the idea that police agencies should implement risk management practices *before* a major liability incident occurs as opposed to after (Alpert et al. 2000). This chapter provides a comprehensive overview of the principles and potential benefits of risk management, as well as suggestions for applying risk management practices to control liability related to vehicular police pursuits.

Samuel Walker and Geoffrey Alpert also wrote an article that discusses the use of early warning systems as risk management in police agencies which was included in the book, *Policing and Misconduct* that was edited by Kimberly Michelle Lersch (Walker and Alpert 2002). An early warning system is a data-based management tool which tracks problematic behavior exhibited by police officers (Walker and Alpert 2002). Early warning systems are used to identify problem officers before they do something that will result in some organizational loss (such as liability claims or lawsuits). Once problem officers are identified by the early warning system they receive some form of intervention, which can include retraining, additional training or verbal counseling by his or her supervisor. One could argue that early warning systems could be a useful tool for agencies that have adopted or plan to adopt risk management to control police liability incidents.

The chapters devoted to risk management in the three previously mentioned books are important and informative; however, these chapters did not include any evidence-based research on the use of risk management by police agencies. The first empirical study on this topic did not appear in print until 2004 (Archbold 2004). Carol Archbold conducted the first study of the use of risk management by police agencies in the United States. This study utilized interview and survey data from a national sample, and in-depth case studies of four police agencies that use risk management to control liability.

In the first stage of Archbold's study, telephone interviews were conducted with a nationwide sample of 354 local and county law enforcement agencies employing 200+ sworn employees. The interviews were used to determine if and how police agencies utilized risk management to manage their liability. A series of telephone interviews were conducted with police administrators, city attorneys, and internal affairs personnel associated with all 354 police agencies in order to get a full picture of how each agency uses risk management. The telephone interviews revealed that only 14 of the 354 (slightly less than 4 %) of the large police agencies use risk management in their police liability management efforts (Archbold 2004; Archbold 2005).

Next, each of the 14 police agencies that reported that they use risk management were faxed a survey. The purpose of the survey instrument was to learn more about how risk management is utilized, how risk management fits into the organizational structure of police agencies, and why these police agencies decided to adopt risk management. All 14 police agencies completed the survey. And finally, four of the 14 research sites were chosen for in-depth case study analyses; the research sites include Charlotte, North Carolina; Los Angeles, California; Las Vegas, Nevada and Portland, Oregon (Archbold 2004 and see also Archbold 2005). These risk management programs were visited to see first-hand how risk management is incorporated into liability management in each agency. Further details from this study can be found in its entirety in the book, *Police accountability, risk management, and legal advising* (Archbold 2004).

Darrell Ross and Madhava Bodapati conducted a study that was published in 2006 which examined the risk exposure and law enforcement liability in the state of Michigan from 1985 to 1999 (Ross and Bodapati 2006). This study used records that were collected and maintained by the Michigan Municipality Risk Management Authority (MMRMA), a group that provides insurance and risk management services to law enforcement agencies in the state of Michigan. The purpose of the study was to determine the common types of litigated cases brought against law enforcement agencies in Michigan and to also examine their trends over time. Analysis of the data revealed that incidents involving automobiles without injuries was the most frequent type of claim, followed by use of excessive force, damage or destruction of property, vehicular pursuits without injuries, and false arrest/imprisonment (Ross and Bodapati 2006). The most costly type of claims involved wrongful death/fatalities followed by attempted suicide while in custody, medical care while in custody, suicide while in custody, and automobile accidents which involved injuries (Ross and Bodapati 2006). Overall, the study found that claims filed against Michigan police agencies along with costs associated with those claims are relatively low; annually, there was an average of 752 claims for 151 law enforcement agencies. The authors concluded that "risk management services and agency practices appear to be making a difference overall (Ross and Bodapati 2006)." This study is important as it is one of the first published studies to assess the impact that risk management has on police liability.

If there are both financial and non-monetary benefits that can potentially result from using risk management, why isn't it more common in American police agencies? Risk management professionals that have helped implement risk management programs in American police organizations have identified what they believe are potential barriers to implementation. First, policing has traditionally been focused on crime fighting without any worry about financial costs (Gallagher 1990b). With an increase in litigation involving police officers in recent years, more police executives are becoming as concerned with fiscal responsibilities as they are with their crime control efforts (Ceniceros 1998). Police agencies need resources to be able to provide quality services to the public, which means that they need to utilize their resources in the most efficient way possible.

Another potential barrier is the cost associated with implementing risk management programs. Large cities are able to justify their need for hiring professional risk managers for reducing costs associated with police liability. Medium-sized and smaller cities have a harder time justifying the need for risk management as their exposure to liability is not as great as police agencies serving communities with much larger populations (Los Angeles County 2003). Some less expensive alternatives to hiring a full-time risk manager or implementing a risk management division includes the expansion of the duties for individuals that work directly with police-related liability (such as city managers or city attorneys), employing only a few risk managers to service a large area or region that encompasses several small or medium cities with less populations or more rural areas, or an "as needed" risk management committee consisting of city attorneys, police department representatives and insurance agents or risk assessors (O’Brien and Wilcox 1985).

Confusion about the best way to measure the impact of risk management within police organizations could be another reason that so few police agencies use this management tool. The monetary benefits of risk management are easy to quantify and analyze in regard to impact; however, some would argue that it is impossible to measure the liability claims and lawsuits that have been prevented as a result of risk management efforts. In addition, the impact on police professionalism and the quality of police services provided to the community are also not easy to quantify (Young 2000). Because resources are often limited in police organizations, it could be difficult to justify the need for an in-house risk manager or division if there are no outcome measures for the non-monetary benefits.

Another barrier to the implementation of risk management within police agencies is the lack of research on the use of risk management by police agencies in the United States. There are several websites on the Internet that provide information on risk management training for police agencies. There are also training seminars offered by individual risk management experts that travel across the country training police personnel (such as G. Patrick Gallagher and Gordon Graham). The problem is that there has been very little evidence-based research on the use of risk management in police agencies.

After reviewing existing literature on risk management in policing, it is clear that additional research needs to be conducted in the future. Despite the increase in costs associated with police liability in the last four decades, very little is known about how risk management might help manage those costs. Other than the two studies conducted by Archbold, and Ross and Bodapadi, there have not been any in-depth studies of the impact that risk management has on costs related to police liability. Future research should include studies similar to the Ross and Bodapadi study in other regions and municipalities across the United States. The use of risk management by medium and small police agencies should also be examined in the future. It should not be assumed that medium and small police agencies do not have organizational loss related to liability incidents. The use of early warning systems as part of risk management efforts should also be examined as there is a growing interest in the use of this particular oversight mechanism. The extent to which risk management enhances police professionalism and police officer accountability should also be studied in the future. In conclusion, we still have a lot to learn about the use and impact of risk management in American police agencies.

Robbery

Philip J. Cook
Sanford School of Public Policy,
Duke University, Durham, NC, USA

Overview

Robbery is a violent crime but also a property crime since the motivation is theft. It is a fear-inspiring crime since it typically involves an unprovoked attack by strangers. In the United States, there has been a large decline in robbery rates since the peak in the early 1990s, especially in the largest cities. Some of the pronounced patterns in robbery are just what we would expect if robbers were rational actors seeking a quick score by gaining physical power or control over the victim. Most robberies are committed with lethal weapons and involve two or more perpetrators, usually young males. Gun-wielding robbers are more likely to choose stronger victims and to successfully complete the theft without much resistance. Nonetheless, gun robberies are much more lethal than robberies with knives or clubs. A variety of situational and police-manpower approaches to robbery reduction have been successful.

Introduction

Robbery is a crime of violence motivated by theft. The spectrum of robbery ranges from schoolyard shakedowns for lunch money to bank holdups with losses reaching into the millions of dollars. Property losses from robbery are, however, usually small or nil, and it is the violence that makes robbery such a serious crime.

Robbery is particularly fear inspiring because it usually involves an unprovoked attack by strangers. In that regard it differs from assault, which typically involves an altercation between acquaintances. The public concern about "crime in the streets" is to a large extent a concern about robbery, and that concern may have profound effects on the life of the city, through its influence on choices about where to live, work, shop, and go out to dinner (Cook and Ludwig 2000). James Q. Wilson and Barbara Boland note that "[i]t is mostly fear of robbery that induces many citizens to stay home at night and to avoid the streets, thereby diminishing the sense of community and increasing the freedom with which crimes may be committed on the streets" (Wilson and Boland 1976, p. 183).

This entry provides a description of trends and patterns in robbery using police statistics and statistics from crime surveys. The focus is on data for the United States, which has the best established of the national crime surveys. The survey data support a fine-grained analysis of the age, sex, race, and number of robbers and victims involved in an incident, as well as the type of weapon and the outcomes of the confrontation with respect to theft and injury. It is helpful to understand these patterns through the lens of the robbers' instrumental concerns – identifying lucrative "targets," preempting resistance, and avoiding arrest – although some violence is simply gratuitous.

Robbery prevention efforts include private protection efforts for prime commercial targets (guards, closed-circuit cameras, reduced cash on hand) and directed police patrol against street robbery. Probably more important has been the evolution toward a cashless economy, reducing the robbers' chances for a quick payoff. Reducing the overall robbery rate is not the only goal – a second public goal is harm reduction. For example, measures to reduce gun use in robbery have the potential to reduce the rate of serious injury and murder.

This entry consists of four main sections and a conclusion. The first section discusses robbery rate trends in the United States since the 1960s – increasing through 1981, down since 1991, and fluctuating in between – and relative to rates elsewhere. The second section, based on victimization dates combined for the years 2000–2005 to provide sufficiently large numbers to support generalizations, examines the demographics of robber perpetration and victimization and robbery outcomes (property loss, injury, and death). The third discusses robbers' strategic choices about whom to rob and how, with what weapon, and what differences those choices make. The fourth discusses interventions aimed at preventing robberies.

A number of conclusions are offered:

- Although data comparability issues preclude confident assertions, American robbery rates as shown in official data and victims' reports appear comparable to those of other developed countries.
- Official and victim data concur in showing a very substantial decline in robbery rates since the early 1990s.
- Most robbers are male (more than 90 % in 2000–2005), young (74 % under 30), and African American (54 %).
- Most robberies do not yield high profits for robbers (only 29 % yielded cash) but nearly half of victims are physically attacked.
- Robberies with guns are less likely to result in victim injuries than are other robberies but are much more likely to result in death.
- A variety of situational and police-manpower approaches to robbery reduction have been successful.

Data and Trends

The volume, trend, and patterns of crime can be measured by the use of two sorts of data: victimization surveys and records of crimes known to the authorities. A careful analysis of data for eight high-income nations offers insight into the difficulty in developing reliable measures (Farrington et al. 2004). As shown in Table 1, the recorded rates circa 1999 ranged from 0.5 per 1,000 (for Switzerland) up to 1.5 per 1,000 (for both the United States and England and Wales). But the survey estimates were far higher and suggest a different lineup; for example, while the survey rate for the United States was 2.5 times the recorded rate during the 1980s and 1990s, for the Netherlands the survey rate was nearly 15 times as high as the recorded rate and was a multiple of the US survey rate. Furthermore, in several of these nations, the trends in the survey measure look quite different than the trends in the recorded measure.

Of the various national crime surveys, the United States National Crime Victimization Survey is best established, generating annual estimates since 1973, and also has an important technical advantage over the others. The NCVS interviews the same households every 6 months over seven cycles, encouraging the respondents to use the previous interview as a mental baseline to define the relevant period. That device helps limit an important source of error in survey-respondent reports, namely, the tendency to report important victimization experiences that occurred outside the specified interval (6 months or a year) – a recall problem known as "telescoping." Other nations do not use this costly procedure and hence may have more telescoping and a positive bias to survey results.

The NCVS helps uncover the "dark figure of crime" that goes unreported to the police. In 2010, for example, the NCVS estimated 568,510 noncommercial robberies, compared to 367,832 robberies of *all* types tabulated through the Uniform Crime Reporting (UCR) system which compiles crimes known to the police. Only about 40 % of noncommercial robberies are reported to the police. The NCVS data are also useful in providing the statistical basis for analyzing demographic patterns of violence – both of the victims and of the perpetrators (based on respondents' reports of their impression of the age, race, sex, and number of assailants). They also provide an empirical basis for characterizing process and outcomes of criminal incidents.

Since the interview subjects are households, commercial robberies and other crimes against businesses are not included. According to 2010 UCR data, about 40 % of robberies reported to the police occur in businesses. The true percentage may be lower if businesses are more likely to report victimization than are individuals.

For the period since 1973, the NCVS data indicate that victimization rates for personal robbery were cyclical with peaks in 1974, 1981, and 1994; since 1994 there has been a sustained drop from 6.3 per 1,000 to just 2.2 per 1,000 in 2010. UCR robbery rates have roughly the same peaks and

Robbery, Table 1 Robbery rates, record, and survey data

	Time period	Growth, survey data (percent)	Growth record data (percent)	Recent recorded rate per 1,000	Ratio: survey to recorded rates
England and Wales	1981–1999	95	266	1.5	6.1
Scotland	1981–1999	61	22	1.0	3.6
Australia	1983–2000	0	300	1.2	7.9
Canada	1981–1998	2	−9	.9	9.7
United States	1981–1999	−51	−42	1.5	2.5
Netherlands	1980–1999	25	270	1.1	14.8
Sweden	1980–1998	NA	85	.7	9.0
Switzerland	1985–1999	41	48	.5	14.2

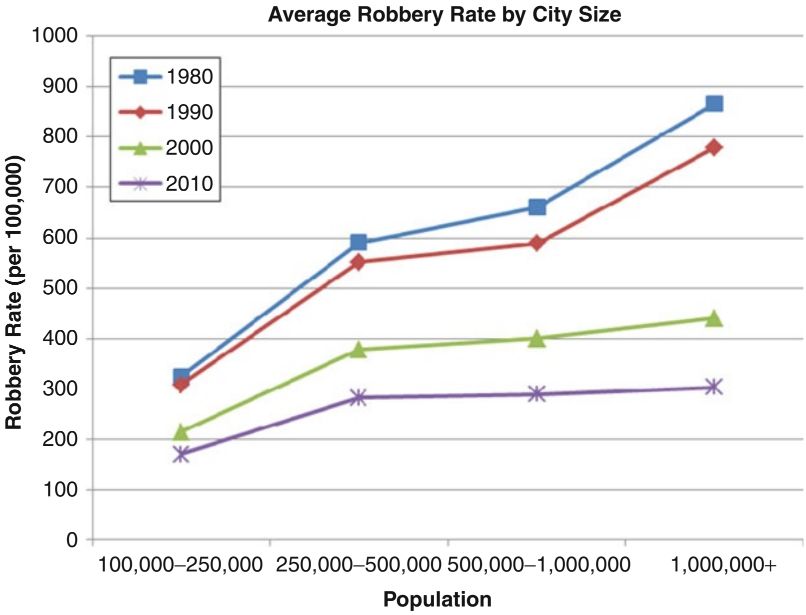
Robbery, Fig. 1 Homicide and robbery rate

valleys as the NCVS rates, and they too show a strong downward trend during the 1990s (Blumstein et al. 1991). As documented by Alfred Blumstein (2000) and shown in Fig. 1, UCR robbery rates have moved up and down for the last several decades in synch with murder rates which are the most reliably measured of all crime rates. (Note that the homicide rate has been scaled up by a factor of 25 in this diagram so that it is on a similar scale as the robbery rate.) It appears, then, that the UCR robbery trends are reliable.

The extraordinary reduction in robbery and other violent crime during the 1990s remains something of a mystery – no expert *predicted* this decline – but some credit surely goes to increases in the size of police forces and stringent sentencing policies that greatly increased the prison population (Blumstein and Wallman 2000; Cook and Laub 2002; Levitt 2004; Blumstein and Wallman 2006; Zimring 2007; Zimring 2012). The crack epidemic that began in the mid-1980s contributed to the surge and later decline of robbery: by one account, crack users turned to robbery rather than other forms of theft (such as burglary) because it was the quickest method of obtaining cash (Baumer et al. 1998). Other plausible (but

Robbery, Fig. 2 Average robbery rate by city size



contested) explanations for the drop in robbery and other violence include the sustained economic expansion of that period, innovations in policing, the delayed effects of the legalization of abortion, and the removal of lead from gasoline.

The 1990s crime drop affected all geographic areas. The greatest percentage improvements occurred within metropolitan statistical areas (MSAs) and especially among large cities with populations over 250,000. All the 25 largest cities experienced noteworthy declines in homicide rates from their peak year (mostly in the early 1990s) to 2001, declines that ranged as high as 73 % for New York and San Diego (Levitt 2004). New York City alone had 17.5 % of all US robberies in 1990, but just 8.4 % in 2005. Remarkably, robbery, always the quintessential urban crime, was no longer correlated with city size by 2000. Figure 2 shows how the urban pattern of robbery rates changed over four decades.

Patterns of Commission, Victimization, and Violence

In what follows, robbery patterns for the United States as a whole are documented by the use of data from the NCVS on noncommercial robberies. The years 2000–2005 are combined to provide an adequate sample of incidents.

Demographics

Robberies are often committed by groups of offenders. For the period 2000–2005, 18 % of incidents involved two robbers, and 20 % involved three or more. (There has been a pronounced trend toward more solo robberies; just 50 % of robberies in 1980, by 2005 they were up to 62 %.) Such incidents are classified here according to the victim/respondent's report of the *oldest* robber's age or race. Groups of robbers almost always consist of demographically similar individuals, with the partial exception of sex: 11 % of robbery incidents involve at least one female offender, but she teamed up with a man in over one-third of those cases.

In robbery, unlike other types of violent crime, the victim and perpetrator are usually strangers (65 % of incidents) and are drawn from different demographic distributions. The majority of robbers in the United States are male, young (36 % under 21, 74 % under 30), and African American (54 %), while the victims are more representative of the US population. There is some tendency for likes to rob likes with respect to age, race, and sex (Cook 1976), but with notable "crossover" – a majority of victims of black robbers are white, and most female victims (37 % of the total) are robbed by males.

Robberies can be classified by location, and for this purpose it is best to get the full spectrum of possibilities, including commercial robberies, which requires UCR data. In 2011, 44 % of all robberies known to the police were on the street and 17 % at a residence. The remaining 39 % were at convenience stores, gas stations, banks, and other commercial locations. The nationwide drop in the robbery rate during the 1990s was concentrated on street robbery, with relative increases in residential and commercial robbery.

Outcomes

When the celebrated bank robber Willie Sutton was asked why he robbed banks, he allegedly replied "because that's where the money is." The NCVS provides data only on noncommercial robberies, committed by robbers who generally did not follow Willie Sutton's putative guidance. Combining all incident reports for 2000–2005 with at least one adult male robber, it turns out that the robbery was unsuccessful in fully one-third of the cases, either because the robber was scared off or the victim had nothing to offer. Cash was stolen in only 29 % of all cases. In the minority of cases that were successful, the median cash stolen was $90. In these and other successful robberies, the loot may include jewelry, clothing, credit cards, household items, and sometimes (in a "carjacking") a motor vehicle. But only a quarter of successful robberies resulted in theft of items worth $250 or more.

The other proximate outcome is injury to the victim. About half of victims report being physically attacked by the robber (rather than just threatened), and one-fifth require medical treatment. Some victims are seriously wounded or killed. In 2011, the FBI classified 734 murders as robbery related (6 % of all murders), which suggests as an order of magnitude that 2.5 in 1,000 robberies resulted in death that year. The true robbery-murder count is probably higher – one detailed study of Chicago robberies found the police department was conservative in using that classification (Zimring and Zuehl 1986).

Since the greatest threat from robbery is the victim's serious injury or murder, it is of considerable interest to know what distinguishes those incidents from the great majority in which the victim comes through unscathed (at least physically). One study compared robbery murders (as documented by the FBI's Supplementary Homicide Reports) to robberies, finding similar distributions with respect to prior relationship (primarily strangers) and demographics (Cook 1987, p. 366). But there was one important difference between robbery and robbery murder – the types of weapons used. About two-thirds of robbery murders are committed with guns, while less than *one*-third of robberies involve guns. Gun robberies are three times more likely to result in the death of the victim than knife robberies, and knife robberies three times more likely than robberies with other weapons (Cook 1987). While it has been much debated whether the type of weapon has a separate causal influence on injury (an "instrumentality effect"), as opposed to merely reflecting the offender's intent, a variety of evidence favors instrumentality (Zimring 1972; Kleck and McElrath 1991; Wells and Horney 2002). A regression analysis of changes in robbery-murder rates in 43 cities found a close relationship between the robbery rate and the robbery-murder rate, as if the latter were simply a probabilistic byproduct of the former. Every additional 1,000 gun robberies added 4 robbery murders to the city's total, while 1,000 nongun robberies added just one robbery murder (Cook 1987, p. 373).

Strategic Choices

Observed outcomes of injury and theft are the result of a series of choices made by the robber and his intended victim. The robber (or group of robbers) chooses the victim, the weapon, and the technique, while the victim must decide whether to cooperate or resist. Based on interviews with robbers and other evidence, it is safe to say that robbers' choices reflect a desire to preempt resistance, secure as much loot as possible, and then make a safe getaway, although actual behavior in these fraught encounters is not necessarily rational (Conklin 1972; Wright and Decker 1997; Jacobs 2000). One useful concept is the "power" of the robber to gain the victim's compliance (Cook 1976). Power depends on the weapon used by the robber; a gun, by creating a lethal threat at a distance, is most powerful, enough for a single robber to control several victims at once. Accomplices also enhance power, as does skill and experience. A solo offender who lacks a gun or accomplices is more likely to select a woman or older person as victim – a majority of gun robberies, on the other hand, are directed against relatively robust commercial targets (Cook 1980).

A multivariate analysis of NCVS data for 2000–2005 (all robberies committed by an adult male) confirms that the chances of successful theft are greatly enhanced when a gun is used or the robber has accomplices. A gun also enhances the amount of loot in those robberies that are successful, in part because gun robbers are able to choose more lucrative targets (couples, males age 25–54), who might otherwise be in a position to defend themselves. This analysis of the payoff to robbery technique can be used to compute the value of using a gun as opposed to, say, a knife. Other things equal, the likelihood of successful theft increases by 12.5 % points, and the average value of loot in successful robberies almost doubles, when compared to using a knife (the second-best weapon alternative from the robber's perspective).

Robbers use different methods for gaining compliance depending in part on the circumstances. The standard technique in a gun and knife robberies is to threaten without actually attacking (78 % and 64 % of gun and knife noncommercial cases, respectively), which is usually sufficient to gain compliance. The standard technique in unarmed robberies or robberies utilizing sticks and clubs is to attack physically (over 60 % of cases) and then attempt to take the valuables by force. The chances of injury follow the same pattern, ranging from just 11 % for gun robberies to 36 % for robberies with clubs. Of course when a gun is present and fired, the resulting injury is far more likely to be fatal, and the chances that the victim will be killed are highest for gun robberies (as documented above).

Detailed case studies have provided evidence that the violence in robbery is not necessarily instrumental. The offenders may exploit the situation by raping or otherwise tormenting the victim. In some cases of robbery murder, it would appear that the killing was purely gratuitous or even "recreational," stemming from the heat of the moment and the interplay between accomplices (Cook 1980; Zimring and Zuehl 1986). Robbery defendants who injured their victims are more likely than others to be arrested for assault following release from prison than are robbery defendants who did not use violence (Cook and Nagin 1979; Cook 1987), suggesting a taste for violence.

The strategic choice framework predicts that drug dealers and other actors in the underground economy would be especially attractive targets, both because the loot is likely to include large amounts of cash and drugs and because victims are not likely to inform the police – although they may attempt to retaliate (Jacobs 2000; Topalli et al. 2002). Crimes of this sort are unlikely to become known unless someone is killed, and indeed, it is common to have a drug connection with robbery murder (Zimring and Zuehl 1986). As observed by one group of criminologists studying drug-dealer robbery, "One of criminology's dirty little secrets is that much serious crime ... takes place beyond the reach of the criminal law because it is perpetrated against individuals who themselves are involved in lawbreaking" (Topalli et al. 2002).

Victims as well as offenders make decisions that influence the outcome. Most important is whether to comply with the robber's demands and, if not, just how to resist. In the NCVS sample of noncommercial robberies, about one-third of victims attempted to forcefully resist. Resistance is associated with a reduced chance of successful theft, but an increased chance of injury. Victims of gun robbery are less likely to resist than those confronted with other weapons. A practical question often arises of whether it is prudent to resist a robber, but unfortunately it is not possible to extract a clear answer from survey data.

Most victims act on the commonsense rule that it is foolish to resist a robber with a gun, and commercial employers often instruct their clerks that if there is a robbery, they should not attempt active resistance.

Interventions

The threat of robbery victimization has far-reaching effects on urban life. The effort to avoid this threat may influence choices about where to live, whether and where to go out at night, the use of public transportation, carrying a weapon, and so forth. A reduction in the robbery threat in a city enhances the residents' standard of living and may well contribute to the city's growth and prosperity (Cook and Ludwig 2000). There are a variety of specific measures, both private and public, that hold some promise in this regard, either in reducing the overall robbery rate or in reducing the related harms.

The private efforts to reduce robbery are to a large extent applications of "situational crime prevention" (Clarke 1983, 1995), which attempts to reduce criminal victimization of specific targets by making them less attractive to criminals. The goal is to make it more difficult to complete the crime successfully, reduce the payoff if successful, and increase the risks of arrest and conviction. For especially attractive robbery targets, most notably banks, an array of measures are typically put in place, including guards, surveillance cameras, alarms, and dye packs mixed in with the cash. (Private security against robbery and other crimes is a rapidly growing industry, and there are now as many private guards as there are sworn police officers (Cook and MacDonald 2011).) Studies suggest that convenience stores, which are frequent targets of robbery, can reduce the risk by installing bright exterior lighting and keeping at least two clerks on duty at night (Loomis et al. 2002). A variety of common robbery targets, including all-night businesses and public buses, have attempted to discourage robbery by limiting the amount of accessible cash – and advertising that fact.

One of the most controversial private responses to the threat of robbery is keeping a gun handy. The immediate goal for those who keep or carry a gun for self-protection is to enhance the capacity to resist a robbery, other assault, or criminal intrusion to home or vehicle. But the laws governing gun possession and carrying have taken on great significance in part because of the claim that widespread gun carrying would create a general deterrent to robbery and other assaults that would benefit all. With that in mind, and under pressure from gun-rights advocates, most states in the USA have loosened their restrictions on carrying concealed firearms (Vernick and Hepburn 2003), now mandating that all who meet minimum requirements have the right to a concealed-carry permit. These "shall issue" laws have been extensively evaluated with conflicting results (Lott and Mustard 1997; Black and Nagin 1998; Ludwig 1998; Lott 2000). A careful review of the evidence suggests the true effects on crime are almost certainly small and are statistically undetectable given other more powerful forces that influence crime trends (Donohue 2003).

There is less controversy about the public's stake in robbers' choice of weaponry; a gun robbery has a greatly enhanced risk of turning deadly when compared with robberies with knives and blunt objects. Gun involvement by young men is closely linked to the prevalence of gun ownership in the community, but there are a variety of regulatory and policing methods that show promise for discouraging gun carrying and criminal use (Cook and Ludwig 2006). One organizing principle for such interventions is to make guns a liability to urban youths and criminals by patrolling against illicit carrying, offering rewards for information on illegal guns, and giving priority to prosecution and sentencing of gun robberies.

More generally, expanding and focusing police resources directed at street crime is a costly but effective method of combating robbery. In England and Wales, the Street Crime Initiative provided funding for anti-robbery policing in 10 of the 43 police-force areas, with large, statistically discernible effects on robbery rates (Machin and Marie 2005). Other studies have provided additional support for the conclusion that additional police suppress crime rates (Levitt 2002; McCrary 2002; Levitt and Miles 2007). The effect sizes are large enough to make a strong case for expanded police funding (Donohue and Ludwig 2007).

Conclusions

When people worry about "crime in the streets," their first concern is robbery. While the financial losses from robbery are of little consequence overall, the fear of robbery and the actual injuries it causes have a profound effect on the quality of life in certain neighborhoods.

A quick payoff is the allure of robbery for many drug addicts and other criminals. The surest quick payoff is cash, but that is becoming increasingly rare as a means of exchange in the first world nations – except for transactions where preserving anonymity is important. For that reason robbery may focus increasingly on underground markets and as a result become less visible but perhaps more violent. Policies to reduce the scope of the underground market will thus be helpful in the effort to curtail robbery.

Role and Function of the Police

Peter K. Manning
College of Criminal Justice, Northeastern
University, Boston, MA, USA

Overview

There is no accepted systematic theoretical paradigm within which policing is viewed. The role and function of the police are typically assumed, and a measurable facet such as crime control is defined as the scholarly interest. Those viewed as essential policing functions and how they should be performed are products of the theoretical context within which the police are viewed, their perceived political role, and the posited character of the police organization. As a result, there are alternative versions of policing and what it is good for. These might be called “practical theories of police” in that they emphasize and valorize selectively some aspects of policing while remaining wedded to the basic deployment strategies of random patrol, crime investigation and response to citizens’ calls while altering the rhetorical strategy, and some policing tactics. They are the products of fads and trends in the sense that they reflect efforts of the police and some scholars to redefine the product without modifying the structure that produces it. For this reason, it is best to treat policing in a somewhat abstract fashion, detailing its roles and functions, rather than providing overviews of research out of context. Research shows that functionally and structurally police in North America and the UK have changed very little (Maguire 2003; Weisburd and Braga 2006), and field studies suggest there is little evidence that police practices have changed (Moskos 2008; Loftus 2010). The study of the role and function of police has changed.

In this context, a review of the role and function of the police is a slightly contentious endeavor. This entry will have the following themes. The first is a necessary broadening of and consideration of systems of law within which police function and types of policing. The second theme concerns the role of police in the drama of governance, the police mandate, and their role as a functional and dramaturgical actor. The third theme is the police organization seen as a collection of roles, segments, and cultures. These are in effect various ways of seeing the role and function of the police. This outline is a kind of funnel that contracts from the beginning characterization of socio-legal types of policing systems to police systems and their role in governance in Anglo-American societies to the organization and its internal configuration. The entry concludes with some reflections.

The Rise of Police Studies

Let us consider the development of police studies in periods characterized by quite different intellectual, policy, and practical focal concerns. The foundational work on the police as an organization in the context of government was done by lawyer-administrators such as Arthur Woods, Harry Emerson Fosdick, and Bruce Smith and later by the Commissioner of the Police of the City of Chicago, O. W. Wilson (Wilson and McLaren 1963). The first modern phase can be traced forward from the work of Westley (1951, 1970) focused on the occupational culture and its support for violence; Banton's (1964) comparative ethnographic study of the police role in urban and rural context; Skolnick's work on policing on the streets as a form of justice without trial (1966); Reiss and Bordua's (1967) empirically based analysis of the police as organization, and their later paper (Bordua and Reiss 1967); Wilson's concise and masterful depiction of the dilemmas of police administration and the socio-political context of the role (1968); Bittner's formulation of the nature of the role as situated intervention (1970); Reiss's trenchant illumination of the public-driven nature of policing (1971); and Van Maanen's (1973); outline of the job as seen from the ground. Manning (1977); and Cain (1973); both influenced by Banton, complemented these works with research on English policing and the role of the officer. A second phase appeared as demands were voiced for changes in policing. This was a product of political response to the riots and protests of the late 1960s and early 1970s. Here, the demands of policy, concerns about extreme racial divisions that still exist, rioting and the police response, and the rise of reported "crime" emerged as political issues. The Law Enforcement Assistance Administration (LEAA) was created and funded research, and the metaphor of a criminal justice system was advanced in the Report of the President's crime commission. A third phase featured more intellectualized version of the same concerns arose in 1980s: a burst of more police-centric applied approaches such as community policing, "broken windows" policing, problem-solving policing, and applied managerial techniques such as crime mapping and crime-oriented meetings and analysis appeared. These quickly became amalgamated with increasingly sophisticated methodological approaches oriented exclusively to reducing officially recorded crimes and trumpeting the "experimental method" (Sherman 1992). This research featured the claim that arrests-are-deterrence and stimulated a slight but abiding countertheme of broader conception of both method (Sampson 2010) and the role and function of policing (Harcourt 2001). A fourth phase emerged arose with the drop in officially reported and recorded crime (ORC) in the early 1990s. As crime fell, the costs of policing and the number of police officers escalated in spite of this reduction that has continued until the present. A shift to a focus on stops, especially of minorities (Justice Policy Institute 2012), arrests for misdemeanors, downgrading of crimes, and drug arrests occurred in the iconic NYPD. There is considerable evidence that this was driven by management pressures (Eterno and Silverman 2012). In many respects, we are still in this fourth phase that combines a concern with crime reduction and national security post 9.11.2001. Perhaps, has it has in Europe, the economic crisis will stimulate consideration of restructuring policing, altering the conditions of work such as pensions, disability, retirement, overtime, and pay (Winsor 2012).

By way of summarizing these four modern phases, metaphorically speaking, the study of the police funded became a dance of convenience in which the music was supplied by Foundations (e.g., the Police Foundation, Heritage Foundation, Manhattan Institute), the Home Office in the UK and the Department of Justice in the USA (National Institute of Justice and the COPS agency), the police professional associations (IACP, PERF and in the UK, ACPO), and the big city police chiefs and commissioners. That is to say, the interests of the police-as-occupation, represented by their associations and leaders, the cooperative governmental agencies, and foundations, created the body of funded quantitative research captured in little technical studies that now dominate the journals. Michael Banton argued many years ago that there is a danger of developing a **sociology for the police** rather than a **sociology of the police**. The danger is quite simply that an occupation's interests, those of the police elite and supporters, are in large part but not exclusively a reflection of their political interests and, to a lesser degree, scholarly interests and theories. These two slightly overlapping streams of activity, scholarship and applied police-generated research, define a dialectic within police studies. They are comments on what the police are good for. No serious scholarship can be an illusionary reflection of the interests of the subjects of its inquiries.

Socio-Legal Systems, Types of Policing, and Defining Policing

Policing varies in historical, cultural, and social context. Even in the Anglo-American police world, it is not and never has been focused on or centrally concerned with legally defined crime and the common law that guards citizens' rights – it deals and defends politically defined order and ordering. Most research and analysis in the role of function of the police assumes a stable political order, while this is problematic even in stable democratic societies. Windows into policing are found in countries in the last century in states of civil war (Ireland, Spain, Ireland, China, Eastern Europe, especially Eastern Germany, the former USSR), occupied countries during World War II (primarily in Eastern Europe, France, the Netherlands, and Belgium), emerging states (Kosovo, Slovenia, and Croatia), police states such as Nazi Germany, Mao's China, and Stalin's Russia, and in radical transitions within and between legitimating systems of law, e.g., the current Middle East. These are anomalous systems which provide sharp contrast to democratic policing systems in stable societies.

Policing in relatively stable societies as a social form is grounded in a systems of law and cultural regulations. These include the following: (a) Islamic fundamentalist, (b) civil law-based systems (Western Europe outside Ireland and the UK, Latin America, Asia, Africa except for South Africa), (c) common-law-based systems (the remainder – North America, the UK, Ireland, etc.), and (d) quasi-legal martial law-based systems in occupied nations. There are also "mixed" systems such as those found in Macau, Hong Kong, Wales and Scotland, South Africa, Quebec, former colonies, and the State of Louisiana. All former colonial countries remain "layered" with local systems of conflict resolution operating in uneasy conjunction with formalized systems of the former colonial power. Some of these are still operating with what Weitzer (1996) calls "divided society models" of policing. These socio-legal systems in turn provide the umbrella under which the police operate in the sense that the two systems of primary concern here, the common law and the continental system, arise from deeply different conceptions of the role of the police and their connection to the state and, more specifically, the role of state security in the police mandate.

The image of policing in English language literature draws on the Peel model of policing, ignoring other sources of the role and function now apparent. While the "tradition" in Anglo-American policing studies is to cite Peel's aims and the restrained, uniformed, reactive, citizen-oriented, and crime-concerned service worker, "policing" in the Western world must include acknowledged and displayed and dramatized policing that is secretive, uses illegal means, focuses on spying, surveillance, and the use of informants in the interest of protecting the state. This form, sometimes called “high policing” (Brodeur 2010), conflates legislative, policing, and judicial powers in its actions, and polices “appearances” – i.e., as such the police watches and tracks citizens viewed as representing risks to the state and anticipates this rather than responding to actual behavior. This is an often denied yet essential feature of democratic policing (see below). As Jobard (this volume) correctly notes, this is a matter essential to the definition of all policing and its hidden yet enduring connection, even in democracies, to state security. Viewing the continental system, with explicit linking of violence and the law that the anomies of policing are most apparent, reveals the point at which the law’s limits are revealed and where violence is needed (Jobard). In this context, the connection of “politics” and “policing” assiduously blurred, denied, and obfuscated in common-law societies is made visible. The covering notion that public police are Peel-like in nature and engaged in crime prevention primarily and have little or no obligation to security functions, even post 9.11, remains. It is clear that on the one hand, the organization undertakes many tasks, as Bittner (1970) argues, in effect anything for which one “calls the cops,” while on the other hand, and that which is emphasized and dramatized as “the job” and how it should be carried out varies in the views of scholars and practitioners. Crime control is a misleading oxymoron.

Public policing has been elevated as the primary and most central of all formal sanctioning systems but bureaucratic full-time policing is a fairly recent invention and it still rests on citizen compliance, the support of complementary legitimate institutions, and the willingness of officers to serve a neutral role and to stay loyal. Policing of all kinds is tertiary to other forms of control, the primary controls such as family and peers, secondary controls such as neighborhoods, and formal associations such as schools and churches. Policing monitors and patrols order but does not create it. It often creates disorder and amplifies and sustains it when seeking to reduce chaos. It applies coercion to sustain politically defined orders. Examples of this are found easily in postriot overreactions, gratuitous violence, killings, and beatings such as happened in New Orleans in 2005. Public policing is one layer of a social control, the most visible perhaps, but, nevertheless, one of many kinds of social control.

Self-help or revenge remains the most common mode of conflict resolution, and there are modes of quasi-official policing associated with organized crime, rebellious, and resistance-oriented groups. These semi-organized systems sanction deviance often in defiance or contrary to the law but are seen as “fair” and “just” even as they are rooted in revenge rather than neutral third-party governmental actions. There are three other types of quasi-official informal policing and sanctioning organizations, i.e., those with legitimate use of force (Klockars 1985): occasional (ad hoc, hue, and cry obligations of citizens traced back to Edwardian period in England), obligatory (posses, vigilantes), and voluntary (militias, reserves, auxiliaries, the historic Texas Rangers), most of which are public, but some have been private policing, e.g., the Ulster volunteers of 1912–1914 later to be called the “b” special constables. Neighborhood associations and patrols are of this sort but are problematic in part because they have little or no accountability.

Of late, it is recognized that secondary social control occupations, those who regulate and respond to behavior informally in public and quasi-public spaces, are important semiformal control agents. These include such occupations as teachers, priests and clergy, bus and cab drivers, train and bus conductors, traffic wardens, and crossing guards.

In the last 20 years, new forms that lie between formal and informal types of policing have been officially sanctioned in the UK and other parts of Europe. Let us call these hybrid policing. This sort of policing is now included in the “police family” and denotes non-sworn officers such as PCSOs in the UK and enterprise zones in the UK and urban development zone agents in the United

States. There is confusion in regard to legitimacy of such agents because these functions can be carried out by such organizations but also by police employed privately, police employed and paid by the public, or some amalgam of these. This can also include third-party policing. Some mixed or hybrid policing, policing with combined uniforms with symbols of both private security companies and public police as in Lincolnshire, is a form of "out-sourcing." This term indicates using public funds to pay for agents to carry out functions connected the public good, e.g., issuing traffic tickets and providing order maintenance and some regulation that does not entail arrest nor authority in excess of that of the citizen. This syncretic innovation is rationalized on the grounds that it reduces costs, in part because it is budgeted differently than routine yearly personnel costs. Such policing functions have a mandate in the sense that they are licensed, legitimate, and have territorial limitations. They draw also on the mandate of public police by simulating their uniforms, interactional style, and the decoration of their vehicles and symbols.

Private Policing. While the line between public and private policing practices is blurred, private police act in the interests of those who employ them, are concerned primarily with the protection of information and property, and employ many structures and tactics to achieve this. These functions are usually connected to policing given private or semipublic areas (malls, sporting venues, etc.) In the United States, private police may carry visible weapons. They may or may not include some arrest powers in private spaces for trespassing. It is important to note also that the RCMP in Canada provides contract policing in Canada outside Quebec, Newfoundland, and Ontario that public police in the Anglo-American world work for private companies routinely and that there are many circumstances of cooperation between public and private police. This cooperative pattern is in part due to the fact that many retired senior police officers have now been employed by security firms or have begun their own. Police officers are also paid to also carry out functions that were previously exclusively public police functions such as insuring traffic safety around construction projects. In Boston these are called "details" and officers are paid by private corporations via the public payroll. The point here is that policing with private interests as the mandate only marginally, if at all, serves the public welfare, even when policing quasi-public property. The functions carried out by private police are far greater than those connected with quasi-public space (Forst and Manning 1999: 103–106). There are very large private security companies, alarm companies, and money transport companies that fall under the label of "private security" (Johnston 2003).

The public police are usually the referent of "police," but they are but one visible node in the larger network or web of policing functions. The police organization includes those who are not warranted or sworn officers. In addition, the organization can include reserve constables, cadets, and part-time officers. The organizational culture includes more than the segmented occupational culture of the police, and the percent of officers in uniform patrol in the UK has been declining for some years (Winsor 2012). The range of functions carried out by the public police is diverse and complex (Forst and Manning 1999: 27–29). Maguire (2003) lists some 28 discrete tasks carried out by patrol officers, and Winsor (2012) lists three times as many roles citing English forces. Bearing in mind that role and task are seldom closely connected in policing and that policing is always an open-ended enterprise, these are not helpful in understanding what is actually done on a day-to-day basis.

There are also publicly funded national and state armed forces, state national guards with their own investigative and intelligence units, and federal agencies with negotiated territorial obligations that also police. The ambiguity in the policing roles of the military is in part that they are constrained by the constitution with respect to operations within the continental United States. These functions are at best unclear as to accountability and scope. On the other hand, the US federal government has deemed the operating domain of their agents as unrestricted by traditional borders and costal boundaries.

There is little evidence of continuous cooperation with and across these types of policing and between formal policing agencies (Bowling and Sheptycki 2012).

A Definition of Public Policing. These considerations of types of policing and their relationship to systems of law and patterns of social control shape the nature of what is called policing in any society. So how should one define formal public policing? Consider a generic working definition of *police in Anglo-American societies* (North America, New Zealand, the United Kingdom, Australia, and Ireland), based on seeing the police as an organization rather than policing as a function. It assumes that the police are a bureaucratic organization and emphasizes the political nature of order and ordering, the new powers of surveillance and tracking that are balanced with coercion and violence. The police, because of their rather loose connection to the law and their political nature, act by exception. That is, they act in the shadow of legitimacy and the law and account or explain later only if required. In this sense, they act outside of or merely in the shadow of the law. It is an empirical question whether police practices consistently follow from these features.

> The police in Anglo-American societies are constituted of many diverse agencies, are authoritatively coordinated and legitimate organizations. They stand ready to apply force up to and including fatal force in politically defined territories. They seek to sustain politically defined order and ordering via tracking, surveillance, coercion, and arrest. As such, they require compliance to command from lower personnel and the citizens and the ability to proceed by exception.

The public police as an institution arise as a result of the development of law, differentiation, and functional specialization in a society. It is an institution that cannot survive without the consistent support of other institutions that complement its aims and practices. They are purveyors of organized coercion and the threat of coercion. The supporting institutions must complement the rationality, fairness, and procedural commitment of policing, or else it creates and sustains its own standards beyond review and remedy. This is Weber's argument Weber (1947) in respect to the collaborative nature of rationality in modern societies. The specialized functions of policing that arise as nation-states emerge and develop rest on broader societal consensus concerning fairness and justice arising from the public trust. They are a product in some sense of a balance of powers among executive, legislative, and judicial branches as set out in the original documents of a nation's establishment. One tendency, seen in crisis periods, is for the executive branch to either co-opt the police, making them directly accountable (as they still are in the Republic of Ireland and have been since 1922), or suspend *the habeas corpus* that in effect places the police under their direction. In this situation, the protections granted by legislation and by the courts are bypassed. Clearly, such considerations contain an explicit matter: the role of a "police officer" is determined by the organization's historical, cultural, and political mandate. Because the police officer in common law has original authority, the police organization is a useful fiction legally: it is constituted by the aggregated collection of officers (this is a contested legal concept and concerns the question of where accountability lies – with the officer, the Chief Constable or Chief, or the organization as a whole).

To understand the relationships between and among such a collection of types or clusters of formal policing agencies requires a label, concept, or some metaphoric work, which provides a way to think about policing organizations and that clarifies the relationships.Brodeur (2010) uses the metaphor of a "web" an assemblage of competing, interacting, organizations that function as if they were in a web. Shearing prefers the metaphor of a network with "nodes" and mentalities based on their technology and practices (Shearing 2005). Brodeur and Shearing show in their systematic treatments that "police," their role and function, cannot be restricted, except by exclusion, to the "public police." Nevertheless, the research and concern of scholars until recently has been with the public police seen within the Anglo-American Peel model. This is warranted because of their symbolic importance, their legal mandate, their control of data and exchange of this data with other agencies (Ericson and Haggerty 1997), and their huge and growing public budgets. The focus on the public urban police has meant scholars until recently have ignored for the most part the influence and importance of the range of types of nonpublic policing, private police, informal, hybrids, auxiliaries, and in public police federal police, state police, reserves, cadets, and policing in the interest of high security.

The Police in the Drama of Governance

The police organization acts, has an audience, and is a social object that people understand as real, constraining, important, and standing for something other than just a person in a blue coat and funny hat. The organization has legal status and is a legal actor. It is thus a "social unit" that has collective meaning, consequence, and symbolic significance. It performs. People respond to and animate the organization as real and doing things – fighting crime, being patriotic, issuing statements, and being an expense. It is in this sense a **social actor** with a social role in the game that is society. This is not a playful or whimsical notion; it is a way of considering the multifaceted role of the police in society. The police have many functions as an organization; it acts and reacts, defines issues, and responds to them. In many respects it is reified or seen as real when it is a rather dispersed, ineffectual entity dependent on citizen information and compliance. The police organization has a number of what might be called **governance functions** or dramas that indirectly reflect the role of the police as representatives of governmental authority. It is this representative function that is omitted in banal statements of tasks, roles, or functions, which are usually ascribed to the police officer. These individual roles and tasks, those which might be called **petite functions**, are discussed later. When dealing with "the police" as an actor, it is necessary to bear in mind at the same time that policing is carried out by individuals with a range of choice to intervene or not, when and how to intervene, and how to account for or describe why they acted or not. Even refusing to act is an action of sorts.

Here are some governance functions, ceremonial, or celebratory functions of the police, some of which are ritualized and repeated as a form of reassurance. They could be examined as propositions linking the police to the state. Let us consider these propositions in brief form. The police act as the face of civil authority displaying recognizable symbols, something that stands for something else, on public occasions – parades, funerals and weddings (of their own), and local commemorations. These stimulate collective solidarity because the police act as totems, icons of state authority for the majority. On the one hand, in their service, like the military, they symbolize volunteering for the common good and their injuries, deaths, and quests are sacrifices on behalf of us all. This is not to elevate the police per se, but to note that they play a role similar to that of the sacrificed in rituals in preliterate societies (Hubert and Mauss 1964). On the other hand, these collective occasions of ritual celebration mark and exclude those seen as outside the ambit of conventional acceptance whether they be minorities, lower class members, or immigrants. The police are conduits of governance, use, and display public resources in the name of the common good patrols, rhetorical strategies that outline their role and mandate in society, and tactics of organized action. This dramatizes their centrality to the collective dramas of control. The police are not passive actors who simply accept the legitimacy conferred upon them by tradition: they work assiduously to expand and sustain their own legitimacy as an organization, and this often conflates law as a set of mundane rules, morality as the "ought" and "should" of a society the sacred, and their miscues, malapropisms, and often banal, violent, and unbecoming actions. Their political role of the police is often subtle and less visible than their imagined media-amplified functions. They in fact symbolize their role in society by attending and protecting functions essential to the survival of democracy. These include monitoring voting, courts, judges, juries and court personnel, inaugurations, and massive events that celebrate the society to itself: American football bowl games, world series, and more mundane games also central to collective representation. They protect those whose who are "well known for their well-known-ness," those with an imagined life, "celebrities;" paid football and basketball players, movie stars, football coaches and their minions, and others temporarily thrust into the role of public icons. Why do Alabama state troopers escort the coach of the football team off and on the field? In their more mundane functions, they serve by their actions to define and perhaps obviate the nature of mundane risks and provide palliatives – crime, natural disasters, threats of terrorism, and the like. They communicate via the media their assessments and successes. They minimize, avoid, or redefine their failures. I have never heard a police officer declare publically: "We have failed miserably to contain control etc. . . . . . . .We apologize for this." They are cast as primordial eternal symbols of success. In the world of symbol work, they are active. They produce sharp and framed meanings for distant and unclear matters that lie outside normal experience – terrorism, mass murders, and impending disasters as well mundane matters of crime control. They are translators of the esoteric to the mundane. In this connection, they name, blame, and publicly constrain that which is seen as marginal, wrong, immoral, or in need of some sort of control. In this way they are redistributional agents: they distribute rewards as well as punishments. Those who are not monitored, not stopped, not questioned, or detained are rewarded with the absence of constraint, while those experiencing these are punished both formally and informally. The everyday actions of policing, those seen as profane, alter and maintain the social hierarchy in ways that are unacknowledged by the police themselves. Thus, for example, stopping those they suspect is "the job" and is disconnected from race, class, gender, and status honor. While the police may locate themselves in a mundane and unpleasant world of "dirty work" (Hughes 1971), they do act in the high and low dramas of society. That is, they seek in their everyday work to define and defend social order generally and its vicissitudes as well as dealing with everyday risks and concerns called "crime" or "disorder." High dramas, on the other hand, are those with public cachet, noticed and amplified by the media and for which accounts or explanations are called for. Low dramas are policing as usual. These dramas, via Twitter, YouTube, Facebook, and other social media, can become global-international. While they perform in little theatres, high and low local drama, they can be suddenly featured as heroes, fools, or villains in unfolding international and national dramas. The once little theatres present the events that by *media amplification* become national and international matters – serial killings and mass murders; local disasters, especially if mishandled by the police; hostage negotiations that go bad; and failed high-profile investigations. Less explosive matters – traffic stops, brutal beatings, arrests, mistakes at work – can bubble up and become unforeseen dramas of public concern. Police are expanding their stages and roles. Anglo-American police are now engaged in global policing of various kinds and in various guises (Bowling and Sheptycki 2012): officially and in informal cooperative roles with nonprofit organizations that sponsor volunteer in developing countries and in UN-based peacekeeping. There is a reflexivity about policing as they become aware of their own social capital. They reproduce by habit and practice notions of and images of social control characteristic of the police field. They frame ambiguous events as matters of police concern. They are the central players in communication dramas about themselves. They are asked for their opinions; they hold press conferences and issue press releases; they appear in court and make statements about current events. They reproduce their versions of dramas of control: who is at fault, who is to blame, who will be punished, and why. Think of public police statements about the threats represented by violent and dangerous gangs, brutal and senseless murderers, and unthinking rioters. These are symbolic packages that condense complicated social matters into known entities. The police are active actors, making up and playing roles. In this sense, they play themselves, acting out, mystifying, idealizing, and cooperating through teamwork to produce an imagery of discrete, mannered, and stylized control and service. In other words, much of their playacting is designed to magnify their own importance and is redundant in communicational terms.

The question arises: how does an organization, a handful of people, contain, control, manage, discipline, and punish a vast population in public and private spaces? They must have the cooperation and compliance of their audiences. There is a blurry, cloudy distance and unknown world "out there" that we little know directly. It cries out for some ordering, some coherence. At best, the police act to mark and sustain boundaries – horizontally and vertically – in the moral world of thoughts and feelings. They also actively act in the ecologically defined world of places, both public and private, and in personal and bodily space. They do this by carrying out patrol, stops, and arrests; by maintaining a visible presence; and by gaining access informally to private spaces – homes, buildings, corporations, and shops. They mark and patrol the edges of public space by their presence.

In summary, while the police as an organization have political interests and police officers have personal political interests, they functions as symbols, as representatives. The police organization must assiduously strive to maintain a degree of autonomy in the political web in which it operates, for this perceived neutrality is essential in a democracy. They do carry out governance functions. These functions are done in aid of the state and its power and authority, as well as sustaining the quality of life. While this list of functions is framed as "public policing," these functions can be examined in the context of the various types of policing listed above: informal, occasional, formal, hybrid, private and public, and the policing of the armed forces. Each has a mandate of some kind.

Policing: The Mandate and Acting It Out

All forms of regulation rest upon the base of self-regulation, or at best "self-help" (Black 1983), and mutual dependence, else it fails to become patterned, sustained, and acceptable. This patterning is institutionalization, the development of legitimate, named, and viable modes of accommodation to persistent anomalies, e.g., sin, death, the transmission of property and kinship, and socialization. As such, they are "going concerns" that mobilize human action and expression and customs for meeting the contingent and problematic in everyday life. In this sense, the police are a modern rationalized and rationalizing institution. Police are a legitimate, authoritative, conflict-processing system. Sociologically, and in metaphoric terms, an occupation seeks a socially accepted *license*, and if it succeeds, it strives for a *mandate* or the right to define the proper attitude and conduct toward the work, as well as even the ways of thinking and acting that are a reserved part of the practice (Hughes 1971:289). These are inclusive rights. On the other hand, it means that the occupation may well exclude and sanction those who act falsely in the name of the occupation – frauds, poseurs, or even criminals – and they will elevate that which they do that others may not. This mandate is a tacit bargain or contract between social groups and the occupation. As such, it is historically carved out and periodically defended by police and their allies. Thus, it is an expanding and contracting entity that reflects political, cultural, and economic forces. It is in this sense both shaped and shaping of public events. In part because of its association with authority, it is quasi-sacred and embedded in ritual, ceremony, and protective magic (actions and words that defend the vested interests of the occupation often counterfactually).

Far from being "transparent," policing is grounded in team secrets that are not shared with the public at large (Weber 1947:233) and in legal protection of its investigations and ongoing court cases. Certainly, policing has a mandate that varies by the public tacit acceptance or trust; it varies by race, gender, class, and age. It is best understood in this regard as compared with other occupations – physicians, plumbers, or professional sex workers. Within the ensemble of policing agencies, publicly funded policing maintains its grip on power and authority because, unlike private agencies, informal policing groups, and armed forces, they can enter a "case" into the criminal justice system for processing and potential prosecution. This is among the most powerful negative sanctions available in modern societies, regardless of the outcome of the processing.

This capacity, when combined with the on-the-ground potential for intervention in that-which-needs-responding to-else-it-will-get-worse (Bittner 1970):34, weds inextricably law, power, and authority. This formulation is the edge through which "politics" and irrationality, in the sense that it lacks long-term consideration of the law, justice, or consequence, enter the scene (Jobard, this volume). This "framing" or defining the situation is not simply a here and now situational contingency action; it is the institutionalized basis for police authority.

Policing is a role drama. The role-occupant acts, does things, and decides things, and this variation in individual performance requires what Goffman (1959):30–70 calls a "front" (props, manner, and setting-appropriate behavior) as well as devices to enhance performance: dramatic realization, mystification, misrepresentation, maintaining expressive control, all in all a kind of ritualization of actions that sustain a *definition of the situation*. Recall that each new situation is an unknown for an officer and that patrol officers subscribe to the notion that while an officer may have seen "everything," he/she believes that one must be ready for the unexpected and to cope with it and control it quickly. The parallel is succinctly stated on page one of The Presentation of Self, but one must add the additional line for police: "and manage the outcome authoritatively."

The Police as a Rational-Legal Bureaucratic Organization

The police organizations found in the United States have a number of well-known features and functions. They are diverse in size, with the modal organization small, under 15 officers; they hire and train officers using local standards and preferences, but officers are more educated and forces are slightly more diverse as time passes; they are locally funded and embedded in local politics and issues rather than national party politics; they respond to and are part of the executive branch of government and are therefore loosely tied to and accountable to the elected executive. The American system by design, a product of the revolutionary tradition and the experience of policing under the British as a colony, is "fragmented" made up of many loosely connected part or organizations. There are about 19–21,000 agencies – federal, state, and local – of which an estimated 13,500 were attached to local agencies. A 2004 census (Bureau of Justice Statistics 2007:2) revealed 12,766 local agencies, 3,067 sheriff's departments, and 1,481 special jurisdiction agencies. This category is an odd assemblage of federal agencies. In summary, the country is sprinkled with many independent agencies, with little centralized coordination of their actions, a weak and rather small federal compliment of agencies, and little of the centralization of function found in the other Anglo-American and European states.

There is no "typical" American agency, because most are quite small. Police agencies in the United States operate within a complex set of mutually contradictory laws, local regulations, and practices; their cooperation patterns are informal and their capacity to communicate with each other varies widely in both quality and quantity of channels. In contrast to the governance functions listed above, the police carry out diverse **petite functions** that are visible, local, and rather pedestrian. Petite functions range from the ridiculous and bizarre and mundane such as capturing wild beasts and sweeping up glass in the street after a road accident to dealing with hostage situations, serial killings, floods, hurricanes, homicides, rapes, and man-made disasters. They are historically frozen into a pattern of strategies of deployment developed in the eighteenth century in Dublin (The Dublin Metropolitan police were founded in 1786): random patrol and response to citizens' requests. The crime investigation function was added in the mid-nineteenth century in London.

Tactics, in part based in reduced time to respond, cheap and rapid communication systems especially the telephone and the computer, and increased education of the population are diverse but are restrained by traditional policing habits. The influence of information technologies is generally to increase speed of response, record keeping, and information retrieval, but the impact of IT on everyday functions is yet unknown. While the American police are well armed and increasingly "militaristic" in dress and dramatization of their role in the media and in their own advertisements, they have become less violent as has the public. Their dramatization or modes of organizational presentation in rhetoric and imagery are multifaceted: peaceful and child and family oriented, available, and kind as well as violent, well armed, distant, cold, and secretive. The police solicited demand, claim it is their role "you call, we haul," yet they screen and manage demand and are occasionally overloaded. They do not equally serve citizens or all parts of the city.

Changes in the Police Organization in the Last Century

The most significant changes in police organization in the post-World War II era (Reiss 1992) are changes in the composition of cities, their spread and the division of policing units into mobile beat, and improved, rapid, and inexpensive technology facilitating input and output of information. Police work, without question, is become more legalistic, demanding in respect of detail and information processing, and more subject to public scrutiny via cell phones, media, computers, and CCTV and other surveillance cameras (public and private). The police are a conservative organization, and their role and function sustains this idea. They preserve the *status quo* as defined loosely by the current legal and political realities. As such, they may find strong resistance as in the civil rights era beginning in Little Rock, Arkansas; Birmingham and Montgomery, Alabama, in the 1950s and 1960s in the South; and the bussing period in Boston in the late 1960s.

Internally, police organizations have become more specialized (the percent working in specialized named units such as "schools," "gangs," "special weapons," and investigation more generally). The percentage of employees who are non-sworn is growing and is over 25 % in large departments. This will grow and has implications for the future employment of sworn officers. With these two changes has grown an ostensive "rationalization" or developing of specific, codified, and explicit rules governing procedures relating to suspension, termination, disability, promotion, transfer, and conditions of work. These developments are countered by the traditional adherence to personalized relationships, sponsorship of protégés, networks of political oriented groups, e.g., crime control versus community orientation amongst captains and above ranks in the patrol division, resistance, and distrust of authority especially of the top command. Gouldner (1954) has suggested this kind of rule-oriented organization is a mixture of a form of formal authority called "punitive bureaucracy"– using rules to punish those who are indifferent or opposed to the management clique – and a mock bureaucracy which denies rules when convenient and works on informal compliance. These changes are accompanied by a move away from foot patrol and visible presence in neighborhoods, a diminution in face-to-face supervision – this being replaced by electronic monitoring by supervisors of mobile digital terminals, cell phones, and electronic records. While this has made policing more reliant on communications systems, the integration, cleaning and replacing, updating, and making these systems more user-friendly has lagged (Manning, this volume on police information technology). The primary capacity for surveillance, tracking, record keeping, and monitoring of citizens generally has vastly increased in the last 20 years. Finally, as Reiss (1992) has pointed out, the constraints of community-based accountability efforts, "transparency" politics, collective bargaining agreements, and contracts more generally have placed the police in a network of obligations now that were more tacit, less complex, and more easily avoided or voided than in the past. The process of rationalization reduces the power of policing as a sacred entity because its uniqueness is slowly diminishing.

Although studies of police technology suggest an increasing reliance on information technologies of various kinds and the rationalization of policing actions, i.e., aligning the ends or stated objectives of policing with the means designed to accomplish them, determining this remains difficult. The **ends** of policing are broad, undefined, and general in nature, and include maintaining order, serving the collective good or quality of life, advancing human rights, law enforcement, and representing trust. These are tacit, assumed, and implicit and police have long found them difficult to define operationally. As a result, they have resorted to indirect surrogates such as response time, arrests, officially recorded crime, clearances, and other more trivial measures such as class for service answered or school visits. In addition the primary **means** to achieve these are debated within and without the police service. Should they be accomplished by "partnerships" and "community policing"? Should they mount "crackdowns," sweeps, and targeted arrests in disadvantaged areas? Are they suited to planning and carrying out long-range problem-solving exercises? Should they do concentrated patrol or continue random wandering? In action, more traditional approaches combine the traditional structure and tactics with a crime focus, one sort of police rationality; other approaches favor community-oriented programs and partnerships, another form of rationality, while the majority of police officers have no interest in policy of any kind, see the job as a kind of entrepreneurial activity, and see their role as a rational attempt at protecting the city.

While in common sense terms, the police are an integrated and coherent rational organization; in fact, a police organization is an arena for contested rationalities associated usually with politically defined clusters or segments of officers based on these rationalities. The groups are in some tension, especially during periods of high officially recorded crime, concentrated homicides, or corruption scandals. That is, members of police departments do not agree on the goals nor the means of policing, and they are divided by segments as well as rank. At the same time, there is publicly expressed tacit agreement and consensus.

Rationality, Efficiency, and Effectiveness

As changes have been forced upon public policing, they have altered their rhetoric to simulate the language of big business. They speak of the work as "business" and supervision as "smart management" and produce annual reports, business plans, and strategic manifestos. They feature concern for "customers" and their "product." Let us consider briefly the nature of the new rational police organization now dramatized. This is an imagined organization that is based on clear objectives, long-term goals, and means geared to these goals. The resources available are tightly geared to this model of operation and closely monitored for results. Clearly, it is preferable in a capitalistic society to urge police to be rational, effective, and efficient while expecting them to deal with whatever arises with endless endurance, resources, morale, and competence. Thus, these terms are used without definition or context. Police are a patrimonial, punishment-centered bureaucracy, with loosely coupled connections between segments and units (see below), and they are a field for contested rationalities. Concepts such as efficiency and effectiveness are misleading and probably irrelevant to judging police operations.

Consider the following features that are in distinct contrast to the claims. There is no conventional market that can be used to distinguish market share, profit or loss, increased value, or net worth that can be traded or exchanged in a marketplace. Police have no customers or clients; they serve the public at large – the collective good. We cannot refuse the services or find other sellers. Taxpayers cannot opt out of paying their taxes or that part that support the police. The "customer" of the police cannot always be right if indeed right at all. Police, like other service organizations, cannot relocate to reduce their costs; they have general territorial obligations that are in effect "open-ended" and for which the demand is elastic. They are locally budgeted and monitored. They are insensitive as a result of contracts stipulating the conditions of work and pay, to variations in the market economy. They claim a mandate based on "full service" 24/7 without screening, prior prejudice, judgment, or exclusion. Their product is trust, in that they are agents of the whole designated to assess the trustworthiness of others and to act on their assessments. They, in turn, rely on public thrust and complicity to operate. This means that any attempt to screen or reduce service, to lay off officers, will be criticized. The police are expected to react to any danger to public order – man-made, natural, or artificial, e.g., nuclear power plant leakage until such time as it is resolved. This means at any given time, police hold back slack resources in anticipation of such a spiked and unanticipated demand. There is no standard number of officers per capita to hold in reserve, and there are no formulas for deployment. Overtime and extra personnel are always available in the case of an emergency. The goals are unclear and objectives contentious, and the means, e.g., arrests, only vaguely connected to the ends of public order, crime prevention, or protection of life and property. The standard practices, or "good practices," are not easily adopted and applied in El Paso and Elmira, Chillicothe, and Chicago. There is no market for police services: they have little or no competition and no standards against which to judge themselves since crime is a function of size of the city other things being equal. There is no bottom line in policing. It would appear also that to be efficient, that is, to use minimal resources to achieve an end, would require policy to guide actions – this is virtually impossible in a police organization, given the number of officers at the bottom of the organization and discretion at the bottom. Perhaps the most viable option in this regard is reducing the cost of employees by hiring civilians and increased use of technology to process data. This of course has little to do with preventing crime in any direct sense. Turning to effectiveness, it is clear no one wants a police force that enforces all or even most of the law, all or even most of the time. The sensible judgment of officers is essential in this regard. Weighing these arguments perhaps underscores the political significance of "crime control," "crime prevention," and "crime control" to police legitimacy. These statistics are matters that, given their control of reporting and arrest statistics, police can shape to their advantage. While the public agrees with the police about their concern about crime, their collective sense is in fact that the police are a public service with diverse governance and everyday functions.

The Police Organization in Action

Having sketched the external governance and petite functions of the police, it is possible to analyze the internal configuration of the police organization. This can be seen in two ways. The first is the police organization as an extension of the state's authority requiring loyalty and commitment. The second is to see it as an ensemble of roles carried out by quasi- independent actors. This role ensemble idea is taken up below.

Loyalty and Commitment. Let us take up the first. In this sense, the notion of an organization is variously a constraint on action choices. The idea of an organization assumes a degree of commitment or consistent behavior in the course of routines that are organizationally defined and attached to an income, hours, and duties. That is one definition of an occupation. Commitment is a mere job description, a way of capturing the process by routines become a role. But an organization requires involvement, attachment or even loyalty, or signs that emotional investment is being made in the organization's actions and ends, if not the means. The question of loyalty is seldom raised in police research, and when it is studied, it is revealed that police officers do like the job and, depending on age, gender, and specialization, tend to be emotionally attached to their work or "the job," but not the organization that employs them which they view with cynicism, distrust, and temerity. These attitude studies are complemented by work on the behavior of police officers in New Orleans after the Hurricane Katrina and shown in Hunt's (Hunt 2010) analysis of officers involved in a successful antiterrorist raid. The issue of loyalty has an edge in policing because the combination of distrust of the public at large and a view of the organization as unsympathetic and dangerous to their career and job interests makes for a powerful force for internal obligation and external stereotyping. It is not so much danger and displacement of aggression and hostility onto marginal others, but a combination of individualistically defined work with periodic risks. This stance toward the world when combined with a crime-fighting stereotypical self-label for overt public consumption sets the boundaries of the job and the social world of the occupation.

An Ensemble of Roles. The *police role* is embedded in uncertainty and the need to resolve it quickly. The role, with its characteristic features, arises not only from the complex of ideas that sustain the job – attitudes, values, beliefs, and material accoutrements, as well as practices – but from its craft-like nature. Like a carpenter, or plumber, officers take the situation that they define as facing them and shape it, if possible to a sensible or reasonable outcome. This result may be the preferred or even the sought after outcome, but "it is what it is" as the current saying goes. There is much that can go wrong. The management makes do with what is possible and adjusts, shapes, cuts, and shims things until they cohere or, at least, (a) do not fall apart and (b) come back to up "banana shaped," or when ". . .the shit hits the fan," (c) allows you to cover your ass in the event that something goes wrong (d) works in the here and now. Police work is done very much in the here and now. It is an intentionally conscious present-oriented doing (or not) hoping things will not get worse. If one can, one avoids paper work and further complications, violence and the related complaints, investigations, and the rest (if anticipated). That for which a record exists should be flattering and compelling to those read about it. What is acceptable to one group of citizens (or officers) will not work with another; for example, threats and exhortations may work on the street but do not suffice for middle-class people; good manners and etiquette work in the suburbs but may be dynamite and lead to ridicule and violence in disadvantaged areas.

Segments. Now consider the second way for seeing the organization: as a context for a loosely connected set of segments. This is the "motivational" outline for the politics of police organizations or how power seeking animates the internal politics of any police organization. As this perhaps suggests, there is no unified or even coherent police ▶ occupational culture in the sense that is often referred to in textbooks. It is not even useful to see it as one occupational culture with subcultures because this implies more unity in the occupation. Even this reified picture of one culture is drawn from research that reports the views of white, male urban patrol officers and their work-based oral culture. This conception excludes the meaningful experiences and views of females, minorities, and the very large civilian population that manages the infrastructure of the organization. In that sense "the police occupational culture" is a misleading gloss on complexity. Since an occupational culture is a response to the patterned uncertainties of the work, the irresolvable, recurrent difficulties of deciding that cannot be resolved factually, it has variable features depending on the prevalent uncertainties. What is usually called "police culture" is reported talk full of hyperbole and exceptions, a kind of tool kit on the one hand to resolve the fundamentally incongruous aspects of the work and a configuration of warning signs about how to keep out of trouble. This means further that much of what is talked about is exceptions, stories that are meant to express cautionary tales, ways 'round trouble, and all those things to be thought of as "on the job difficulties." It is helpful to think of the police organization as a loose confederation of sense-making *segments*, people who face similar uncertainties, express this coping verbally, and interact more frequently with those in their segment than with those outside it. Clearly, the responsibilities and functions of social segments in the organization, the patrol officer, those in supervision and management, investigators, and officers in specialized units do differ. The non-sworn segment of the organization, those called by police "civilians," provides an important contrast, but they are not discussed in detail here because there are no studies of this group. They reflect, it would appear they reflect the more stereotypical attitudes of the patrol segment with who they most interact (Manning 2008), but this is subject to more careful investigation.

A Map of Occupational Concerns

Consider Table 1. The columns across the table are the segments: lower participants, sergeants and middle management generally, top command, investigators, and specialized squads. The rows show the kinds of contingencies or uncertainties that pattern their occupational concerns. These include how officers entered the organization, their perceived audience, risks, rewards, and source of authority. There are several important points to note. Entry becomes more "political" and personalistic as one moves from left to right on the table. There is an assumption of equality of all accepted upon their entry but this changes quickly within the first few years of work (Van Maanen 1973). The perceived risks become in some sense narrower and more geared to specific skills and craft-competence. The audience of importance shifts radically when one moves from the officer and middle management segments. The audience is more public in the top command and investigator role. The authority of the street officer is personal, local, and immediate but those in supervisory and specialized units must cultivate special skills and competencies. The rewards concern change from concrete and known to more subtle questions of career and move away from immediate questions of pay, overtime, comp time, and secure retirement. These are cross-sectional rather than dynamic and set out the primary distinctions within the police world.

Now consider Table 1 in more detail. Note that the columns note the various segments of the

Role and Function of the Police, Table 1 Police occupational cultures

	Officers	Supervisors	High command	Investigators	Special units (SWAT/gangs)
Entry	• Screened • Various criteria	• Place and • An exam and • Seniority	• Political/ interview • Outside participants • Clique	• Selection • By Interview • Seniority • Brief training • Apprenticeship	• Recommendations • Request/approval • Protégés, networks
Risks	• Streets • Mistakes • Paperwork	• Officers' errors • Complaints	• Political/media • Second career	• Perjury/court • Paper lies • Boredom • Big cases	• Danger • Media • Uneven work demands
Audience	• Lateral • Peers	• Upward • Laterall	• Worthies • Clique • (Troops))	• Peers in investigative work • Media	• Other specialists • Media/public
Authority	• Original • Personal	• Streetwise • Rule-wise	• Personal/role/ position • Little actual power	• Original • Being clever • Well-spoken	• Quasi-legal
Rewards	• Overtime "details" • Comp. time • A niché	• Overtime • Promotion • Reputation with peers	• Respect (media attention) • Authority/ leadership	• Wearing plain clothes +allowance • Overtime • Participating in special squads • Flexible hours • Working "big cases"	• Peer respect • Flexible hours • Public fame

occupation (i.e., groups that interact more within that set of people than with others and partially defined by rank): patrol, supervisors, top command investigators, and special units. The rows set out the various features of the job as they see it, the lens through which the occupation is viewed: these include how they come to the position, their perceived risks and audiences, their view of the nature and source of their authority, and the rewards they associate with the work they do. Note that officers are hired by various criteria, see their risks as being "on the street" and associated paper work, are oriented to their peers, and see their authority as personal and original. Their rewards vary, and this is one bass for divisions within the segment – the nature and extent of the rewards sought – formal or informal. A niche is a kind of hideaway spot protected from transfer and demotion based on special non-rank-related skills such as working easily with computers, cars, or interpersonal relations – in the Chief's office, for example. Higher rank is a rather vague goal, not sought by most officers, so is not a key feature of the patrol officers' reward systems. Supervisors, mostly sergeants and lieutenants, gain their rank by a combination of changing factors – written exams, oral exams, and reputation. They are concerned about the risks associated with an officer's mistakes, especially those that are featured in the media, and they are "middle or marginal" people because they must balance the expectations and work styles of their squad (8–15 people for a sergeant) and those of the top command. They work with some combination of the rules, formal discipline, and informal persuasion and are generally respected. They may be rule-wise or streetwise, and their reputations as such preceded them. They may be given overtime or not or seek promotion and value the respect of their officers or squad. High or top command is constituted of the ranking officers, although the top handful in any given organization has considerably more informal power than those between them the sgts. Few studies have been done of top command and by inference one sees them as politically skilled; often rising via detective work; oriented to external audiences; seeking perhaps a second career in politics, security, or academe; and eager to cultivate power though linkages to others of like mindedness within the organization (networks of protégés, followers, and political supporters). They are sensitive to political, media, and even academic reputation and are often now highly educated (J.D., M.A., or Ph.D.). Turning now to investigators, "plain clothes" officers, they are generally chosen by reputation and connections which are then sanctified by other procedures. They are often sought out and cultivated if they have a reputation as being good at "crime work." They work as apprentices and may have been detective in a temporary position. Their risks are crime and crime-related and surround the rare case that goes to court. They always claim to be "overworked" and overloaded with cases, regardless of the actual workload, the clearance rate, or the complexity of the cases in which they are engaged. They are peer oriented and overvalue detective work considering it the heart of the job when combined with good patrol work (which can simplify their cases!) and value flair, cleverness, interviewing skills, and court aplomb. They are visibly rewarded, well paid, as well as linked into contractual pay for court whether they appear or not. Special squads vary in size, training weaponry, and rewards. Now almost all police departments have some specialized squads in addition to investigators. They are selected, cultivated, and generally "well connected" within the police for their skills and the prestige attached to carrying out violent, heroic deeds. They value and seek risk yet are aware it can be the undoing of a career in this sport of work. The work is often uneven and boring. Their audience is other specialists in their department and nationally. Because they deal with exceptions, hostage taking, riots, demonstrations, disasters, and rare events, their work is always on the borderline of legality. They are well rewarded and honored by peers, the media, and the general public. Their equipment, appearance, and especially their weapons are a notable source of public awe.

Dynamics. This scheme of segments and their features has a dynamic respect. These are vertical and horizon *cliques*, that is, informal friendships and sponsorships of like-minded officers; these links can be kinship, cohort members – those with whom you experienced the training academy – past partnerships, gender, ethnicity, or race. For example, young officers are informally selected for special squads in part on the basis of sponsorship from respected members or former members of such units, and these squads more than other segments reproduce themselves in respect to key identities – similar race, gender, and ethnicity (Hunt 2010). There are also movements in rank by promotion and demotion, changes in cohorts in given hiring patterns (numbers and composition), and leaving via disability, retirement, or termination. There are thus "cohort effects" that are visible in police organizations currently – the absence of hiring and the retirement of officers has created a thin middle segment and disproportionate number of newly hired officers serving on the street. As returning veterans are given preference in hiring, the incoming cohorts will be older, more disciplined, and experienced.

It should also be clear from Table 1 that there is no single role that police officers fill (as opposed to the rule the organization plays in the society), and no single ► occupational culture, even in the patrol division. There are in fact several segments and cohorts in competition for resources, career goals, and informal rewards. The extent to which these segments and dynamics are shaped and affected by diversity of race, gender, and sexual orientation is an open question. It would appear that several generalizations can be made: diversity exists more at the patrol officer rank than elsewhere in the organization, that women and minorities hold lower and higher ranks more than at middle-level supervisory ranks, and that changes in such ratios have moved very slowly in the 30 or so years since "diversity" has been urged. The claims about major change in police organizations as a result of recent hiring are yet to be proven.

Cohesiveness. If this is not a coherent culture, what holds this set of segments together? It would appear to be a number of features of the occupation.

- Every officer enters at the bottom, goes through the academy and field training, circulates through various units of the force, and is assigned to patrol or "fast response." All that rise to leadership share these experiences. The top command is selected by promotion within the organization and rarely is recruited from outside.
- Personalistic patterns of loyalty based on past friendships, cohorts in training, experience in special units, and the territorial units or divisions in which officers have served are highly valued. This is one source of the social glue that sustains relationships between people who work alone in widespread distances from each other carrying out quite different roles and tasks. These connections cross ranks and segments.
- Loyalty between and among ranks is patterned by but not determined by rank and command and control relationships. Yet, such personal loyalty counters rational rule enforcement and sustains what Weber (1947) calls "substantive rationality."
- Interactions on the job operate with metaphors of cohesion, e.g., "the police family" and "professional policing." These are invoked to draw out commonalities in public discourse.
- "Common sense" is used to describe the nature of the job, and it is believed to be widely shared throughout the organization. The common sense reality of policing is based upon the notion that all police officers begin at the bottom, that the craft is learned there, that shared values, practices, and norms arise from these experiences, and that "that's where the job is": at the "coal face." Insofar as the public has no access to these experiences, they are dismissed as judges of police performance. In critical incidents, the media and politicians are dismissed as ignorant and opportunistic in their criticism.
- Mutual dependencies arise from the shared uncertainties – the fear of capricious enforcement of the rules by supervisors that induces compliance amongst the lower participants and fear of their errors and mismanagement being exposed by the top command. There is also the worry of those at the top that the officers on the street might make an egregious

error that reflects on their authority and imagery. These typically involve excessive violence, such as vehicular chases ending in crashes, deaths and serious injuries, beatings, and shootings.

- Public displays of unity, participation in public celebrations such as parades, funerals, sports-based ceremonies, and as a result of acting collectively and in a unified, forceful manner when combating riots and disorder present the front stage of policing in dramaturgical terms (Goffman 1959). These are the rare occasions in which police act as a paramilitary unit with all the visible costumes, weapons, music, and audiences.
- Occupational consensus is sustained by the vague, unspecified "other" that respectable people fear and which, in turn, the police are expected to combat, manage, destroy, or erase from the publics' mind. It is the belief in the support of the respectable people that nurtures morale in spite of the "dirty work" and criticisms. This is more acute and verbalized in large cities where the valued audience is almost exclusively other "cops."
- Doing good police work, ironically, is seen as dragging some situation out of a chaos and making the best of it. There is a clear notion about what is "good police work" that is tacit and indicated by stories, and bad police work such as "bad shootings," but these are elastic notions and always put in the context "You had to be there." This might be called applying flair to complexity. "Flair" is managing and anticipating all those things which any reasonable person would do in such a situation as the person doing it saw it (not how an outsider looking at the deciding after the fact might see it).
- Powerful cliques of like-minded officers, groups including younger protégés, and their sponsors, based in part on kinship and ethnicity, shape careers. They promote and support favored officers as well as either do not protect others or actively prevent their promotions, transfers, and access to temporary postings. This is the semi-invisible tissue that binds some officers and excludes and extrudes others. Cliques are joined loosely into networks that link officers up and down the rank structure. The ambitious are typically members of the current leadership network and its protégés and a network composed of those currently out of power who may gain control with the appointment of the next Chief, Commissioner, or Chief Constable.

Other Divisions. There are matters other than already-mentioned ones of civilian versus officer status and rank and the interests of rank and rank segments (lower participants, middle management, and top command) that *divide* the organization in more subtle fashion:

- Strong lines divide the organization by gender, race, and ambition. While gender and race discrimination are well known in all organizations, the police organization is notable for its profound anti-intellectual and anti-educational milieu. This bias also includes the overtly ambitious who are often relatively well educated. Educational credentials are seen as a means to increase pay and the retirement base, rather than as a source of wisdom, judgment, skill, or knowledge. Educational credentials are deemed as irrelevant to the craft.
- Rules are the source of punishment and are used to substantiate decisions about discipline and performance. This feature, the use of rules as punishment, rather than as guidelines for choice, makes police organizations "punishment oriented bureaucracies" (Gouldner 1954).
- Cycles of rule enforcement increase the complexity of the organization in the eyes of the lower participants. They view rule enforcement as impossible to anticipate, always a possibility given any decision, capricious, and unfair.
- Rank and salary rewards are few. Ambitious officers in large departments, recognizing the personalistic and apparently arbitrary nature of "success," are often alienated and/or frustrated with the job. There are few opportunities to lateral movement to other police organizations.
- Emotional connections, losses, and achievements punctuate the police organization. Failures in high-profile cases, transfer and

symbolic demotions, unexpected promotions in which officers jump a rank or two, promotions to "inside jobs" such as the police chief's staff, forced retirements as a result of realignment of members of the powerful top command segment, and other career contingencies are all fraught with and produce emotion. Ironically, because emotional sensitivity and responsiveness other than anger are negatively sanctioned in the organization, these emotional burdens are denied and remain explicated yet powerful (Hunt 2010).

It is important, given this gloss on the occupational culture, and the role of what might be called the lower participants in the organizational hierarchy, to note several important qualifications. The patrol division is the largest segment within the organization, and it dominates the rationale for the job within the organization, i.e., the view that the organization is there in some radical real sense to "fight crime" on the streets and that this is the real job. This ideology denies the well-known facts that policing is boring, rarely involves crime, arrests, or violence, and requires scientific and legal work of a large number of "civilians" (about 26 % of large departments), investigators, managers and planners, "politicians" such as the top command, and consistent public support and finance. Nevertheless, this is the ideology shared up and down the organization and by many police researchers who carry out "experiments" designed solely to reduce officially recorded crime regardless of other (unmeasured and unanticipated) effects on the quality of life. It is in effect an organization which based on interaction is segmented, like preliterate cultures, and not a single culture, but many overlapping and competing cultures. The organization is more like a chorus than a solo performer.

Conclusion

The study of the role and function of the police is based on assumptions, most of them with an implicit interest in reform. Police as an institution reflect systems of law and culture, as well as the nature of the governance system within which they function. The police carry out both grand functions in respect to governance and more mundane or everyday petite functions. They have a flexible mandate, strategies and tactics, and function as rational-legal bureaucracies. There have been a number of changes in policing, but its core functions remain intact. Shifting attention to the inner functioning of the police organization, four major topics were addressed: the police role, loyalty, and commitment; the segmentalized nature of the organization and related dynamics; the sources of solidarity; and the remaining salient divisions and tensions within the organization.

Role and Function of the Police Manager

Kenneth J. Peak
Department of Criminal Justice, University
of Nevada, Reno, Reno, NV, USA

Overview

If, as Shakespeare (1597) wrote in "Henry IV," it is true that "Uneasy lies the head that wears a crown," then certainly the nature of policing in general has never allowed police leaders the luxury of being able to "lie easy." The police profession, like the rest of the nation, is undergoing radical changes in leadership and supervision.

Furthermore, practices that worked for police managers of the past will no longer suffice today. The autocratic, control oriented police leadership methods of the past are changing to the empowerment and participative management styles; the paramilitary command and control operations used even a few years ago do not work well with today's officers, who respond instead to intellectual challenges, stimulation, and motivation. More specifically, past expectations and measures of the police function were quite different, often requiring that officers essentially perform like human pinballs – reactively hurrying from call to call, exiting the patrol vehicle at the scene and taking the report, and then returning to the patrol car to resume patrol (seldom if ever accomplishing anything long-term regarding crime control); furthermore, officers were typically evaluated by their police leaders in terms of numbers: arrests, traffic citations, response times, and even the numbers of miles driven during the duty shift, all of which were indicators of productivity. Officers were not encouraged to visit with citizens to obtain feedback about neighborhood crime and disorder; in fact, they were expected by their leadership, as stated by police expert Chris Braiden (1993), to "park their brains at the door of the stationhouse, and follow orders like a robot." Many of today's police executives can well remember these facets of policing that prevailed during that era, when they were young officers.

Adding to the historical challenges of police leaders are the contemporary economic woes across the USA – perhaps affected more than ever before by the financial contractions and upheavals in foreign venues – which have led to unprecedented municipal bankruptcies, police layoffs, and even a lack of job security for police personnel. Therefore, undoubtedly some of the most important and challenging positions in our society and times involve police leadership.

This essay examines the roles and functions of those leaders, including administrators, middle managers, and supervisors. Leadership is the heart and soul of any organization, and the idea of leadership has been with us for a long time. Yet leadership is still, and will always be something of an amorphous concept, dependent on the situation and the motivations and abilities of the people involved. There are theories that can guide leaders, but for some, good leadership may be a bit like the US Supreme Court's attempts at defining obscenity – summarized by Justice Stewart when he said: "I know it when I see it." This essay will thus serve to bring this concept into clearer relief.

Definitions of Key Terms

Although the terms *administration*, *manager/middle management*, and *supervisor* are often used synonymously, each is a unique concept that occasionally overlaps with the others. *Administration* encompasses both management and supervision. Administration is a process whereby a group of people are organized and directed toward achievement of the group's objective. Administration focuses on the overall organization and its mission and its relationship with other organizations and groups external to it. Administrators are often concerned with the department's direction and its policies and with ensuring that the department has the resources to fulfill its community's expectations. Police administrators generally include the chief, assistant chiefs, and high-ranking staff who support the chief in administering the department.

Middle management, which is also a part of administration, is most closely associated with the day-to-day operations of the various elements within the organization. For example, most police departments have a variety of operational units such as patrol, criminal investigation, traffic, gang enforcement, domestic violence, or community relations. Each of these units is run by someone who is most aptly described as a manager. In most cases, these managers are captains or lieutenants. These managers ensure that their units fulfill their departmental mission and work closely with other units to ensure that conflict or problems do not develop. They also attend to planning, budgeting, and human resource or personnel needs to ensure that the unit is adequately prepared to carry out its responsibilities.

Supervision involves the direction of officers and civilians in their day-to-day activities, often on a one-to-one basis. Often termed "first-line supervisors" (and typically being sergeants in a police or prison organization), these individuals ensure that subordinate officers adhere to departmental policies, complete tasks correctly and on a timely basis, and interact with the public in a professional manner. Supervisors often observe their subordinates completing assignments and sometimes take charge of situations, especially when a deployment of a large number of officers is needed. They also work closely with managers to ensure that officers' activities are consistent with the unit's mission and objectives.

This essay focuses more on the *administrative* level, but will briefly discuss the roles of middle managers and supervisors as well.

Applicable Theories

It has been said that behind every good practice is a good theory. Certainly any number of theories could be offered to inform and guide the actions of police leaders, explain how they should manage and motivate their personnel, and so on. This section discusses three applicable theories underlying police leadership: Katz's three skills of chief executive officers, the managerial grid, and situational leadership.

Early ideas about leadership tended to take a simplistic view, assuming that leadership was simply a matter of birth: the so-called "Great Man" theory of leadership, where leaders were born into leadership positions (e.g., monarchs). This definition is inadequate, however, because leadership today involves much more than one's birthright, and is a complex undertaking as well.

There is also a long-standing debate concerning whether one's ability to manage is an art or a science – that is, whether certain people are "born with" or predisposed to having the qualities necessary for being effective managers; or, conversely, whether management is an "acquired" ability or science because people can be taught to be effective managers. Many people believe management contains the elements of both, as it requires both managerial skill that is personal (art), as well as a systematized body of knowledge (science) for preparing, organizing, and directing subordinates to accomplish the goals of the organization.

Katz's Three Essential Skills

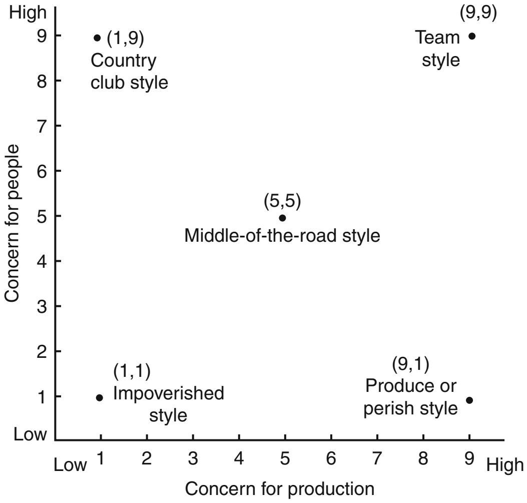
Robert Katz (1974) identified three essential skills that leaders should possess: technical, human, and conceptual. Each of these skills, when performed effectively, results in the achievement of objectives and goals, which is the primary thrust of organization and management. *Technical* skills are those a leader needs to ensure that specific tasks are performed correctly. They are based on proven knowledge, procedures, or techniques. Technical skills may involve knowledge in areas such as high-risk tactics, law, and criminal procedures. The police sergeant usually depends on training and departmental policies for technical knowledge. The areas in which leaders need technical skills include computer applications, budgeting, strategic planning, labor relations, public relations, and human resources management. They must also have knowledge of the technical skills required for the successful completion of tasks that are within his or her command. *Human* skills involve working with people and include being thoroughly familiar with what motivates employees and how to utilize group processes. Katz visualized human skills as including "the executive's ability to work effectively as a group member and to build cooperative effort within the team he leads. Katz added that the human relations skill involves tolerance of ambiguity and empathy. Tolerance of ambiguity means that the manager is able to handle problems when insufficient information precludes making a totally informed decision. Empathy is the ability to put oneself in another's place or to understand another's plight. *Conceptual* skills involve coordinating and integrating all the activities and interests of the organization toward a common objective. Katz considered such skills to include "an ability to translate knowledge into action" and emphasized that these skills can be taught to actual and prospective leaders. Thus, good leaders are not simply born but can be trained to assume their responsibilities.

All three of these skills are present in varying degrees for each level of leadership. As one moves up the hierarchy, conceptual skills become more important and technical skills less important. The common denominator for all levels of leadership, however, is *human* skills. In today's unionized and litigious environment, it is inconceivable that an administrator could neglect the human skills.

The Managerial Grid

The managerial grid, developed by Robert R. Blake and Jane S. Mouton (1962), has two dimensions: (1) concern for production and performance, and (2) concern for people (e.g., human relations, empathy). View the former, production, as being placed on a horizontal axis and the latter, concern for people, as being placed on a vertical axis, with both numbered from 1 to 9 (1 meaning low concern, to 9, indicating a high concern). The way in which a person combines these two dimensions will determine one's leadership style in terms of one of the five principal styles identified on the grid.

For example, one's management style that is located in the lower-left-hand corner of the grid would represent a minimal concern for task or service and a minimal concern for people. Conversely, one whose style is located at the lower-right-hand corner of the grid identifies a style having a primary concern for the task or output and a minimal concern for people. The upper-left-hand corner is often referred to as "country club management," with minimum effort given to output or task. The upper-right would indicate high concern for both people and production – and thus a team management approach of mutual respect and trust. In the center – a "middle-of-the-road" style – the leader has a more compromising, "be fair but firm" philosophy, providing a balance between output and people concerns.



Situational Leadership

Not too different from the managerial grid is situational leadership theory, which recognizes that the workplace is a complex setting and subject to rapid changes; therefore, it is unlikely that a single leadership style would be adequate. Simply put, this theory argues that the leadership style to be used in an organization will depend on the situation – the subordinates' readiness, motivation to do their job, as well as their ability or competence to accomplish it. Therefore, as Hersey and Blanchard (1977) asserted, the leader's behavior is in relationship to followers' behavior, and the leader must evaluate subordinates' status in terms of their willingness or motivation, and ability or competence. To be effective, subordinates must be mature in their view of and approach to their job; maturity is defined by such attributes as setting high but attainable goals, taking responsibility for task accomplishment, and the education and/or experience of the individual. This ability can be easily viewed on a continuum: At one end are those subordinates who are perhaps new to the job and neither willing nor able to take responsibility for task accomplishment; at the other extreme are those who are, say, more experienced and confident, and thus both willing and able to take responsibility for task accomplishment. As the maturity level of followers grows, from one of being inexperienced to experienced and capable, this theory would maintain that the leader's style can and should change and adapt as well. For example, a police supervisor with a new subordinate who is nowhere ready to perform the demands of the job – his maturity level is low, and he is unable to do the job – would be most effective if employing an style of leadership that is more authoritarian, providing more close supervision, one-way communication supervision and telling what how, what, and when they will perform certain tasks. Conversely, an employee who is "mature," has the willingness and ability to perform the job, calls for a leadership style that is more hands-off, with the leader delegating more responsibility and allowing the subordinate more decision making authority. The onus of this style of leadership is that it is dependent on leaders to diagnose follower ability and then adjust their leadership style to the given situation. Doing so is often easier said than done.

Making a Police Organization "Great"

Another approach to successful leadership, in the form of a book that rapidly became desirable reading for many executives, was provided by Jim Collins (2001) in *Good to Great: Why Some Companies Make the Leap and Others Don't*, which sought to answer the compelling question: Can a good company become a great company and, if so, how? Collins and his team of assistants searched for companies that made a "leap to greatness," as defined by stock market performance and long-term success; they found 11 companies that met their criteria and spent more than 10 years studying what made them great. Following that, and acknowledging the growing interest in his book by non-business entities, Collins later published a monograph entitled *Good to Great and the Social Sectors* (Collins 2005) concerning how lessons concerning "greatness" could be modified to fit government agencies. Certainly, much of the success of great police organizations has to do with their leadership.

Collins coined the term *Level 5 leader* to describe the highest level of executive capabilities (Levels 1 through 4 are highly capable individual, contributing team member, competent manager, and effective leader). Level 5 executives are ambitious, but their ambition is directed first and foremost to the organization and its success, not to personal renown. Level 5 leaders, Collins stressed, are "fanatically driven, infected with an incurable need to produce results" (quoted in Wexler et al. 2007: 7).

Such leaders, Collins found, do not exhibit enormous egos; instead, they are self-effacing, quiet, reserved, even shy. Perhaps this has to do with the nature of their organizations. Unlike business executives, police leaders have to answer to the public; unions and civil service systems further inhibit their power. Therefore, Level 5 leadership in a police organization may involve a greater degree of legislative-type skills – relying heavily on persuasion, political currency, and shared interests to create the conditions for the right decisions to happen (Wexler et al. 2007).

Collins also used a bus metaphor when talking about the transformation from good to great, with leaders *first* getting the right people on the bus, and the wrong people off the bus and *then* figuring out where to drive it) (Wexler et al. 2007). Interestingly, Collins emphasized that the true challenges for a leader is not about assembling the right team who will be motivated (the right people will be self-motivated). Rather, putting them in the right seats on the bus is the critical challenge. When police executives are appointed or promoted, they inherit nearly all of their personnel, including poor performers who are unenthusiastic about the organization's vision and philosophy. Some of these people may be near retirement (about ready to "get off the bus"). Collins believes that picking the right people for the right jobs and getting the wrong people off the bus are critical (Wexler et al. 2007).

This is why performance evaluations are so critical. Unfortunately, however, many police departments still have not created evaluation tools that adequately reflect the work police do. The tendency is to measure what is easy to measure: orderliness (neatness, attendance, punctuality) and conformity to organizational rules and regulations. Until police agencies invest in valid and reliable instruments for measuring the real work of policing, it will remain very difficult to move the nonperformers out of the organization.

Perhaps the most difficult part of achieving greatness is *sustaining* that greatness. Police chiefs have notoriously short tenure in office. Therefore, in their world, some of Collins's principles may be particularly important – for example, finding Level 5 leaders who pay close attention to preparing for the next generation of leaders, giving managers authority to make key decisions, sending them to leadership academies and conferences, and encouraging them to think on their own and ask questions. This process is termed *succession planning* and is discussed below.

Police Administration Evolves: From Beginning to Present-Day

Policing Begins in the USA: The Political Era, 1840s to 1930s

Policing, as it exists today as a full-time career or occupation, began in America in 1844 in New York City, where it was deliberately placed under the control of the city government and city politicians. The American plan required that each ward in the city be a separate patrol district. The process for selecting officers was therefore different as well. City mayors chose the recruits from a list of names submitted by the aldermen and tax assessors of each ward; the mayor then submitted his choices to the city council for approval. Thus, most of the power over the police went to the ward aldermen, rather than to the police executive. Instead, the system allowed and even encouraged political patronage and rewards for friends (Johnson 1981).

Police administration during this era was thus largely a paper tiger; indeed, the New York law providing for the hiring of a chief of police gave no power to the chief in hiring the authorized 800 officers, nor to assign their duties or to fire them (Johnson 1981).

As other municipal police agencies developed in the East, three important issues confronted police administrators: whether the police should be in uniform, whether they should be armed, and whether they should use force. The wearing of a uniform was one of the basic principles of crime prevention – that police officers be visible, and that crime victims cound locate a police officer in a hurry. Furthermore, uniforms would make it difficult for officers to avoid their duties, since it would strip them of their anonymity. However, police officers themselves tended to prefer not to wear a uniform, and some even threatened to sue if compelled to don a uniform. To remedy the problem, New York City officials took advantage of the fact that their officers served four-year terms of office; when those terms expired in 1853, the city's police commissioners announced they would not rehire any officer who refused to wear a uniform. Thus in 1854 New York became the first American city with a uniformed police force.

A more serious issue was the carrying of arms. At stake was the personal safety of the officers and the citizens they served. Nearly everyone viewed an armed police force with considerable suspicion, however. Eventually, because the new police could hardly withstand attacks by armed assailants, it was agreed that an armed police force was unavoidable (Johnson 1981).

Eventually, the use of force, the third issue, would become necessary and commonplace for American officers. Indeed, the uncertainty about whether an offender was armed perpetuated the need for an officer to rely on physical prowess for survival on the streets. In New York, the police reform board was headed by Theodore Roosevelt. His appointed officers were criticized by disgruntled Tammanyites (corrupt New York City politicians) who favored the political patronage system of hiring police. Roosevelt's approach violated the American tradition of hiring local boys for local jobs.

Police administrators presided over agencies that had other problems as well. For example, from the onset of professional American policing, there was little or no lateral movement from one department to another; consequently, police departments soon became inbred, and tradition became the most important determinant of police behavior. A major teaching tool was the endless string of war stories the recruit heard, and the emphasis in most departments was on doing things as they had always been done. Innovation was frowned upon, and rookies were taught that things had to remain the same.

Police administrators of the late nineteenth century were also occupied with riots, strikes, parades, and fires. Labor disputes often meant long hours of extra duty for their officers, for which no extra pay was received. The police typically had little empathy or identification with strikers or strikebreakers; therefore the use of the baton to put down riots, known as the "baton charge," was not uncommon (Richardson 1974).

During the late nineteenth century, large cities gradually became more orderly places. The number of riots dropped. In the post–Civil War period, however, ethnic group conflict sometimes resulted in individual and group acts of violence and disorder, but daily urban life generally became more predictable and controlled. Ethnic and religious disputes were found in many police departments, however. In New York, the Irish officers controlled many hires and promotions, and there were still strong political influences at work. George Walling, an NYPD superintendent for eleven years, lamented after his retirement that he had largely been just a figurehead. Politics were played to such an extent that even non-ranking patrol officers used political backers to obtain promotions, desired assignments, and transfers (Richardson 1974).

Partly because of their initial closeness to politicians, police corruption also surfaced at this time. Corrupt officers wanted beats close to the gamblers, saloonkeepers, madams, and pimps – people who could not operate if the officers were "untouchable" or "100 % coppers" (Richardson 1974: 55–56). Political pull for corrupt officers could work for or against them; the officer who incurred the wrath of his superiors could be transferred to the outposts, where he would have no chance for financial advancement. While serving as police commissioner in New York, Theodore Roosevelt frequently made clandestine trips to the beats to check his officers. Any malingerers found in the saloons were summoned to headquarters in the morning (Richardson 1974).

The Reform Era and Attempts to End Political Patronage: 1930s to 1980

During the early twentieth century, reformers sought to reject political involvement of the police, and civil service systems were created to eliminate patronage and ward influences in hiring and firing police officers. In some cities, police chiefs did not permit their officers to live in the same beat they patrolled in order to isolate them as completely as possible from political influences. Police departments became one of the most autonomous agencies in urban government. Policing also became a matter viewed as best left to the discretion of police executives, and agencies became highly centralized, with the sole goal of controlling crime. Melding with the community was more eschewed, and any non-crime activities officers were required to perform was considered as "social work." Thus the reform era (also termed the professional era) of policing would soon be in full bloom.

Further removing policing from its earlier people-oriented, decentralized nature (and probably reducing job satisfaction in the process), the management-oriented scientific theory of administration was advocated by Frederick Taylor during the early twentieth century. Taylor first studied the work process, breaking down jobs to their basic steps and emphasizing time and motion studies, all with the goal of maximizing production. From this emphasis on production and unity of control flowed the notion that police officers were best managed by a hierarchical pyramid of control. Police leaders routinized and standardized police work; officers were to enforce laws and make arrests whenever they could, and discretion was limited as much as possible. When special problems arose, special units (for example, vice, juvenile, drugs, tactical) were created rather than assigning problems to patrol officers.

August Vollmer became a major force in the development of professional policing and its administration – but in a positive and prescient manner. In April 1905 at age 29, Vollmer became the town marshal in Berkeley, California (Vollmer 1933). Vollmer was the first chief to order his men to patrol on bicycles. He then persuaded the City Council to purchase a system of red lights, which hung at street intersection and served as an emergency notification system for police officers. He also began to question the suspects he arrested concerning their methods, and became convinced of the value of scientific knowledge in criminal investigation. Vollmer's most daring innovation came in 1908: the idea of a police school. The first formal training program for police officers in the country drew on the expertise of university professors as well as police officers (Peak 2012).

In 1916, Vollmer hired a professor of pharmacology and bacteriology to run the department's crime laboratory, and by 1917 the entire patrol force became the first to operate out of automobiles; in 1918, he began to hire college students as part-time officers and to administer a battery of tests to all applicants. Vollmer also advocated the idea that the police should function as social workers, doing more than merely arresting offenders while seeking to prevent crime (Peak 2012).

The Crime Fighter Image

The 1930s marked an important turning point in the history of police reform. O. W. Wilson emerged as the leading authority on police administration, and the crime fighter image gained popularity. Wilson, a student of Vollmer, followed in his mentor's footsteps by advocating efficiency within the police bureaucracy through scientific techniques. While chief of police in Wichita, Kansas, Wilson conducted the first systematic study of one-officer squad cars. A major contribution was the publication of Wilson's (1950) classic textbook, *Police Administration*, which set forth ideas regarding police deployment, discipline, and organizational structure. Wilson would later teach at UC Berkeley, and in 1947 he founded the first professional School of Criminology. Wilson became the principal architect of the police reform strategy.

Police as the "Thin Blue Line": Chief William H. Parker

The movement to transform the police into professional crime fighters perhaps found its staunchest champion in William H. Parker, who became the Los Angeles police chief in 1950. His greatest success, typical of the new professionalism, came in administrative reorganization. The command structure was simplified, and rigorous selection and training of personnel became a major characteristic of the LAPD – which became the model for reform across the nation (Johnson 1981). Parker conceived of the police as a thin blue line, protecting society from barbarism and Communist subversion. He viewed urban society as a jungle, needing the restraining hand of the police; only the law and law enforcement saved society from the horrors of anarchy. The police had to enforce the law without fear or favor – with few restrictions on police methods such as wiretaps and searches and seizures (Richardson 1974).

The Community Problem-Solving Era

Until the 1970s, there were few outside, scientific inquiries concerning police functions and methods, for two reasons. First was a tendency on the part of the police to resist outside scrutiny and research into their operations. Many police administrators perceived a threat to their career and to the image of the organization, as well as a concern about the legitimacy of the research itself. Second, few people in policing perceived a need to challenge traditional methods of operation, and police methods were not even open to debate.

However, the turmoil of the 1970s compelled the police to open their doors to the outside world and allow academics to study their functions. This turmoil – which centered on the raging Vietnam War, race relations, and equal opportunity – included not only riots, protests, and sit-ins, but also such brutal police actions as those that occurred in Chicago in 1968 during the Democratic National Convention; people were served a nightly television display of police using clubs and gas to control rioters. Furthermore, five national commissions were established during the 1960s and 1970s, some of which lamented the "lawlessness" of the police and their lack of professionalism

In the early 1970s it was suggested that the performance of patrol officers would improve more by using job redesign based on certain motivations. This suggestion later evolved into a concept known as "team policing," which sought to restructure police departments, improve police-community relations, enhance police officer morale, and facilitate change within the police organization. Its primary element was a decentralized neighborhood focus to the delivery of police services. Officers were to be generalists, trained to investigate crimes and basically attend to all of the problems in their area, with a team of officers being assigned to a particular neighborhood and responsible for all police services in that area – the community problem-solving era.

There were other developments for the police during the late 1970s and early 1980s. Foot patrol became more popular, and many jurisdictions even demanded it. Foot patrol was found to produce a significant increase in public satisfaction with police service, a reduction of perceived crime problems, and an increase in the perceived level of safety of the neighborhood (Police Foundation 1981).

In addition, research conducted during the 1970s suggested that *information* could help police improve their ability to deal with crime. These studies created new opportunities for the police to understand the increasing concerns of citizens' groups about disorder (e.g., gangs, prostitutes) and to work with citizens to do something about it. Police executives discovered that when they asked citizens about their priorities, citizens often provided useful information.

Simultaneously, problem-oriented policing was being tested in several cities. These studies found that patrol officers have the capacity to do problem solving successfully and can work with citizens and other agencies to solve problems when given more autonomy and training to analyze the underlying causes of problems and to find creative solutions.

Thus policing moved into the current community era, with a renewed emphasis on community collaboration for many police tasks and crime *prevention*. Administrators organize their agencies so as to be more decentralized, pushing decision making to the lower levels of the organization.

Local Police Administrators: Police Chiefs and Sheriffs

The chief of police (sometimes known as commissioner or superintendent) is generally considered to be one of the most influential and prestigious persons in local government. Indeed, people in this position often amass considerable power and influence in their jurisdiction. Mayors, city managers and administrators, members of the agency, labor organizations, citizens, special-interest groups, and the media all have differing role expectations of the chief of police that often conflict.

The mayor or city manager likely wants the chief of police to promote departmental efficiency, reduce crime, improve service, and so on. Others appreciate the chief who simply keeps morale high and citizens' complaints low. The mayor also expects the chief to communicate with city management about police-related issues and to be part of the city management team; to communicate city management's policies to police personnel; to establish agency policies, goals, and objectives and put them in writing; to develop an administrative system for managing people, equipment, and the budget in a professional and businesslike manner; to administer disciplinary action consistently and fairly when required; and to select personnel whose performance will ably and professionally promote the organization's objectives.

Members of the agency also have expectations of the chief executive: to be their advocate, supporting them when necessary and representing the agency's interests when dealing with judges and prosecutors who may be indifferent or hostile. Citizens tend to expect the chief of police to provide efficient and cost-effective police services while keeping crime and tax rates down (often an area of built-in conflict) and preventing corruption and illegal use of force. Special-interest groups expect the chief to advocate policy positions that they favor. Finally, the media expect the chief to cooperate fully with their efforts to obtain fast and complete information on crime.

Qualifications for the position of police chief vary widely, depending on the size of the agency and the region of the country. Level of education is commonly found to be an important consideration; today, many agencies require a college education plus several years of progressively responsible police management experience. Police chief executives also need several important management skills, perhaps chief among them being the ability to motivate and control personnel and to relate to the community.

Regarding their hiring, cities must often decide whether it would be better to promote someone from within the ranks or hire from outside (perhaps using the assessment center process, described below). Both approaches have advantages and disadvantages. For example, internal candidates would be better known to personnel within the agency and other agencies of criminal justice (e.g., prosecuting attorney) and possibly the governing board. Conversely, one who is brought in from the outside may have new knowledge, skills, and abilities learned and/or practiced at other city or county venues, less "baggage" than what one might accumulate in the home city or county, and so on.

The position of sheriff has a long tradition, rooted in the time of the Norman conquest of England (in 1066), and it played an important part in the early law enforcement activities of colonial America. Because of the diversity of sheriff's offices throughout the country, it is difficult to describe a typical sheriff's department; these offices run the gamut from the traditional, highly political, limited-service office to the modern, fairly nonpolitical, full-service police organization. It is possible, however, to list functions commonly associated with the sheriff's office: serving civil processes (e.g., divorce papers, liens, evictions, garnishments and attachments, extradition and transportation of prisoners); collecting certain taxes and conducting real estate sales for the county; performing routine order-maintenance duties by enforcing state statutes and county ordinances; performing traffic and criminal investigations; serving as bailiff of the courts; maintaining and operating the county jail.

Sheriffs are elected in all but two states (Rhode Island and Hawaii; note, however, that in some consolidated jurisdictions, such as Miami–Dade county, Florida, sheriffs are also appointed); thus, they tend to be aligned with a political party. As elected officials, sheriffs are important political figures and, in many rural areas, represent the most powerful political force in the county. As a result, sheriffs are far more independent than appointed municipal police chiefs, who can be removed from office by the mayors or city managers who appoint them. However, because they are elected, sheriffs receive considerable media scrutiny and are subject to state accountability processes.

Because of this electoral system, it is possible that the only qualification for the office is the ability to get votes. In some areas of the country, the sheriff's term of office is limited to one 2-year term at a time (a sheriff cannot succeed himself or herself); thus, the office has been known to be rotated between the sheriff and undersheriff. In most counties, however, the sheriff has a 4-year term of office and can be reelected.

The sheriff enjoys no tenure guarantee, although one study found that sheriffs (averaging 6.7 years in office) had longer tenure in office than chiefs of police (5.4 years). The politicization of the office of sheriff can result in high turnover rates of personnel who do not have civil service protection. The uncertainty concerning tenure is not conducive to long-range (strategic) planning. Largely as a result of the political nature of the office, sheriffs tend to be older, less likely to have been promoted through the ranks of the agency, and less likely to be college graduates and to have specialized training than police chiefs. Research has also found that sheriffs in small agencies have more difficulty with organizational problems (field activities, budget management), and that sheriffs in large agencies find dealing with local officials and planning and evaluation to be more troublesome (Hayes 2001).

What Police Executives Do: Essential Functions

Finally, to better understand what police leaders do on a more day-to-day basis, adapting Henry Mintzberg's (1975) general model of chief executive officers (CEOs) to police work is instructive. Included in the model are three major roles or categories (interpersonal, informational, decision maker) and several subcategories, which allows for grouping and delineating the police executives' occupational roles.

The Interpersonal Role

The interpersonal role includes *figurehead*, *leadership*, and *liaison* duties. As a figurehead, the CEO performs various ceremonial functions. Examples include riding in parades and attending other civic events; speaking before school and university classes and civic organizations; meeting with visiting officials and dignitaries; attending academy graduation and swearing-in ceremonies and some weddings and funerals; and visiting injured officers in the hospital. The CEO performs these duties simply because of his or her position within the organization; the duties come with being a figurehead.

The leadership function requires the CEO to motivate and coordinate workers while resolving different goals and needs within the department and the community. For example, a chief or sheriff may have to urge the governing board to enact a code or ordinance that, whether popular or not, is in the best interest of the jurisdiction; CEOs also provide leadership in such matters as bond issues (e.g., to raise money for more officers or to build new stationhouse facilities) and advise the governing body on the effects of proposed ordinances.

The role as liaison is performed when the CEO of a police organization interacts with other organizations and coordinates work flows. Here, the police chief or sheriff might meet informally each month to discuss common problems and strategies. They might also do the same with representatives of the courts, the juvenile system, and other criminal justice agencies.

The Informational Role

The informational role is composed of *monitoring/inspecting*, *dissemination*, and *spokesperson* functions. Monitoring/inspecting involve the CEO constantly looking at the workings of the department to ensure that things are operating smoothly by "roaming the ship," sitting in on staff meetings, and generally being a part of efforts that discuss agency problems and functions.

The dissemination tasks involve getting information to members of the department. This may include memorandums, special orders, general orders, and policies. The spokesperson function is related, but it is more focused on getting information to the news media. News organizations are in a competitive field in which scoops and deadlines and the public's right to know are all-important. Still, the media must understand those occasions when a criminal investigation can be seriously affected by premature or overblown coverage.

The Decision-Maker Role

As a decision maker, the police executive serves as *an entrepreneur*, *a disturbance handler*, a *resource allocator*, and a *negotiator*. As entrepreneur, the CEO must sell ideas to the governing board or the department. Ideas might include new computers or a new communications system, a policing strategy (such as community-oriented policing and problem solving), or different work methods, all of which are intended to improve the organization.

As a resource allocator, the CEO must have a clear idea of the budget and what the priorities are and must listen to citizen complaints and act accordingly. For example, ongoing complaints of motorists speeding in a specific area will result in a shifting of patrol resources to that area or neighborhood. Finally, as a negotiator, the police manager resolves employee grievances and sits as a member of the negotiating team for labor relations.

Middle Managers and Supervisors

Captains and Lieutenants

Leonhard Fuld, one of the early progressive police administration researchers, said in 1909 that the captain is one of the most important officers in the organization. Fuld believed that the position had two broad duties – policing and administration. The captain was held responsible for preserving the public peace and protecting life and property within the precinct. Fuld defined the captain's administrative duties as being of three kinds: clerical, janitorial, and supervisory (1909).

Although every ranking officer in the police department exercises some managerial skills and duties, here we are concerned with the managers to whom first-line managers report, for they generally are unit commanders. In a mid-sized or large police agency, a patrol shift or watch may be commanded by a captain. The lieutenants, reporting to the captain in the normal hierarchy, may assist the captain in running the shift, but when there is a shortage of sergeants as a result of vacations or retirements, the lieutenant may assume the duties of a first-line manager. In some respects, the lieutenant's position in some departments is a training ground for future unit commanders (the rank of captain or higher).

In a medium-sized or large police organization, captains devote a substantial amount of time coordinating their units' activities with those of other units and overseeing the operation of their units. At the same time, however, captains also perform supervisory duties (e.g., writing reports, reviewing incoming complaints and subordinates' reports, ensuring that subordinates comply with general and special orders, completing employees' performance evaluations, serving on promotional and hiring boards). Whereas a sergeant or lieutenant may be supervising individual officers, a captain is more concerned with unit activities and the overall performance of the officers under his or her command. Furthermore, as can be seen from this list, the unit commander functions to some extent like a police chief or sheriff, but on a smaller scale. The chief performs these functions for the total department, while the unit commander is concerned with only one unit (Peak et al. 2010).

Lieutenants, as the companion middle-manager to captains, perform some tasks that are purely administrative in nature but typically involve more of the day to day activities that are related to patrol operations: preparing duty rosters, conducting roll call, preparing various reports, and maintaining time sheets. At times, lieutenants may also perform duties that resemble those that are supervisory in nature, such as assisting in supervising or directing the activities of the unit, ensuring that departmental and governmental policies are followed, reviewing the work of individuals or groups in the section, responding to field calls that require an on-scene commander, and reviewing various reports. These functions include overseeing officers and sergeants to ensure that different tasks are completed.

First-Line Supervisors: The Patrol Sergeant

As indicated above, another very important level of leadership – indeed, to the majority of police, who are rank-and-file officers, the *most* important leadership level – is that of patrol sergeant. Officers are often told that it is best to rotate into different assignments before testing for sergeant to gain exposure to a variety of police functions and managers. The promotional system, then, favors well-rounded officers. As with the chief executives' hiring process, an assessment center will provide candidates with valuable training and testing experience. Other factors that might come into play as part of the promotional process include education and training, years of experience, supervisory ratings, psychological evaluations, and departmental commendations (Peak 2012).

Police administrators understand that a good patrol officer is not automatically a good supervisor. Because supervisors are promoted from within the ranks, they are often placed in charge of their friends and peers. Longstanding relationships are put under stress when a new sergeant suddenly has official authority over former equals. Leniency or preferential treatment often is expected of new sergeants by their former peers. A new supervisor therefore must go through a transitional phase to learn how to exercise command and get cooperation from subordinates.

The supervisor's role, put simply, is to get his or her subordinates to do their very best. This role involves a host of actions, including communicating, motivating, leading, team building, training, appraising, counseling, and disciplining. They are in close proximity to their subordinates, the patrol officers, and thus can determine each subordinate's strengths and weaknesses, and ensure that each officer's conduct coincides with the organization's mission, values, goals, and objectives. Supervisors must be good communicators, disseminating information to subordinates, ensuring that general and special orders from captains and lieutenants are followed, reviewing all officers' offense and traffic crash reports, listen to and assist officers with personal or professional problems, respond to officers' calls for service, keep superiors apprised of ongoing situations and problems, and be able to interpret laws and policies for subordinates.

Obtaining the Best: The Assessment Center

In order to obtain the most capable people for police chief executive positions (as well as for middle-management and even supervisory positions), the assessment center method has proved to be an efficacious means of hiring and promoting personnel. (*Note*: Sheriffs are normally elected, not hired or promoted into their position; thus, the assessment center approach is of little use for that position.)

After developing a job description which lists responsibilities and skills for the position to be filled, then each candidate's abilities and skill levels should be evaluated, using one or more of the following techniques: interviews; psychological tests; in-basket exercises; management tasks; group discussions; role-playing exercises such as simulations of interviews with subordinates, the public, and news media; fact-finding exercises; oral presentation exercises; and written communications exercises.

During each exercise, several assessors or raters analyze each candidate's performance and record some type of evaluation; when the assessment center process ends, each rater submits his or her rating information to the person making the hiring or promotion decision. Typically selected because they have held the position for which candidates are now vying, assessors must not only know the types of problems and duties incumbent in the position, but also should be keen observers of human behavior.

Although obviously much more expensive and labor-intensive to perform, the assessment center can serve to avoid many of the errors of alternative methods of selecting police leaders and is highly recommended for jurisdictions who literally wish to "test" their candidates and thus make the best choice.

Evaluating Police Administrators

How good is a municipal police chief or county sheriff? The answer to that question probably depends on whom one asks. To some, the police chief executive's arrival is the best thing that ever happened to the area; to others, he or she is the worst thing. One reason for the differing viewpoints is that people's criteria for evaluating their chief or sheriff will vary. Therefore, rating the CEO's performance in this complex job involves several potential "traps." CEOs are human; they do make mistakes, but citizen perceptions of them and their performance are often wrong. Therefore, it is difficult to assess accurately how the CEO is performing; no litmus test or simple fill-in-the-boxes exercise exists. Several broad, general guidelines can be applied, however, when evaluating these CEOs.

Inappropriate Criteria

Some criteria that are generally inappropriate for evaluating CEOs include such considerations as: *popularity in the department* (the longer the CEO's tenure, the greater the likelihood that people both inside and outside the department will have something to gripe about); d*epartmental morale* (morale is a fragile thing, and most organizations have chronic and notorious complainers; thus, the morale of a department is not necessarily the result of the CEOs leadership); *a rising crime rate* (a variety of social and economic factors influence community crime levels; therefore, to blame the chief executive for the crime rate is inappropriate if not unfair – given, however, that the chief executive should know how and when to develop programs and strategies to combat rising crime rates); *single incident or issue* (a police beating or shooting of a citizen can cause a loud hue and cry and even calls for the chief's head; however, more often a multidimensional review of the chief's total performance should be made, and the firing of the chief does not ensure that the basic problem causing the upheaval will be eliminated).

Appropriate Criteria

A police executive's evaluation should focus only on qualities, characteristics, and behavior required to perform the job. Honesty and integrity are probably the chief's most important qualities, followed by leadership effectiveness. The direction of the department, its commitment to professional and ethical standards, and its basic values emanate from the chief's leadership role. The chief's ability to motivate people without shoving them and to inspire people both inside and outside the department should also be considered.

Any assessment of the chief executive must consider leadership effectiveness. The chief's ability to be a good follower and take a subordinate position to the mayor and city manager/council is also important. It is important that the chief know where the lines are drawn, when it is time to quit leading and start following.

CEOs manage a significant amount of resources – human and financial, equipment, and physical facilities. CEOs must make timely and responsible decisions, as well as realize the impact and legal ramifications of those decisions. The chief executive must also delegate authority and decision making to others rather than taking on too much, which often results in a sluggish operation. Finally, a chief executive must be innovative and creative in thinking. Today's CEO must be willing to keep up with the challenges facing law enforcement and need to move the agency into a new era of research, experimentation and risk-taking – to become a "learning organization."

Several other areas of the chief executive's performance must also be evaluated. The first relates to departmental values: do the department's values reflect a commitment to the rights of individuals and its employees? Does the CEO manage force carefully and aggressively to ensure that the public is not subjected to unlawful or unwarranted physical force by police? Does the CEO require the agency to have clear policies, rules, and procedures to guide employee? Are those directives are constantly updated and enforced fairly and consistently? Has the CEO introduced or implemented crime strategies to make the community safer?

The labor climate of the organization is an especially difficult area for today's police executive; civil service, unions, appeal boards, the courts, and the changing profile of today's police officer have made managing labor relations a constant challenge.

Finally, the CEO's understanding of where the department stands with the community should be evaluated. No other sector of government in our society has more frequent and direct contact with the public than the police.

The Future of Police Management: Succession Planning

Soon the administration, management, and supervision of police agencies could be in a crisis stage unless measures are taken in the near future to prepare for what is coming: the current aging, turnover, and retirement of baby boomers and other generational employees. Today an essential part of every chief's job is to prepare colleagues in the organization for the next advance in their careers; indeed, today the mark of a good leader is the ability to ensure a ready supply of capable leaders for the future.

Thorough preparation of successors can help a chief establish an important legacy – one that will sustain the improvements and progress that have been made, offer opportunities for mentoring, and instill the importance of the organization's history.

Chiefs need to take a long view and look at succession planning and leadership development as a continuous process that changes the organizational culture. To provide the ongoing supply of talent needed to meet organizational needs, chiefs should use recruitment, development tools (such as job coaching, mentoring, understudy, job rotation, lateral moves, higher-level exposure, acting assignments, and instructing), and career planning (Davis and Hanson 2006).

Organizations may already have a sufficient pipeline of strong leaders – people who are competent in handling the ground-level, tactical operations but who are not trained in how to look at the big picture. While not everyone can excel at both levels of execution, efforts must definitely be made to help prospective leaders develop a broader vision – as one author put it, prepare employees to take on broader roles and "escape the silos" (Ready 2004: 93). To develop police leaders who do not see the world in zero-sum terms but instead can appreciate the bigger picture requires people to leave their comfort zones and to offer them challenging assignments in different roles (Ready 2004).

A number of excellent police promotional academies and management institutes exist for developing chief executives, middle managers, and supervisors in the kinds of desired skills described above. In addition, *agencies* can provide skill development opportunities by having those persons with leadership potential do such things as plan an event, write a training bulletin, update policies or procedures, conduct training and research, write a proposal or grant, counsel peers, become a mentor, write contingency plans, and so forth. Meanwhile, the *individual* can lay plans for the future through such activities as doing academic coursework, participating in and leading civic events, attending voluntary conferences and training sessions, reading the relevant literature, studying national and local reports, guest lecturing in college or academy classes, engaging in research, and so on (Michelson 2006).

With today's leadership theory holding that law enforcement executives should adopt a participative management style, also known as *democratic leadership*, except when emergencies arise, an autocratic management style that includes public criticism can cause resentment among subordinates rather than a sense of teamwork or a spirit of cooperation. This style may also inhibit the development of future leaders and undermine the cooperative leadership process. Leadership is learned behavior, and new leaders can be developed through properly designed leadership experiences (Hernez-Broome and Hughes 2004).

Routine Activities Approach

Jonathan Allen Kringen and Marcus Felson
School of Criminal Justice, Texas State
University-San Marcos, San Marcos, TX, USA

Overview

The routine activity approach is a theoretical perspective for describing and explaining how crime rates vary over time and space. The approach applies to variations and changes in both large and small areas, over both short and long stretches of time. The approach differs from many other criminological theories because it looks beyond individual offenders to focus on crime events and emphasizes how these events draw upon a much larger set of legal activities.

Basic Theory Described as Stated in 1979

The routine activity approach began by studying "direct-contact predatory crimes," namely, those offenses in which one person directly attacks another person or takes the property of another. Crime events normally require a physical convergence of three minimal elements: (1) a likely offender, (2) a suitable target, and (3) the absence of a capable guardian (Cohen and Felson 1979). Routine noncrime activities are central for distributing these elements across space and through time resulting in circumstances in which offenders converge with targets while guardians are absent. A guardian is not normally a police officer or security guard, but rather a citizen or employee whose proximity can discourage a crime from occurring.

While the majority of theoretical criminology focuses specifically on criminal motivation, the routine activities approach focuses on crime incidents, treating criminality as but one feature within a larger system of activities. Without denying that offender motivation is necessary, it is far from sufficient for understanding crime; accordingly, the routine activities approach focuses upon criminal events themselves and the prerequisites required for their occurrence. Variation in these prerequisites can explain changes in crime rates without requiring any changes in the structural or individual conditions that motivate offenders.

The routine activity approach argues that the absence of any of the three elements is sufficient to effectively thwart crime. Because the three elements vary as a result of the normal day to day activities of both criminal and noncriminal individuals, the effects of routine activities can be difficult to recognize. The idea of a guardian provides a straightforward example. Cohen and Felson (1979) note that because guardianship is implicit in everyday life and is often marked by the absence of violations, it is easy to overlook. Whereas police actions are widely analyzed, guardianship by ordinary individuals as they progress through their routine activities was largely neglected in sociological research on crime. However, recent research has begun to analyze the effects of guardians on crime using both experimental and quasi-experimental methods (Hollis-Peel et al. 2011). Because guardianship by ordinary individuals links together seemingly unrelated social roles and relationships to the occurrence of illegal acts, it represents a phenomena not readily explained by sociological theory. However, this phenomenon may be extremely important in understanding crime.

Massive Crime Wave and Inapplicability of Earlier Theoretical Predictions

The period between 1960 and 1975 was characterized by marked increases in reported rates of crime. Controlling for population size, robbery rates had increased by 263 %, aggravated assault by 164 %, forcible rape by 174 %, and homicide by 188 %. Nonviolent offenses had experienced similar trends with burglary up by 200 % and auto theft increasing by 150 %. These trends represented a sociological paradox, as the conditions generally assumed by sociologists to cause crime had actually improved over the same period. High school completion had risen, unemployment had fallen, median family income had grown, and the number of people living below the poverty line had diminished. Other important predictors of crime had improved as well.

The proportion of the population living in the inner city and the percent of foreign born individuals residing in high-crime areas had both declined. Although the percent black had increased slightly during that period, as did the percent of the population widowed or divorced, these changes were in no way sufficient to explain the crime rate trends. Even the influx of the Post World War II baby boom into adolescence could only account for a small part of the crime wave that actually occurred. Although cross-sectional crime analysis seemed to support conventional theories, and although such theories may be useful for explaining crime trends for particular subgroups or specific communities during certain time periods, they could not explain these general crime trends over longer periods. Incorporating microlevel assumptions about individual behavior and macrolevel ideas about how crime fits into community life that emerge from human ecology, the routine activity approach offered an alternative and more effective theoretical framework.

Human Ecology Origins

Amos Hawley (1950) propagated a theory of community life, treating communities not simply as units of territory but also as tangles of symbiotic and competitive relationships. These relationships vary as human activities are preformed over both space and time. Hawley identified three important temporal components of community structure that are especially important for the routine activity approach: tempo, rhythm, and timing. Tempo refers to the number of events occurring per unit of time, as exemplified by a crime rate. A rhythm is the regular periodicity with which an event occurs; thus, crime has a daily or hourly rhythm, a weekly rhythm, and a monthly rhythm. For example, in the course of a day, certain crimes go up in the afternoon near schools and in the evening in entertainment districts, reflecting the combined significance of time and space. Timing refers to the coordination or coincidence of different activities and is extremely important for the routine activity approach. The afternoon upsurge in crime corresponds to the daily rhythm of schooling and when school releases likely offenders and suitable targets for crime.

Hawley’s central emphasis was on sustenance activities, upon which all other activities depend. Thus, the structure of work in community life influences leisure and other activities that must draw resources from it. More generally, the structure of illegal activities depends upon the organization of everyday sustenance activities – including work, school, and family life. Accordingly, the rhythms of daily life include the daily journeys to work and school, affecting the locations of offenders and crime targets and their spatiotemporal convergences. Timing leads to questions about the interdependence between crime and noncrime activities, as well as the comovements of likely offenders and suitable crime targets in the course of a day.

Although the routine activity approach considered many temporal features of crime, it emphasized activities within each day and their impact on the specific spatiotemporal convergence of crime’s minimal elements, with offenders finding or stumbling upon targets with guardians absent. The approach supplemented Hawley’s work by including a technological impetus for change as envisioned by William F. Ogburn (1922). As a result, the routine activity approach replaced traditional cultural and social explanations of crime with an approach that brought technological change to the forefront thereby shifting crime rate analysis away from race, divorce, education, and other independent variables which could not in practice explain the crime wave during the 1960s and 1970s.

Central Social Changes Relevant to Crime

Human ecology led to the question, “Where does crime draw its sustenance?” The answer was found in the material goods produced by society and the tangible activities by which society sustained itself. A proliferation of lightweight consumer goods, high in value and low in weight, provided vast new opportunities to commit crime. The new targets for property crime emerged with the technology of plastics and transistors bringing down the weight of electronic goods. Thus, the routine activity approach looked at the increased value per pound for small television sets and the dramatic increases in things to steal. The approach looked also at the female labor force participation rate and the dispersion of activities away from family and household, these making it possible for offenders to find targets away from the security of home or to find people home alone. Intrinsic to the routine activity approach was a detailed statistical review of changes in daily life and documentation of dramatic new exposures to risk of property and violent crime victimization. The development of the victimization survey provided new data about crime events that made the routine activity approach possible, along with some related theoretical ideas developed by others.

Key Links, Developments, and Controversies

Link to Lifestyle Theory

At about the same time as the routine activity approach, similar ideas emerged in the Netherlands (Van Dijk and Steinmetz 1983) as well as Great Britain (Mayhew et al. 1976). However, the most well-known parallel work was the lifestyle theory of Hindelang et al. (1978). Lifestyle theory suggests that differential exposure to offenders results in differential rates of victimization (Fattah 1991). Therefore, understanding variance in exposure is paramount to understanding victimization. Exposure to offenders varies with structural factors commonly associated with sociological theories of crime (e.g., age, race, and neighborhood of residence). However, exposure also varies as a function of the victim's personal lifestyle. The work and leisure activities of an individual may increase exposure to potential offenders, enhancing risk of victimization. This implies that risk of victimization may be reduced by modifying such exposures.

Although routine activity theory and lifestyle theory are often viewed as identical, that is not the case. On the one hand, routine activity ideas emphasize the criminogenic effects of everyday routines, such as work, school, and family life. In contrast, lifestyle theory gives more attention to personal lifestyle choices in leisure life. The two theories are not, however, completely distinct, since the former includes lifestyles and the latter includes work. The difference is a matter of emphasis, yet it suggests that the two theories should not be treated as one and the same.

Link to Situational Prevention

Originally, the routine activity approach did not offer policy prescriptions. Instead, it simply stated that high crime rates might be endemic in a modern society given the crime opportunities it produces. When Clarke and Felson met in London in 1981, the former suggested that if more crime opportunity makes more crime, it follows that less crime opportunity makes less crime. From that point on, routine activity theory and situational prevention began to interpenetrate, as increasingly evident in subsequent publications. Thus, the routine activity approach developed policy relevance, culminating in the joint publication Opportunity Makes the Thief (Felson and Clarke 1998).

Situational crime prevention is the application of "opportunity-reducing measures that (1) are directed as highly specific forms of crime, (2) involve the management, design, or manipulation of the immediate environment in as systematic and permanent way as possible, (3) make crime more difficult or risky, or less rewarding and excusable as judged by a wide range of offenders" (Clarke 1997, p. 4). Situational prevention advocates surveillance and target hardening through the management and manipulation of the environment which equates to altering the suitability of targets and the presence of guardians. Thus, situational prevention adopts aspects of the routing activities approach.

Link to Other Approaches and the Emergence of Crime Science

The routine activity approach is increasingly linked to other approaches. Situational crime prevention, which focuses on the circumstances that give rise to specific kinds of crime, seeks to make crime less attractive to offenders by manipulating the situational factors favoring crime (Clarke 1997). Crime prevention through environmental design (CPTED) takes a similar tack by focusing on environmental conditions and the opportunities that they offer potential offenders (Zahm 2007). Victimology shifts the focus away from criminal motivation and instead focuses on victim-offender interactions and the social and personal settings where crimes take place (Fattah 2000). Environmental criminology recognizes crime as a function of law, offender motivation, and target characteristics superimposed on an unseen environmental backcloth where the rhythms of life interact with environmental constraints (Brantingham and Brantingham 1993).

While each of these approaches considers unique aspects of crime, they share the common thread of explaining crime rather than trying to explain criminal motivation. After focusing attention on crime itself, attention can be given to the problem of reducing crime rather than simply dealing with the criminal (Gottfredson and Clarke 1990). This results in an emerging area of study distinct from mainstream criminology known simply as crime science (Laycock 2003).

Incorporating Social Control

Initially, the routine activities approach simply assumed offender motivation. However, later work addressed this limitation by incorporating the idea of informal social control (Felson 1986). The idea of informal social control adopted within the routine activities perspective represents a simplification of Hirschi's (1969) control theory. While Hirschi conceived informal social control as involving four specific elements (commitments, attachments, involvements, and beliefs), the routine activities perspective considers a simplified single effect of all four. Felson (1986) described all four of Hirschi's elements using a single word: handle. Crime is reduced when society gains a handle on potential offenders. This handle on individuals is formed when society establishes a social bond with the individuals. Because individuals might lose this bond if others become upset with their behavior, society is able to exert informal social control and handle potential offenders (Felson 1986).

Handlers

Routine activities acknowledged from the beginning that the presence of a capable guardian prevented crime. However, little distinction was made between guardians who supervise motivated offenders and guardians who supervise suitable targets. Later presentations are elaborated on this distinction by distinguishing between handlers and guardians. Whereas guardians supervise targets, handlers supervise offenders. The intimate handler emerged as a handler who supervises specific offenders using personal knowledge. Intimate handlers limit an offender's ability to engage in criminal acts using informal social control. Family, community members, and peers can all act as intimate handlers.

Facilitators

While the routine activities approach has been related to situational crime prevention, Clarke (1992) argues that the routine activities approach would have greater impact on situational crime prevention if it were to incorporate the idea of a crime facilitator. A crime facilitator is anything that comprises an essential tool for the commission of a particular type of crime. Examples of crime facilitators include some items commonly associated with crime such as weapons or lock picks as well as items typically associated with noncriminal behavior such as automobiles, telephones, and computers. Further, crime facilitators can include items that act as disinhibitors such as alcohol and drugs. The distinguishing characteristic of a crime facilitator is the simple fact that the item itself is involved in the criminal act. Because crime facilitators are distributed unevenly throughout space and time, the varying availability of crime facilitators is directly related to the routine activities of individuals both criminal and noncriminal.

Place Managers and Eck's Triplets

Another contribution to routine activities theory comes from John Eck (1994). Eck incorporates the idea of a place manager into the approach. A place manager is someone who is responsible for a particular space. Unlike a capable guardian who is protecting the suitable target, a place manager protects the place itself. Because the offender and target must converge somewhere in space, an individual guarding a particular space can avert crime even though they are not specifically interested in either the target or the offender. Doormen, security guards, and building superintendents are examples of place managers who can serve to discourage crime.

For Eck, the incorporation of place managers in conjunction with intimate handlers creates a situation where criminal opportunity is strictly limited. Known as Eck's triplets, this situation occurs when a likely offender is supervised by an intimate handler, a suitable target is supervised by a capable guardian, and the time and space where the offender and the target converge are supervised by a place manager, thus drastically reducing criminal opportunity. However, the effect of the triplet can be viewed in other ways as well. Offenders can be seen as discouraged by the proximity of guardians, managers, and handlers to targets, places, and the offenders themselves. In contrast, the effect can be viewed as relying upon the social ties that guardians, managers, and handlers have with targets, places, and offenders. Either way, the result is the same. A would-be offender must lose his handler and find an unprotected target in a location free of an intrusive manager to commit a successful crime.

Supervision When Offenders Control the Area

Supervision is typically viewed as a process that discourages crime. Capable guardians, intimate handlers, and place managers all serve to limit the criminal opportunities available to would-be offenders by virtue of their familiarity with targets, offenders, and places. However, familiarity does not always reduce crime. Offenders can assume a similar role and actually supervise guardians, handlers, and managers. Offenders may either seek to prevent these individuals from interfering or may actually find suitable victims among them. The process of familiarity generally strengthens the position of whichever group has the upper hand. When adversaries of crime have a stronger position, then familiarity serves to reduce offenders' ability to commit crimes. However, when offenders have a stronger position, then familiarity serves to enhance their ability to commit crimes. Offenders may have the upper hand in areas that have lost their basic controls. For example, areas with a high ratio of active offenders to others that have large numbers of abandoned properties likely tilt the balance of power to offenders. In such areas, offenders can rely on their familiarity with individuals and locations to commit crimes and evade supervision.

Non-predatory Offenses

The routine activities approach originally considered only direct-contact predatory violations. These violations were defined as illegal acts in which an individual definitely and intentionally took or damaged another's property. The offenses were likewise limited to only those that involved direct physical contact between at least one offender and at least one person or object that the offender attempted to take or damage (Cohen and Felson 1979). Later, Felson (1987) developed a crime classification system using four general categories of crime. The categories include crimes which are exploitative (where one person takes or damages the property of another), crimes which are mutualistic (those linking multiple individuals acting in complementary roles such as gambling or prostitution), crimes which are competitive (those involving multiple parties acting in the same role against each other such as fighting), and crimes which are individualistic (isolated illegal actions such as solo drug use or suicide).

Although the original conception of the routine activities approach applied only to exploitative offenses, the basic reasoning of the perspective extends to all four types of crime. All four types require that certain minimal elements converge in space and time for a crime to take place. Whereas predatory violations require an offender, a target, and the lack of a guardian, the other types have similar requirements. Mutualistic crimes require that at least two individuals inclined toward the offense meet in the absence of others who might interfere. An example is prostitution where a prostitute must meet a client in the absence of police and spouse. Competitive offenses have a similar requirement.

Fighters must encounter each other in the absence of peacemakers. Even individualistic violations involve a convergence of events. For example, suicides must avoid meddlers.

White-Collar Offenses

Some scholars have argued that white-collar crime can be understood using the routine activities approach (Weisburd et al. 2001). White-collar offenders are offenders who have specialized access to crime targets due to their work role, profession, or organizational position. Therefore, white-collar crimes can be viewed simply as crimes of special access. Viewing white-collar crimes in this way removes the sociological stereotypes associated with the behavior and explains why white-collar crime can be largely understood through the routine activities approach.

The vast majority of white-collar crime is mundane. It is easily accomplished by unskilled individuals and results in little economic return (Wright and Cullen 2000). Further, white-collar crimes rarely involve white-collar workers. Instead, the vast majority of white-collar crimes are committed by low-level individuals seeking material gain (Felson and Boba 2010). Because the motivations for white-collar crime are remarkably similar to those for burglary, there is little evidence to suggest that white-collar crime should be viewed any differently.

The only important feature which distinguishes white-collar crime arises from the specialized access derived from an offender's work role. The offender's position can provide greater criminal opportunity because official duties can provide access to targets. All offenders need access to targets, and white-collar offenders are no different. Whereas some offenders such as robbers take advantage of overlapping activity spaces to find targets, others such as burglars may take advantage of personal ties using personal information to determine which residences to burglarize. White-collar offenders take advantage of the unique access afforded them by their employment in their search for suitable targets. Quite simply, white-collar offenders have found a particular solution to the offender's general problem of finding suitable targets.

Organized Crime

Most organized crime is much smaller in scale and organization than depicted in the media (Reuter 1983). However, the study of organized crime still suffers from a variety of distractions related to the televised image. The degree of planning and sophistication required for offender to cooperate is generally overestimated, while the interaction between criminal cooperation and legitimate activities is typically underestimated (Felson 2006). This has resulted in extant studies of organized crime focusing on social networks in attempts to understand criminal organizations. This myopic approach overvalues linkages within specific groups which limits research into the nature of criminal organizations. In contrast, the routine activities perspective suggests that the important linkages for understanding organized crime are the linkages between events rather than between individuals.

Because offenders are likely to converge in certain settings, these settings allow criminal cooperation to persist even when the individuals vary. These offender convergence settings provide a stage for engaging in a variety of illicit activities. These locations provide a place where offenders can engage in illicit transactions as well as seek out accomplices. While some settings where offenders convergence exist solely for criminal activity, others involve legitimate activities. These places provide a social life for offenders who may generate criminal plans while engaged in otherwise innocuous activities. Thus, the nature of criminal organization may owe more to the routine activities of offenders themselves than to offenders' social networks.

Cyber Offenses

Cybercrime represents a relatively new topic within the field of criminology. Although few studies have attempted to analyze cybercrime, some scholars have argued that the routine activities perspective may provide a useful theoretical model for such research (Bossler and Holt 2009). The routine activities perspective may be applicable because, like other crimes, cybercrime requires that a motivated offender and a suitable target converge in the absence of a capable guardian. However, others dispute this assertion. They argue that because virtual environments are spatially and temporally disconnected, they are remarkably different than the traditional environments in which the routine activities approach has been previously applied. The disorganization caused by individuals and websites connecting and disconnecting over short periods of time may limit the applicability of the basic constructs of the routine activities approach (Yar 2005).

While this remains an open empirical question, research into cybercrime indicates that risk of cyber victimization is related to the specific tasks an individual undertakes on the internet, not simply internet use itself (Holt and Bossler 2008). For example, malware victimization was shown to be related to computer deviance (Bossler and Holt 2009). This suggests that individuals who choose to engage in deviant cyber acts place themselves in proximity to motivated offenders. Together, this line of research supports the applicability of the routine activities approach to cybercrime as it suggests that cyber victimization may result from convergence patterns of both victims and offenders within cyberspace.

Possible Controversies in the Literature

Two controversies concerning the routine activities approach are noteworthy. The first controversy extends back to the approach's original presentation. From its inception, the routine activities approach has been criticized as not conceptually distinct from social disorganization theory. However, several differences clearly distinguish between the two perspectives. Whereas social disorganization theory emphasizes broad places, the routine activities perspective concerns much smaller geographies such as specific streets, blocks, and addresses. The temporal emphasis varies between the two as well. Social disorganization focuses on changes over decades, but the routine activities approach focuses on temporal changes from hour to hour. While social disorganization treats offenders as the key personal focus, routine activities include targets and guardians. Finally, social disorganization theory is driven by the impact of social influences. In contrast, the routine activities perspective is driven by the idea of socio-physical convergences.

The second controversy concerns the proper dependent variable for the routine activities approach. Because the approach specifies that certain activities like household and family activities entail lower risk of criminal victimization than other activities (i.e., non-household/nonfamily), victimization represents the conceptual dependent variable. However, various studies have operationalized victimization in different ways. In the original paper, Cohen and Felson considered risk per billion person hours. Later, Clarke introduced the idea of partitioning risk by time spent in particular categories of activity. This idea resulted in the idea of risk per million hours parked in each place. This concept was later extended by Lemieux (2010) who conducted a more thorough analysis of risk per 10 million person hours in each of a variety of activities. Lemieux included sleeping, shopping, commuting to and from work, commuting to and from other areas, conducting other activities at home, working, commuting to and from school, engaging in leisure away from home, and attending school. Lemieux concluded that sleeping and shopping were the least dangerous activities while leisure away from the home and attending school were the most dangerous.

Conclusions

The routine activities perspective provides an important conceptual tool in the study of crime. Originally conceived to explain the prevalence of a particular type of crime during a specific period of time, the routine activities perspective has been adopted to explain many different types of crime in a wide variety of environments. While this versatility represents one of the great strengths of routine activities, the consistency of the original insights throughout the development represents the approach's single greatest attribute. This is no doubt the result of the elegant simplicity of the perspective itself.

While the future of routine activities is unclear, the close relationship between routine activities, situational crime prevention, and CPTED will provide a variety of opportunities for continued development. Because routine activities research focuses on microlevel processes, the routine activities approach leads to specific policy recommendations. As a result, the perspective is useful to both scholars and practitioners alike.

Russian Mafia

James O. Finckenauer
School of Criminal Justice, Rutgers University,
Newark, NJ, USA

Overview

What is the so-called Russian mafia? Answering this question is not easy. The difficulty arises out of a number of circumstances that will shape this discussion. First, the phenomenon called Russian mafia is not and cannot be strictly Russian. A second complication is the fact that the term mafia had come to be indiscriminately used in the former Soviet Union, where it referred widely to any sort of activity or enterprise that was perceived to be outside of the law. Thirdly and most importantly, there is the most unusual story of Russia and Russians with respect to crime, organized crime, and corruption – a history that spans at least back to the seventeenth century, takes in the 70 plus years of Soviet rule, and finally focuses on the "New Russian" generation since the collapse of the Soviet Union in 1991. Each of these factors, but most particularly the last, helps explain the current situation with respect to organized crime in Russia itself, as well as the transnational organized crime that emanates from Russia with widespread global impact. Finally, following the explanation and understanding of this particular organized crime problem, there is the ultimate challenge of what to do about it.

Background

Describing and attempting to explain the popularly known "Russian mafia" is a task with a number of complications. Contrary to what might appear to be the obvious, it requires first dealing with the characterization of its being "Russian." This is because Russia and Russians have long been all-encompassing labels. As was particularly the case during the time of the Soviet Union (1918–1991), the world regarded persons from all the countries that made up the former USSR as essentially being Russians. *Russian* came to include persons not only from the other 14 Soviet republics but also from the hundreds of different ethnic groups. Although Russia is the largest and perhaps best known of the former Soviet states and although there are many ethnic Russians who have immigrated elsewhere, indeed including some who are criminals and engaged in organized crime, and not all of those currently popularly characterized as being part of the so-called Russian mafia are actually Russian. Instead, they are, for example, Armenian, Georgian, Ukrainian, Azeri, or Chechen or they are actually from Eastern Europe, such as the Albanians. The point is this phenomenon known as the Russian mafia is not and cannot be strictly Russian. This is also why law enforcement agencies in the United States more typically refer to the criminal groups in this category as Eurasian Organized Crime.

Even thornier is the concept of "mafia." Strictly speaking, mafia is a very particular kind of organized crime. It is especially associated with Sicily and southern Italy. Made members of the true mafia – inducted in formal ceremonies – are considered to be men of honor. They are bound by traditions that have been passed down for generations, such as respecting *omerta* or the vow of silence.

The mafia's traditional business has been providing protection and acting in quasi-governmental roles. The latter is a particularly important defining element. It means that mafias are most likely to be found in countries or regions that lack strong governmental structures and healthy civil societies. Such locations are usually characterized by rampant corruption, weak or absent rule of law and protections for civil liberties, and/or civil disorder. In these circumstances, a mafia or mafias take on "protective" functions and judicial functions, meting out judgments and sanctions. Although the term mafia has come to be used indiscriminately to refer to all kinds of criminal organizations, in many places, mafia is not synonymous with organized crime. Rather, it is one form of organized crime.

The term mafia was particularly indiscriminately used in the former Soviet Union. It referred widely to any sort of activity or enterprise that was being controlled or that at least appeared to be controlled. Thus, mafia could refer for example to organized criminal groups, clans that controlled politics and the economy in particular regions, corrupt government employees, or even the Communist Party itself. The noted Russian journalist, Yuri Shchekochikhin, who covered the ubiquitous mafia in the USSR extensively, said the label mafia was being applied to practically anything and everything – unions, hospitals, prostitutes, chess players, etc.

In any instance when terms are used somewhat arbitrarily, they tend to become practically meaningless. As a result of this longstanding definitional ambiguity, the subject to be dealt with here is consequently a rather amorphous one. Yet a further complication derives from the unique history and character of Russia and Russians with respect to crime, organized crime, and corruption – a history that spans at least back to the seventeenth century, the 70 plus years of Soviet rule, and then the generation since the collapse of the Soviet Union in 1991.

History and Origins

Organized crime in various forms has a 400-year history in Russia. This is a history characterized by authoritarian governments, beginning with the czars, who were then followed by the hegemony of the Communist Party and its dictatorial rulers. Indeed, authoritarianism, albeit it in a somewhat different form, extends into today under the rule of Russian President Vladimir Putin. Putin, the former head of the KGB (the Soviet secret police), calls his form of authoritarianism democracy with order.

Throughout Russian history, its rulers showed little or no regard for individual rights and liberties. Government and its laws and rules were not seen as representing and protecting the people. A consequence of this history was and is blurred distinctions between what is legal and illegal and what is public versus private. Stealing the czar's timber, for example, was not considered criminal by the Russian people, whereas one peasant stealing anything from another was. Commitment to the rule of law, a backbone of democracy and civil society, has thus always been very feeble in Russia.

Serguei Cheloukhine (2008), who has studied and written extensively about Russian organized crime, describes its beginnings as follows:

> Historically, the professionalization of criminal groups in Russia was a product of strong patriarchal traditions, hostility towards the state and an underdeveloped, largely agrarian economy. During the 17th century, corruption combined with the tyranny of state officials and landowners was widespread in Russia. This was in part a reflection of the lack of respect for the dignity of the individual – most people were regarded primarily as property and such property was not protected by a rule of law, but was due to the "benevolence" of the autocracy towards the country's nobility.

It was during these centuries prior to the Soviet era, when the czars ruled Russia, that one of the most prevalent crimes was theft, especially as indicated from the czar's properties. The thieves' rationalization was that property that belonged to the czar – to the state – did not belong to anyone, or belonged to everyone, and thus was fair game to be stolen. Although not unique to Russia, this sort of rationalization is important because it reflects the origins of the division between permissible and impermissible crimes that rose to new heights in the Soviet Union. And it continues to be very much in evidence today.

Another piece of this explanatory puzzle can be found in the reading of Russian literature. From Nikolai Gogol (*The Government Inspector*) to Ilya Ilf and Yevgeni Petrov's *The Twelve Chairs* and *The Golden Calf*, to Alexander Zinoviev (*The Yawning Heights* and *Homo Sovieticus*), and to more recent authors such as Victor Pelevin

(*Homo Zapiens*) and Gary Shteyngart (*Absurdistan*), writers have described the insidious corruption and the particular long-standing relationship between corruption and crime in Russia. A sign that this norm continues was reflected in a 2012 New York Times article that opened a discussion of the issue as follows: "CORRUPTION [sic] in Russia is so pervasive that the whole society accepts the unacceptable as normal, as the only way of survival, as the way things 'just are.'"

Crime in the USSR

Following the Russian Revolution of 1917 that resulted in the overthrow and ultimate execution of Czar Nicholas II and his family, the Bolsheviks embarked upon their ambitious agenda of creating a new society, intended to be crime-free and also to produce a new "Soviet Man" who would be hardworking, communal, patriotic, and loyal to the state. Oddly however, it was during the 1917 revolution that the Bolsheviks collaborated closely with professional criminals to overthrow first the czar and then the first short-lived revolutionary government. Thus, from the outset, there was a kind of hypocrisy about the supposed Soviet utopia. The Russian revolutionaries working hand in glove with criminals to attain the spoils of power reflects a picture of Russia today – the marriage between political power and crime. A very similar kind of criminal-political nexus – among entrepreneurs, criminal organizations, and government officials – very aptly describes the current nature of serious crime in Russia.

In most instances, organized crime arises to meet market demands for goods and services that are either illegal, regulated, or simply in short supply. In addition to goods that were illegal such as a variety of Western products, almost from the beginning, most goods and services were in chronically short supply in the USSR. This led to, or fed, the emergence of what was known as a shadow economy and to a black market. The shadow economy produced legal goods "off the books" that were sold or bartered illegally. The black market usually dealt in illegal goods, such as prohibited items from the West or drugs, for example. As indicated, it was common during the Soviet era to refer to practitioners in a variety of these activities as being mafias.

Soviet citizens used *blat* – connections and informal networks – to access the black market and shadow economy. Blat (Russian: блат) is a term which appeared in the Soviet Union to refer to the use of informal agreements, exchange of services, connections, Party contacts, or black market deals to achieve results or get ahead. While obviously not unheard of elsewhere, agreements/connections became the primary way of doing business in the USSR. *Blatnoy* came to refer to someone who got a job or got into a university using connections or sometimes bribes – again not unique to Russia, but just much more prevalent. This system was in many ways similar to the Chinese practice of *Quanxi*.

As a result of eight decades of these practices, there are at least two effects that are relevant to the current nature of Russian organized crime: It created or refined a distinct mentality about conniving to survive, and it stimulated the development of a shadowy entrepreneurial class operating outside the law. The previously mentioned writer Zinoviev's *Homo Sovieticus* was a string puller, an operator, a time server, a freeloader, and, above all, a survivor. He was also the ancestor of today's new Russians.

The offshoots of this peculiar history include, for example, the monetarization of organized crime in Russia, in which dealing in goods and services shifted to dealing in currency. This inheritance also includes the crony capitalism and widespread corruption that are so characteristic of Russia's economy and politics today.

During the 1960s, organized crime in Soviet Russia evolved into a three-tiered pyramid-like structure. The top tier was made up of high-level government and Communist Party bureaucrats – those referred to as the *apparatchiks* and the *nomenklatura*. Party officials enjoyed special privileges that were denied to the vast majority of the Russian people. They lived in special more luxurious housing; had their own vacation hideaways; consumed special foods, wines, and liquors that were otherwise unavailable; traveled widely and bought expensive clothes; and sent their sons and daughters to the best schools. Party members lived in high style off of the country's vast resources while all the while claiming to be representing the people's interests in a socialistic state of mythical equality. The hypocrisy of this lie was apparent to the population, and once again reinforced the lesson about what one really needed to do to get ahead in life.

Below the Communist Party, the middle tier of the crime pyramid was comprised of the shadow economy (underground) operators and the black marketers. They, for example, oversaw the production of the shoddy goods to fulfill the 5-year plan quotas. As long as the plan was fulfilled or better yet exceeded, the quality of the products was irrelevant – again a foundation for cynicism. These operators also procured the illegal goods and products that were then passed on up the pyramid. They did all this while siphoning off what they saw as their share.

Finally, the bottom tier consisted of the professional criminals. This group included a whole range of criminal types from petty thieves up to an including the *vory v zakone* or thieves in law. The *vory* were products of the Soviet gulag or prison system, what Cheloukhine describes as "a university of the underworld." These leaders of the underworld were (and still are in some instances) the most sophisticated of the professional criminals. They lived within a set of rules known as the thieves' law, dedicated themselves to a life of crime, and rejected involvement with the legitimate world. In many respects, although not all, they bore some resemblance to the traditional definition of mafia or at least more so than did any other form of Russian organized crime.

The Post-Soviet Era

There were great hopes for Russia after 1991. Unfortunately, many of those hopes have not materialized. Instead of enjoying the fruits of freedom and democracy and a thriving market economy, Russia has been racked by a host of social, economic, and political ills. The Russian people have been confronted with worsening living standards, poor health care, rampant inflation, corruption, alcoholism, drug addiction, and surging crime rates. Russia faces a shrinking population because of declining birth rates and decreasing life expectancy, especially among Russian men. The latter is attributable to the increased alcoholism.

The predatory nature of the Russian economy – an economy whose driving philosophy seems to be to steal as much as you can as fast as you can – is closely intertwined with official corruption and organized crime. One result is that, for the vast majority of Russians, life is much worse today than it was at the beginning of the decade of the 1990s – an outcome that would have been almost inconceivable in 1991. Another result is that the legal and criminal justice processes, and any fledgling effort toward the rule of law, have been overwhelmed by the enormity of the challenge of crime.

In the years following the collapse of the former Soviet Union, there was a rapid growth in organized economic crime. During Boris Yeltsin's presidency, both political and economic chaos reigned as Russia stumbled from a state command economy to something resembling a market economy. Predators who had cut their teeth in the shadow economy, the black market, and the criminal corruption of the Soviet era were best positioned to take advantage of the chaos – lining their pockets and those of their friends. The so-named oligarchs – the millionaires and billionaires who profited the most – were beneficiaries of the policy of privatization, that is, the selling off of the state's assets. Enormously lucrative properties were obtained for investments far below their worth largely through collusion and insider trading.

As the country moved to privatize its vast holdings, that is, sell to private owners what was previously owned by the state, organized crime in partnership with corrupt officials engaged in a wholesale rape of the privatization process, buying up valuable properties at fire sale prices via insider trading information. The economy that resulted from the various perversions of economic reform has thus not been an economy governed by market principles but is instead, as indicated, a predatory economy.

Following Yeltsin, first the Putin and then the Alexander Medvedev governments grappled with the problems of developing laws and regulations to govern private business and economic activities. But organized criminal groups were clearly able to exploit the opportunities that became available. This wave of criminal activity was a destabilizing influence as Russia struggled to achieve economic and political reform. It thwarted foreign investment, widened the gap between rich and poor, and ultimately undermined confidence in the government.

Given this context, the particular character of Russian organized crime that has arisen over the last 20 years reflects not only a high level of criminal sophistication and well-developed networks of corruption but also a broad scale of activities and influence exerted over a considerable portion of the economy. Russian organized crime is not a single monolith but rather a conglomeration of criminal groups. Some of these groups are large and some small; some are ethnically based and some are not; some specialize in particular crimes and others are more diverse. In sum, when one speaks of Russian organized crime, one is not speaking of a single entity.

The criminal activities and enterprises of these various groups can be categorized into two broad groupings. In one group are such crimes as extortion, robbery, car theft, drug trafficking, and prostitution. These kinds of crimes are the staples of organized crime in many parts of the world. But it is really the second category of crimes that most distinguishes Russia from many other countries. Between 1991 and 2008, for example, Russian organized crime gained control of a significant share of the nation's economy (estimates run to 40 % or more in certain sectors). The lack of laws, lax regulation, corruption, and violence enabled criminal groups to make substantial inroads into several lucrative economic sectors, including energy, metallurgy, construction, banking, fishery, retail trade, liquor production, and transportation. The Russian Ministry of Internal Affairs (MIA) estimated that almost 2,000 different economic enterprises were actually under the control of organized crime groups. This latter category of high-level economic crimes was much more likely to involve a class of sophisticated criminals known broadly as the *avtoritety* or authorities. This is a collection of businessmen/criminals who are drawn from the ranks of former black marketeers and shadow economy operators, government bureaucrats, and the security services, among other roots. Whereas the drug crimes, protection rackets, loan sharking, and so on were the bread and butter for the old style gangsters and the *vory v zakone*, the avtoritety favored corruption, embezzlement, financial crimes, and other forms of white-collar crime. It should be emphasized, however, that these two categories are not mutually exclusive.

Shelley has pointed out that hundreds of banks in Russia are owned or controlled by organized crime groups and that these groups use the banks to launder money, for pyramid schemes, and so on. The capital flight out of Russia, says Shelley, is one of the most damaging aspects of Russian organized crime activity.

Organized crime has been able to penetrate Russian business and state enterprises to a degree that is unheard of in most other countries of the world, even including those where organized crime is present. As already indicated, this penetration occurs in a variety of forms. For example, protection rackets are operated by what are called *kryshas* or roofs. Nearly every business in the major cities must make extortion payments for "protection" by a krysha. This protection sometimes comes in the form of acquiring unwanted partners.

Russian organized crime in Russia itself has most recently evolved into new forms that are diminishing the role of the old *vory v zakone*. Professionalization, globalization, legalization, and patrimonialism characterize these new forms. Their skill at white-collar crimes, for example, electronic crimes and crimes victimizing banking and financial institutions, gives witness to the professionalism of the new Russian criminals. At the same time, a Russian diaspora has developed – particularly in Canada, Israel, and the United States, for example. This diaspora provides a potential critical mass for the development of organized crime in those areas. The globalization is also evident in such activities as worldwide money laundering and in the trafficking of a variety of goods and persons. Through effective use of the mass media and charitable donations and through heavy giving to political campaigns and even electing their own candidates to political office, Russian organized crime has moved to legalize, in effect to legitimize itself. Finally, patrimonialism – via the kind of insider training, the issuance of preferential licenses, and the illegal banking of state funds, referred to earlier – is the other major force driving organized crime into the center of "normal" political activity. Whereas in most societies crime is an outside threat external to the society, in Russia, organized crime is not only pervasive but is very much mainstream.

One expert on Russian organized crime, Mark Galeotti, has pointed out that "Russia's internal situation is the most significant asset of Russian organized crime." The fact that law enforcement officials are corrupt and that politicians are intertwined with criminals makes Russia a safe haven for laundering ill-gotten gains through its banks but also for hiding a variety of other criminal activities and the criminals themselves. Galeotti thinks this might be changing because the political costs of being associated with criminal networks have increased because of pressures from society to reform. Also, he cites the internal "silovik wars," which bring to light rivals' illegal businesses and crimes. As a result, "the 'price tag' for political protection is increasing and those who are not willing to pay are made an example of."

Galeotti says there are now three generations of criminal groupings in Russia: The oldest group is made up of those who came out of the gulag, including the *vory v zakone*. Then there are the *avtoritety*, referred to earlier. Many of these criminal entrepreneurs have moved into the upper levels of the economic and political systems. The newest and third generation is comprised of criminal operatives who likewise have embedded themselves in the ruling political and economic apparatus. Galeotti says "these [latter] criminals come from within the elite and although they are cosmopolitan, educated in the West, and know how to operate internationally, they have opted to continue the criminal activities of their parents as an easy and quick way of making big money."

The kind of sucker mentality that is a legacy of the Russian experience obviously continues to be very much alive and well – not only in Russia but also in Russian émigré communities overseas as well. This is a mentality that extolls getting ahead by getting over. It is based upon an inherent belief that one generally moves up and makes it in the world, not by hard and honest work which is for suckers but rather by scheming and scamming and by using *blat*.

Combating Russian Organized Crime

The current environment in Russia is very conducive to the emergence and sustenance of organized crime and to the export of that crime abroad. Among the structural tools any society needs to resist and combat organized crime are an aware and active civil society, a culture of lawfulness, and a strong public disgust for crime and corruption. At least partly as a legacy of its connive to survive history, such society and culture do not now exist in Russia. Also needed, but likewise in still quite an anemic state for some of the same reasons, is an independent and incorruptible legal and judicial system.

Russia does not have effective legal tools for fighting organized crime nor does it have an effective law enforcement system. As Serio (2008) has noted:

> . . .in order to create an effective organized crime control program, five elements are needed. First, criminal statutes which allow for the prosecution of a criminal enterprise as a whole. . ..Second, there need to be laws which allow for the use of confidential informants and undercover operations. Third, the use of cooperating witness testimony in court proceedings is critical for the successful prosecution of organized crime cases. Fourth, the legal base must permit electronic surveillance and the use of wiretap evidence in court proceedings. And fifth, an effective witness protection program must be in place. Virtually none of these tools are in place in Russia in a meaningful way. . ..

There are a number of explanations for why these legal tools are unavailable or limited in Russia, ranging from holdover concerns about having too much power put into the hands of prosecutors or other law enforcement entities (where it has been abused in the past) to the fact there are a number of occupants of the Russian parliament who are or have been either directly or indirectly involved in organized crime and thus have reason to protect those interests by blocking the passage of certain laws.

"Russian Mafia" Abroad

It has been estimated by the Russian Ministry of Internal Affairs (MIA) that there are some so-named Russian criminal groups operating in upwards of 50 countries. Their greatest presence is in Europe and North America, but they have also shown up in Australia and Israel, for example. As in other historical instances of organized crime, for example, La Cosa Nostra, the most opportune locations for this Russian crime are where there is a budding Russian community that creates a critical mass for victimization. A common language, common culture, common fear of law enforcement, ignorance and distrust of local institutions, and family members back in the former USSR present an inviting target and criminal opportunity.

Russian criminals are known to have been active in the United States since the mid-1970s. Their activity at that time was, however, quite limited and localized in the main Russian-speaking community in Brighton Beach, in Brooklyn, New York. During the 1980s, the numbers of persons from the former Soviet Union allegedly involved in crime grew, and the crimes themselves became more sophisticated and organized. For example, a series of bootleg gasoline tax evasion schemes netted their perpetrators millions of dollars.

Although the types of crimes typically perpetrated require organization to carry them off, the criminal groups engaged in them do not generally possess the characteristics most associated with traditional organized crime. Instead, they have loosely connected and fluid criminal networks. These do not have continuity over time and crimes. They do not have hierarchical structures. They do not attempt to gain monopolization of the criminal market, nor do they systematically use violence and corruption to further their ends. This is not to say they are not violent, for example, but rather that their use of violence tends to be more situation specific and sporadic than systematic. Violence tends to be most associated with their extortion and protection rackets. Most importantly for this discussion, these kinds of free-floating networks do not have any of the characteristics associated with traditional notions of what a mafia is and looks like.

Growing beyond the initial Brighton Beach location, Russian (or better Eurasian) criminals have more recently been said to be active in major metropolitan areas in a number of US states, with California being a particular case. There, Eurasian Organized Crime (EOC) is principally made up of Armenians, Russians, and Ukrainians. Their criminal activities include firearms trafficking, auto theft, cargo theft, extortion, murder, prostitution, money laundering, drugs, and human smuggling and trafficking. Their real specialties, however, are health care and financial frauds. They are said to familiarize themselves with both state and federal government health care policies so as to bilk insurance companies and programs such as Medicare and Medicaid. They engage as well in a wide variety of other frauds. It is this specialization, along with such crimes as identity theft, the black market purchases of various kinds of professional licensing, and staged auto accidents, that most clearly demonstrate the continuing effects of the kind of criminal socialization that gave birth to today's criminals from the former Soviet Union. It is this that is the legacy of the hundreds of years of Russian history.

Two of the better known US prosecutions of criminals from the former Soviet Union are the cases involving Vyacheslav Ivankov, who was Russian, and Semyon Mogilevich, who is Ukrainian. Ivankov, who was nicknamed Yaponchik or Little Japanese, was convicted in 1996 of extortion and marriage fraud. He served 7 years in prison in the United States and was then deported back to Russia where he was subsequently assassinated. He is believed to have been a *vor* and the highest ranking Russian organized crime figure ever in the United States. The Mogilevich case, involving an ongoing prosecution, charges Mogilevich and others with a scheme to defraud investors in the Canadian company YBM Magnex International, Inc. The specific charges are wire fraud, mail fraud, and money laundering.

Given their history, as we see, the predominant crimes of persons from the former USSR in the United States are frauds and scams. The criminal networks they have established are diverse in the criminal opportunities they exploit, and they reflect a blend of legal and illegal activities. Their crimes reflect their descent from the old system of blat, the black market, and the shadow economy. What these criminal networks and their activities do not resemble, however, is what is commonly accepted as constituting that we know as a mafia or at least something that is mafia-like.

Conclusion

So is there a Russian mafia after all? In Russia itself, there are certainly criminal organizations that look and act like a mafia. They have indeed penetrated and embedded themselves in the governing apparatus and are running a number of security operations that entail functions normally in the domain of government. Some experts believe that there is such a nexus between the state and organized crime in Russia and that organized crime has actually become an instrument of state power. Particularly significant, they believe, is the presence of organized crime in such strategic markets as energy and metals, as well as with respect to nuclear power. Another area of both domestic and international threat is in cybercrime, where Russia has many sophisticated perpetrators that are instruments of Russian organized crime.

There are a number of other criminal groups in Russia, however, that although similarly labeled as being mafias, do not actually have mafia trappings. And interestingly, even in Russia, a large number (perhaps even a majority) of criminal groups are not actually or solely Russian. Instead, they are Chechen, Azeri, Dagestani, and Georgian, among others. Of the estimated 800–1,000 or so *vory v zakone* still believed to be active in organized crime groups, the majority of them are said by the MIA to be Georgian.

Without a doubt, organized crime emanating from the former Soviet Union is a major threat, both domestically and internationally. In this sense, it does not matter that "it" is neither Russian nor a mafia. The extent to which a variety of criminal groups under this label have infiltrated business and government in Russia threatens the possibilities for progressive reform and could threaten the stability and national security of the country. Abroad, the ease of international travel, the liberalization of emigration policies, the expansion of foreign trade, the high-tech nature of communications, and the possibilities for money laundering are all changes and vulnerabilities being exploited by criminals from the former Soviet Union. Whatever the label, more and better tools, and more and better collaboration and cooperation within the world community to combat this problem are in everyone's interests.

Sample Selection Models

Brian Johnson
Department of Criminology and Criminal
Justice, University of Maryland, College Park,
MD, USA

Overview

Analytical issues involving sample selection are pervasive in criminological research. This entry provides an introductory overview of the sample selection problem followed by discussion of several common statistical models designed to address sample selection bias in criminological research. Examples of research involving sample selection models are discussed along with the different types of sample selection that can occur and their appropriate modeling strategies. The entry concludes with a brief overview of common criticisms and concerns surrounding sample selection models in the field and discusses future directions for development in this area.

Introduction

Social scientists have long recognized the ubiquitous threat of sample selection. Whether relying on surveys, interviews, official records, or even experiments, sample selection issues are pervasive in criminological research. Whenever information is available on a nonrandom subsample of the population of interest, or when observations are selected through a process that is not independent of the outcome of interest, sample selection bias represents a key threat to empirical validity (Bushway et al. 2007). Examples of selection bias in criminological work are wide ranging. From examinations of police discretion (Worral 2002; Lundman and Kaufman 2003; D'Alessio and Stolzenberg 2003; Kingsnorth et al. 1999) to sentencing disparity (Berk 1983; Hagan and Palloni 1986; Klepper et al. 1983), from publication bias in meta-analysis (Wilson 2010) to the effects of adolescent work on crime (Apel et al. 2008), and from tests of self-control theory (Paternoster and Brame 1998) to examinations of life-course criminology (Laub and Sampson 2003), selection bias often rears its ugly head in criminological research. Indeed, it can be difficult to identify any criminological research question that is not threatened to some degree by sample selection. This entry briefly reviews analytical issues surrounding sample selection bias, including why sample selection leads to biased and inconsistent estimates, how sample selection has been dealt with in criminological research, and how important conceptual distinctions in different types of selection can be classified and understood. The focus is on statistical models that are designed specifically for situations involving censoring or truncation of

the dependent variable, which are collectively referred to here as “sample selection models.”

Sample Selection in Criminological Research

The threat of selection bias is omnipresent in social research, and it is a fundamental aspect of many criminological inquiries – it can result from sundry causes, including natural human behaviors, specific research designs or implementations, or a host of other unforeseen individual, organizational, and environmental causes. Sample selection can result from instrument bias, such as when a survey instrument is designed to collect certain information from only a subset of respondents. It can be caused by sampling strategies that systematically omit certain populations, such as the homeless or incarcerated populations (Mosher et al. 2002). It can also arise through sample attrition, such as when different types of subjects are more likely to drop out of a study than others. Not only is sample selection an important source of bias, but sample selectivity itself may at times be of substantive interest to the researcher as well. If the selection mechanisms affecting the sample are fully known, they can be accounted for through sampling weights or related mechanisms, but rarely are all selection processes easily identifiable or explicitly defined in criminological research.

Various different treatments of sample selection issues have conceptualized the problem in terms of nonresponse, sample attribution, model misspecification, and/or omitted variable bias (Gondolf 2000; Maxwell et al. 2002; Berk 1983; Heckman 1979; Little and Rubin 1987). Selection bias can be understood as a sampling issue (the researcher is limited to information from a nonrandom subsample of the population of interest), a selection problem (observations are selected in such a way that they are not independent of the outcome of interest), or as a statistical problem (a correlation exists between the error term and the independent variable in the model). However it is conceived, though, the basic problem is the same – a researcher is limited to information on the dependent variable that comes from some subsample of observations that is not randomly drawn from the population of interest and therefore is not representative of the larger population to which inferences are to be made. Because statistical inferences are grounded in the principles of random sampling, generalizations based on nonrandom subsamples are likely to lead to faulty causal inferences.

The prototypical example comes from economics, where researchers are often interested in estimating wages, but wages are only observed for employed individuals (e.g., Heckman 1974; Moffitt 1999; Hagan 1990). Hagan (1990), for instance, examined this issue in the context of gender stratification in the justice system, examining income inequality among male and female lawyers. He found that both men and women who were more committed to work roles were more likely to be employed full time, and because commitment to work affected earnings, comparisons based only on full-time employees led to biased estimates of income differentials in the legal profession.

Similar examples are common in other areas of criminological research. Scholars interested in criminal punishment, for instance, only observe severity of charges for arrested offenders, sentence lengths for incarcerated offenders, and recidivism outcomes for offenders who have been released from jail or prison. Of course the same factors associated with being arrested, incarcerated or reoffending are also likely to affect initial charge severity, sentence lengths, and the likelihood of release. The problem, then, is that the process that determines which cases will be observed is fundamentally related to the outcome of interest to the researcher. This means that at any given stage of criminal case processing, the observed sample is unlikely to be representative of the larger population of all offenders from which it originated. Selective attrition through different stages of the justice system produces nonrandom samples of offenders, so estimates based on these subsamples provide biased inferences about relationships in the larger population of interest. Kingsnorth et al. (1999), for instance, investigated the role that victim characteristics and offender-victim relationships played in the severity of case processing outcomes from initial intake to final disposition in a sample of sexual assaults. As they recognized, "Unobserved factors may influence whether a case is continued to the next step," therefore "Failure to take these unobserved influences into account... leads to the problem of sample selection bias" (Kingsnorth et al. 1999, p. 284). Out of the 467 cases in their sample, only 41 % were fully prosecuted and even fewer received terms of incarceration. To address this, these authors implemented sample selection models in an attempt to control for selection bias in their analysis of sentence lengths.

Another source of potential selection bias can arise in offending or victimization surveys that have skip patterns built into them (Winship and Mare 1992). For instance, a researcher might ask survey respondents to report whether or not they have ever been arrested, and then ask additional questions of arrested respondents, such as how the arrest affected their level of satisfaction with police. Analyses based on these questions, though, would only be observed for arrested respondents, so inferences drawn from them would be subject to important selection biases. Negative attitudes towards police, for example, may affect both the probability of arrest and postarrest satisfaction levels, leading to biased inferences for the population. Early research on police satisfaction that relied on police-citizen encounters was limited in this way because it relied on data from only citizens who came in contact with the police (Reisig and Parks 2000). Estimates of satisfaction with the police from this type of selected sample will be biased if there are any differences in satisfaction between individuals who have had contact with the police and those that have not.

Even research designs that incorporate random experiments are often threatened by selection bias. Although experiments represent the quintessential tool for randomizing observations, controlling for unmeasured variables, and drawing improved causal inferences (Weisburd 2010), they are far from catholicons for sample selection. As Sampson (2010, pp. 490–491) recently argued, randomization is "the trump card that the experimentalist plays in the causal inference game" though too often scholars "focus on the benefits of randomization rather than the selection mechanisms that produce the samples in the first place." His point is that randomization can only address selection bias if the researcher begins with a random sample from the population of interest, and often this is not the case. Even when a random sample is available, though, noncompliance, information diffusion or contagion, or sample attrition, interference, and missing data problems may jeopardize causal inferences in experimental research (Berk 2005; Sampson 2010). For instance, differential nonparticipation or implementation across experimental sites can often reintroduce the types of selection bias that experimentation is designed to overcome.

In the majority of research, though, scholars are limited to nonexperimental or observational data. Spohn and Holleran (2002), for example, compared recidivism outcomes in a sample of drug-involved offenders, some of whom were sentenced to probation and others who received prison. They rightly recognized that "offenders sentenced to prison" are "qualitatively different from offenders placed on probation" and that "offenders deemed more threatening and more likely to return to a life of crime will, all else being equal, face higher odds of incarceration" (Spohn and Holleran 2002, p. 340). The problem is that offenders are not randomly assigned to prison and probation so such analyses risk comparing apples to oranges. The authors attempt to control for these differences by including "each offender's predicted probability of incarceration" in their models of recidivism (341). Although this is not explicitly a sample selection model, it follows the same general logic. Similarly, D'Alessio and Stolzenberg (2003, p. 1390) investigated the impact of race on arrest using NIBRS data for four violent crimes. To simplify the analysis, they excluded cases involving multiple offenders or multiple victims. The problem is that race may not exert the same influence in these cases as in cases with a single offender and single victim. They therefore include a "logit-based 'hazard rate' variable to account for the exclusion of crime incidents with multiple offenders and/or victims" – this is essentially a sample selection model to correct for selection bias.

Smith and Paternoster (1990) explore the role of selection bias more explicitly in their examination of the effect of juvenile placement on future offending. From the perspective of labeling theorists, formal sanctions can trigger secondary deviance, in which an individual's self-identity is transformed to accept the deviant label, leading to "deviance amplification" or increased involvement in future deviant behaviors (Lemert 1951). As these authors point out, though, if youth who are more likely to recidivate are also more likely to receive a sentence to juvenile court, then the relationship between the two could be caused by selection bias. In this case the measure of court referral would be capturing unobserved correlates of recidivism that are not included in the statistical model (e.g., predisposition to delinquency), and the result is biased and inconsistent estimates of the effect of placement on recidivism. If there are any omitted variables that affect both placement and future offending, then it may be that youth who are assigned more severe court dispositions would have been more delinquent regardless of their placement in juvenile court. Using data on juvenile offenders in Florida, Smith and Paternoster initially found a positive effect of juvenile court placement on subsequent referral; however, when they employed sample selection models to control for selection bias, this effect disappeared entirely. They interpret this as evidence that the deviance amplification thesis is largely the result of unaccounted-for selection effects in juvenile case processing.

There are numerous other examples of potential selection effects in criminological research. For instance, Brame (2000) discusses the bias that can characterize missing outcome data in randomized experiments and offers an example of this in the context of police response to domestic disputes. Western and Pettit (2005) use data from inmate surveys to impute missing wages for incarcerated offenders who would otherwise be excluded from earnings estimates. They find that the apparent decrease in the black-white wage gap in recent years is largely the product of increasing selection bias due to greater numbers of young African American males being incarcerated. Rhodes et al. (2001) provides a useful discussion of the use of instrumental variables to address selection bias in the context of nonlinear survival models, which offer an alternative approach for examining such things as treatment effects in offender recidivism studies. Paternoster and Brame (1998) examine select propositions rooted in self-control theory by investigating the association between criminal and analogous behaviors using data from the Cambridge Study. They estimate a bivariate probit model that quantifies the magnitude of the association between criminal and analogous behaviors. Similarly, Sampson et al. (2002, p. 466) in their review of neighborhood-level research suggest that "the issue of selection bias is probably the biggest challenge facing neighborhood-level research." They point out that selection bias can arise from residential mobility decisions, when individuals self-select into neighborhoods. In short, these brief examples serve to demonstrate that sample selection issues characterize a dynamic range of criminological research questions. Sample selection models offer one useful analytical approach for addressing selection bias, but before discussing these models, it is necessary to first understand the different ways that sample selection can occur.

Varieties of Sample Selection

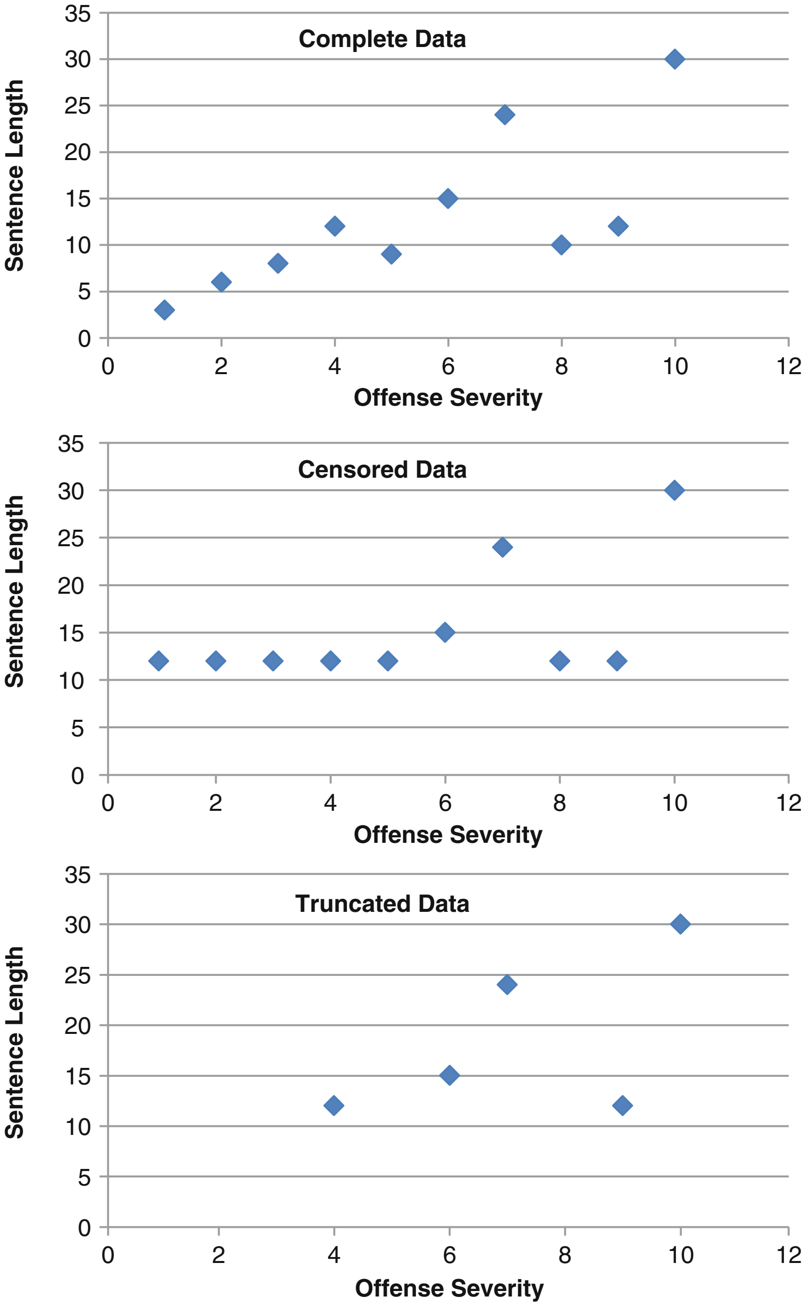
In order to know whether or not sample selection models are appropriate, one must first know what type of selection is present. Sample selection on the dependent variable can occur in two primary ways, which directly affects the type of selection model that should be estimated. Some types of sample selection involve what is referred to as *explicit selection*, which occurs when the selection process is "explicitly" tied to the dependent variable; that is, whether or not a case is observed is a direct function of the score on the dependent variable. Put another way, Y is known only if some criterion defined in terms of Y is met. The researcher does not observe the value of Y for specific values of the dependent variable. Other types of sample selection are characterized by what is referred to as *implicit* or *incidental selection*, which occurs when the selection process results from some external, stochastic function related to the dependent variable. With incidental selection, the likelihood that an observation is excluded from the sample is determined by a separate probabilistic function, and each observation on the dependent variable has some nonzero chance of inclusion. Put another way, Y is observed only if criteria defined in terms of some other random variable is met. Implicit selection processes necessitate different types of selection models than explicit selection processes, so before the researcher can make a decision about how to best account for selection bias, this basic distinction must be understood.

Regardless of whether one is faced with explicit or implicit selection, though, the sample itself can also be characterized by an important distinction between *truncated data* and *censored data*. Truncation occurs when excluded observations provide no data on either the dependent or independent variable. Unobserved cases are unknown for all variables in the data. That is, X is observed only if Y is observed. Censoring, on the other hand, occurs when information is only missing or incomplete on the dependent variable. Information for the other variables in the data is recorded for all cases. That is, X is observed for the entire sample, regardless of whether Y is observed or not. Typically, censored data involves the clustering of observations at some threshold in the data, such that exact values above or below some cutoff are unknown and therefore set to the threshold value. With censored data we have all of the observations on the independent variables, but we don't know the "true" values on the dependent variable if they fall below or above the threshold. These basic distinctions are visually represented in Fig. 1 using the example of sentence lengths that are censored or truncated at 1 year, where each data point represents the sentence of one offender in the data.

To make the discussion more concrete, image that you want to estimate the effect of a criminal record on one's future earnings (e.g., Nagin and Waldfogel 1998). In scenario 1, you use official data that are only collected for a sample of individuals with earnings above the poverty line. This results in explicit selection because the dependent variable, income, determines which cases are observed, and it represents a truncated sample, because no information is known about either prior record or income for omitted cases. In scenario 2, income and criminal history data are collected for all offenders, but incomes below the poverty line are only recorded as "below the poverty line." Exact income values are therefore unknown for offenders who fall below this threshold. In this case, you still have explicit selection based on the dependent variable, but the sample is now censored. Data on criminal history are available for all offenders, but exact information on income is unknown for subjects below the poverty line. In scenario 3, you collect survey data in which income values are missing for a nonrandom subsample of offenders. Sample selection in this case is not an explicit function of the dependent variable in which every value above or below some cutoff value is excluded. Instead, it results from a stochastic process in which the *probability* of being unobserved is nonrandom. For instance, offenders with low incomes may be less likely to answer the survey at all, in which case you have incidental selection with truncation, or perhaps they respond to the survey but refuse to answer the income question, in which case you have incidental selection with censoring. Although different selection processes necessitate different modeling solutions, in general, similar biases result from cases involving both explicit and incidental selection processes.

These basic distinctions are further illustrated in Table 1, which uses the example of criminal sentencing data. Imagine that a researcher is interested in estimating the effect of crime severity on length of imprisonment. The first question is whether there is an explicit or implicit selection process at work. If data on the dependent variable are only collected for prisoners (i.e., offenders sentenced to at least 1 year of incarceration),

Sample Selection Models, Fig. 1 Censored and truncated data distributions



then the researcher is faced with explicit selection. Whether or not the dependent variable is observed is determined fully by the length of imprisonment. The second question then is whether the data are truncated or censored. If data on the independent variable, crime severity, is only collected for prisoners, then the data are truncated – they are missing entirely for offenders who receive less than 12 months of incarceration, as in the upper left-hand box of Table 1. If, however, crime severity data are collected on all convicted offenders, but the dependent variable is only recorded as "less than 1 year" for nonprisoners in the data, then the data are censored,

Sample Selection Models, Table 1 Typology of types of sample selection

		Type of selection	
		Explicit selection	Incidental selection
Type of sample	Truncated	Exact prison lengths are only observed for sentences of 1 year or more. No data are collected from offenders sentenced to less than 1 year of imprisonment	The probability that prison length is observed is a function of other factors related to the likelihood of imprisonment and no data are collected from non-prisoners
	Censored	Exact prison lengths are only observed for sentences of 1 year or more. Data on offense severity are collected from all offenders but sentences are only recorded as “less than 1 year” for non-prisoners	The probability that prison length is observed is a function of other factors related to the likelihood of imprisonment. Data on independent variables are collected from all offenders but prison lengths are only known for prisoners

Sample Selection Models, Table 2 Censored, truncated and sample selected models

	Y	X	Example
Censored (explicit, censored)	Y is known only if some criterion defined in terms of y is met	X is observed for the entire sample, regardless of whether Y is observed or not	Exact prison lengths are recorded only for terms of 1 year or greater. Shorter sentences are recorded as “less than 1 year”
Truncated (explicit, truncated)	Y is known only if some criterion defined in terms of y is met	X is observed only if Y is observed	Prison lengths are only recorded for terms of 1 year or greater. No data are collected for offenders sentenced to less than 1 year of incarceration
Sample selected (incidental, censored)	Y is observed only if criteria defined in terms of some other random variable (Z) are met	X and W (the determinants of whether Z = 1) are observed for the entire sample, regardless of whether Y is observed or not	Prison lengths are recorded only for offenders who are imprisoned and the probability of imprisonment is a function of other factors, such as offense severity

Adapted from Breen (1996)

as in the lower left-hand box in Table 2. Information on the independent variable would be available for all offenders, but exact sentence lengths would be unobserved for offenders sentenced to less than 1 year of incarceration. The alternative to explicit selection is implicit selection. If the likelihood that any given prison length is observed is a function of other factors related to sentencing, then implicit selection is at work. If no data are collected from certain offenders, then the sample is once again truncated as in the upper right-hand box of Table 1. If, however, prison lengths are missing as a function of other sentencing factors related to imprisonment, but offense severity is known for all offenders, then the sample is characterized by incidental selection with censoring as in the lower right-hand box of Table 1.

Figure 2, adapted from Bushway et al. (2007), provides a schematic heuristic outlining the decision-making process involved in selecting an appropriate selection model depending on the type of sample selection that is present. Detailed discussion of these models follows below, but the point here is that it is essential to understand the type of selection one is faced with before deciding how to attempt to correct for selection bias. In the face of explicit selection, the sample selection process is inherently tied to the dependent variable. When data are truncated, truncated

regression models can be estimated. When data are censored, Tobit regression models may be appropriate (Tobin 1958). These two approaches are similar except that the Tobit model is able to incorporate information on the independent variables of censored cases in the parameter estimates of the substantive equation, whereas this information is unavailable in truncated samples. When incidental selection is present, one must make a determination about whether or not the selection process is independent of the outcome of interest. If the selection process is unrelated to the outcome, then by definition selection bias is not a problem and two separate, independent models can be estimated, known as the two-part model (discussed below). If, however, the selection process is related to the outcome, then selection bias becomes a concern, and Heckman's two-part sample selection model may provide improved model estimates.

The astute reader will notice that regardless of which type of selection process is operative, under incidental selection, both model choices apply only to censored data. The reason for this is because with truncated data, no information is available on the characteristics of the excluded cases, so it becomes impossible to model the selection process in the presence of incidental selection involving truncated data. Theoretically, it is possible that an exogenous selection process determines which cases are omitted, but if no data is collected from the omitted cases, this process cannot be formally modeled with traditional selection models. For this reason, some treatments (e.g., Breen 1996) of selection bias collapse the four boxes in Table 1 into the three categories summarized in Table 2. Once a researcher knows what type of sample selection is occurring, then it becomes possible to choose an appropriate statistical model. For censored samples, the fundamental logic involves a two-stage modeling procedure that attempts to first capture the selection process and then correct for it in the substantive model of interest.

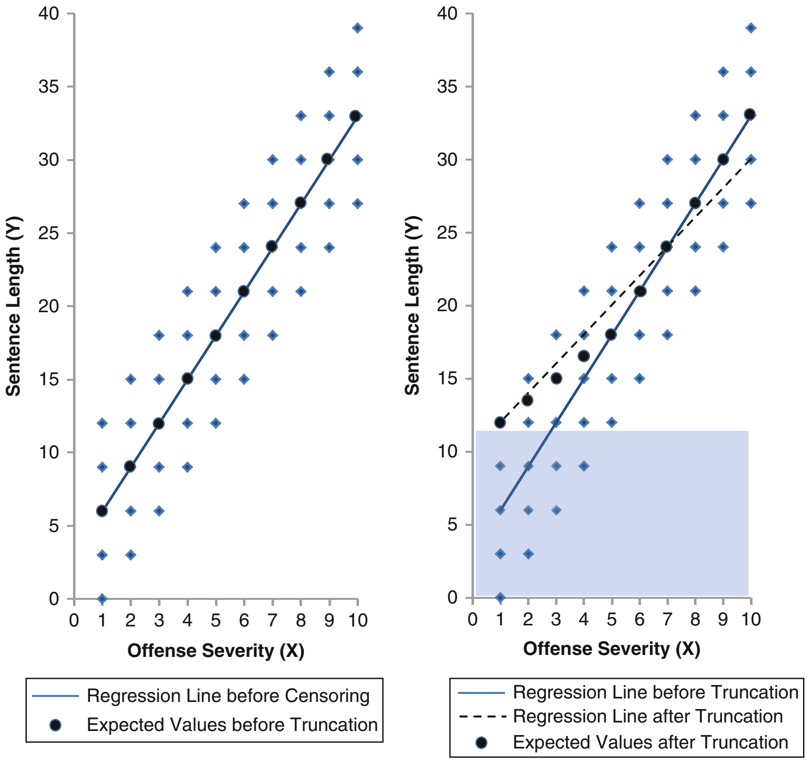
The Sample Selection Problem

Before turning to an elaboration of common types of statistical models that can be employed when faced with sample selection, it is instructive to first consider the limitations of the ordinary least squares regression model and how analyses conducted on selected subsamples can lead to biased statistical inferences. For illustrative purposes, the ordinary regression model is presented in Eq. 1:

$$Y = \beta X + \varepsilon \tag{1}$$

In this model, Y is a continuous outcome, such as sentence length; X is an exogenous independent variable, such as crime severity; and ε is a normally distributed error term with an

Sample Selection Models, Fig. 3 The effects of truncation on the ordinary regression line and expected values



expected value of zero for each value of *X*. We assume that the functional form between *X* and *Y* is linear and additive, that the conditional distribution of *Y* is normal with uniform standard deviations, that observations are independent, and that *X* is uncorrelated with the error term ε. When these assumptions are met, the OLS estimator will provide unbiased and consistent estimates of the model parameters. Selection processes typically introduce an association between the error term and the exogenous variable in the model; in this context, then, selection bias can be understood as a violation of traditional OLS model assumptions.

Imagine that you want to examine the relationship between crime severity and sentence length in a random sample of 50 convicted offenders. The sample selection problem is that not all sentence lengths are observed. If the unobserved cases are comprised of a random subset of cases, then selection bias is not a problem. Typically, though, prison sentences are reserved for confinement sentences of 1 year or more, with shorter sentences being served in county jail. In an analysis of sentence lengths that relies on prison data, then, shorter terms of confinement (and concomitantly less serious crimes) will be systematically excluded from observation. In this example, the researcher would be faced with explicit selection in a truncated sample, though it is just as easy to conceive of related examples that involve implicit selection and/or censored samples and the biases introduced are comparable. This scenario is demonstrated in Fig. 3, which reproduces a similar example discussed in Berk (1983).

The shaded area represents sentence lengths of less than 12 months, which are omitted from the prison data. The solid line is the regression line based on all of the values if sentences of less than 12 months are included, and the dashed line is an approximation of the regression line you might expect based on only the non-truncated observations. Recall that one of the key assumptions of OLS is that the expected value for the disturbance term is zero for all values of *X*. That is, the fitted values from the model should match the means of the observed data. In the complete data shown in the left-hand panel above, the expected values fall directly on the solid regression line. For instance, when offense severity is one, the expected sentence based on the five data points would be 6 months. In the truncated sample, however, the expected values no longer conform to the original regression line, nor do they align with the adjusted line after truncation. For offense severity scores below five (where the truncation occurs), the expected values fall systematically above the original regression line. Sample selection in this case results in expected values that are shifted upward. For instance, when offense severity is one in the truncated sample, the expected sentence is shifted from 6 to 12 months. When offense severity is equal to two, the expected sentence shifts from 9 to 13.5 months and so on. The regression line no longer coincides with the expected values at each value of X, and the errors associated with the regression line will no longer have expected values of zero in this range. The regression line estimated on the truncated sample systematically falls on or above the expected values when offense severity is low, and it falls below the expected values when offense severity is high. The truncation of low values on Y therefore introduces a correlation between the exogenous variable, offense severity, and the error term in the regression model, which violates OLS assumptions and leads to bias in the estimated parameters.

Several observations are readily apparent from Fig. 3. First, the regression line for the truncated observations is different from the regression line for the complete data. Compared to the true relationship for all offenders, the truncated relationship is attenuated. The effect of selection bias in this instance is to underestimate the relationship between offense severity and sentence length. Of course other types of censoring in other scenarios may just as easily lead to overestimates of relationships in the population. Second, the expected values (the black circles) after censoring no longer conform to the expected linear relationship between X and Y. This reflects the fact that the degree of censoring is increased at lower values of the exogenous variable. The regression line, in a sense, is flattened as it nears the censoring floor. This violates another assumption of ordinary least squares, namely, that the relationship between the independent and dependent variable is linear. In this context, then, the problem of selection bias can be understood as a specification error regarding the wrong functional form of the relationship (Berk 1983).

There are several implications to the violations of these model assumptions. First, external validity is compromised. The estimated relationship in the censored sample does not represent the true relationship between offense severity and sentence length for all sentenced offenders. The regression slope is a biased estimate of the true relationship in the population. Second, internal validity is also compromised. This is seldom understood. It is common for researchers to claim an interest in only the selected subsample as a means of deflecting concerns over selection bias, but because the regression line from the truncated sample will systematically overestimate the relationship between X and Y for lower values of offense severity and underestimate it for higher values, the error term will be positively correlated with X, which will produce biased and inconsistent parameter estimates, *even if one claims an interest in only the subsample of observed cases*. In sum, the systematic exclusion of nonrandom observations from a sample is likely to inadvertently induce a relationship between observed variables and the error term, which produces biased and inconsistent parameter estimates. This unintended correlation is at the heart of the selection bias problem in diverse criminological research.

To further demonstrate, imagine an ordinary regression equation where Y is a measure of the number of future arrests, X is whether or not an offender went through some treatment program expected to lower the number of arrests, and β estimates the effect of program participation on future arrests. The least squares solution to β is provided in Eq. 2.1, and the expected value for $\hat{\beta}$ after substitution is given in Eq. 2.2:

$$\hat{\beta} = (\acute{X}X)^{-1}\acute{X}Y \tag{2.1}$$

$$E(\hat{\beta}) = \beta + E[(\acute{X}X)^{-1}\acute{X}\varepsilon] \tag{2.2}$$

If the covariance between X and ε is 0, then the second term on the right-hand side of the equation is zero and the expected value of $\hat{\beta}$ is equal to its true value β. If however X and ε are correlated, then this term does not drop out of the equation and the estimated value for β is no longer equal to its true value. This reflects the influence of selection bias on the program effect in our example. Heckman (1976, 1979) demonstrates that this type of selection problem can be understood in terms of a specification error where the second parameter in Eq. 2.2 represents an omitted variable that is not included in the ordinary regression model. This omitted variable will produce biased estimates of our program effect in the current example. By systematically excluding certain observations, one introduces the need for an additional regressor to capture the selection process. Heckman's solution is the use of a two-step estimator that first models the sample selection process and then introduces an additional regressor to capture the selection process in the outcome equation. As others have shown, the degree of bias introduced by sample selection will depend on a number of factors, including the degree and location of censoring and the strength of the correlation between the exogenous variable and the error terms in the two equations (Stolzenberg and Relles 1990, 1997; Bushway et al. 2007).

State of the Art: Statistical Models for Addressing Sample Selection

The Simple Two-Part Model

To be clear, statistical inferences based on subsets of data are not inherently problematic. If the missing observations comprise a random subset of cases from the population, OLS will continue to provide unbiased and consistent estimates with only a loss of efficiency. In the case of incidental selection with randomly missing data, for example, a simple two-part model (TPM) can be estimated (Duan et al. 1983, 1984). The researcher can model the selection process using a binary outcome model, such as a probit or logit, followed by a separate OLS model for the continuous outcome of interest, which is estimated on the selected subset of observed cases. This two-part model is presented in Eqs. 3.1 and 3.2:

$$P = \gamma Z + \delta \tag{3.1}$$

$$Y = \beta X + \varepsilon \tag{3.2}$$

In this model, P is a dummy variable equal to 1 if the subject is selected and 0 otherwise, and Y is the substantive outcome of interest. Z represents an exogenous independent variable related to the probability of being selected, and all the parameters in Eq. 3.2 are equivalent to Eq. 1. The assumption of the two-part model is that the error term in Eq. 3.2 is uncorrelated with the error term in Eq. 3.1. That is, we must assume that there are no unobserved factors that are related to both the selection process and the substantive outcome of interest. Statistically speaking, we assume that the conditional expectation of ε is zero for all values of X. Under these conditions, there is no selection bias and the simple two-part model above will provide unbiased and consistent estimates of the coefficients of interest. When these assumptions are violated, however, parameter estimates from this "uncorrected" model will be biased and inconsistent. When that is the case, a variety of statistical models can be estimated in an attempt to address the selection effect.

Tobit and Truncated Regression

As Fig. 3 suggests, the Tobit model is appropriate when a researcher is faced with explicit selection with a continuous outcome that is censored or bounded by a limiting value. In some sense, this is the simplest model for addressing sample selection because it involves a single selection process based on the dependent variable (i.e., explicit selection). This model, first proposed by Tobin (1958), accounts for the fact that all values falling above (or below) a certain threshold on the dependent value are observed as part of a continuous distribution, whereas values falling below (or above) some threshold are censored. These censored cases remain in the data and provide information on the independent, but information on the dependent variable is treated as unknown. The model assumes a normal error distribution and a linear relationship between the exogenous predictor and a latent continuous variable, which differs from the observed values because it includes the range of values that fall below the censoring threshold. The relationship between the observed and latent variables is summarized in Eq. 4:

$$\begin{aligned} Y &= Y^* \text{ if } Y^* > c \\ Y &= c \text{ if } Y^* \leq c \end{aligned} \tag{4}$$

Y represents the observed dimension of the dependent variable, Y^* the latent dimension, and c the censoring value given censoring occurs from below. In practice, the censoring threshold can take on different values under different theoretical frameworks and may involve multiple censoring values at either or both ends of the distribution. Scores for the observed values of the dependent variable, then, are equivalent to scores on the latent variable when they are above the censoring value, and when they fall at or below the censoring value, they equal the cutoff value. Conceptually, the Tobit model treats the censored values on the outcome as part of an underlying latent continuum, the values which are treated as unknown for observations that fall below the censoring value. For example, Y^* might represent the latent propensity to offend, which is only realized as actual offending, Y, for offenders who have been arrested in the data. Although numerous observations may share a value of 0 in the data, in theory they have different values on the underlying latent variable. The explanatory variables in the model, then, are linearly related to this latent dimension of the dependent variable Y^* as shown in Eq. 5, which can be rewritten in terms of the observed variable, Y, in Eq. 6:

$$Y^* = \beta X + \varepsilon \tag{5}$$

$$\begin{aligned} Y &= \beta X + \varepsilon \text{ if } Y > c \\ Y &= c \text{ if } Y \leq c \end{aligned} \tag{6}$$

The model assumes the errors ε are independent and normally distributed with a constant variance and can be estimated using maximum likelihood procedures that combine a standard probit model for the censoring of values with an ordinary linear model for the observed values (Osgood et al. 2002). The expected value of Y, then, is equal to the conditional probability of censoring times the conditional expectation of Y given it falls above the censoring threshold. The same explanatory variable is used to characterize both the probability of censoring and the linear relationship of X to Y for uncensored observations. The Tobit model assumes that the error terms from the probit and linear models are a singular normal density (i.e., that they are equal) and that the independent variables and their associated coefficients from the two models are equivalent. Heckman (1976) shows that the Tobit model can be understood as a special case of the two-step sample selection model (discussed below) in which the error terms, explanatory variables, and regression coefficients are constrained to be equal in the selection and substantive equations. Equivalency among the explanatory factors is a key assumption of the Tobit model, though alternative formulations have been proposed that relax these assumptions. For instance, Cragg (1971) offers a reformulation of the model that allows the effects of explanatory variables to vary between the selection and substantive equations, and Smith and Brame (2003) discuss the advantages of this model. Useful elaborations of Tobit regression that are relatively accessible are provided in Breen (1996), Long (1997), and Osgood et al. (2002).

The Tobit model is appropriate when there is explicit selection with censored data. As Table 1 suggests, however, explicit selection may also occur with truncated samples in which case information is missing on both the independent and dependent variables in omitted cases. In such a scenario, truncated regression models can be employed to correct model estimates (represented by the upper left-hand box in Table 1). Because implicit selection processes require information on the explanatory variables to model the stochastic selection process, there is no straightforward solution to sample selection involving truncated samples with implicit selection (represented by the upper right-hand box in Table 1). The truncated regression model is similar to the Tobit model in that the dependent variable Y is only observed if some censoring value c is exceeded. In the Tobit model, however, the selection process is captured using a probit model, whereas in a truncated model the requisite information for the probit equation is now missing. However, the log-likelihood function for the truncated regression model can be estimated using maximum likelihood. It is similar to the Tobit log-likelihood function for the uncensored observations, but the density function for the truncated normal distribution includes an additional term that captures the truncation point. In essence, the model assumes that the conditional distribution of the dependent variable is normal and that the excluded values, if observed, would also follow a normal distribution. The truncated regression model has not been used extensively in criminological research but Hausman and Wise (1977) and Breen (1996) provide useful elaborations of it.

Heckman's Two-Part Sample Selection Model

Perhaps the most widely used approach for addressing sample selection bias in criminology has been Heckman's two-part sample selection model. Figure 3 makes it clear that the model is appropriate when the researcher is faced with incidental selection in a censored sample. Unlike the Tobit model, which assumes a single process characterizes both the selection process and the outcome of interest, Heckman's sample selection model provides for a separate stochastic process that determines selection into the sample. The first step in calculating this model is to estimate a probit model for the selection process, which is then used to control for the probability of being excluded from the sample in the substantive equation of interest. In essence, the two-part model calculates a predicted probability of being excluded from the observed sample, and then it controls for that probability in the substantive equation of interest. The statistical model that summarizes Heckman's two-part solution for selection bias is represented by Eqs. 7.1 and 7.2 below:

$$P = \gamma Z + \delta \tag{7.1}$$

$$Y = \beta X + \sigma\rho\lambda(\beta X) + \varepsilon \tag{7.2}$$

Comparison of Eqs. 7.1 and 7.2 with 3.1 and 3.2 makes it clear that the essential difference between the simple uncorrected two-part model and Heckman's two-part sample selection model is that the latter includes the additional regressor $\sigma\rho\lambda(\beta X)$, where $\lambda(\beta X)$ is equal to $\varphi(\beta X)/(1-\Phi(\beta X))$, or the inverse Mills' ratio, which represents "a monotone decreasing function of the probability that an observation is selected into the sample" (Heckman 1979, p. 156). This is also sometimes referred to as the "hazard rate" because it captures the instantaneous probability of exclusion conditional on being at risk for each observation. The ρ in Eq. 3.2 represents the correlation between the two error terms, δ and ε, which is assumed to follow a bivariate normal distribution, and the σ parameter represents the effect of selection on the outcome Y. If the correlation between the two errors is zero ($\rho = 0$), then the extra parameter drops out of the equation and there is no selection bias.

To calculate Heckman's sample selection model, the probit equation is first estimated and the predicted probabilities are retained and then subsequently used to calculate the inverse Mills' ratio described above. Using the probit equation, expected values for the residuals for each individual in the data are saved, conditional on the observed variables Z, and whether or not an individual was selected ($P = 1$) or not ($P = 0$) (i.e., $E[\delta|X, P]$) (see Heckman 1978, p. 938). If the case is selected (i.e., if $P = 1$), then $E[\delta|X, P = 1]$ is equal to $\frac{\varphi(\hat{P})}{\Phi(\hat{P})}$ where φ and Φ represent the standard normal density and cumulative distribution functions, respectively. If the case is not selected, (i.e., if $P = 0$), then $E[\delta/X, P = 0]$ is equal to $\frac{-\varphi(\hat{P})}{[1-\Phi(\hat{P})]}$. In essence, the conditional residuals are used to capture information for each individual on unobservable factors that are related to the selection process. To illustrate, consider two individuals, one whose predicted value is 0.5 and one whose predicted value is −0.5. Calculating the probabilities of being selected into the sample, we get a value of 0.69 for the first individual and a value of 0.31 for the second. Now imagine that both individuals are selected, even though the first individual had a much higher predicted probability. This suggests that the individual with the lower predicted probability who was nevertheless selected into the sample was more likely to have had unobserved factors that were positively associated with selection. Among cases that are selected, then, those with lower probabilities should have larger (i.e., more positive) residuals. If we plug the hypothetical probabilities above into the expectation for $E[\delta/\mathrm{X}, P]$, we get a value of 1.14 for the case with the lower probability of selection and a value of only 0.51 for the case with the higher probability of selection. The values of the conditional residuals from the selection equation therefore serve to help capture the unobserved factors that are related to selection. In a sense, the Heckman model uses the conditional residuals from the selection equation to create an additional regressor that helps to control for unobserved heterogeneity.

This additional regressor is included in the substantive equation of interest in Eq. 3.2 to correct for selection bias. As Heckman (1979) shows, the least squares estimator will be unbiased but inefficient. Inefficiency is introduced by the censoring of the data, which produces heteroskedasticity in the error terms and leads to downwardly biased estimates of the population variance. This necessitates a correction for the standard errors in the model. According to Bushway et al. (2007), standard errors on average can be underestimated by between 10 % and 30 %. These authors identify a number of common errors that characterize prior attempts to use Heckman's model in criminological applications, such as the miscalculation of the inverse Mills' ratio and failure to properly correct for misestimated standard errors. These issues are now easily addressed by canned routines for Heckman's model that are now readily available in standard statistical packages and properly calculate lambda and correct the standard errors. In Stata, for instance, the basic two-step sample selection model can be estimated as follows: "*heckman Y X*, *twostep select(Z)*" where *Y* is the dependent variable, *X* is the vector of independent variables included in the substantive equation of interest, and Z is the vector of independent variables included in the probit selection equation. All that the researcher has to do is to specify a sample selection model and then identify which exogenous variables to include in the selection and substantive equations, respectively. In addition to the two-step procedure outlined above, the Heckman model can also be estimated using maximum likelihood. In general, the maximum likelihood estimator will be more efficient than the two-stage estimator though it may be more sensitive to violations of model assumptions (Bushway et al. 2007).

Importantly, when *Z* and *X* contain the same set of independent variables, the Heckman sample selection model is only identified by the nonlinearity introduced by the inverse Mills' ratio. Prior research demonstrates that this can lead to severe inflation of standard errors, which results from collinearity between the correction term and the other regressors in the model (Stolzenberg and Relles 1990). When the same predictors are used in the selection and substantive equations, the sigma term in Eq. 7.2 will be correlated with *X*. Therefore, whenever possible, *exclusion restrictions* should be included in the sample selection model. Exclusion restrictions are similar to instrumental variables – they are predictors that are related to the selection process but not related to the substantive outcome. For example, Albonetti (1991) included evidentiary measures in her selection equation for the likelihood of conviction, but not her substantive equation for sentence severity. Similarly, Smith and Paternoster (1990) included the caseload and number of diversionary programs in their selection model for juvenile placement but not for their substantive equation examining recidivism. The key is to identify factors that are theoretically related to the selection process but not to the outcome of interest, and whenever possible, researchers should search for and include valid exclusion restrictions when estimating this model.

The Bivariate Probit Model

Heckman's sample selection model applies to the case in which the substantive outcome of interest is a continuous variable. When the dependent variable is dichotomous, as is often the case in criminological research, then an alternative specification can be employed. The bivariate probit model involves estimation of two probit equations allowing their error terms to be correlated. This is useful when there is a binary selection process and a binary outcome in the substantive equation of interest (Heckman 1976). Whenever two dichotomous dependent variables are jointly determined, or when there is reason to believe that error terms of two binary outcomes are correlated, then the bivariate probit model can offer a useful approach for modeling this dependence. The basic model is summarized in Eqs. 8.1 and 8.2:

$$P_2 = \gamma Z + \delta \tag{8.1}$$

$$P_1 = \beta X + \varepsilon \tag{8.2}$$

If the two error terms in Eqs. 8.1 and 8.2 are independent (i.e., $Cov(\delta, \varepsilon) = 0$), then selection bias is not a problem and the two equations can be estimated separately. If, however, the two errors are related (e.g., $(\delta = \eta + u_1)$ and $(\varepsilon = \eta + u_2)$), so that part of the error (i.e., (η)) is common to both equations, then the same type of selection bias discussed above will bias model estimates. When this is the case, interest shifts to the joint probability of P_2 and P_1. The model assumes the error terms in each equation are normally distributed and that their joint distribution is bivariate normal, and as with the Heckman model above, the association between errors is represented by the correlation coefficient rho (ρ). The bivariate probit can be estimated using maximum likelihood procedures that are readily available in common statistical packages. In Stata, for instance, the bivariate probit model can be estimated as follows: "*heckprob P_1 X, select(P_2)*" where P_1 is the second probit outcome, X is the vector of independent variables included in that equation, and Z is the vector of independent variables included in the first probit equation.

The bivariate probit can be used in basic applications to allow the two outcomes to be correlated, or it can be used equivalently to the Heckman selection model to capture a binary selection process that determines inclusion in a binary substantive outcome of interest. Paternoster and Brame (1998), for instance, investigated whether or not criminal behavior was associated with analogous noncriminal behavior (Paternoster and Brame 1998) where both criminal and analogous behaviors were measured as dichotomous outcomes. They used a bivariate probit to model the joint distribution of the two outcomes in order to estimate the strength of their association. Berinsky (2004), on the other hand, utilized the bivariate probit to explicitly correct for sample selection, where the first model was whether or not a respondent answered a survey question and the second was a dichotomous measure of racial attitudes. For the bivariate probit, it is essential that valid exclusion restrictions be included. Dubin and Rivers (1990) discuss application of the binary selection model, and Sartori (2003) offers an alternative estimator that may be preferable if exclusion restrictions are unavailable.

Contemporary Controversies

A number of scholars both in and outside of criminology have discussed at length the potential strengths and weaknesses of sample selection models (Bushway et al. 2007; Winship and Mare 1992; Duan et al. 1983, 1984; Manning et al. 1987; Leung and Yu 1996; Jones 2000; Norton et al. 2008). As Breen (1996, p. 58) summarized, "it is now clear that these models need to be approached with a degree of care." Sample selection models work the best when there are strong exclusion restrictions and when distributional assumptions are clearly met. As others have shown, routinized application of sample selection models without careful circumspection can produce estimates that are no better and sometimes worse than those obtained through ordinary regression techniques obtained from simple two-part models (Duan et al. 1983, 1984). A number of potential concerns need to be considered when deciding whether or not it is advisable to employ a sample selection model.

First, sample selection models have been shown to be sensitive to violations of their distributional assumptions, including heteroskedasticity of errors and violations of normality. Whereas OLS estimates are consistent but not efficient in the presence of heteroskedasticity, estimates from sample selection models are neither consistent nor efficient (Amemiya 1985). Alternative functional forms can be specified for error distributions to address the first issue (Maddala 1983), and a semi-parametric or non-parametric methods that relax model assumptions might be used to address the latter (Heckman et al. 1999; Vella 1999; Moffitt 1999; Chay and Powell 2001). Winship and Mare (1992) discuss some of these approaches, though applications of them remain rare in criminological work. Still, the first step in deciding whether or not sample selection models are appropriate is to examine the validity of distributional assumptions regarding homoskedasticity and normality – Chesher and Irish (1987) provide a useful discussion of how this can be approached. Even if we assume that distributional assumptions are met, though, the performance of sample selection models is affected by additional factors that include the strength of the correlation (ρ) between the error terms in the selection and substantive equations, the degree of overlap in the variables included in the selection and substantive equations, and the size of the sample and degree of censoring in the data. The stronger the correlation is between errors, the larger the threat of sample selection bias and, in general, the greater need for sample selection corrections. Therefore, a researcher needs to have strong theory regarding the association between the selection process and the outcome of interest to help guide the decision to use sample selection models.

Second, it is important for researchers to carefully search for, identify, and incorporate theoretically valid exclusion restrictions into their sample selection models. A number of commentators have expressed reservations about identifying the model using only the nonlinear functional form (e.g., Berk and Ray 1982). Doing so typically leads to high variance estimates and often results in problematic levels of multicollinearity between the correction term and the other independent variables in the model. The problem tends to be exacerbated when the selection model poorly fits the data and has low levels of explained variance. If we do a poor job of capturing the selection process, then the correction for selection will have limited utility.

Third, the performance of sample selection models is also tied to the degree of censoring in the data. In samples with minimal censoring, the sample selection models may not be needed. Low degrees of censoring will introduce less bias into parameter estimates than high degrees of censoring. However, in samples with high degrees of censoring, these models can also be problematic. Stolzenberg and Relles (1990, p. 406), for instance, examined the effectiveness of sample selection corrections in small samples with severe censoring and concluded that "Heckman's method reduced the accuracy of coefficient estimates as often as it improved them." They concluded that "there is considerable evidence that the method can easily do more harm than good, and that its careless and mechanical application runs much danger" (Stolzenberg and Relles 1990, pp. 408–409). To abandon sample selection models altogether, however, would be to throw out the baby with the bathwater. In general, larger samples are preferable to smaller samples when implementing sample selection corrections, whereas the simple uncorrected two-part model is likely to be preferred when explained variance is low or when the estimate of the correlation between error terms is near zero. When sample selection models are deemed appropriate, the maximum likelihood estimators will be more efficient than Heckman's original two-step approach. In practice, the effects of the size of rho, the overlap in the predictors in the two equations, and the sample size and degree of censoring are often intertwined and can be difficult to disentangle. The researcher is therefore often faced with the unhappy decision to either estimate the simple two-part model, which will knowingly produce biased estimates, or alternatively to implement a sample selection model that can under certain conditions make estimates worse. Luckily, there are several approaches that can help assess the feasibility of implementing sample selection models to correct for selection bias.

Lueng and Yu (1996, 2000) discuss the conditions under which sample selection models can suffer from multicollinearity problems, and they discuss some practical approaches for dealing with this problem. Specifically, they recommend researchers calculate the "condition number" as a measure of collinearity, and they recommend that condition numbers over 20 indicate Heckman's correction is likely to perform worse than simple uncorrected two-part models. Other diagnostic tests are also available. For instance, Manski (1990) outlines a useful approach for bounding estimates of selection bias (see also Nagin and Manski 1999). The interval of the bounds varies inversely with the degree of censoring so lower proportions of censored cases result in narrower bounding ranges. Winship and Mare (1992) discuss his method and related approaches. More recently, Stolzenberg and Relles (1997) have outlined a useful methodology for estimating the amount of bias associated with specific parameter estimates in a model, and Bushway et al. (2007) demonstrate the utility of this approach by applying it to the context of criminal sentencing. The approach allows one to quantify the amount of bias introduced by the selection process, providing for better informed decisions regarding the necessity of using sample selection models in place of ordinary regression. Before deciding whether or not to implement sample selection models, then, it is instructive to first examine distributional assumptions, to carefully search for valid exclusion restrictions, and to conduct exploratory analyses that help assess the degree of the problem and the necessity of addressing it.

Conclusion

Sample selectivity has long been a topic of applied theoretical and methodological work in sociology and economics (Heckman 1974; Winship and Mare 1992; LaLonde 1986; Berk 1983), and in recent years it has become a popular analytical technique in criminology and criminal justice (Bushway et al. 2007). Although sample selection models can provide a very useful approach for addressing important selection biases that are pervasive in criminological research, "Infallible models for sample selection bias do not exist" (Winship and Mare 1992, p. 347) and "whatever happens to be the methodological tool du jour is too often oversold" (Berk 2005, p. 2). This suggests the need for careful consideration of the potential strengths and weaknesses of sample selection corrections in applied criminological work. As Winship and Mare (1992, p. 329) argue, "models for selection bias are only as good as their assumptions about the way that selection occurs, and estimation strategies are needed that are robust under a variety of assumptions."

Numerous extensions of these basic models are continuously being developed. Outcome measures are at times available for both the selected and unselected samples (e.g., Spohn and Holleran 2002). Moreover, it is not uncommon for certain applications to include multiple selection points across multiple outcomes of interest. Research on the criminal justice system, for instance, inherently involves multiple censoring points across successive stages of criminal case processing (Kingsnorth et al. 1999). In some applications, multiple censoring or truncation points may even be different for different subjects in a sample, and in general, the basic models discussed herein can readily accommodate such complexities without drastically increasing the difficulty of their application (Breen 1996; Maddala 1983).

The challenge for criminologists faced with sample selection then is to be diligent and circumspect, carefully formulating a theoretical model of the selection process before selecting an appropriate modeling strategy. Importantly, there are a number of different approaches that can be useful for addressing different forms of selection bias, such as experiments, statistical matching procedures, and instrumental variable approaches (e.g., Bushway and Apel 2010; Loughran and Mulvey 2010; Taxman and Rhodes 2010), and in many ways models for sample selection share considerable affinity with other quasi-experimental approaches for addressing selection bias (Lalonde 1986; Heckman and Robb 1986). Researchers should therefore investigate sample selection concerns through a variety of complementary methods whenever possible. Smith and Paternoster (1990) offer an excellent example of this type of research. They rightfully argue that "there is no one generic cure for selectivity bias and that applications of these models must make substantive sense in the context of specific applications" (Smith and Paternoster 1990, p. 1125). Similarly, Winship and Mare (1992, p. 328) conclude that "The large number of available methods and the difficulty of modeling selection indicate that researchers should be explicit about the assumptions behind their methods and should present results that derive from a variety of methods." The sample selection models discussed in this entry offer one useful approach for investigating and potentially correcting for selection bias when researchers are faced with censored or truncated data on their dependent variable of interest.

Sample Selection Problems

Robert Apel
School of Criminal Justice, Rutgers University,
Newark, NJ, USA

Overview

In a seminal series of contributions that would culminate in his being awarded the Nobel Prize in Economics in 2000, James Heckman proposed a deceptively simple solution to the problem posed by sample selection bias (Heckman 1976, 1979). In the classic formulation of the problem, the analyst desires to estimate a wage or earnings function from a collection of individuals sampled randomly from the population. While one wishes to generalize to the population of all wage offers, it is obvious that wages are only observed for individuals who are employed. The problem that arises is that these individuals are a self-selected (i.e., nonrandom) subset of the population, and consequently their wages cannot necessarily be used to estimate what the wages of nonworking individuals would have been, had they chosen to work. So a regression of (log) wages on a determinant such as schooling, limited to the subsample of workers, will potentially yield biased estimates of the impact of schooling on wages for the population of interest.

In criminology, a similar challenge is encountered in studies of the determinants of criminal sentencing. For example, one might be interested in studying the impact of legally irrelevant factors (e.g., gender, race) on sentencing decisions once legally relevant factors (e.g., offense seriousness, criminal history) have been netted out. However, sentence lengths are only observed for convicted offenders who are sent to prison. The determinants of sentence length among these individuals are not necessarily representative of what the determinants of sentence length would have been among non-incarcerated individuals, had they instead been incarcerated. Whereas the population of interest entails all criminal sentences rather than strictly carceral ones, the latter are a decidedly nonrandom subset of all convicted offenders. Many other examples that have criminological relevance are provided in Berk (1983), Winship and Mare (1992), Bushway et al. (2007).

Heckman (1976, 1979) formulated the problem as one of missing data giving rise to specification error. If the process that determines whether an individual is "uncensored" with respect to the outcome of interest (e.g., employed, incarcerated) is correlated with the process that determines the mean outcome, then the least squares estimator is biased and inconsistent. Heckman's insight was that exclusion of censored units from a sample will lead to bias and inconsistency, even if one is only interested in generalizing to the population of uncensored units (Berk 1983).

This chapter is devoted to an investigation of the sample selection problem, a presentation of the various solutions that have been proposed, and a discussion of the limitations of these solutions. An empirical illustration will then be provided, using data from the National Longitudinal Survey of Youth 1997 to examine the relationship between criminal behavior and legal earnings.

The Sample Selection Problem

The sample selection problem is one of estimating the relationship between two or more variables for a population, when information on the dependent variable is only observed for a nonrandom subset of a sample from that population. Consider estimating a model of earnings from employment. The population equation of interest is the following:

$$\begin{aligned} Y_i^* &= \beta_0 + \beta_1 X_{1i} + \cdots + \beta_j X_{ji} + e_i \\ &= \boldsymbol{X\beta} + e_i \end{aligned} \tag{1}$$

where the coefficients and regressors are consolidated into **Xβ** for notational convenience. Here, $\mathrm{Y_i}^*$ is a random variable representing *latent earnings*. The sample selection problem arises because $\mathrm{Y_i}^*$ is only partially observed – earnings are unobserved or censored among the subsample of individuals who are not employed. A second random variable, which can be thought of as *employment propensity*, determines whether earnings are observed or censored. This is also a latent variable, denoted $\mathrm{D_i}^*$, that is parameterized in the following manner:

$$\begin{aligned} D_i^* &= \alpha_0 + \alpha_1 Z_{1i} + \cdots + \alpha_k Z_{ki} + u_i \\ &= \boldsymbol{Z\alpha} + u_i \end{aligned} \tag{2}$$

where the coefficients and regressors are consolidated into $\boldsymbol{Z\alpha}$ for notational convenience. Concerning the residuals from these two equations, $\mathrm{e_i}$ is assumed to be distributed normal and $\mathrm{u_i}$ is assumed to be distributed standard normal. Their joint distribution is assumed to be bivariate normal:

$$\begin{pmatrix} e_i \\ u_i \end{pmatrix} \sim N\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \sigma_e^2 & \sigma_{e,u} \\ \sigma_{e,u} & 1 \end{pmatrix}\right]$$

As an aside, the correlation between the unobserved determinants of the two latent response variables $\mathrm{Y_i}^*$ and $\mathrm{D_i}^*$ is provided by the equation:

$$\rho_{e,u} = \frac{\sigma_{e,u}}{\sigma_e}$$

Berk (1983) refers to Eq. 1 as the "substantive equation," and to Eq. 2 as the "selection equation." Of course, neither $\mathrm{Y_i}^*$ nor $\mathrm{D_i}^*$ are fully observed. Instead, the two latent variables have observed counterparts. Namely, latent earnings $(\mathrm{Y_i}^*)$ are only observed when employment propensity $(\mathrm{D_i}^*)$ exceeds a defined threshold:

$$Y_i = \begin{cases} 0 & \mathit{if}\ D_i^* < 0 \\ Y_i^* & \mathit{if}\ D_i^* > 0 \end{cases}$$

Note that the choice of 0 as the threshold is a convenient normalization. If we substitute the linear predictor in Eq. 2 for $\mathrm{D_i}^*$ and rearrange terms, it can be shown that latent earnings are only observed if:

$$u_i > -\mathbf{Z}\boldsymbol{\alpha}$$

Taking the expectation of the observed Y_i for the subsample with nonzero earnings, we now have the following:

$$E\left(Y_i | W_i, D_i^* > 0\right) = \boldsymbol{X\beta} + E(e_i | u_i > -\mathbf{Z}\boldsymbol{\alpha}) \quad (3)$$

The last term in Eq. 3 illustrates the source of the sample selection problem and is the key insight provided by Heckman (1976, 1979). Namely, a least squares regression model of earnings, fitted only for the subsample with nonzero earnings, can lead to omitted variables bias because of the exclusion of a potentially relevant regressor – the conditional mean of the latent earnings residual for the uncensored subsample. If this last term is 0, there is no omitted variables bias, and inferences based on the subsample with nonzero earnings are valid for the general population, including those with censored earnings. Obviously, the sample selection problem arises when the conditional mean is not 0.

Consider the implications of the above for the question of interest in this chapter – the relationship between arrest and employment earnings. It is plausible that this relationship, estimated only from the subsample of individuals with nonzero earnings, is rendered biased and inconsistent because of the fact that these individuals are not a random subset of the sample. Specifically, the unobservables which determine whether or not someone works are likely to be correlated with the observables which determine someone's mean earnings, conditional on working. This means that regressors which are truly correlated with earnings might be statistically insignificant when the model is estimated from individuals with nonzero earnings. Similarly, regressors which are truly uncorrelated with earnings might be statistically significant.

Heckman's Two-Step Solution

To overcome the sample selection problem, Heckman (1976, 1979) proposed an elegant, two-step solution – the so-called Heckman selection correction. His solution entails direct estimation of the selection term in Eq. 3 and its inclusion as a regressor in the equation of substantive interest. The first step of this procedure is to estimate a model of the probability of being uncensored, in this case, the probability of having nonzero earnings. This begins by linking employment propensity (D_i^*), which is unobserved, to a binary response variable according to the following rule:

$$D_i = \begin{cases} 0 & \mathit{if}\ D_i^* < 0 \\ 1 & \mathit{if}\ D_i^* > 0 \end{cases}$$

This binary variable is then treated as the dependent variable in a probit regression model:

$$\begin{aligned} \Phi^{-1}[Pr(D_i = 1)] &= \alpha_0 + \alpha_1 Z_{1i} + \cdots \\ &\quad + \alpha_k Z_{ki} \\ &= \mathbf{Z}\boldsymbol{\alpha} \end{aligned} \quad (4)$$

The second step of Heckman's procedure requires inserting a transformation of the linear predictor from Eq. 4 into the substantive equation, estimated from the subsample with positive earnings:

$$\begin{aligned} (Y_i | D_i = 1) \\ &= \beta_0 + \beta_1 X_{1i} + \cdots + \beta_j X_{ji} \\ &\quad + \beta_{j+1}\lambda(-\mathbf{Z}\boldsymbol{\alpha}) + e_i \end{aligned} \quad (5)$$

The new term, $\lambda(\cdot)$, is known as the "inverse Mills ratio" (IMR) of the argument:

$$\lambda(-\mathbf{Z}\boldsymbol{\alpha}) = \frac{\phi(-\mathbf{Z}\boldsymbol{\alpha})}{1 - \Phi(-\mathbf{Z}\boldsymbol{\alpha})} = \frac{\phi(\mathbf{Z}\boldsymbol{\alpha})}{\Phi(\mathbf{Z}\boldsymbol{\alpha})}$$

The numerator $\phi(\cdot)$ represents the standard normal density function (p.d.f.) evaluated at the argument, whereas the denominator $\Phi(\cdot)$ represents the standard normal distribution function (c.d.f.) evaluated at the same argument. In empirical applications, of course, the true IMR is unknown. Instead, the estimate of the linear predictor from the probit regression model in Eq. 4 is substituted into the ratio:

$$\hat{\lambda}(-\mathbf{Z\alpha}) = \frac{\phi(\hat{\alpha}_0 + \hat{\alpha}_1 Z_{1i} + \cdots + \hat{\alpha}_k Z_{ki})}{\Phi(\hat{\alpha}_0 + \hat{\alpha}_1 Z_{1i} + \cdots + \hat{\alpha}_k Z_{ki})}$$

The IMR has a number of important properties. For one, it is nonnegative and is therefore bounded by 0 and ∞. In addition, because the denominator yields the estimated probability that an individual is uncensored (i.e., has positive earnings), individuals with a small probability of being uncensored will tend to have a large λ(·). Secondarily, the parameter β_{j+1} is formally identified in Eq. 5, even when the same set of regressors is included in both the first and second steps of the procedure. This is because λ(·) is a nonlinear transformation of the parameter estimates from the first step. Finally, the significance of the estimated coefficient for λ(·) is informative about the degree to which nonrandom sample selection introduces bias into the substantive equation. To be precise, the significance of the parameter conforming to λ(·) is a test of the significance of the correlation between the unobserved determinants of Y_i^* and D_i^*. Specifically, it can be shown that:

$$\beta_{j+1} = \rho_{e,u}\sigma_e = \sigma_{e,u}$$

As a final technical note on the two-step estimator, it is important to point out that least squares regression of Eq. 5 will yield consistent estimates of the coefficients in **β**. The covariance estimator, on the other hand, is inconsistent and will produce misleading standard errors. This is partly because the residuals in the two-step model are heteroscedastic and partly because the selection term represents an estimate rather than the actual selection term. Therefore, robust estimation of the covariance matrix is typically recommended, or else bootstrapping.

Limitations of the Two-Step Procedure

The appeal of Heckman's solution to the sample selection problem derives from the fact that it is an intuitive and tractable method, requiring only estimation of a probit regression model followed by a linear regression model (although see Bushway et al. 2007, for examples of misapplication of the method in criminology). The model should not be treated as a panacea to the sample selection problem, however, for it has well-known limitations. Several of these are described below (see also Stolzenberg and Relles 1990, 1997).

One limitation of Heckman's model in many research settings is the often mechanical application of the procedure. This has been especially pronounced in sociology and criminology (see Bushway et al. 2007). This is largely a consequence of the absence of formal selection models in these disciplines, leading many researchers to conceive of the sample selection problem as a purely technical rather than theoretical issue. In economics, on the other hand, there are often well-defined theories that inform researchers about the proper specification of the selection and substantive models. Theory can provide helpful guidance about regressors which can be included in the selection model but excluded from the substantive model. Such regressors, called "instrumental variables" (IV's), can improve the empirical performance of the two-step estimator.

A second limitation of Heckman's model is that the selection term tends to be highly collinear with the regressors in the substantive equation. This is because the same regressors appear in both the selection and substantive equations. High collinearity can make the standard errors of the two-step estimator so inflated, in fact, that it loses its appeal altogether. The trade-off between consistency and efficiency is an important one. Under some circumstances, the inconsistency of the uncorrected least squares estimator is preferred to the inefficiency of the selection-corrected least squares estimator. Although the two-step model is formally identified even when the regressors in the two equations are identical, the estimator has better asymptotic properties when a researcher imposes one or more exclusion restrictions which can be justified a priori. Exclusion restrictions cannot only strengthen the theoretical grounding of the model (as mentioned in the previous paragraph) but can improve the statistical performance of the two-step estimator. As a matter of empirical practice, then, the use of instrumental variables in the selection model, along with collinearity diagnostics for the substantive model, is recommended.

A third limitation of Heckman's two-step estimator is that it is comparatively less efficient than other estimators. Heckman's model is what is known as a limited information maximum likelihood (LIML) estimator. The two-step approach had practical utility at the time that Heckman (1976, 1979) proposed the model, simply because the alternatives were computationally burdensome. With today's computing capability, however, asymptotic efficiency can be achieved by employing a full information maximum likelihood (FIML) estimator, which simultaneously models the selection and substantive equations. The FIML estimator maximizes the following log likelihood function:

$$\sum_{D_i=0} ln\ \Phi(-\mathbf{Z}\boldsymbol{\alpha}) + \sum_{D_i=1} ln\left[\frac{1}{\sigma_e}\phi\left(\frac{Y_i - \mathbf{X}\boldsymbol{\beta}}{\sigma_e}\right)\right] + \sum_{D_i=1} ln\ \Phi\left[\frac{\mathbf{Z}\boldsymbol{\alpha} + \rho_{e,u}(Y_i - \mathbf{X}\boldsymbol{\beta})/\sigma_e}{\sqrt{1-\rho_{e,u}^2}}\right]$$

An Empirical Illustration of the Two-Step Procedure

Data from the National Longitudinal Survey of Youth 1997 (NLSY97) are used to provide an empirical illustration of the two-step solution to the sample selection problem. The NLSY97 is representative of all youth in the United States born in 1980–1984. This dataset is used to explore the relationship between arrest and earnings from employment. The analysis is limited to the 4,599 males who participated in the survey, among whom 85 % ($N = 3{,}895$) contributed nonmissing data on the variables of interest. At the second interview – the interview from which the outcome variable is measured – the respondents range in age from 13 to 19, with a mean age of 15.9 years. Descriptive statistics for all measures included in the analysis are provided in Table 1.

The outcome in the substantive model is total weekly earnings from employment. This measure is taken from the second wave of the survey (1998) and represents earnings from "formal employment" or "paycheck jobs." Sample selection bias is a potential concern here, because only half of the sample (50.9 %) is employed between the first and second interviews. Among the subsample that is employed, mean earnings are 147 dollars per month. The earnings distribution among these subsamples is shown in Fig. 1.

The independent variables that are used to model employment earnings include cohort, race (white), schooling (highest grade completed), family structure (live with both biological parents, household size), residential location (central city residence, local unemployment rate), previous work experience (percentage of weeks worked, number of jobs), variety of delinquent behaviors, and total arrests. To ensure proper temporal ordering vis-à-vis earnings, these measures are taken from the first wave of the survey (1997). For this empirical exercise, the regressor of interest is arrest. The question that guides the analysis is, "What impact does arrest have on earnings?"

Three instrumental variables are included in the selection model and excluded from the substantive model. These represent variables that are thought to influence whether a respondent is employed, but are not believed to otherwise have any direct influence on earnings among those who are employed. The instrumental variables that are chosen represent provisions of the child labor law which prevails in the state in which a respondent resides as of the second interview (details on the laws are provided in Apel et al. 2008). Three such provisions impose limits on how intensively young people are allowed to work during the school year – the number of hours per week, the number of hours per weekday, and the work curfew on weeknights. For convenience, a binary indicator is constructed for each provision, denoting whether or not a respondent is allowed to work 40 h or more per week (53.6 %), 8 h or more per weekday (57.8 %), and later than 10 PM on weeknights (47.4 %). Interactions of these variables are also included in the selection model.

Sample Selection Problems, Table 1 Descriptive statistics and the selection model of employment

			Probit model of employment	
Variable	Min, max	Mean (std. dev.)	Coeff. (std. err.)	Marginal effect
Response variables (wave 2)				
Employed in a formal job	0, 1	50.9 %	–	–
Weekly earnings if employed	0.5, 800.0	147.0 (103.7)	–	–

$^{+}p < 0.10$; $*p < 0.05$; $**p < 0.01$; $***p < 0.001$ (two-tailed tests)

The first step in the analysis is to model the probability that a respondent is uncensored, that is, has nonzero earnings. This is a probit regression model, the coefficients, standard errors, and marginal effects from which are provided in the last set of columns in Table 1. By way of a brief summary, youth who are more likely to work include those who are older, are white, have more schooling, have less local unemployment, and have more prior work experience. Youth who are more heavily involved in delinquent behavior are also more likely to work, although youth who have accumulated an arrest history are less likely to work. It is important to point out that the instrumental variables are jointly significant ($\chi^2 = 36.4$; df $= 7$; $p < 0.00001$), and six out of the seven main and interaction effects are statistically significant.

In Table 2, results from a variety of specifications of the earnings function are provided. All models are estimated from the subsample of male youth with nonzero earnings, but they differ as to whether a selection correction is made. The first two columns provide coefficients from models in which no correction is made for sample selection – coefficients from the least squares regression model and the truncated regression model are provided. The coefficients from the two are of the same direction and almost identical significance. The difference is that the coefficients from least squares regression are about half the size of the coefficients from truncated regression. This is because the latter model explicitly accounts for the truncation in earnings at 0 (notice that the estimate of the model standard deviation, represented by σ_e, is 40 % larger in the truncated regression model) and is the typical starting point for analyses of this sort. As an aside, the truncated regression model represents the second part of the two-part model advocated by Cragg (1971; for criminological applications, see Smith and Brame 2003).

As for the question more immediately at hand, the number of arrests is unrelated to weekly earnings in the uncorrected models. Although the coefficient is negative, it is not statistically significant. On the other hand, more extensive delinquent involvement is positively and significantly correlated with earnings. This is consistent with other research findings that high-risk youth tend to be more extensively involved in the labor market (Apel et al. 2008). A test of an interaction between delinquency and arrest is not significant.

The last two columns provide results from models which are corrected for sample selection – coefficients from Heckman's two-step estimator and the full information maximum likelihood (FIML) estimator are provided. While the coefficient for arrest is not significant in the two-step model, it is marginally significant in the FIML model. The latter model suggests that each arrest reduces earnings by $2.80 per week. Considering that the mean wage at the second interview is $5.72 per hour, each arrest as of the first interview lowers earnings by the equivalent of about one-half hour's worth of work per week between the first and second interviews.

Notice that the selection correction entails inclusion of a new regressor in the earnings model – $\lambda(-\mathbf{Z\alpha})$, or lambda, the inverse Mills ratio. The coefficient that conforms to this regressor is $\sigma_{e,u}$, or the covariance of the residuals in the models at the first and second steps. The models also provide an estimate of the correlation between the residuals at the first and second steps – $\rho_{e,u}$, or rho. The relationship between the estimates of these quantities can be expressed as follows:

$$\hat{\rho}_{e,u} = \frac{\hat{\sigma}_{e,u}}{\hat{\sigma}_e} = \frac{\hat{\beta}_{\lambda(-Z\alpha)}}{\hat{\sigma}_e}$$

Importantly, the coefficient on lambda is meaningful. Since it is positive and statistically significant, it indicates that there is positive selection, meaning that the unobservables which make a young male more prone to work (e.g., motivation, work orientation) also tend to yield him higher mean earnings. So, selection into the nonzero earnings subsample produces higher expected earnings compared to someone drawn at random from the population, with the same set of characteristics, who chooses not to work. Therefore, models which do not perform a selection correction will produce estimates which are biased and inconsistent. Upon first glance, then, the selection-corrected models are preferred to the truncated regression model.

By the same token, there are circumstances in which the cure for the sample selection problem is oftentimes worse than the disease. Recall that high collinearity between the regressors and the selection term, lambda, can produce inefficiency, which can undermine the consistency advantage of the two-step and FIML estimators. Unfortunately, high collinearity cannot be ruled out in the present analysis, even with exclusion restrictions for the child labor law provisions. A regression of the inverse Mills ratio on all of the covariates yields a squared multiple correlation (R-square) of 0.875. And this is only marginally better than an inverse Mills ratio which omits the instrumental variables, producing an R-square of 0.907. This suggests that the selection-corrected models might be plagued by high collinearity between the regressors and the inverse Mills ratio and that the instrumental variables which are chosen might not be sufficiently strongly related to employment to justify their use as instruments. On second glance, therefore, the truncated regression model might be preferred to the selection-corrected models after all.

Conclusion

The sample selection problem which led to the formulation of Heckman's two-step estimator (Heckman 1976, 1979) is a very general problem. Casual consideration leaves one with the impression that sample selection is pervasive in social scientific analysis. Namely, any restriction that leads to the elimination of a potentially nonrandom subset of a sample that is intended to be representative of a larger population can give rise to the sample selection problem. Viewed in this light, Heckman's two-step estimator, and the growing class of models to which it belongs, is more than a peculiar method which is strictly of interest to economists. It is a tool that should be readily available in any researcher's toolbox.

To be sure, Heckman's two-step solution to the sample selection problem is not free of its detractions. It has well-known limitations, some of which have been described in this chapter. In fact, Heckman (1976, 1979) himself was cautious about his proposed model, recommending that it be used in the course of preliminary investigation rather than as the sole model. Any final determination of which set of models provides the most credible parameter estimates requires careful consideration of underlying assumptions and the consequences of violating those assumptions.

Synonyms

Juvenile awareness programs; Prison aversion programs

Overview

"Scared Straight" and other programs involve organized visits to prison by juvenile delinquents or children at risk for criminal behavior. Programs are designed to deter participants from future offending through firsthand observation of prison life and interaction with adult inmates.

Drawing on the findings from a recently updated systematic review, this entry describes these programs and examines the research evidence on the effects of these programs on delinquency. This entry shows that not only do these programs fail to deter crime but they actually increase it. Government officials permitting this program need to adopt rigorous evaluation to ensure that they are not causing more harm to the very citizens they pledge to protect.

Background

In the 1970s, inmates serving life sentences at a New Jersey (USA) prison began a program to "scare" or deter at-risk or delinquent children from a future life of crime. The program, known as "Scared Straight," featured as its main component an aggressive presentation by inmates to juveniles visiting the prison facility. The presentation depicted life in adult prisons, and often included exaggerated stories of rape and murder (Finckenauer 1982). A television documentary on the program aired in 1979 provided evidence that 16 of the 17 delinquents remained law abiding for 3 months after attending "Scared Straight" – a 94 % success rate (Finckenauer 1982). Other data provided in the film indicated success rates that varied between 80 % and 90 % (Finckenauer 1982). The program received considerable and favorable media attention and was soon replicated in over 30 jurisdictions nationwide, resulting in special Congressional hearings on the program and the film by the United States House Committee on Education and Labor, Subcommittee on Human Resources (Petrosino et al. 2000).

Programs such as "Scared Straight" are based on deterrence theory. Advocates and developers of these programs believe that it is possible to use these realistic depictions of life in prison and/or presentations by inmates to deter juvenile offenders (or children at risk for becoming delinquent) from further (or initial) involvement with crime. Although the harsh and sometimes vulgar presentation in the earlier New Jersey version is the most famous, inmate presentations are now sometimes designed to be more educational than confrontational but with a similar crime prevention goal (Finckenauer and Gavin 1999). Programs that feature interactive discussions between youth and inmates as speakers who describe their life experiences and the current reality of prison life have a rather long history in the United States (Michigan D.O.C. 1967). It is not surprising such programs are popular: They fit with common notions of how to prevent or reduce crime (by "getting tough"); they are very inexpensive (a Maryland program was estimated to cost less than $1 US per participant); and they provide one way for incarcerated offenders to contribute productively to society by preventing youngsters from following down the same path (Finckenauer 1982).

A randomized controlled trial of the New Jersey program published in 1982, however, reported no effect on the criminal behavior of participants in comparison with a no-treatment control group (Finckenauer 1982). In fact, Finckenauer reported that participants in the experimental program were more likely to be arrested following the program. Other randomized trials reported in the United States also questioned the effectiveness of "Scared Straight"–type programs in reducing subsequent criminality (Greater Egypt Regional Planning and Development Commission 1979; Lewis 1983). Consistent with these findings, reviewers of research on the effects of crime prevention programs have not found deterrence-oriented programs like "Scared Straight" to be effective (Lipsey 1992).

Despite the convergence of evidence from studies and reviews, "Scared Straight"–type programs remain popular and continue to be used in the United States (Finckenauer and Gavin 1999). For example, a program in Carson City, Nevada (USA) brings juvenile delinquents on a tour of an adult Nevada State Prison (Scripps 1999). One youngster claimed that the part of the tour that made the most impact on him was "All the inmates calling us for sex and fighting for our belongings" (Scripps 1999). The United Community Action Network has its own program called "Wisetalk" in which at-risk youth are locked in a jail cell for over an hour with four to five parolees. They claim that only 10 of 300 youngsters exposed to this intervention have been rearrested (United Community Action Network 2001). In 2001, a group of guards – apparently without the knowledge of administrators – strip-searched Washington, DC students during their tours of a local jail under the guise of that they were using "a sound strategy to turn around the lives of wayward kids" – claiming the prior success of "Scared Straight" (Blum and Woodlee 2001).

"Scared Straight" and other "kids visit prison" programs are not unique to the United States. For example, it is called the "day in prison" or "day in gaol" in Australia (O'Malley et al. 1993), "day visits" in the United Kingdom (Lloyd 1995), and the "Ullersmo Project" in Norway (Storvoll and Hovland 1998). Hall (1999) reports positively on a program in Germany designed to scared straight young offenders with ties to Neo-Nazi and other organized hate groups. The program has been also tried in Canada (O'Malley et al. 1993). A recent television program (*Banged* Up) aired in the United Kingdom depicting their version of the program (Blunkett 2008; Wilson and Groombridge 2010).

In 1999, "Scared Straight: 20 Years Later" was shown on United States television and claimed similar results to the 1979 film (Muhammed 1999). In this version, the film reports that 10 of the 12 juveniles attending the program have remained offense free in the 3 months follow-up (Muhammed 1999). As in the 1979 television program, no data on a control or comparison group of young people were presented. Positive reports and descriptions of Scared Straight–type programs have also been reported elsewhere (e.g., in Germany [Hall 1999], and in Florida [Rasmussen 1996]), although it is sometimes embedded as one component in a multicomponent juvenile intervention package (Trusty 1995; Rasmussen 1996).

In 2000, Petrosino and his colleagues reported on a preliminary systematic review of nine randomized field trials, drawing on the raw percentage differences in each study. They found that programs such as "Scared Straight" generally increased crime between 1 % and 28 % in the experimental group when compared to a no-treatment control group. In 2002, a formal Campbell review was published (simultaneously with the Cochrane Collaboration) – updating the 2000 work and utilizing more sophisticated meta-analytic techniques. They reported similarly negative findings for Scared Straight and juvenile awareness programs. This entry provides an update of these earlier reports, extending searches to cover literature published through 2011.

Despite the results of this review and updates, Scared Straight and similar programs continue to be promoted as a crime prevention strategy. For example, Illinois' then-Governor Rod Blagojevich signed a bill into law in 2003 that mandated the Chicago Public School system to set up a program called "Choices" (United Press International 2003). The program would identify students at risk for committing future crime and set up a program to give them "tours of state prison" to discourage any future criminal conduct (United Press International 2003). More recently, the Arts and Entertainment (A&E) station has been running a weekly series entitled, "Beyond Scared Straight." Created by the producer of the original Scared Straight program (Arnold Shapiro), the program is now the highest rated in A&E's history. The success of the television show has renewed interest in Scared Straight and similar programs as a crime prevention strategy (e.g., Dehnart 2011) but has also resulted in criticism that it ignores a long history of scientific evidence (e.g., Robinson and Slowikowski 2011). The Puerto Rico Department of Corrections and Rehabilitation also launched the "Loving Freedom" program, an intervention designed to imitate Scared Straight (Mullen 2012).

The question about whether Scared Straight and similar programs has a crime deterrent effect is best answered by examining the existing scientific evidence. Of course, prior research is no guarantee that interventions will work (or not work) in a future setting, but a reader might ask herself the following question upon reading the results of the aforementioned systematic review: Would I want a doctor to prescribe a treatment for my child that has the same track record of research results?

Methods

The findings reported here are based on the most recent update of the Campbell and Cochrane Collaboration reviews on the subject. In these reviews, studies were only included if they used random (or seemingly – quasi-random) procedures to assign participants to treatment and control groups. The control must not have received another prevention program. Furthermore, only studies that involved juveniles i.e., children 18 years of age or under) or overlapping samples of children and young adults (i.e., ages 13–21) were included. Studies could have included delinquents, pre-delinquents, or non-delinquent youths. Studies also were required to include a visit by program participants to a prison facility as a part of the intervention. Most of the included studies involved inmate presentations (Finckenauer 1982; Cook 1992), and they sometimes featured orientation sessions and prison tours. Finally, studies had to include at least one outcome of subsequent offending behavior. This outcome was measured by indices such as arrests, convictions, contacts with police, and self-reported offenses. Further information on the methodology and search methods is available in the original review.

Narrative Findings

Collectively, the nine included studies from the systematic review were conducted in eight different states of the United States, with Michigan the site for two studies (Yarborough 1979; Michigan D.O.C. 1967). No set of researchers conducted more than one experiment. The studies span the years 1967–1992. The first five studies located were unpublished and were disseminated in government documents or dissertations; the remaining four were found in academic journal or book publications. The average age of the juvenile participants in each study ranged from 15 to 17. Only the New Jersey study included girls (Finckenauer 1982). Racial composition across the nine experiments was diverse, ranging from 36 % to 84 % white. Nearly 1,000 (946) juveniles or young adults participated in the nine experimental studies. A narrative description of the included studies follows.

In an internal, unpublished government document, the Michigan Department of Corrections (1967) reported a trial testing a program that involved taking adjudicated juvenile boys on a tour of a state reformatory. Unfortunately, the report is remarkably brief. Sixty juvenile delinquent boys were randomly assigned to attend two tours of a state reformatory or to a no-treatment control group. Tours included 15 juveniles at a time. No other part of the program is described. Recidivism was measured as a petition in juvenile court for either a new offense or a violation of existing probation order. The Michigan department of Corrections found that 43 % of the experimental group re-offended, compared to only 17 % of the control group. This large negative result curiously receives little attention in the original document.

Another program at the Menard Correctional Facility (GERP&DC 1979) started in 1978 and is described as a frank and realistic portrayal of adult prison life. The researchers randomly assigned 161 youths aged 13–18 to attend the program or a no-treatment control. The participants were a mix of delinquents or children at risk of becoming delinquent. Participants were compared on their subsequent contact with police, on two personality inventories (Piers-Berne and Jesness) and surveys of parents, teachers, inmates, and young people. The outcomes are also negative in direction but not statistically significant, with 17 % of the experimental participants being recontacted by police in contrast to 12 % of the controls (GERP&DC 1979). The authors concluded that “based on all available findings one would be ill advised to recommend continuation or expansion of the juvenile prison tours. All empirical findings indicate little positive outcome, indeed, they may actually indicate negative effects” (p. 19). Researchers report no effect for the program on two attitude tests (Jesness Inventory, Piers Harris Self-Concept Scale). In contrast, interview and mail surveys of participants and their parents and teachers indicated unanimous support for the program (p. 12). Researchers also note how positive and enthusiastic inmates were about their efforts.

In the Juvenile Offenders Learn Truth (JOLT) program (Yarborough 1979), juvenile delinquents in contact with one of four Michigan county courts participated. Each juvenile spent 5 total hours in the facility. Half of this time was spent in a confrontational “rap” session. This followed a tour of the facility, during which participants were escorted to a cell and exposed to interaction with inmates (e.g., taunting). In the evaluation, 227 youngsters were randomly assigned to JOLT or to a no-treatment control. Participants were compared on a variety of crime outcomes collected from participating courts at 3- and 6-month follow-ups. This second Michigan study reported very little difference between the intervention and control group (Yarborough 1979). The average offense rate for program participants, however, was 69 % compared to 47 % for the control group. Yarborough (p. 14) concluded that, "…the inescapable conclusion was that youngsters who participated in the program, undergoing the JOLT experience, did no better than their control counterparts."

The Face-to-Face program (Vreeland 1981) included a 13-h orientation session in which the juvenile lived as an inmate followed by counseling. Participants were 15–17 years of age and on probation from Dallas County Juvenile Court; most averaged two to three offenses before the study. A total of 160 boys were randomly assigned to four conditions: prison orientation and counseling, orientation only, counseling only, or a no-treatment control group. Vreeland examined official court records and self-reported delinquency at 6 months. This evaluation also reported little effect for the intervention (Vreeland 1981). Vreeland reported that the control participants outperformed the three treatment groups on official delinquency (28 % delinquent versus 39 % for the prison orientation plus counseling, 36 % for the prison only, and 39 % for the counseling only). This more robust measure contradicts data from the self-report measures used, which suggest that all three treatment groups did better than the no-treatment controls. None of these findings reached a level of statistical significance. Viewing all the data, Vreeland concluded that there was no evidence that Face-to-Face was an effective delinquency prevention program. He finds no effect for "Face-to-Face" on several attitudinal measures, including the "Attitudes Toward Obeying Law Scale."

The New Jersey Lifers' Program (Finckenauer 1982) began in 1975 and stressed confrontation with groups of juveniles ages 11–18 who participated in a rap session. Finckenauer randomly assigned 82 juveniles, some of whom were not delinquents, to the program or to a no-treatment control group. He then followed them for 6 months in the community, using official court records to assess their behavior. Finckenauer reported that 41 % of the children and young people who attended the "Scared Straight" program in New Jersey committed new offenses, while only 11 % of the controls did, a difference that was statistically significant (Finckenauer 1982). He also reported that the program participants committed more serious offenses and that the program had no impact on nine attitude measures with the exception of a measure called "attitudes toward crime." On this measure, experimental participants did much worse than controls. We deal with Finckenauer's own concerns about randomization integrity in a sensitivity analysis, which is reported later.

The California SQUIRES Program (Lewis 1983) is supposedly the oldest such program in the United States, beginning in 1964. The SQUIRES program included male juvenile delinquents from two California counties between the ages of 14 and 18, most with multiple prior arrests. The intervention included confrontational rap sessions with rough language, guided tours of prison with personal interaction with prisoners, and a review of pictures depicting prison violence. The intervention took place 1 day per week over 3 weeks. The rap session was 3 h long, and normally included 20 youngsters at a time. In the study, 108 participants were randomly assigned to treatment or to a no-treatment control group. Lewis compared participants on seven crime outcomes at 12 months. Lewis reported that 81 % of the program participants were arrested compared to 67 % of the controls. He also found that the program did worse with seriously delinquent youths, leading him to conclude that such children and young people could not be "turned around by short-term programs such as SQUIRES…a pattern for higher risk youth suggested that the SQUIRES program may have been detrimental" (p. 222). The only deterrent effect for the program was the average length of time it took to be rearrested: 4.1 months for experimental participants and 3.3 months for controls. Data were reported on eight attitudinal measures, and Lewis reported that the program favored the experimental group on all of them, again underscoring the difficulty of achieving behavioral change even when positively affecting the attitudes of juvenile delinquents.

The Kansas Juvenile Education Program (Locke et al. 1986) was designed to educate children about the law and the consequences of violating it. The program also tried to roughly match juveniles with inmates based on personality types. Fifty-two juvenile delinquents (ages 14–19) from three Kansas counties were randomly assigned while on probation to KEP or a no-treatment control. The investigators examined official (from police and court sources) and self-report crime outcomes at 6 months. Locke and his colleagues reported little effect of the Juvenile Education Program. Both groups improved from pretest to posttest, but the investigators concluded that there were no differences between experimental and control groups on any of the crime outcomes measured. Investigators also reported no effect for the program on the Jesness and Cerkovich attitude tests.

Project Aware (Cook and Spirrison 1992) was a nonconfrontational, educational program comprising one 5 h session run by prisoners. The intervention was delivered to juveniles in groups numbering from 6 to 30. In the study, 176 juveniles (ages 12–16) under the jurisdiction of the county youth court were randomly assigned to the program or to a no-treatment control. The experimental and control groups were compared on a variety of crime outcomes retrieved from court records at 12 and 24 months. Little difference was found between experimental and control participants in the study. For example, the mean offending rate for controls at 12 months was 1.25 for control cases versus 1.32 for Project Aware participants. Both groups improved from 12 to 24 months, but the control mean offending rate was still lower than the experimental group. The investigators concluded that, “attending the treatment program had no significant effect on the frequency or severity of subsequent offenses” (p. 97). The investigators also reported on two educational measures: school attendance and dropout. Curiously, they report an effect for the program on school dropout data, but not that “. . .it is not clear how the program succeeded in reducing dropout rates. . .” (p. 97).

The only positive findings, though not statistically significant, were reported in Virginia (Orchowsky and Taylor 1981). The Insiders Program (Orchowsky and Taylor 1981) was described as an inmate-run, confrontational intervention with verbal intimidation and graphic descriptions of adult prison life. Juveniles were locked in a cell 15 at a time and told about the daily routine by a guard. They then participated in a 2-h confrontational rap session with inmates. Juvenile delinquents from three court service units in Virginia participated in the study. The investigators randomly assigned 80 juveniles ages 13–20 with two or more prior adjudications for delinquency to the Insiders program or a no-treatment control group. Orchowsky and Taylor report on a variety of crime outcome measures at 6-, 9-, and 12-month intervals. Although the difference at 6 months was not statistically significant (39 % of controls had new court intakes versus 41 % of experimental participants), they favor the experimental participants at 9 and 12 months. The investigators noted, however, that the attrition rates in their experiment were dramatic. At 9 months, 42 % of the original sample dropped out, and at 12 months, 55 % dropped out. The investigators conducted analyses that seemed to indicate that the constituted groups were still comparable on selected factors.

Most of the studies dealt with delinquent youths already in contact with the juvenile justice system. All of the experiments were simple two-group experiments except Vreeland’s evaluation of the Texas Face-to-Face program (Vreeland 1981). Only one study used quasi-random alternation techniques to assign participants (Cook 1992); the remaining studies claimed to use randomization although not all were explicit about how such assignment was conducted. Only the Texas study (Vreeland 1981) included data from

Effects of Scared Straight and other similar programs: Meta-analysis of first effect crime outcomes (Random Effects Analysis)

Scared Straight Programs, Fig. 1 Random effects model results (Petrosino et al. 2004)

self-report measures. In two studies (Cook 1992; Locke et al. 1986), no post-intervention offending rates were reported. Also, the follow-up periods were diverse and included measurements at 3, 6, 9, 12, and 24 months.

The results of the meta-analysis presented in the systematic review are further evidence of the harmfulness of these programs. The review reported the crime outcomes for official measures at the first-effect or first follow-up interval (and usually the only) period reported. Each analysis focused on proportion data (i.e., the proportion of each group re-offending), as the outcomes reporting means or averages is sparse and often does not include the standard deviations. Thus, because the data rely on dichotomous outcomes, analyses used the odds ratios (OR) as the measure of program effect, contrasting the odds of crime in the treatment program relative to the control.

The analysis of the data in comparison Fig. 1 from the seven studies reporting reoffending rates shows that intervention increases the crime or delinquency outcomes at the first follow-up period. The mean odds ratio across studies assuming a random effects model indicates an overall harmful effect of these programs (mean odds ratio = 1.72, 95 % confidence interval of 1.13–2.62). Thus, the intervention increases the odds of offending (Fig. 1).

These randomized trials, conducted over a 25-year period in eight different jurisdictions, provide evidence that "Scared Straight" and other "juvenile awareness" programs are not effective as a stand-alone crime prevention strategy. More importantly, they provide empirical evidence that these programs likely increase the odds that children exposed to them will commit offenses in future. Despite the variability in the type of intervention used, ranging from harsh, confrontational interactions to tours of the facility converge on the same result: an increase in criminality in the experimental group when compared to a no-treatment control. Doing nothing would have been better than exposing juveniles to the program.

Converging Evidence

Other reviews also examined the efficacy of "Scared Straight" and similar programs. A meta-analysis of juvenile prevention and treatment programs by Lipsey (1992) found a small negative effect for 11 "shock incarceration" and "Scared Straight" programs, with the experimental groups having a 7 % higher recidivism rate than controls relative to a 50 % recidivism baseline. Gendreau and his colleagues (1997) also reported a meta-analysis of "get tough" or "get smart" sanctions. These included interventions designed to deter future crime like "Scared Straight" as well as interventions designed to punish or control offenders at less cost such as intensive supervision while on probation or parole. The reviewers computed correlations of program participation and recidivism outcomes. Examining 15 experimental or quasi-experimental evaluations of Scared Straight–type programs, they also found a small negative (harmful) effect (average correlation of 0.07). Simply put, participating in the program was *associated with an increase in crime*.

Possible Controversies in the Literature

This evidence places the onus on every jurisdiction to show how their current or proposed program is different than the ones studied here. Given that, they should then put in place rigorous evaluation to ensure that no harm is caused by the intervention. Some literature indicates the program can have a positive effect on the inmate providers and that argument is sometimes used to legitimize use of the program. These arguments are undoubtedly used under the assumption that the program does no harm. In light of these findings, assertions that "Scared Straight" and similar programs ought to be used because it achieves other things raises ethical questions about potentially harming children (and others in the community who may be victimized) in order to accomplish other important, but latent, goals.

Petrosino and colleagues have received communications from different prison facilities that are using a juvenile awareness program. One argument these programs make to sustain using such programs is that the research reported here does not apply to their particular program. One recommendation here is that correctional research units, either at the facility or at a regional or national government level, collaborate with program staff to conduct a rigorous evaluation. If such units do not exist or cannot conduct their own study, they should collaborate with a local university, college, or research firm that could undertake this work to ensure that the program is working as planned and not unintentionally causing more harm than good. The findings, however, across a diversity of programs, jurisdictions, and samples (in conjunction with the converging evidence from other reviews) suggests that the fundamental concept behind Scared Straight and other juvenile awareness programs may be flawed.

Open Questions

One question that continues to arise about these findings is why "Scared Straight" and similar programs seem to lead to more crime rather than less in its participants. What is the critical mechanism? Understanding why something works or fails is of great interest to evaluators, program designers, and criminological theorists. Holley and Brewster (1996), evaluators for the Oklahoma "Speak Outs" program, wondered about the criminogenic effect of these programs when they asked:

> If one argued that a two hour visit cannot perform the miracle of deterring socially unacceptable behavior . . ., it can also be argued that it was extremely simplistic to assert that a two hour visit can perform the miracle of *causing* socially unacceptable behavior. (p. 130)

Although there were many good post hoc theories about why these programs had negative effects, the evaluations were not structured to provide the kind of mediating variables or "causal models" necessary for an empirical response to this question in a systematic review.

Another key question concerns why these programs continue to be used. The research evidence to date indicates that these programs simply do not work. Despite this evidence, these programs continue to be used. This concern is particularly problematic given the recent paucity of high-quality research studies evaluating these programs. Why do policymakers continue to implement programs that are found to be harmful?

Arnold Shapiro (cited in Dehnart 2011) criticized the studies reviewed here because none of them were reported after 1992. "Scared Straight" has evolved and is now a very different program, and two decades have passed since that last study was published. This further reinforces the need for jurisdictions using this strategy to conduct rigorous evaluation, but it is difficult to obtain funding from agencies because Scared Straight is viewed as a failed strategy for youth.

Conclusions

The research on Scared Straight–type programs cannot predict with certainty that every such program will fail or – worse yet – lead to harmful effects on juvenile participants. But, the prior evidence indicates that there is a greater probability than not that it will be harmful. Would you permit a doctor to use a medical treatment on your child with a similar track record of results?

Despite the gloomy findings reported here and elsewhere, "Scared Straight" and its derivatives continue in use, although a randomized trial has not been reported since 1992. As Finckenauer and Gavin (Finckenauer 1999) noted, when the negative results from the California SQUIRES study came out, the response was to end the evaluation – not the program. Today, the SQUIRES program continues, evaluated by the testimonials of prisoners and participants alike. Despite evidence, belief in the program's efficacy continue. Middleton and his colleagues report on the extension of this strategy in one UK town to scare ordinary schoolchildren by using former correctional officers to set up a prison-type atmosphere in the public school system (Middleton et al. 2001). In 1982, Finckenauer called this the "Panacea Phenomenon," describing how policymakers, practitioners, media reporters, and others sometimes latch onto quick, short-term, and inexpensive cures to solve difficult social problems (Finckenauer 1982). Others claim that the program by itself is of little value but could be instrumental if embedded in an overall multicomponent package of interventions delivered to youths. More recently, the success of the A&E program, Beyond Scared Straight, has increased enthusiasm for this program as a crime prevention strategy.

It may be true that Scared Straight and like programs do not work because they only convey a threat that juveniles do not think will be carried out. What about the evidence for deterrence when it is not an inmate providing a third-party threat but the juvenile system officially processes the youth? There have been a wide range of randomized trials that test for the effects of official processing in juvenile courts with some other intervention (such as diverting the kid from such processing). Is there evidence that the delivery of a threat – official system processing – deters future criminal behavior? In 2010, Petrosino, et al. examined 29 randomized trials that evaluated the effects of some diversionary alternative (services or outright release) and compared it to official processing or progression deeper into the juvenile justice system. That review, published by the Campbell Collaboration, also indicated that formal system processing or progression had no crime deterrent effect, and in some instances increased crime in contrast to diversionary alternatives. In addition, formal processing is a more expensive approach than most diversionary programs, and coupled with the crime reduction effect, could result in some savings for jurisdictions (Petrosino et al. 2010). This review indicates that the delivery of a threat (official processing) did not deter future juvenile offending, compared to doing nothing, and actually reported worse outcomes than if the youth was assigned to a diversionary program with services.

Scenario Designs

M. Lyn Exum and Megan Sims
Department of Criminal Justice and Criminology, University of North Carolina at Charlotte, Charlotte, NC, USA

Overview

Suppose you drove by yourself one evening to meet some friends at a bar that is about 10 miles from

> your house. You have been drinking throughout the evening and by the time you're ready to leave, you suspect your blood alcohol level might exceed the legal limit. Suppose you have to be at work early the next morning. You can either drive home or find some other way home, but if you leave your car, you will have to return early the next morning to pick it up. (Pogarsky 2004, p. 119)

Hypothetical scenarios like the one above are commonly used to study criminal decision making. In the typical study, participants are asked to envision themselves experiencing the situation described in the scenario and then to self-report how likely they would be to respond in an illegal manner (e.g., drive while drunk). They also rate various costs and benefits that might result from engaging in the offense. Using these data, researchers attempt to reconstruct the decision to offend by modeling participants' self-reported criminal intentions as a function of the perceived costs and benefits, along with other individual and situational factors.

This entry discusses the contributions of the hypothetical scenario method (HSM) to the study of criminal decision making. The rise of the HSM within the deterrence/rational choice literature is first presented, followed by a summary of the key findings from this literature. Finally, emerging areas of research and future challenges for HSM scholars are highlighted.

The Rise of the HSM

The deterrence and rational choice perspectives are the dominant theoretical frameworks in which to study criminal decision making. Both theories assert that human beings freely chose to engage in (or abstain from) crime after assessing the consequences of the act. Both theories also contend that differences in the qualities of these consequences – such as their certainty, swiftness, and severity – will lead to different decisional outcomes. However, the two theories diverge with respect to the *types* of consequences that influence criminal decision making. In its purest form, deterrence theory focuses on the crime-inhibiting effects of formal legal sanctions, such as arrest and incarceration (Nagin 1978). In contrast, the rational choice perspective recognizes that informal sanctions as well as the benefits of crime operate in conjunction with formal sanctions to shape the decision to offend (Grasmick and Bursik 1990; Piliavin et al. 1986).

Although the philosophical underpinnings of deterrence and rational choice can be traced back to the eighteenth century, empirical research on these theories did not appear until the 1960s (Paternoster 2010). These initial tests typically compared objective measures of punishment (such as incarceration rates) to aggregate rates of crime, and in general, the results showed weak/mixed support for the notion of deterrence. Scholars subsequently argued that instead of relying on objective measures of punishment, test of criminal decision making should focus on individuals' *perceptions* of punishment, regardless of how accurate those perceptions may be. From a methodological standpoint, this shift from objective to perceptual measures meant that researchers would now need to survey individuals and have them self-report their involvement in crime as well as their perceptions of the legal consequences of their behavior. Initially, this vein of research relied heavily on cross-sectional surveys; however, given the inherent temporal ordering problems in cross-sectional data, many scholars turned to longitudinal studies to study criminal decision making.

Notwithstanding their methodological advantages, longitudinal studies of deterrence and rational choice theory are unable to capture participants' perceptions of consequences *at the exact moment* the decision to offend (or abstain) is made. Instead, these studies capture self-reported perceived consequences at Time 1 and then use these perceptions to predict participants' subsequent involvement in crime occurring prior to the Time 2 testing period (which may be as much as 1–2 years in the future). With such a large time interval, the opportunity for perceptions to change is ever present. Although evidence suggests there is some similarity in the perceived consequences at Time 1 and Time 2, one cannot be fully certain that these perceptions remained stable throughout the duration of the study interval – including the moment when participants came face to face with a real-world criminal opportunity (see Piliavin et al. 1986, pp. 115–116).

In order to better measure the perceived consequences of crime at the moment the decision to offend/abstain occurs, some researchers began focusing on whether participants *believed* they would engage in a particular criminal act, as opposed to focusing on whether participants had actually committed the act (e.g., Grasmick and Bursik 1990). As participants then contemplated their penchant toward the offense, researchers could query them on the perceived consequences of offending. While this technique seemingly allows researchers to study criminal decision making at the moment it unfolds, it does not provide participants with adequate contextual information about the potential criminal opportunity – information that participants may need in order to accurately assess the consequences of the offense. As a result, participants' perceived consequences in these studies may be unreliable (Klepper and Nagin 1989).

In response, researchers turned to the hypothetical scenario method. Through the use of structured vignettes, the HSM allows researchers to present participants with an opportunity to offend – albeit an imaginary one. The vignettes, which are usually no more than a paragraph in length, contain important contextual information about the criminal opportunity (e.g., you are drunk at a bar 10 miles from your house, it's late, you need your car early the next day). Through the use of these vignettes, researchers can present participants with virtually any type of criminal/imprudent opportunity, such as sexual assault (Bouffard 2002b), physical aggression (Exum 2002), drunk driving (Piquero and Pogarsky 2002), corporate price fixing (Piquero et al. 2005), academic cheating (Tibbetts 1999), sports doping (Strelan and Boeckmann 2006), and even police misconduct (Pogarsky and Piquero 2004).

Unlike the typical cross-sectional or longitudinal studies of decision making, the measure of offending in HSM studies is not the participants' actual involvement in crime; instead, it is the participants' self-reported *intentions* to offend. Researchers acknowledge that such self-reported intentions are not measures of real-world behavior (Bachman et al. 1992; Paternoster and Simpson 1996) nor should they be interpreted as "synonymous with actual performance" (Tibbetts and Herz 1996, p. 203). At the same time, researchers also contend that measures of criminal intentions should be strongly correlated with actual offending (Tibbetts 1999; Piquero and Tibbetts 1996) and can be interpreted as indicators of participants' predisposition or proneness to crime (Paternoster and Simpson 1996; Pogarsky 2004).

In sum, the HSM is wholly distinct in its approach to studying the decision-making processes proposed by deterrence and rational choice theories. Unlike research using objective measures of punishment, the HSM captures individuals' subjective perceptions of the consequences of crime. Unlike traditional cross-sectional studies, the HSM does not have inherent temporal ordering problems. Unlike traditional longitudinal studies, the HSM allows researchers to measure participants' perceived consequences at the moment they contemplate a criminal opportunity. Unlike studies that simply ask about participants' intentions to commit some kind of generically defined crime, the HSM provides participants with a specific narrative for the criminal opportunity that, in turn, should make participants' responses more reliable. As a result of all these features, the HSM stands as one of the most versatile and methodologically sophisticated techniques in which to study the decision to offend.

Key Findings from the HSM Literature

The Role of Perceived Punishments

Much has been written about the empirical status of deterrence theory (e.g., Nagin 1978; Paternoster 2010; Pratt et al. 2008), especially as it pertains to the certainty and severity of formal legal sanctions. In general, these reviews find that the deterrent effect of sanction certainty – though weak – is greater than the effect for sanction severity. However, these reviews generally provide a summary of the deterrence literature as a whole and therefore cannot isolate the findings from only those studies using the HSM.

Pratt et al.'s (2008) meta-analysis is the exception. It disaggregates effect size estimates for punishment certainty and severity across studies of differing research methodologies, including the HSM. Interestingly, the findings from these HSM studies largely mirror those of other, more global reviews of the deterrence literature. The certainty effect for formal legal sanctions was found to be weak (mean effect size = −0.14) but nevertheless stronger than the effect for sanction severity (mean effect size = −0.05). The threat of nonlegal sanctions, such as the loss of respect or employment, was found to exert a deterrent effect that was identical to that of the certainty of formal sanctions (mean effect size = −0.14). (Note that the severity effect for these nonlegal sanctions was not estimated in the study.) Collectively, these meta-analytic findings suggest that punishment certainty and severity play a minor role in the decision to offend.

Far less attention has been devoted to studying the impact of the swiftness of punishment. In one of the few HSM studies to examine celerity, Nagin and Pogarsky (2001) used a factorial survey to manipulate the length of time in which the punishment for drunk driving was expected to occur. Across a variety of multivariate models and after controlling for a host of factors such as the certainty and severity of punishment, celerity did not exert a significant deterrent effect on self-reported intentions to drive drunk. In a subsequent HSM study examining police misconduct, Pogarsky and Piquero (2004) manipulated the swiftness of punishment an officer might experience from failing to charge an off-duty officer with drunk driving and from performing an unauthorized background check on a new neighbor. This time, the results for celerity were found to vary by the type of misconduct. The swiftness of punishment had a significant deterrent effect on failing to report a fellow officer for drunk driving but had no significant effect on performing an unauthorized background check. Pogarsky and Piquero speculate that these differences may be partly attributed to differences in the perceived gravity of the offenses, suggesting severity and swiftness may interact to produce an overall deterrent effect. Be that as it may, the findings from these two HSM studies tentatively suggest that the swiftness of punishment – at least, by itself – has a minimal impact on criminal decision making.

The Role of Perceived Benefits

Many HSM studies, especially those with a rational choice orientation, have examined the influence of the perceived benefits of crime – with "benefits" defined to include some form of physical and/or psychological reward. Across a host of HSM studies examining a variety of offenses, this research generally shows that the potential benefits of crime are a critical component in the decision to offend. For example, HSM research finds that the benefits from crime exert a positive and significant effect on self-reported intentions to engage in computer software piracy (Higgins 2007), drunk driving (Bouffard 2007; Nagin and Paternoster 1994), physical assault (Carmichael and Piquero 2004; Exum 2002), sexual assault (Loewenstein et al. 1997; Nagin and Paternoster 1994), theft/shoplifting (Piquero and Tibbetts 1996; Tibbetts and Herz 1996), corporate offending (Paternoster and Simpson 1996; Piquero et al. 2005), plagiarism (Ogilvie and Stewart 2010), and test cheating (Sitren and Applegate 2007; Tibbetts 1999). Furthermore, the benefits of crime have been shown to be even more influential to the decision to offend than are formal and informal criminal sanctions (Nagin and Paternoster 1993).

This is not to say that perceived benefits are universally predictive of offending. In fact, some HSM studies find certain benefits of crime (and under certain conditions) to be unrelated to offending intentions and/or to contribute little predictive power in multivariate models of criminal decision making (e.g., Bouffard 2002b; Elis and Simpson 1995; Ogilvie and Stewart 2010; Paternoster and Simpson 1996; Piquero et al. 2005; Simpson and Piquero 2002). Nevertheless, and as a whole, the empirical evidence from the HSM literature overwhelmingly indicates that the perceived payoffs from crime promote the decision to offend.

The Role of Consequence Salience

Bouffard (2002b) has argued that models of criminal decision making should not only consider the certainty and severity of perceived consequences but also the salience of those consequences. Conceptually, salience is distinct from certainty, severity, and swiftness in that it captures "how much weight a given factor carried in the actual decision-making process" (p. 123; see also Bouffard 2007). In other words, salience reflects how *important* the consequence is to the potential offender when contemplating the criminal opportunity. Additionally, salience is purported to be a dynamic quality that is influenced by state-level factors such as emotional arousal. As a result, individuals in emotionally charged states may identify consequences that are highly certain and highly severe, but in the "heat of the moment," individuals simply do not view these consequences as terribly important. Similarly, under certain emotional states, the benefits of a criminal act – no matter how unlikely or how inconsequential – may nevertheless carry a lot of weight in the decision to offend.

To examine whether salience is a unique concept, Bouffard (2007) presented participants with a hypothetical drunk driving scenario and asked them to report the certainty, severity, and importance of the consequences associated with the offense. Factor analysis revealed mixed results, with the salience measures for perceived costs indeed loading on a unique factor, but the salience measures for perceived benefits loading on a factor with perceived certainty. To determine whether salience is a dynamic element of decision making, Bouffard (2002b) randomly assigned male participants to view either sexually explicit or neutral images prior to reading a sexual assault scenario. Participants then rated the certainty, severity, and salience of their perceived consequences. Here again, the findings were mixed. Sexual arousal appeared to minimize the salience of the negative consequences of sexual aggression, but it did not enhance the importance of the perceived benefits.

Arguably, the most important question regarding consequence salience is whether it influences an individual's decision to offend. The HSM research examining this question is scarce and somewhat inconsistent. For example, Bouffard (2002a) reports a series of bivariate correlations between participants' intentions to drive drunk and the salience of their perceived consequences of the act. These correlations were found to be in the expected direction, statistically significant, and weak to moderate in magnitude. However, when salience measures were correlated with intentions to engage in sexually coercion, the correlations were generally weaker with only a few statistically distinguishable from zero. Furthermore, in a series of multivariate analyses of the sexual coercion data, Bouffard (2002b) found the salience of perceived benefits – but not of the perceived costs – to impact self-reported intention scores. As a whole, the extant research on salience suggests that it is a dimension of participants' perceived consequences that appears to have some level of influence on criminal decision making. More research in this area is needed, however.

The Role of Morality

Many HSM studies have examined the role of morality on criminal decision making. In this research, the perceived immorality of the act is treated as a type of internal sanction, with high immorality ratings predicted to be inversely related with offending intentions. Note that while immorality is similar in nature to the informal sanctions of guilt and shame, it is typically regarded as a distinct construct that is generally rated in terms of its severity (i.e., "how morally wrong would it be to...") but not its certainty.

Bachman and colleagues (1992) were among the first to use the HSM to examine the influence of morality on criminal decision making. After controlling for perceptions of formal and informal sanctions, participants' ratings of immorality exerted a significant inhibitory effect on their self-reported intentions to engage in sexual assault. This inhibitory effect of morality has been found in other HSM studies as well, including those examining physical assault, drunk driving, corporate offending, shoplifting/theft, sports doping, and academic cheating (Bachman et al. 1992; Carmichael and Piquero 2004; Elis and Simpson 1995; Higgins 2007; Loewenstein et al. 1997; Nagin and Paternoster 1994; Paternoster and Simpson 1996; Piquero et al. 2005; Piquero and Tibbetts 1996; Simpson and Piquero 2002; Strelan and Boeckmann 2006; Tibbetts and Herz 1996).

Morality is sometimes viewed as the gatekeeper of the hedonic calculus. That is, before the perceived costs or benefits of a criminal act can be incorporated into the decision to offend, the act itself must first be a part of the person's repertoire of morally acceptable behavior. If it is not, then the individual is fully constrained by his morality and – as a result – any threats of punishment or enticements from benefits are irrelevant. If such a gatekeeper conceptualization is accurate, then the perceived consequences of crime should have their greatest effects among those with weak moral inhibitions and have their weakest effects among those with strong moral inhibitions (Bachman et al. 1992). Although only a few HSM studies have specifically sought to examine this interaction between morality and the role of perceived consequences, there is evidence to support the gatekeeper function of morality.

For example, Bachman et al. (1992) found that among participants who rated a sexual assault scenario to be more morally offensive, perceptions of formal punishments did not significantly alter the intention to offend. Yet, among participants who found the sexual assault to be less morally offensive, formal sanctions exerted a significant deterrent effect. Similar results have also been found among business executives and MBA students who read corporate crime scenarios (Paternoster and Simpson 1996). Although more research is needed in this area, the HSM studies that are available indicate that crime is a nonmarket area among individuals with strong moral fortitude. In other words, among the righteous, the decision to act is less utilitarian and more deontological.

The Role of Self-Control

Conceived as time-stable personality trait, self-control is purported to exert a *direct* effect on criminal intentions (Piquero and Tibbetts 1996). That is, because individuals with low self-control are impulsive risk takers, they should be less able to abstain from a criminal opportunity when it presents itself. However, self-control is also thought to exert an *indirect* effect on offending intentions by altering the individuals' perceptions of consequences of crime. That is, given that individuals with low self-control are present oriented, they should be less able to perceive the long-term negative consequences of their criminal actions, thereby resulting in greater criminal proclivities. There is some HSM research to support both of these claims.

For example, Nagin and Paternoster (1993) found evidence for a direct effect of self-control on offending intentions. After controlling for such factors as prior criminal behavior, the characteristics of the criminal opportunity, and the perceived costs/benefits of the act, a one standard deviation change in low self-control scores resulted in a 39 % increase in theft intentions, a 17 % increase in drunk driving intentions, and an 83 % increase in sexual assault intentions (see also Nagin and Paternoster 1994). In support of an indirect effect, Piquero and Tibbetts (1996) found that low self-control accentuated the perceived benefits and minimized the perceived costs associated with shoplifting and drunk driving – effects that, in turn, significantly influenced participants' intentions to offend (see also Carmichael and Piquero 2004; Higgins 2007).

However, most HSM studies that have included a measure of self-control have found either null effects or effects that are not stable across different models of decision making. For example, neither Tibbetts and Myers (1999) nor Sitren and Applegate (2007) found evidence that self-control levels directly influence college students' intentions to cheat on an exam. Similarly, Simpson and Piquero (2002) found no evidence to suggest that self-control levels predict corporate offending among business executives and MBA students. Furthermore, others have shown that the effects of self-control operate inconsistently across the sex of the participant (Tibbetts and Herz 1996), the operational definition of self-control (Piquero and Bouffard 2007), the dependent variable (Loewenstein et al. 1997; Pogarsky and Piquero 2004), and the participants' anticipated mood when completing the hypothetical act (Carmichael and Piquero 2004). Thus, while there is some support for the notion that self-control levels directly and indirectly impact criminal decision making, the overarching findings from the HSM literature raise doubt as to whether these effects are, in fact, noteworthy and robust.

The Role of Altered States of Mind

Tests of deterrence and rational choice theory have generally ignored the offender's emotional, physiological, and psychopharmacological state during the criminal decision-making process. This omission is striking given the proposed theoretical relationships between altered states of mind and cognition (see Exum 2002; Loewenstein et al. 1997). Fortunately, the HSM is easily capable of incorporating the study of altered states on decision making, and a few such studies have taken advantage of this.

For example, in their study on the effects of sexual arousal on sexually aggressive decision making, Loewenstein et al. (1997) randomly assigned male participants to view photographs of nude women or of fully clothed fashion models prior to reading a hypothetical date rape scenario. Compared to the non-aroused participants, those who were aroused endorsed greater sexually aggressive intentions. However, few differences were found across arousal conditions with respect to participants' perceived consequences of sexual aggression. In a similar experiment, Bouffard (2002b) found that self-reported arousal levels were positively related to offending intentions but inconsistently related to the perceived consequences. In a subsequent and more detailed analysis, Bouffard (2011) concluded there are in fact differential deterrent effects across arousal states, with the perceived costs of crime exerting their greatest deterrent effects among those who reported lower arousal levels. Collectively, these studies suggest that arousal increases sexually aggressive tendencies – not by altering participants' perceptions of the consequences – but by somehow moderating the underlying relationship between perceived consequences and the intention to offend.

Also using an experimental design, Exum (2002) examined the effect of alcohol intoxication and anger on participants' responses to a physical assault scenario. Participants were randomly assigned to drink either a nonalcoholic or alcoholic beverage, the latter designed to elevate blood alcohol levels to approximately 0.08 %. Half of the participants in each group were then confronted by the researcher in such a way to induce anger, whereas the remaining half was not. Participants then read a physical assault scenario and responded to a battery of rational choice questions. Results indicated that alcohol and anger interacted to increase one of two measures of aggressive intentions; however, consistent with other research (Loewenstein et al. 1997; Bouffard 2011), there was no support for the idea that the altered states of mind affected participants' perceptions of costs and benefits. At the same time, exploratory analyses revealed that the collection of consequences used to model decision making were not equally predictive of intentions across the experimental conditions. This suggests that – while the perceptions of costs and benefits were largely the same across all participants – those in the intoxication and anger conditions used these perceptions differently in their decision-making processes. These findings further suggest that altered states of mind moderate the decision to offend.

Carmichael and Piquero (2004) also examined the effect of perceived anger on physical assault. Anger was not experimentally manipulated in this study; instead, participants were asked to read a bar fight scenario and then self-report how angry they thought they would feel in that particular situation. Controlling for the perceived costs and benefits of the assault, anger scores were positively and significantly related to aggressive intentions. Furthermore, the perceived negative consequences of assault exerted significant deterrent effects among the low anger group but not in the high anger group, again suggesting that anger moderates the decision-making process. Collectively, this small body of HSM research serves as a reminder that decision making does not occur in a vacuum and that emotional, visceral, and pharmacological forces shape the decision to offend.

Conclusions from the HSM Literature

The HSM research on criminal decision making finds that the certainty of punishment (both formal and informal) has a weak deterrent effect and the severity of punishment has an even weaker effect. Although rarely examined, the swiftness of punishment also seems to carry little weight in the decision to offend. In stark contrast, the perceived benefits from crime appear to be a key element in criminal decision making. However, some criminal acts appear to be so morally objectionable to participants that they will simply refrain from the act regardless of the benefits. Similarly, dynamic factors such as one's state of mind may alter the salience of these perceived consequences as well as moderate the rational process thought to underlie criminal decision making. Trait-level characteristics such as low self-control may not only make it more difficult for individuals to self-regulate their behavior in the presence of a criminal opportunity, but they may also change the way individuals assess the risks and benefits associated with that opportunity (but note, however, that the self-control effects may not be very robust). As a result of these various state- and trait-level factors, criminal decisions that appear to be completely "irrational" to the outside observer be seen as wholly rational from within the perspective of the actor.

Emerging Areas of Research and Challenges

Given that the HSM is a relatively new technique within the study of criminal decision making, one could consider most any line of HSM research to be an "emerging" area. With that being said, below are four areas of criminological HSM research that deserve special attention. These four issues have great potential to advance (or challenge) much of what criminologists claim to know about the decision to offend.

Studying Deterrence Among Deterrables

Although there is reason to believe that individuals vary in their responsivity to the perceived consequences of crime (see Bachman et al. 1992; Carmichael and Piquero 2004; Paternoster and Simpson 1996), tests of deterrence theory typically ignore these individual susceptibilities and instead examine the properties of punishment across an aggregate sample of participants. Pogarsky (2002) challenged this approach, arguing that deterrence theory should be tested only among those who are truly deterrable, as opposed to those who are either so bound to conformity or so wedded to deviance that extralegal sanctions have no impact on their behavior. Using the HSM and participants' self-reported intentions to drive drunk, Pogarsky (2002) developed a method of identifying the subsample of "deterrables" within a group of study participants. He then examined the impact of formal sanctions among the deterrables and, for comparison, among the full sample.

Results from the full sample largely confirm the findings from past studies of deterrence theory – namely, that certainty has a greater effect than severity. However, in the analysis of only the deterrables, severity had a greater effect than certainty. Thus, the conventional wisdom that "certainty is more important that severity" appears to be challenged when studying only those people who are, in fact, swayed by sanction threats. Future HSM research should build on Pogarsky's method of disaggregating samples into deterrable and non-deterrable groups and continue to examine the role of formal and informal sanctions among those most responsive to punishments. The findings have important implications not only for criminological theory but for public policy.

The Positive Punishment Effect

Contrary to the notion that sanctions deter future behavior, some studies find a *positive* relationship between punishment and subsequent offending (e.g., Piquero and Pogarsky 2002).

Pogarsky and Piquero (2003) outlined two possible explanations for this positive punishment effect: selection and resetting. The selection explanation contends that offenders with stronger criminal propensities are more likely to come to the attention of the police (i.e., get punished) and also be more likely to recidivate. In contrast, the resetting explanation argues that offenders who experience a stroke of bad luck (e.g., get punished) are more apt to take elevated risks in the future (e.g., recidivating) because they believe their bad luck is not likely to return anytime soon. In other words, shortly after experiencing punishment, the offender's perceived certainty of sanctioning is "reset" to a nominal value.

To examine the possibility of resetting, Pogarsky and Piquero (2003) administered a hypothetical drunk driving scenario to a sample of undergraduates and asked them a series of questions about their perceptions of punishment and prior punishment experiences. Support for the resetting explanation was mixed and varied by the participant's level of risk for offending. That is, consistent with the notion of resetting, low-risk offenders who had previously been punished reported lower certainty estimates than those low-risk offenders who had not been previously punished. However, no evidence of resetting was found among high-risk offenders, with all high-risk offenders perceiving comparable sanctioning risks regardless of past punishment experiences. While more research is needed in this area to better understand the nature of positive punishment effects, future studies should also seek to integrate research on "deterrables" with that on resetting. Although it is too early to tell, it may be the case that those who are most responsive to sanction threats (the deterrables) are also the very same "low-risk" offenders who tend to reset their perceived threat levels following punishment.

Researcher-Generated Versus Self-Generated Consequences

When potential offenders encounter a criminal opportunity in the real world, they freely deduce their own set of costs and benefits to contemplate. However, in the typical HSM study, participants are asked to contemplate a predetermined, uniform set of consequences generated by researchers. Such a reliance on researcher-generated consequences inevitably forces an artificial structure on the otherwise organic decision to offend. Bouffard, Exum, and Collins (2010) examined the impact of this artificial structure by presenting participants with a hypothetical shoplifting scenario and then randomly assigning them to either (1) assess a standard battery of researcher-generated consequences or (2) assess a set of costs and benefits that the participants themselves self-generated. By comparing and contrasting the two sets of consequence ratings, Bouffard and colleagues could begin to examine the extent to which individuals' decision-making processes were being influenced by the study's methodology.

The findings show that when participants are asked to assess the benefits of crime that were identified by the researcher, they are more likely to regard the consequences as possible outcomes (Bouffard et al., 2010). Illustratively, when participants were specifically asked to consider the "thrill" derived from the hypothetical theft, 64 % reported the act would afford some degree of fun/excitement. In contrast, when participants were asked to self-identify all the "good things" that might happen to them if they committed the hypothetical act, only 10 % indicated it would be fun/exciting. Similarly, participants were more likely to see the costs of shoplifting as potential outcomes when these costs were identified by the researcher versus when they were self-generated. A noteworthy example is the cost of deviating from one's morality. Whereas 99 % of participants who received researcher-generated consequences reported that shoplifting felt immoral, only 3 % of participants who self-generated consequences reported feelings of immorality.

Recall that past research using the HSM finds moral inhibitions to be influential considerations in the decision to offend (e.g., Bachman et al. 1992; Loewenstein et al. 1997; Paternoster and Simpson 1996). The findings from Bouffard et al.'s (2010) study suggest that the morality effect reported in this literature may, in part, be a methodological artifact and largely attributed to the use of researcher-generated consequences. However, future research is needed to better understand how the hypothetical scenario methodology (in general) and the manner in which costs and benefits are presented (in particular) impact the findings from HSM studies.

The Accuracy of Self-Reported Intentions to Offend

Recall that the typical dependent variable in HSM studies is not participants' actual offending behavior but is instead their self-reported *intentions* to offend. According to the theory of reasoned action, such intentions can be viewed as valid estimates of real-world behavior because "...barring unforeseen events, a person will usually act in accordance with his or her intention" (Ajzen and Fishbein 1980, p. 5). Consistent with this notion, research generally finds the correlation between participants' intentions to act and their corresponding behavior to be positive and significant (Ajzen and Fishbein 1980; Armitage and Conner 2001). However, this correlation is largely based on the study of conventional behaviors such as voting, watching television, or going to church. Only a handful of studies have examined the intentions/behavior relationship for deviant behaviors, and while the results from these studies are promising on the surface, a closer examination reveals potential methodological and/or measurement problems that may weaken the interpretation of these intentions/behavior correlations (Exum et al. 2011; cf. Pogarsky 2004).

To further examine the predictive accuracy of self-reported intentions to offend, Exum et al. (2011) gave undergraduate students a copy of a fictitious newspaper article describing an ongoing music piracy operation on campus. Students were led to believe the article was real and had recently appeared in the local paper. The article described a graduate student who was reportedly emailing illegal copies of digital music files for free to anyone with a university email account. Also included in the article were the graduate student's name and email address. After reading the article, study participants were asked to self-report their likelihood of contacting the graduate student and requesting illegal files from him. In the following weeks, the graduate student – who was a research confederate – monitored his email account for any requests from participants. In this way, participants' self-reported intentions to offend could be validated against their own requests for illegal music files.

Despite the variability in offending intentions, including a few participants who reported a 100 % chance of emailing the graduate student, no one in the study actually requested music files from the confederate. This suggests that self-reported criminal intentions (at least, as they apply to this form of music piracy) have a low false-negative rate but a high false-positive rate. Stated differently, all participants who reported little-to-no intentions of contacting the confederate abstained from the behavior, resulting in a false-negative rate of 0 %. However, all participants who reported strong-to-definitive intentions of contacting the confederate abstained as well, resulting in a false-positive rate of 100 % (Exum et al. 2012). This suggests that when presented with a hypothetical offending scenario, participants may fall prey to a false sense of bravado and self-report strong intentions to offend, only later to cower at the real-world opportunity. Given that self-reported intentions to offend are an essential element of HSM studies of deterrence/rational choice, additional research is needed to examine the accuracy of these offending intentions (see also Pogarsky 2004). The implications of this line research have the potential to challenge most everything we know about the nature of criminal decision making.

Conclusion

More than 200 years ago, Jeremy Bentham (1970/1789) described the deliberative process in which all individuals are thought to engage as they contemplate a criminal act:

> Sum up all the values of all the *pleasures* on one side, and those of all the *pains* on the other. The balance, if it be on the side of pleasure, will give the *good* tendency of the act upon the whole with the respect to the interest of that *individual* person.... (p. 40, emphasis in the original)

Two centuries later, criminologists continue to struggle with the best way to test these ideas. The biggest impediment appears to be obtaining a measure of participants' perceived "pleasures" and "pains" at the moment participants decide to engage in or abstain from crime. The hypothetical scenario method is arguably the best technique to date for doing this, thereby making it uniquely situated to study criminal decision making at the moment it unfolds. Today, much of what we now know about the decision to offend – e.g., the negligible effect of punishment, the lure of perceived benefits, and the different calculative processes across individual- and state-level factors – has been either discovered through or confirmed by HSM research.

As scholars seek to build upon our current understanding of criminal decision making, they will inevitably rely on the HSM to some degree. The technique's versatility, its ease of administration, and its ability to accommodate experimental manipulations make it an ideal platform for designing and implementing research studies. At the same time, the HSM's greatest strength – i.e., its ability to get inside the "black box" of the mind and study decision making during the contemplation of a criminal opportunity – comes with a great weakness. The HSM can only allow researchers to model the decisions that underlie criminal *intentions* and not actual criminal *behavior*. As a result, the HSM can inform our understanding of real-world criminal decision making only to the extent that individuals' self-reported intentions are predictive of their actual criminal conduct. Until the predictive accuracy of criminal intentions is more fully understood, the study of criminal decision making will benefit most from triangulating the findings from a host of studies that use a variety of research methodologies, including the HSM.

School Aggression

► Bullying Prevention: Assessing Existing Meta-Evaluations

School Bullying as a Risk Factor for Later Criminal Offending

Maria M. Ttofi[1], David P. Farrington[1] and Friedrich Lösel[1,2]

[1]Institute of Criminology, University of Cambridge, Cambridge, UK

[2]Institute of Psychology, University of Erlangen–Nuremberg, Erlangen, Germany

Overview

School bullying has received the attention of researchers and program planners in both developed and developing countries. It is a special category of aggressive behavior that has been addressed through numerous anti-bullying programs and, in some cases, through wider multiple component programs. Various anti-bullying agencies have highlighted the importance of intervention research for the development of safer school communities, where students can develop their full potential without being exposed to bullying and its detrimental effects. A vast number of cross-sectional studies have provided evidence of the negative impact of bullying on children's concurrent health.

This entry reports on an updated systematic review and meta-analysis that was undertaken under the aegis of the Swedish National Council for Crime Prevention and further supported by the British Academy and conducted by the current authors. Only longitudinal prospective studies were included in the review, which aimed to examine to what extent school bullying predicts later offending and violence. Significant effect sizes were found even after controlling for other major childhood risk factors. Being a bully increased the likelihood of being an offender by more than half and increased the likelihood of being violent by two thirds. These results either reflect the persistence of an underlying aggressive or antisocial tendency or a facilitating effect of school bullying on later offending and violence (or both).

The implication is that high quality bullying prevention programs (and possibly multiple component programs which also target aggression) should be promoted. They could be viewed as an early form of crime prevention. They can potentially have long-term effects by improving the future psychosocial adjustment of school bullies and reducing the associated health, welfare, education, and other costs.

Introduction

School bullying has recently become a topic of major public concern and has attracted a lot of media attention, with articles in major newspapers and magazines reporting cases of children who committed (or attempted) suicide because of their victimization at school and parents suing school authorities for their failure to protect their offspring from continued bullying victimization (e.g., Ttofi and Farrington 2012). There is, nevertheless, a number of "skeptics" who still perceive school bullying as being part of a normal developmental process, or as one of those school experiences that prepare children for the grown-up world. Scientific evidence regarding possible detrimental effects of school bullying on children's mental health and future psychosocial adjustment can only be provided through a systematic review and meta-analysis, providing an unbiased standardized effect size and defining the magnitude of the effect.

Background Research

School bullying is a special category of aggressive behavior involving repeated unprovoked acts against less powerful (emotionally or physically) individuals (Farrington 1993; Olweus 1993). Of course, schools, like other institutions, will always be a place in which the basic human motive of aggression will be demonstrated. However, school bullying should not be confused with more or less normal aggressive interactions such as rough and tumble play.

Scientific interest in the problem of bullying and its negative short-term and long-term effects emerged after the well-publicized suicides of three Norwegian boys in 1982, which were attributed to severe peer bullying (Olweus 1993). School bullying has gradually become a topic of major public concern via "bullying awareness days," national initiatives in various (European) countries (Smith and Brain 2000), and anti-bullying research networks across the world (e.g., Anti-Bullying Alliance; BRNET; International Observatory for Violence in Schools; PREVNet).

Any suggestion regarding the short-term negative impact of peer aggression and victimization seems reasonable even to the lay mind. Establishing, on the other hand, the long-term effects of school bullying and arguing that children involved in peer aggression are more likely to follow an antisocial path (compared with noninvolved students) is more challenging. Some early longitudinal studies did provide evidence of the long-term impact of school bullying and, notably, established the intergenerational transmission of school bullying. In the Cambridge Study in Delinquent Development, for example, boys who were bullies at age fourteen tended, at age thirty-two, to have children who were bullies (Farrington 1993). As another example, in his follow-up study of over 700 Stockholm boys, Olweus (1993) reported that 36 % of bullies at ages thirteen to sixteen were convicted three or more times between ages sixteen and twenty-four, compared with 10 % of the remainder.

There have been surprisingly few recently published longitudinal studies on the developmental pathways of children involved in school bullying since the seminal work of Olweus in Scandinavia and some other European examples. Two special issues in peer-reviewed journals have recently been published in an attempt to address this gap in research literature (Farrington et al. 2011; Ttofi et al. 2011a). Both issues presented new findings on the long-term negative consequences of school bullying based on major prospective longitudinal studies from around the world. Longitudinal investigators of twenty-nine studies conducted analyses for a more comprehensive British Academy funded project, which examined the long-term association of school bullying with both internalizing (such as anxiety, self-esteem, and stress) and externalizing (such as aggression, alcohol, and drug use) problems (see Farrington et al. 2012, Table 4, for a list of all contributors).

The special issue of *Criminal Behaviour and Mental Health* focused on the association between bullying perpetration at school and offending later in life. A systematic review and meta-analysis on the topic was carried out (Ttofi et al. 2011c). The special issue of the *Journal of Aggression, Conflict and Peace Research* focused on the association between bullying victimization (i.e., being bullied) and internalizing problems later in life, such as anxiety and depression. A systematic review and meta-analysis was again carried out examining the extent to which bullying victimization at school predicted depression (Ttofi et al. 2011b), showing that the probability of being depressed up to seven years later in life (M = 7.13 years; SD = 8.79) was significantly higher for victims of school bullying than for control students, i.e., children not involved in school bullying.

Building upon the above-mentioned research activities, an effort was made to update the relevant systematic reviews (Farrington et al. 2012) and to study further outcomes, such as violence (Ttofi et al. 2012). This entry presents results from the updated systematic review on the association of school bullying with offending later in life. Additional analyses are presented on the long-term link of bullying with violence.

Methods

The main objectives of the systematic review were two-fold. Firstly, to assess whether bullying at school (perpetration and victimization) was a significant risk factor predicting offending and violence later in life (unadjusted effect sizes). Secondly, to assess whether these associations were still significant after controlling for other major childhood risk factors, measured at the baseline period (adjusted effect sizes). Results on offending and violence were carefully treated in separate analyses and the outcome measures under each category generally did not overlap. However, it is possible that in some studies, outcome measures such as “police arrests” would include violence. “Offending” included outcome measures such as police or court contact, property offending, criminal convictions, property theft, vandalism, shoplifting, vehicle theft, etc. “Violence” included outcome measures such as forced sexual contact, criminal violence, physical fights, violent convictions, violent offending, weapon carrying, assault, etc.

Further analyses were conducted to investigate moderators that might explain variability in effect sizes, such as the age at which bullying was measured (Time 1), the age at which the outcome measures were taken (Time 2), the number of covariates controlled for in the adjusted effect sizes, the length of the follow-up period (measured in years), and the way in which the outcomes were measured (i.e., official data versus self-reports).

Stringent inclusion and exclusion criteria were set in advance. For example, reports were included only if they were based on prospective longitudinal data. The predictor must have been a measure of school bullying (and not other more general forms of peer aggression/victimization) and must have preceded the outcome (i.e., offending or violence). A clear measurement of offending and/or violence must have been included in the report as an outcome measure. Studies were included if participants were school-aged children in the community and exposure to bullying (perpetration and victimization) specified the school years. Published and unpublished reports of the literature were included in order to minimize the possibility of publication bias in the results.

Reports were excluded if the character of the data was qualitative in nature (e.g., qualitative data based on interviews) and did not allow calculation of an effect size. This did not apply if a qualitative method (e.g., interviews or observation studies) was used to obtain a quantitative measure. If the outcome measure (offending or violence) was part of a wider theoretical construct (e.g., externalizing or antisocial behavior), then the relevant report was again excluded. Reports based on clinic samples or incarcerated youth were also excluded.

Extensive searches were carried out and a detailed description of them can be found in the Swedish report (Farrington et al. 2012) and the most recent work focusing on violent outcomes (Ttofi et al. 2012). In total, the same searching strategies were repeated in 19 electronic databases, and the full volumes of 63 journals were searched either online or in print. In the Swedish report, readers can also find detailed tables of the key features of each report, such as the sample size, the country where the study took place, the exact confounds controlled for at the baseline period, etc.

Results

In total, 661 reports concerned with the association of school bullying with internalizing (e.g., anxiety, depression, self-esteem, etc.) and externalizing (e.g., aggressive behavior, conduct problems, offending, etc.) problems were located. All reports were screened in line with the inclusion and exclusion criteria and classified in five different categories (see Farrington et al. 2012, Table 5). Further to a detailed screening of all manuscripts, a total number of 48 reports, corresponding to 29 longitudinal studies, presented data on the long-term association of school bullying (perpetration and victimization) with offending in adolescence or young adulthood (see Farrington et al. 2012, Table 6). A total number of 51 reports from 28 longitudinal studies were included in the systematic review on the association of school bullying (perpetration and victimization) with violence in adolescence or young adulthood (see Ttofi et al. 2012, Table 1).

When different manuscripts relating to the same longitudinal study reported different effect sizes (because of differences, e.g., in the sample size or in the follow-up period that the authors have used), the combination of effect sizes across reports is not straightforward as these effect sizes are based on dependent samples. These dependencies were taken into account, as ignoring them would result in standard errors that were too small, often by a large degree. Advice from leading experts in the field was sought on this matter (Wilson 2010). Clear rules were set in advance for computing effect sizes across reports from the same longitudinal study (see Farrington et al. 2012; Ttofi et al. 2012).

Bullying Perpetration at School and Offending Later in Life

Eighteen studies provided an effect size for bullying perpetration versus offending. The summary unadjusted effect size across the 18 studies was OR = 2.64 (95 % CI: 2.17–3.20; z = 9.83) for the random-effects model. The random-effects model was used since the heterogeneity test, Q, of 84.89 was highly significant at p = 0.0001. When the three studies with only unadjusted effect sizes were excluded, the summary effect size for the remaining 15 studies – for the random-effects model – was OR = 2.54 (95 % CI: 2.05–3.14, z = 8.52). Again, there was significant variability in effect sizes across these studies (Q = 76.03, p = 0.0001).

After controlling for covariates, the adjusted summary effect size was reduced to OR = 1.89 (95 % CI: 1.60–2.23; z = 7.49) but this was still highly significant (see Farrington et al. 2012; Figs. 3 and 4). This OR indicates quite a strong relationship between bullying perpetration and later offending. For example, if a quarter of children were bullies and a quarter were offenders, this value of the OR would correspond to 34.5 % of bullies becoming offenders, compared with 21.8 % of non-bullies. Thus, being a bully increases the risk of being an offender (even after controlling for other childhood risk factors) by more than half.

For the adjusted summary effect size, various moderators were investigated to explain the heterogeneity in effect sizes across studies, which was significant (Q = 36.82, p = 0.001). These included the number of covariates controlled for at baseline (range: 1–20; M = 7.00; SD = 5.22), the age at which school bullying was measured (range: 6.23–15.54; M = 11.26; SD = 2.68), the age of participants when outcome measures were taken (range: 10.00–24.64; M = 17.10; SD = 4.91), and the length of the follow-up period, measured in years (range: 0.42–16.50; M = 5.84; SD = 4.56).

The age at which bullying was measured was positively associated with the effect size, but the regression coefficient was not statistically significant (B = 0.019, SE = 0.024, p = 0.428). The length of the follow-up period was significantly negatively associated with the effect size (B = −0.027, SE = 0.012, p = 0.018). As expected, the age of the study participants when outcome measures were taken was significantly negatively related to the effect size (B = −0.025, SE = 0.012, p = 0.039). The above two negative relationships suggest that bullying perpetration has a stronger effect in the short term. The relationship between the number of covariates controlled for and the effect size was in the expected negative direction and also significant (B = −0.027, SE = 0.013, p = 0.037). Therefore, the adjusted effect size decreased as the number of covariates controlled for increased.

Other moderators that may explain variability in effect sizes include the type of longitudinal studies (i.e., prospective versus retrospective) and the way in which the outcomes were measured (i.e., official data versus self-reports). In the Farrington et al. (2012) report, the reader can obtain information about these moderators (see their Table 6). Only three studies out of fifteen presented outcome measures based on official records for offending, making a moderator analysis inappropriate (due to uneven study numbers). Finally, only one study presented results based on a retrospective measure of bullying victimization, so any analyses on this matter would be meaningless.

If the studies included in a meta-analysis are a biased sample of all relevant studies, then the mean effect computed will reflect this bias (Borenstein et al. 2009, p. 277). It is clear from our thorough searching strategies that every precaution was taken to ensure that all eligible studies would be represented in the meta-analysis. In order to further increase the validity of the meta-analysis findings, a number of publication bias analyses were carried out.

Firstly, the Duval and Tweedie's Trim-and-Fill procedure was used. This technique displays the differences in effect sizes that could be attributable to bias by imputing effect sizes until the error distribution more closely approximates normality, offering the best *estimate* of the unbiased effect size (Borenstein et al. 2009, p. 286). No imputed effect sizes appeared on the relevant funnel plot (they would have been presented as solid black dots; see Farrington et al. 2012, Fig. 6), indicating no publication bias. The imputed summary effect size (represented by a solid black diamond) had not shifted at all.

Indeed, under the fixed effect model, the point estimate and 95 % confidence interval for the combined studies was 1.86 (95 % CI: 1.71–2.03). Using Trim-and-Fill procedure, these values remained unchanged. Under the random-effects model, the point estimate and 95 % confidence interval for the combined studies was 1.89 (95 % CI: 1.60–2.23). Using Trim-and-Fill procedure, these values were again unchanged.

Furthermore, Rosenthal's Fail-Safe N test (Rosenthal 1979) was conducted. One concern of publication bias is that some nonsignificant studies are missing from a given analysis and that these studies, if included, would nullify the observed effect. Rosenthal suggested that, rather than simply speculate about the impact of the missing studies, we compute the number of nonsignificant studies that would be required to nullify the effect. If this number is small, then there is reason for concern because some nonsignificant studies may have been never communicated to the scientific community (e.g., due to "publication bias"). However, if this number is large, one can be confident that the treatment effect, while possibly inflated by the exclusion of some studies, is nevertheless not zero.

Bullying Perpetration at School and Violence Later in Life

A total number of 15 studies were concerned with the association of bullying perpetration with aggression and violence later in life. The unadjusted summary effect size across these studies was OR = 3.09 (95 % CI: 2.35–4.07; z = 8.10). For one study, only an unadjusted effect size was available. The unadjusted effect size for the remaining 14 studies was OR = 2.97 (95 % CI: 2.25–3.92; z = 7.71; Q = 151.81, $p = 0.0001$; $I^2 = 91.44$). All individual studies yielded a significant effect size (see Ttofi et al. 2012, Fig. 1). After controlling for covariates, the adjusted summary effect size was reduced to OR = 2.04 (95 % CI: 1.69–2.45; z = 7.53) but this was still highly significant (see Ttofi et al. 2012, Fig. 2). This OR indicates quite a strong relationship between bullying perpetration and later violence. For example, if a quarter of children were bullies and a quarter were violent, this value of OR would correspond to 35.8 % of bullies becoming violent, compared with 21.4 % of non-bullies. Thus, being a bully increases the risk of being violent (even after controlling for other childhood risk factors) by two thirds.

Although all individual studies yielded an effect size supporting the link between school bullying and aggression/violence later in life, the magnitude and the significance of the effect varied across these studies. Various moderator analyses were conducted in order to explain this variability (Q = 75.801, $p = 0.0001$, $I^2 = 82.85$). These included the number of covariates controlled for at baseline (range: 2–20; M = 6.93; SD = 5.25), the age at which school bullying was measured (range: 8.00–15.54; M = 12.04; SD = 2.35), the age of participants when outcome measures were taken (range: 10.00–24.64; M = 17.65; SD = 4.83), and the length of the follow-up period, measured in years (range: 0.42–16.50; M = 5.61; SD = 4.88).

The age of participants when bullying was measured was significantly negatively correlated with the effect size (B = −0.065; SE = 0.021; $p = 0.002$), suggesting that the younger the children were when they exhibited this form of problem behavior, the more likely it was that they would be violent later in life. The age of participants when outcome measures were taken was also significantly negatively related to the effect size (B = −0.033; SE = 0.009; $p = 0.0005$). In other words, the lower the age of the participants when aggression or violence was measured, the larger the effect, possibly because this was associated with a shorter follow-up period. This is consistent with the significant negative association between the length of follow-up period and the magnitude of the effect size (B = −0.017; SE = 0.009; $p = 0.051$). As expected, the magnitude of the effect size decreased as the number of confounds controlled for increased (B = −0.013; Intercept = 0.668; SE = 0.010; $p = 0.185$), but the relevant regression coefficient was not significant.

As with the previous meta-analysis, a number of sensitivity analyses were conducted. Firstly, the Duval and Tweedie's Trim-and-Fill procedure was performed. Three imputed effect sizes appeared on the relevant funnel plot (see Ttofi et al. 2012, Fig. 3) and the imputed summary effect size (represented by a solid black diamond) had shifted slightly, suggesting a trivial overestimation of the summary effect size.

As already mentioned, the difference was very small. Under the fixed effect model, the point estimate and 95 % confidence interval for the combined studies was 1.83 (95 % CI: 1.71–1.95). Using Trim-and-Fill procedure, the imputed point estimate was 1.76 (95 % CI: 1.65–1.88). Under the random-effects model, the point estimate and 95 % confidence interval for the combined studies was 2.04 (95 % CI: 1.69–2.45). Using Trim-and-Fill procedure, the imputed point estimate was 1.77 (95 % CI: 1.45–2.16).

Finally, the Rosenthal's Fail-Safe N test was performed. This meta-analysis incorporated data from 14 studies, which yielded a z-value of 17.12216 and corresponding 2-tailed *p*-value of 0.000001. The fail-safe N is 1055. This means that one would need to locate and include 1055 "null" studies in order for the combined 2-tailed *p*-value to exceed 0.050. Put another way, 75.4 missing studies would be needed for every observed study for the effect to be nullified. It is impossible that such a large number of studies were conducted but not published or not included in our analysis.

Further Findings

Further analyses were performed to examine the association of bullying victimization with later offending before (Unadjusted OR = 1.32; 95 % CI: 1.13–1.55, z = 3.40) and after controlling for other major childhood risk factors (Adjusted OR = 1.14; 95 % CI: 0.997–1.310, z = 1.91) and relevant forest plots are shown in the Farrington et al. (2012) report (see Figs. 11 and 12). This was a very weak relationship. Moderator analyses and publication bias analyses similar to those presented in the current entry were also presented in that report.

Finally, analyses were performed to examine the association of bullying victimization with later violence before (Unadjusted OR = 1.65; 95 % CI: 1.42–1.92; z = 6.48) and after (Adjusted OR = 1.42; 95 % CI: 1.248–1.6172; z = 5.3117) controlling for covariates (see Ttofi et al. 2012, Figs. 4 and 5). Again, moderator analyses and publication bias analyses similar to those presented in the current entry are also presented in that report.

Sensitivity analyses were performed for these two sets of meta-analyses and the results showed in general no evidence of publication bias (see Farrington et al. 2012; Ttofi et al. 2012).

Possible Controversies in the Literature

The results of these systematic reviews and meta-analyses suggest that there are long-term detrimental effects of school bullying on later offending and violence. This was even the case when confounded variables that are risk factors for bullying or victimization as well as the undesirable outcomes were controlled for. Therefore, one can conclude that school bullying is an independent predictor of the later psychosocial development of perpetrators as well as of victims. It is the first time that this conclusion is not only based on a few selected primary studies and narrative reviews, but, instead, on comprehensive meta-analyses of prospective longitudinal studies that included new data from a substantial body of yet unpublished research. The findings remained robust in sensitivity analyses testing potential publication biases, of which there was no sign.

The relation of bullying perpetration with later offending and violence might reflect the persistence of an underlying disposition for antisocial behavior that has different manifestations over time (Farrington 1993; Lösel and Bliesener 2003). However, as the relation remained after controlling for other childhood risk factors, bullying perpetration may also increase the likelihood of later offending and violence.

Of course, one should acknowledge that any direct mention of causality should be carefully treated. Although most studies use bullying as the predictor of later outcomes, implying in this way a specific temporal sequence, alternative models have been suggested. Very few bullying studies have examined alternative models on whether bullying is a cause or a consequence of psychopathologic behavior (e.g., Boulton et al. 2010; Kim et al. 2006). This is not a trivial matter and it would shed more light on the temporal sequence and the causal ordering between bullying and other internalizing or externalizing behaviors. The substantial adjusted effect size for victimization versus later depression found in a previous meta-analysis (Farrington et al. 2012; Ttofi et al. 2011b), for example, suggests in a way that the frequent internalizing symptoms of victims are not only a trigger for being bullied, but a psychological consequence.

Systematic reviews on risk factors are important as they can advance theory and also help to develop effective prevention programs (Murray et al. 2009). For example, it would be interesting to examine whether victims of bullying suffer from low self-esteem or whether school bullies lack cognitive or affective empathy. Such findings, based on relevant systematic reviews, could guide future intervention initiatives, while also refining theory about the causes of bullying perpetration and victimization.

Open Questions and Future Research Directions

In the current meta-analysis, studies were included and analyzed based on "level analyses." Levels of bullying perpetration were compared with later levels of offending and violence. It would also have been interesting to complete a systematic review on "change analyses," examining whether changes in bullying from Time 1 to Time 2 are followed by changes in an outcome from Time 2 to Time 3. However, there are hardly any studies on this matter, since such analyses would require relevant data from multiple waves. Such analyses would allow, to an extent, making safer inferences about causality, although change data are subject to greater variability than level data. Systematic reviews of longitudinal studies which control for confounded variables can give some hints on whether variables are simple correlational risk factors, risk markers, or causal risk factors (Kraemer et al. 2005).

Future research should also examine possible gender-specific and ethnic-specific effects of bullying on later violent behavior and offending. Such information was hardly ever available in the current literature. To investigate and disentangle the impact of these and other variables on the relation between bullying and later outcomes, more longitudinal studies with a sound control for childhood risk factors are needed. The results of meta-regression analyses were not always as expected in the meta-analyses for the British Academy project on "Health and Criminal Outcomes of School Bullying" because of the large differences in the type of covariates researchers controlled for. However, one should note that the lack of a sufficient number of studies with consistent patterns of characteristics is a typical problem in meta-analyses (Lipsey 2003).

Future research should also examine mediators or possible causal mechanisms between school bullying and the various outcomes. The underlying mechanisms, for example, may be the reinforcement obtained by dominating others and the development of an identity as a "bully" that goes beyond the school context.

Conclusions

This is the first time that research has provided an *unbiased standardized effect size* regarding the predictive efficiency of school bullying in relation to violence and offending later in life. The significant summary effect sizes have important implications for policy and practice as they give a stronger voice to anti-bullying agencies and reestablish the moral imperative of school communities to create an appropriate violence-free school climate.

High quality bullying prevention programs should be promoted (Farrington and Ttofi 2009; Ttofi and Farrington 2011). They could be viewed as an early form of crime prevention. These programs can potentially have long-term effects by improving the future psychosocial adjustment of school bullies and reducing the associated health, welfare, education, and other costs. The effectiveness of other school-based programs for the prevention of problem behaviors has been examined through thorough systematic reviews (e.g., Wilson et al. 2001) and it is possible that such programs, or other general multicomponent programs, might have positive effects in reducing aggression and bullying behavior.

Previous research has provided strong evidence about the monetary value of saving high-risk youth (Cohen and Piquero 2009). Children involved in school bullying are undoubtedly youth at risk, with significantly higher probabilities of following an antisocial path. What remains unanswered is the identification of protective factors that interrupt the continuity from school bullying to later adverse outcomes and confer resiliency on this special category of high-risk youth (Ttofi and Farrington 2012).

Overview

By rights, schools should be sanctuaries against criminal victimization, but the truth is otherwise. A threatening environment is not conducive to academic success. The US federal law implementing No Child Left Behind (NCLB, the most recent national education-reform initiative in the USA) stipulates that school systems must have programs in place to reduce levels of violence. The legislation authorizing NCLB has a specific provision that "persistently dangerous" schools be identified by the states and that students attending such schools be given the option of transferring to another school. In practice, only a few dozen schools nationwide have been identified as persistently dangerous, but that fact reflects politics more than the empirical reality.

As it turns out, obtaining reliable information about crime in schools is a challenge – for researchers as well as for state and federal officials. There are several sources of data in addition to the schools' own reports, but each source is error prone. There are some rather remarkable differences among them with respect to estimated crime rates and patterns.

Based on our review of the evidence, we offer several lessons about crime in school and about the sources of statistics on crime. First, with respect to sources, we find that crime surveys with adolescent respondents give results that are remarkably sensitive to the survey method. For example, in-school victimization rates from the Youth Behavior Risk Surveillance System (YRBSS) are more than 20 times as high as comparable victimization rates estimated from the National Crime Victimization Survey (NCVS), and they produce qualitatively different patterns over time. It is always a good idea to validate estimates from one source against others, but that may be especially true with youth surveys. On the other hand, we find administrative data to be better than expected.

We are able to reach some conclusions about crime patterns that we feel are sufficiently robust to be believable. Among our conclusions are these:

- Victimization rates for 12–18-year-olds are as high in school as out (and higher for the 12–14-year-olds), despite the fact that youths spend many fewer waking hours in school.
- Victimization patterns are quite different in and out of school. Violent crimes tend to be

less serious in school (where only 1 % of homicide victimizations occur).

- Property crime victimization rates are remarkably homogeneous across race and also sex; alternative data sources are not consistent with respect to racial patterns of school violence.
- "Persistently dangerous schools" appear to be a real phenomenon and far more prevalent than are officially identified as such.

We begin this entry with a discussion of the important data sources and then go on to discuss victimization patterns for students. We then explore the issue of persistently dangerous schools using a unique data set. We conclude with an analysis of arrest patterns.

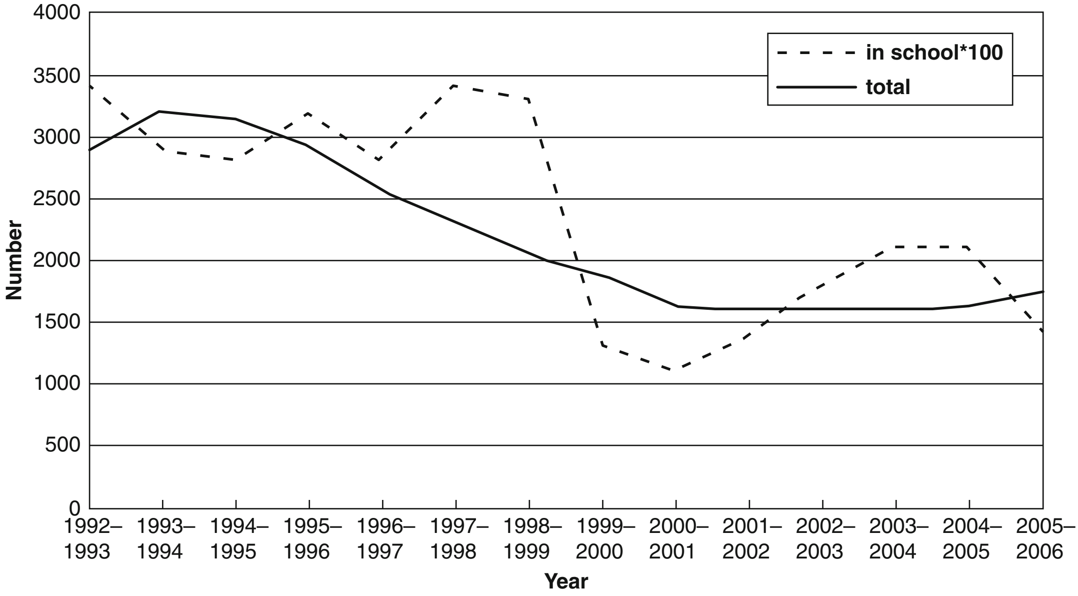
Data Sources

The primary source of the US crime data for many purposes is the FBI's Uniform Crime Reports, compiled from crimes known to the police and reported by police departments. The UCR's crime data do not provide information on the characteristics of victims and are of little help in estimating crime rates in schools. Some jurisdictions report crimes in much more detail through the National Incident-Based Reporting System (NIBRS): in this system police agencies submit a record of each known crime that includes the age, sex, and race of the victim, the location of the crime, and the characteristics of the perpetrator (when known). These data can be used to provide a detailed description of crimes involving school-aged youths, distinguishing, for example, between crimes on school grounds and elsewhere (Jacob and Lefgren 2003). There are two problems, however, with this source. First, participation rates are very low: only 20 % of police agencies, representing 16 % of the US population, were participating in NIBRS as of 2003 (http://www.ojp.usdoj.gov/bjs/nibrsstatus.htm, accessed November 19, 2008). And second, crimes committed on school property may be less likely to become known to the police than crimes occurring elsewhere.

As a result of the limitations of police data, school crime statistics are usually generated from school reports or surveys. In the School Survey on Crime and Safety (SSoCS), a sample of about 3,000 public-school principals report to the US Department of Education the number of violent incidents and thefts and indicate how many of these incidents were reported to the police. In addition there are several recurrent sample surveys: the National Crime Victimization Survey and the biannual School Crime Supplement to this Survey (sponsored by the National Center for Education Statistics, or NCES) and the Youth Risk Behavior Surveillance System (YRBSS), sponsored by the Centers for Disease Control and Prevention (CDC). The NCES compiles data from all these sources into a report called the *Indicators of School Crime and Safety* (e.g., Dinkes et al. 2007). When the estimates from these alternative sources are compared, there emerge some rather dramatic differences, leaving the investigator with the challenge of deciding where the truth lies.

Youthful Victimization in School and Out

Here we report crime victimization rates for school-aged youths, comparing, when possible, the rates at school and at other locations. We begin with murder, which is the only crime for which the statistics are reasonably accurate. Figure 1 depicts the trend in murders on school property for youths ages 5–18, compared with the overall murder count for that age group. There were about 30 school murders of youths each year from 1992–1993 to 1998–1999, a period notorious for the series of school rampage shootings that culminated with Columbine High School on April 20, 1999. During that event 12 students and a teacher were murdered and 23 students injured, before the shooters committed suicide. In the year following Columbine, the national in-school murder count dropped sharply and has remained relatively low since then. The overall murder rate for the same age group follows a similar pattern, though the decline began earlier and is less abrupt. The most important lesson from these data is that only about 1 in 100 murders of this age group occurs in school. That was true during the peak years of the early 1990s and also true a decade later. By this measure, then, school



School Crime Statistics, Fig. 1 Number of homicides involving young victims, in school and out, 1992–1993 to 2005–2006. Note: "In school" includes on school property, on the way to or from regular sessions at school, and while attending or traveling to or from a school-sponsored event (Source: Data on number of homicides in school are from School-Associated Violent Deaths Surveillance Study (SAVD), tabulated in Indicators of School Crime and Safety (Dinkes et al. 2007, p. 68); and data on number of homicides total are from National Center for Injury Prevention and Control and Web-based Injury Statistics Query and Reporting System Fatal (WISQARS^{TM} Fatal), retrieved Nov 2008 from http://cdc.gov/ncipc/wisqars)

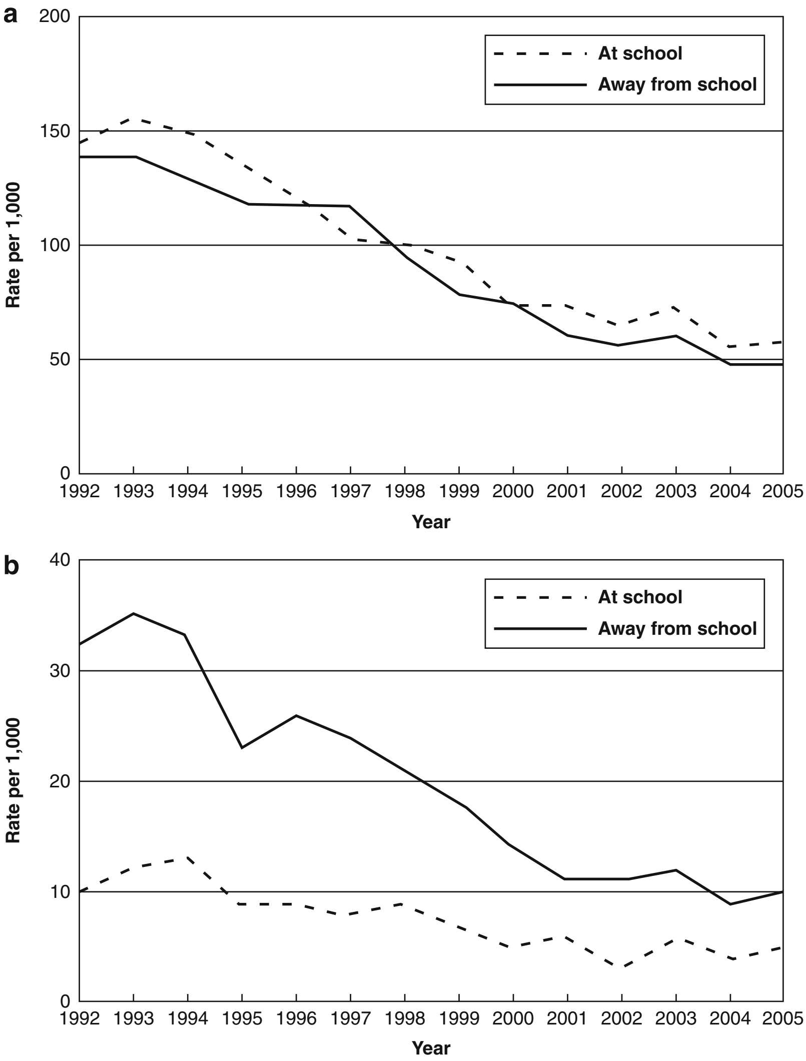
appears much safer than other locations for school-aged youths.

However, schools have a much larger share of the nonfatal crimes with school-aged victims. Figure 2 depicts the trend for victimization rates of youths aged 12–18, including both theft and violence. Youths who have completed 12 years of school are excluded from this tabulation. The rates per 1,000 follow the trend for youth homicide (as well as the national trend for criminal victimization for all age groups) – a sustained and rather dramatic reduction, so that the 2005 figures are about one-third of the peak in 1993. For our immediate purpose here, the important thing to notice is that the victimization rate in school is about the same as out of school. That parity is the net result of theft, which has higher rates at school, and violence, which for most of the period has lower rates at school (although in-school and out-of-school rates of violence converged in 2004). Note that since youths spend over 80 % of their waking hours during a calendar year out of school (Gottfredson 2001, p. 21), the parity in victimization rates implies that youths are far more likely to be victimized during an hour in school than an hour elsewhere.

For the serious violent crimes of rape, robbery, and aggravated assault, NCVS victimization rates are twice as high away from school as at school during recent years, as shown in Panel B. Since the corresponding ratio for murder is 100 to 1, we conclude that serious violent crimes committed out of school are far more likely to become murders than is true for similar crimes in school.

These NCVS results may well be misleading and should be validated. Youth survey data on crime are notoriously unreliable. In particular, crime survey results are exquisitely sensitive to the details of how the data are collected. One survey that provides an alternative to NCVS for estimating victimization rates is the Youth Risk Behavior Surveillance System (YRBSS), sponsored by the CDC. This survey yields estimates of victimization rates for serious violent crime

School Crime Statistics, Fig. 2 *Panel A*: Victimization rates at school and out for youths ages 12–18, 1992–2005: theft and violence. *Panel B*: Victimization rates at school and out for youths ages 12–18, 1992–2005, serious crimes of violence. Note: Theft includes purse snatching, pickpocketing, and all attempted and completed thefts except motor vehicle thefts. Theft does not include robbery in which threat or use of force is involved. Violence includes serious crimes of violence and simple assault. Serious crimes of violence include rape, sexual assault, robbery, and aggravated assault. "At school" includes inside the school building, on school property, or on the way to or from school (Source: National Crime Victimization Survey (NCVS), tabulated in Indicators of School Crime and Safety (Dinkes et al. 2007, p. 70))



that are an order-of-magnitude higher than the NCVS rates. For example, in the 2005 YRBSS, 8 % of students in grades 9–12 reported being threatened or injured with a weapon on school property during the previous 12 months. That compares with the serious-violence victimization rate at school for 15–18-year-olds in the NCVS of 0.4 %. Thus, the YRBSS rate is 20 times as high, even though logic suggests that it should be *less*, given that the YRBSS refers to prevalence of victimization and the NCVS figure is overall incidence (so that multiple victimizations reported by the same respondent are included in computing the rate). Further, the NCVS category of "serious violence" encompasses more types of crime than the YRBSS category of "threatened or injured with a weapon."

What could account for this vast difference in results? First, the NCVS sample is interviewed every 6 months, and the previous interview serves as a bracket to help the respondent place events in time. Thus, the NCVS sample members are asked to report on events that occurred since the previous interview. The YRBSS, on the other hand, is a one-shot survey with no natural bracket on the time interval; respondents are asked to report on the previous 12 months, which creates the likelihood that some will report on serious events that occurred outside the designated period (a phenomenon known as "telescoping"). A second important difference is that all YRBSS respondents are asked the specific question about whether they were threatened or injured with a weapon on school property, whereas the only NCVS respondents who are asked about such an incident are those who first respond affirmatively to a more general screener question. Third, the NCVS questionnaire is administered to the respondent (in person or over the telephone) at home, whereas the YRBSS questionnaire is self-administered by the respondent while in school. These and other differences, none of which are relevant in a literal sense, appear to be hugely important to the respondents' answers in practice. Cook (1987) notes that the Safe Schools study (which had much in common with the YRBSS with respect to administration) estimated one million robberies in schools, compared with the estimate of 30,000 in the NCVS for the same period.

Given the disparate results from youth surveys, it is of interest to consider administrative data. The SSoCS gathers reports from public-school principals about crimes occurring during school hours. For the 2005–2006 school year, principals for middle and high schools reported a total of 928,000 violent crimes and 206,000 thefts (see Table 1). These counts are not precisely comparable to the NCVS results for 12–18-year-olds. Unlike the NCVS, the SSoCS is limited to public schools. The NCVS age range of 12–18 is roughly but not exactly comparable to the SSoCS category of "middle and high school." Nevertheless, the estimates should be close. In fact, the violence reports are higher (by half) in the SSoCS than in the NCVS for 12–18-year-olds, while the SSoCS theft reports are much lower. It is not surprising that school officials do not know about many of the thefts that occur on school property, but the fact that they are aware of more violence that shows up in the NCVS defies ready explanation.

Thus, the truth about crime in school – or even a rough approximation of the truth – is elusive. Our inclination is to believe that the SSoCS reports provide a reliable lower bound for the "true" volume of crime, understating the true total to the extent that officials are never made aware of some crimes, and may generally be inclined to underreport in order to make their schools look as safe as possible. If true, then the NCVS appears to provide a notable underestimate of the volume of violence in schools – but the difference is nothing like that suggested by the very high YRBSS results. We are inclined to believe that the NCVS data are superior to the YRBSS because the method of administration discourages exaggeration by respondents, and the bracketing provides some discipline on memory. We also note that the downward trend in NCVS rates (shown in Fig. 2) reproduces well-documented trends during that period for the entire US population and hence is credible. The YRBSS victimization rates, on the other hand, exhibit no such trend during this period, showing if anything an upward tilt since 1993. For those reasons we report additional NCVS results in what follows, even though we are willing to believe that these are also far off the mark.

School Crime Statistics, Table 1 Comparison of SSoCS and NCVS crime counts

	SSoCS crime count: public middle and high schools 2005–2006 school year	NCVS crime count in school ages 12–18 2005
Violent crimes	928,000	628,000
Theft	206,000	868,000

Sources: http://nces.ed.gov/pubs2007/2007361.pdf; http://nces.ed.gov/programs/crimeindicators/crimeindicators2007/tables/table_02_1.asp?referrer=report

Table 2 summarizes demographic patterns in victimization rates at school for youths aged 12–18. Note that these data exclude the responses of students who have already completed 12 years of schooling. They do not exclude school dropouts. The rates shown here are averaged over the three most recent years of the School Supplement of the NCVS. Note that "theft" and "violence" sum to the total – "serious violence" is included in "violence."

Theft rates are remarkably uniform across all demographic categories, averaging 41/1,000.

School Crime Statistics, Table 2 At-school victimization rates/1,000 for youths age 12–18

	Total	Theft	Violence	Serious violence
Male	73	41	32	7
Female	61	41	21	4
Ages 12–14	75	42	33	6
Ages 15–18	61	40	21	5
Urban	75	41	34	9
Suburban	67	43	24	5
Rural	58	37	22	2
White	72	45	27	4
Black	64	38	27	5
Hispanic	55	29	26	5
Other	53	33	20	2
Overall	67	41	27	6

Source: NCVS results averaged for 2001, 2003, and 2005

Violence rates are a bit lower overall and more textured, although the differences among groups are still not as large as one might expect. Males are half again as likely to be victims of violence as females, and youths 12–14 are half again as likely as older youths. Urban schools experience a higher per capita rate of violent incidents than suburban or rural schools. Most surprising is that whites, blacks, and Hispanics report virtually the same rates of violence and serious violence.

The same NCVS data provide estimates for victimization rates away from school. The patterns are not much different, with two exceptions. First, blacks report a higher rate of serious violent crimes (17/1,000) than whites and Hispanics (both at 10/1,000). Second, and perhaps most intriguing, is that the age pattern away from school is the reverse of the age pattern at school. The younger group, aged 12–14, has somewhat higher victimization rates at school than the older group, but the older group has much higher victimization rates than the younger group away from school. The results are depicted in Fig. 3. The explanation may in part be due to the fact that the older group includes a number of school dropouts who, since they are not attending school, are unlikely to be victimized on school property. Perhaps more important is that older youths have greater mobility and freedom outside of school and thus more opportunity to get into trouble.

In assessing the credibility of these results, we are inclined to believe the NCVS-based comparisons between in-school and out-of-school victimizations, since it is the same respondents and hence the same biases are likely to apply. The surprising homogeneity of theft and violence victimization between blacks, whites, and Hispanics can be checked against interschool patterns in the SSoCS. We do that below and find support for the theft results but an apparent contradiction with the results on violence.

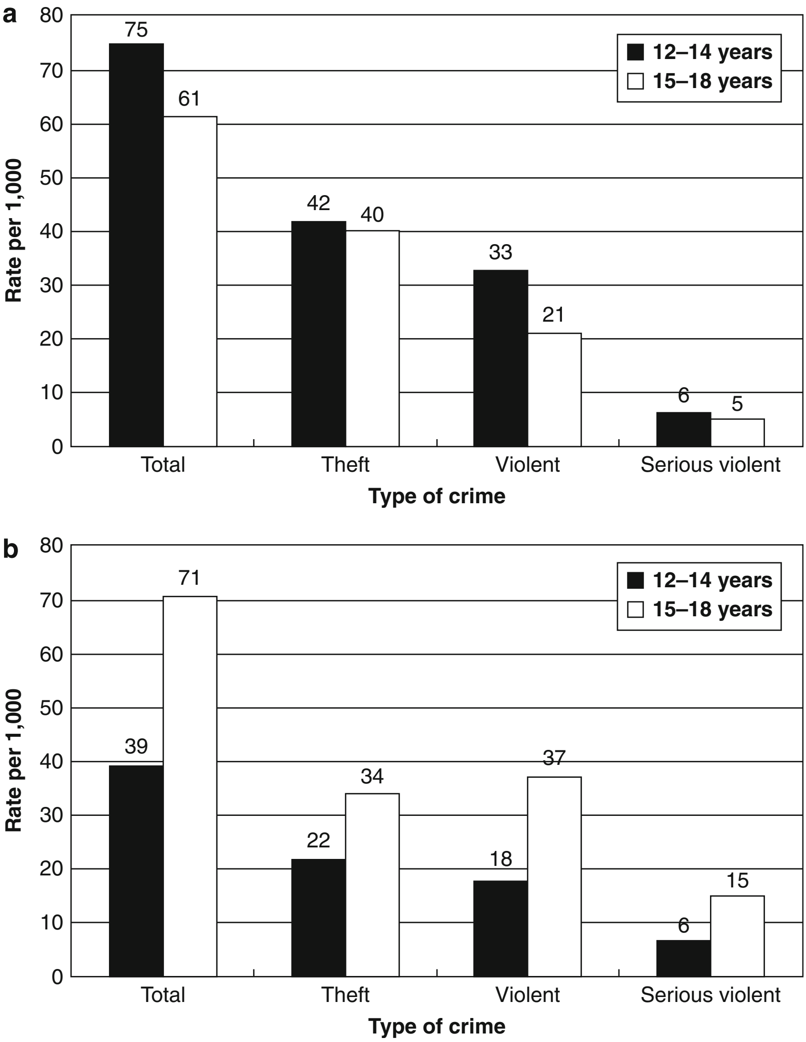
Finally, we note the high prevalence of bullying in school. While not necessarily a crime, bullying can greatly color the school experience for some children. The NCVS School Crime Supplement found that in 2005, 28 % of youths ages 12–18 reported being bullied in school – of those, 79 % said they were bullied inside school, 28 % outside on school grounds, and 8 % on the school bus (Dinkes et al. 2007, p. 95).

Differences Among Schools

Up until this point, we have described crime patterns primarily with respect to the characteristics of the victims. From another perspective, school crime is a characteristic of the school, and there is strong evidence that school characteristics and policies influence crime victimization rates (Cook et al. 2010).

The 2005–2006 SSoCS classifies schools by grade level, enrollment size, urbanicity, and percent minority enrollment. The rate of violent incidents reported by principals is much higher for middle schools than either elementary or high schools, somewhat higher for city schools than those in suburban or rural communities, and higher in predominantly minority schools than those with less than half minority. Notably, there is little relationship between the size of the school and the violence victimization rate. The results for theft tend to be less patterned. Table 3 summarizes the results.

In one respect these patterns are at odds with NCVS victimization patterns. It appears that the relatively high rate of violence in minority schools is at odds with the NCVS finding that there is little difference in victimization rates by race. One possibility is that black respondents are



School Crime Statistics, Fig. 3 *Panel A*: Victimization rates at school for youths ages 12–14 and 15–18. *Panel B*: Victimization rates away from school for youths 12–14 and 15–18. Note: Total crimes include theft and violent crimes. Theft includes purse snatching, pickpocketing, and all attempted and completed thefts except motor vehicle thefts. Theft does not include robbery in which threat or use of force is involved. Violent crimes include serious violent crimes and simple assault. Serious violent crimes include rape, sexual assault, robbery, and aggravated assault. "At school" includes inside the school building, on school property, or on the way to or from school. NCVS results are averaged for 2001, 2003, and 2005 (Source: National Crime Victimization Survey (NCVS), tabulated in Indicators of School Crime and Safety (DeVoe et al. 2003, pp. 55–66; DeVoe et al. 2005, pp. 72–73; Dinkes et al. 2007, pp. 70–71))

less likely to report violent victimizations than white respondents in the NCVS or alternatively (as reported in Kinsler 2009) that school administrators in predominantly black schools are relatively likely to record violent crimes. The same source, SSoCS, reports information on gang-related crime. In 2005–2006, 11 % of middle schools and 16 % of high schools reported at least one crime that was gang related. Gang-related crimes were concentrated in large, urban, and predominantly minority schools (Nolle et al. 2007, Table 4). Some confirmation for these patterns comes from the NCVS School Supplement data. Students were asked about gangs in their schools. Affirmative responses were much more likely by black and Hispanic students and by students in urban areas.

Another way to illustrate the variability across schools in crime levels is by comparing the distribution of the number of crimes reported per school with a distribution that would be generated under a random process. This type of exercise is common in criminological research. In a study of more than 23,000 boys born in two birth cohorts in Philadelphia, Tracy et al. (1990), for example, discovered that a small fraction of the boys (5–6 %) committed a majority of the delinquent acts. Similarly, researchers who study neighborhood crime have observed that it, too, is clustered at certain addresses. Weisburd et al. (2004),

School Crime Statistics, Table 3 Crime rates by school characteristic

	Violence rate/1,000 students	Theft rate/1,000 students
Level		
Primary	25.2	1.6
Middle	51.6	7.8
High school	25.7	8.7
Enrollment		
<300	34.5	4.3
300–499	34.0	3.3
500–999	30.9	4.5
1,000 or more	28.6	7.2
% minority enrollment		
<5 %	26.9	4.8
5–20	22.9	5.2
20–50	28.4	5.5
50 or more	39.9	4.8

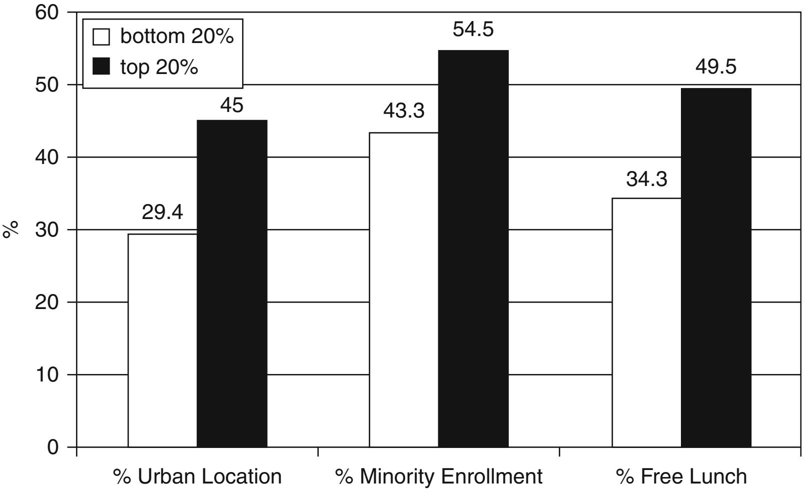
[a] Assumes 29 % of schools dangerous in 1 year are "persistently dangerous" (see text)

studying street segments in Seattle over a 14-year period, found that 4–5 % of the street segments account for about 50 % of incidents in each of the years examined. The distribution of crime at the school level is also concentrated, although not to the same degree.

We examined the distribution of school crime in the 2007–2008 SSoCS data using schools with enrollments of at least 1,000 students (N = 8,843), because we assumed rank orders based on crime rates would be unstable for small schools. These analyses used sample weights provided by NCES and also weighted by student enrollment. In these data, the 22.5 % of large schools with the highest *per capita* crime rates account for 50 % of all crimes reported by principals. The top 20 % of schools experience much higher crime rates than does the bottom 20 %: the victimization rates per 1,000 students for students in the most and least safe 20 % of schools are 9.8 and 111.3 for all crimes. The difference is even more striking for rates of violent crime – more than 13 times higher in the top 20 % of schools (4.9 vs. 65.7 per 1,000). These results suggest that although the average school is indeed a relatively safe place, a minority are notoriously unsafe. Figure 4 contrasts the safest 20 % of schools with the most dangerous 20 %. The more dangerous schools are much more likely to be urban schools, schools serving a high percentage of minority students, and schools serving more disadvantaged student populations.

The NCLB Act requires states to establish a mechanism for identifying such unsafe schools. Once a school has been labeled through this process as "persistently dangerous," parents must be given the option of transferring their child to a safer school. Every state has responded to this requirement by defining "persistently dangerous" and establishing a procedure for identifying such schools. The definitions differ considerably from state to state according to the specific offenses considered to be indicators of dangerousness; whether or not an official response (e.g., expulsion, arrest, conviction) to the incident is required before it is considered a dangerous offense and whether or not a dangerous offense occurring in or around the school has to have been committed by a student; the cut-point for the number or rate of offenses above which a school is to be considered dangerous; and the number of years in the dangerous status required to be considered "persistently" dangerous. Also, some states use a multistage process for identifying unsafe schools. For example, Florida's policy calls for a first stage in which a school is considered potentially dangerous if, for 3 consecutive years, it (a) has a federal Gun-Free School Act violation and (b) expels 1 % or more of a student body that is greater than 500 students, or 5



School Crime Statistics, Fig. 4 Comparison of the characteristics of the schools with the lowest and the highest 20 % of crime rate. Based on schools with enrollment of at least 1,000 students. Weighted by student enrollment and sample weight (Source: Original tabulation from data files. School Survey on Crime and Safety (SSoCS) (2007–2008))

students if the student body is 500 students or less, for homicide, battery, sexual battery, or weapons possession-related offenses. Any school so identified must, in a second stage, conduct an anonymous school-wide survey of students, parents, and school personnel. Only schools in which 51 % or more of survey respondents judge the school to be unsafe are labeled persistently dangerous (Education Commission of the States 2004).

Beginning with the 2003–2004 school year, the number of persistently dangerous schools reported by all states combined to the US Department of Education has ranged from 36 to 49, averaging 44. That low count raises the question of just how effective is the NCLB legislation for encouraging states to identify unsafe schools. We used the SSoCS survey data to identify schools that might reasonably be considered persistently dangerous. As noted above, there is no standard definition to guide this effort. Almost all states, however, include incidents involving serious violent behavior and weapons-related offenses, and many states also include incidents involving illegal drug use, possession, and distribution. Almost all states require that the rate of incidents per 100 enrolled students be between 1 and 3 before a school will be considered dangerous. Most states require that schools remain in this status for 3 years, but some require only two. We therefore classified schools in the SSoCS sample as dangerous during the 2007–2008 school year if, according to their principals' reports, the number of serious violent offenses (e.g., rape, sexual battery other than rape, physical attack or fight with a weapon, threat of physical attack with a weapon, and robbery with or without a weapon) plus the number of weapons-related incidents (those involving firearms, explosive devises, knifes, or sharp objects) exceeded 2 per 100 enrolled students. We repeated this analysis adding the number of incidents involving illegal drugs (distribution, use, or possession) to the classification of dangerous. Doing so increases the number of schools identified as dangerous. Our conclusion about the under-identification of unsafe schools using the NCLB procedure would therefore be stronger if these drug offenses were included.

Although the SSoCS survey is cross-sectional by design, it is administered to a random sample of US school every 2 years. The sample design is stratified and over-samples middle and high schools. Some schools happen to be included in multiple years just by chance. By merging the 2007–2008 survey data with data from the two prior SSoCS surveys (2003–2004 and 2005–2006), we created a longitudinal sample containing 475 schools. This longitudinal sample overrepresents secondary schools, large schools, and schools in areas that are not located in rural areas but is nevertheless helpful for examining the extent to which dangerousness persists across time.

Table 4 shows that applying our definition of dangerousness to the entire sample of schools in each of the 3 years resulted in identifying between 1.9 % and 2.0 % of the nation's schools in each survey year. The associated point estimates for the numbers of dangerous schools identified were 1,547 (2003–2004), 1,542 (2005–2006), and 1,624 (2007–2008). Using the longitudinal sample, we determined that 29 % of schools identified as dangerous in 1 year were also identified as such 2 years earlier. This exercise suggests that between 447 and 471 schools might be considered persistently dangerous in any given year. That estimate is about ten times as high as the average number of persistently dangerous schools identified to the US Department of Education each year, just 44.

Concluding Thoughts

There are a variety of sources of statistics on crime in schools, which are not entirely consistent with respect to levels, patterns, and trends. Anyone wishing to make sense of the available statistics should first become informed on the details of how the data are generated and consider the likely biases and as much as possible compare different sources.

We believe that the homicide statistics are accurate but that other police data on school crime are not to be trusted. For nonfatal crimes, we place some credence in the NCVS for students, which is a recurrent survey implemented by the US Census Bureau. What one learns from this source is that crime victimization in schools for students followed the downward trend in national crime rates during the 1990s and remains at a relatively low level since 2000. That there would be a common trend that makes sense and is one illustration of a more general result that crime in schools is closely linked to crime in the community.

Another credible result is that there is a great deal of crime in schools perpetrated by and against students. However, the estimated rates and patterns differ widely among the various sources in common use. According to the NCVS, in-school victimization rates are similar to rates experienced outside of school. But we found order-of-magnitude differences in school crime rates from NCVS and YRBSS, CDC's recurrent youth survey in which youths self-report their own victimizations. The SSoCS, based on reports from school principals, also produces counts of violent crimes that are 50 % higher than the NCVS counts. We would nominate SSoCS as the most reliable source for violent crime, but there is no basis for comparison with out-of-school crimes. We can be confident that homicide is very rare in school (relatively and absolutely). All sources confirm that a much higher percentage of minor assaults occur in schools than serious assaults. It also seems reasonable to conclude that school crime is far from randomly distributed across schools. A relatively small number of schools experience inordinately high rates of theft and violence. Rates of crime in the least safe 20 % of schools are more than ten times higher than the rates of crime in the safest 20 %. Students in these schools are likely to avoid school for fear of their own safety, teacher turnover is likely to be high, and the quality of time dedicated to learning is likely to be diminished. Unfortunately, no reliable mechanism has been established to identify which of these schools should be identified as "persistently dangerous." The consequences for being labeled "persistently dangerous" under NCLB are sufficiently punitive to create a strong incentive for principals to underreport and for state boards of education to establish policies that minimize application of that label.

What should be done to advance knowledge about school crime and to provide a reliable mechanism for identifying schools requiring assistance? The place to begin the research agenda on crime in schools is with a close look at the quality of the data in current use. Despite the many problems we identified earlier, it is too often true that users do not investigate the quality of the data or check one source against another. It would be a useful service to all users if there were a comprehensive investigation of the differences in crime rates and patterns across these data sets, together with an investigation of the sources of disagreement. One thing that is clear is that survey results with adolescent subjects are exquisitely sensitive to where and how the questions are administered.

Beyond acquiring a better understanding of the sources of discrepancy across different methods for obtaining school crime data, a serious effort is needed to develop shared understandings of what constitutes a dangerous school. Rather than asking each state to develop its own idiosyncratic definition and identification procedure, we suggest that a higher level dialogue is needed to understand the cut-point above which the school environment is trulydangerous to students and staff or seriously hinders learning. A discussion about how school safety might be monitored more systematically is needed. We suggest that rather than counting the number of certain incidents or responses to certain offenses, which are likely to be extremely rare and confounded with characteristics of school's surveillance and reporting practices, a more direct measure of school safety might come from student and staff surveys of perceptions of safety and the extent to which they avoid the school or certain areas in the school for fear of their own safety. Such survey measures have been a staple of school climate research since the 1970s and have proven to be highly reliable and stable measures of the school environment. At least one state (Florida) already uses such a strategy to identify persistently dangerous schools.

We also suggest that once a reliable mechanism is in place for identifying schools with problematic crime levels, efforts should be directed towards making the schools safer. Rigorous research (Gottfredson et al. 2002; Hahn et al. 2007; Wilson and Lipsey 2007) has identified a variety of school-based prevention and intervention practices that are likely to reduce the level of crime experienced in these schools.

Overview

The crime control model of school security has led to an environment of school prisonization and student criminalization. The increasing use of restrictive security practices contrasts with both the decline in school crime and violence as well as the research suggesting that these practices may not be effective. Additionally, this intensification runs the risk of invading students' privacy and creating a negative school environment. Much research suggests that it would be better for schools to focus on other evidence-based strategies to reduce school disorder and respond to student misbehavior. If schools continue to use restrictive security practices that mirror the criminal justice system, they may, ironically, ensure that certain students are found in that system in the future.

The Prisonization of School Security

It is abundantly clear that most modern schools, particularly urban public schools, utilize a crime control model when defining and managing student behavior. This has occurred largely in response to school shootings and other visible instances of student violence (Addington 2009). More and more schools have implemented prison-like practices in an effort to improve their security (Giroux 2003), resulting in the use of many restrictive security practices and procedures intended to deter school crime and ensure the safety of students and staff. Indeed, recent statistics indicate that at least 55 % of all schools, and nearly all urban schools, now have security and surveillance programs (Devoe et al. 2005; Gottfredson and Gottfredson 2001).

Examples of restrictive security practices seen in many schools range from requiring formal dress codes (Gottfredson and Gottfredson 2001) to installing metal detectors (Brooks et al. 2000). To further detect the presence of weapons and other contraband, schools may perform regular locker searches, require students to carry clear book bags, and use drug-sniffing dogs (Brooks et al. 2000; DeVoe et al. 2005; Gottfredson and Gottfredson 2001). Visitors to campuses are generally required to sign in before entering school buildings and student identification badges are often mandated to facilitate immediate identification of rule-breakers and to deter defiance and delinquency (Brooks et al. 2000).Hallways are often supervised by school staff and administrators (Devoe et al. 2005) or even by uniformed security guards or uniformed and armed security resource officers (SROs; Giroux 2003). Additionally, many schools have chosen to install security cameras that provide constant surveillance to most areas within a school (Devoe et al. 2005). Most institutions have locked or monitored doors and gates to prevent unauthorized individuals from entering school grounds and to prohibit students from leaving campus (Devoe et al. 2005; Gottfredson and Gottfredson 2001). Schools are even investigating the use of cutting-edge technology to enhance security, such as iris recognition software, webcams, and radio frequency identification tags on ID badges (Addington 2009). Ironically, even with the increased implementation of these prison-like practices, parents and school boards have continued to call for stricter measures of control (Brooks et al. 2000) to manage the fear and anxiety surrounding school.

The intensification of school security has also led to an increase in the criminalization of students, such that schools often manage and punish student behavior in a way that is analogous to the treatment of adult criminals (Giroux 2003; Kupchik and Monahan 2006; Tredway et al. 2007). For example, the actions of students who violate school rules are often described with criminal justice language (Tredway et al. 2007): “suspects” or “repeat offenders” are subjected to “investigations,” “interrogations,” and “searches” by dogs or SROs and may then be involved in “lineups” and school “courts.” The students are then punished in ways similar to the sentences received by adult criminals; zero tolerance policies, for instance, function as the school equivalent of mandatory minimum criminal sentencing statutes. These policies have increased the use of harsh discipline, such as student exclusion through expulsion and suspension, even though these disciplinary responses have various negative impacts on both students and schools (Welch and Payne 2011). Excluded students are more likely to experience school failure, drop out of school, and engage in delinquency and drug use both in and out of school. Unfortunately, just as the use of more restrictive school security measures has increased, so has the use of these and other harsh disciplinary techniques.

Although it could be assumed that the intensification of school security is a result of increased school crime and violence, evidence suggests this is not the case (Welch and Payne 2011). In fact, these changes have occurred despite a documented decline in student delinquency and drug use, violent victimization in schools, and school-related deaths (Brooks et al. 2000; Devoe et al. 2005). Other possible explanations for this intensification include popular anxiety about high-profile instances of school violence, termed the "Columbine effect" (Addington 2009); increased school accountability for the academic performance of students (Hirschifield 2008); concerns about possible litigation in response to violent incidents on campus (Hirschifield 2008); and responses to the growing proportion of minority students (Welch and Payne 2011). While many of these explanations fall short in certain ways (Hirschfield 2008), it is likely that a combination of these factors have allowed this intensification to continue, leading schools to become less oriented around education and more like prisons focused on punishment (Giroux 2003).

Trends in School Security

The use of restrictive security practices in schools has been increasing over the past decade. Using data from the School Survey on Crime and Safety, Payne and Eckert (2011) discussed the percentage of public school principals who reported using various security measures during the years 1996, 1999, 2003, 2005, and 2007 (Table 1). The School Survey on Crime and Safety is a national questionnaire administered to public school principals by the National Center for Education Statistics. Approximately 3,500 principals from schools at all levels are asked questions on topics such as school disorder and crime, safety and discipline, and prevention programs and policies. Between the years 1996 and 2007, the imposition of school uniforms increased from 3 % to 17.5 %, drug testing of certain students increased from 4.1 % to 6.4 %, and the use of identification badges for students increased from 3.9 % to 7.6 %. Other measures show even more dramatic increases, such as the use of identification badges for faculty (25.4–58.3 %), video surveillance (19.4–55 %), and controlled access to school grounds (19.4–55 %). Finally, Table 1 shows that more and more schools controlled access to their buildings over this time, from 53 % in 1996 to 89.5 % in 2007.

School Security Practices and Crime, Table 1 Percentage of schools reporting use of security measures, School Survey on Crime and Safety

Security measure	1996	1999	2003	2005	2007
School uniforms	3.0	11.8	13.8	13.8	17.5
Drug testing of students	–	4.1	5.3	5.0	6.4
Badges or IDs for students	–	3.9	6.4	6.1	7.6
Badges or IDs for faculty	–	25.4	48.0	47.8	58.3
Video surveillance	–	19.4	36.0	42.8	55.0
Controlled access to school grounds	24.0	33.7	36.2	41.1	42.6
Controlled access to buildings	53.0	74.6	83.0	84.9	89.5
Drug sweeps	19.0	21.0	21.3	23.0	21.5
Random sweeps for contraband	–	11.8	12.8	13.1	11.4
Random metal detector checks	4.0	7.2	5.6	4.9	5.3
Pass through metal detectors daily	1.0	0.9	1.1	1.1	–
Closed during lunch	80.0	90.0	66.0	66.1	65.0
Clear book bags or banning of bags	–	5.9	6.2	6.4	6.0
Visitor sign in	96.0	96.6	98.3	97.6	98.7

Source: Payne and Eckert 2011

Similar trends are seen when Payne and Eckert (2011) analyzed student reports of security measures from the National Crime Victimization Survey: School Crime Supplement during the school years of 1999, 2001, 2003, 2005, and 2007 (Table 2). Designed by the National Center for Education Statistics and the Bureau of Justice Statistics, the School Crime Supplement is an occasional addendum to the annual NVCS that gathers specific information from individual students regarding school-related disorder and victimization on a national level. Data measuring students' perceptions of safety and crime at school are collected from approximately 6,500 12-through 18-year-old students attending public and private schools.

School Security Practices and Crime, Table 2 Percentage of students reporting use of security measures, School Crime Supplement

Security measure	1999	2001	2003	2005	2007
Security cameras	–	38.5	47.9	57.6	66.0
Security guards	54.1	63.6	69.6	67.9	68.8
Locked doors during day	38.1	48.8	52.8	54.2	60.9
Metal detectors	9.0	8.7	10.1	10.7	10.1
Badges and picture ID	–	21.2	22.5	24.7	24.3
Locker checks	53.3	53.5	53.0	52.9	53.6

Visitor sign in	87.1	90.2	91.7	92.7	94.3

Source: Payne and Eckert 2011

Of particular note is the increase of various measures between 1999 and 2001: A clear upward shift was reported in locked entrances and exit doors (38.1 % in 1999 to 48.8 % in 2001) and school security guards or law enforcement personnel (54.1 % in 1999 to 63.6 % in 2001). This trend continued through 2007, with the biggest increases in security in the areas of locked doors (38.1 % in 1999 to 60.9 % in 2007), security guards or law enforcement personnel (54.1 % in 1999 to 68.8 % in 2007), and surveillance cameras (38.5 % in 2001 to 66 % in 2007).

When schools are grouped by characteristics such as level, location, and size, differences in the type and amount of school security measures are seen (Payne and Eckert 2011). For instance, elementary schools are generally the least likely to implement restrictive security practices, followed by middle schools then high schools. One exception, however, is controlled access to buildings and school grounds, which is more often seen in elementary schools. In addition, larger schools are more likely than smaller schools to use most enhanced security measures, as are urban schools when compared with schools in towns or rural areas. Finally, schools with a greater percentage of minority students and students who receive free or reduced-price lunches are more likely to implement these practices (Payne and Eckert 2011).

The Effectiveness of Security Measures

Very little research exists that evaluates the effectiveness of school security measures. The pervasiveness of these measures combined with the lack of knowledge regarding their impact is of concern; if these practices are ineffective, they could allow schools to feel secure when they are not and may even create a dangerous environment by diverting money and resources from measures that do actually work (Addington 2009).

Several studies that have been conducted examine the effectiveness of security measures based on perceptions of specific practices rather than actual impact. Overall, school community members perceive particular measures as positive and believe that they prevent crime and disorder. For instance, both students and staff view SROs as effective; similar beliefs are held by school administrators regarding security cameras. Unfortunately, there is little evidence to support these perceptions (for a full review, see Addington 2009).

The small amount of evaluation research that has examined more objective outcomes related to the use of security measures is inconclusive. An early study of school security examined the impact of metal detectors in three program and 12 comparison high schools in New York City (Ginsberg and Loffredo 1993). Surveys were completed by 13,999 students in June 1992. Students in schools with metal detectors were less likely to carry weapons inside the school building or to and from school. However, there were no student differences in weapon carrying in other locations nor in threats or physical fights anywhere (Ginsberg and Loffredo 1993).

Mayer and Leone (1999) examined the relationships among school security, discipline management, student self-protection, and school disorder. Data were taken from 6,947 public school students in grades 7–12 who were interviewed as part of the 1995 School Crime Supplement. The structural equation model that was estimated contained four constructs: secure building, which included security measures such as guards, visitor sign in, metal detectors, and locked doors; system of law, which reflected students' perceptions of rules and rule enforcement; school disorder, which included gang presence, drug availability, and personal attack and theft; and individual self-protection, which contained student avoidance of school location and fear of attack. Results suggested that schools which used physical security measures, such as metal detectors and locked doors, experienced more crime and disorder, as did schools that used personnel-based measures, such as security guards and hall monitors. In contrast, schools that focused on communication of schools rules and consequences for rule infractions experienced less disorder.

Finally, Chen (2008) analyzed a model of school crime that included two forms of physical school security: the number of ways a school controls access to campus and the number of ways in which a school monitors student activities. Both measures were hypothesized to be negatively related to the number of crimes that had occurred in the school in the past 12 months. Other factors in the model included urbanicity, community crime, student socioeconomic status, school size, student mobility, student misbehavior, and serious disciplinary penalties such as transfers and suspensions. Data were taken from 712 secondary schools whose principals had participated in the 2000 School Survey on Crime and Safety. Bivariate correlations showed that the number of ways a school controls access to their buildings was positively correlated with the number of crimes, while the number of ways a school monitors student activities was not significantly related to crimes. When the full model was estimated using structural equation modeling, the path between school security (a latent variable containing both building access control and student activity monitoring) and number of criminal incidents was negative but nonsignificant, contrary to the study's hypothesis. These findings suggest that, while school security measures may not increase crime as reported by Mayer and Leone (1999), they do not appear to reduce crime either (Chen 2008).

Ultimately, there is little evidence supporting the effectiveness of security measures. In addition, the few studies that do exist suffer from severe limitations. First, several of the studies measure effectiveness through perceptions of school community members, rather than actual impact on school disorder (see Addington 2009). In addition, all of these studies rely on cross-sectional data with no baseline measures of school disorder, thus making it impossible to truly establish the temporal order of the implementation of security measures and the level of school disorder (Ginsberg and Loffredo 1993; Mayer and Leone 1999; Chen 2008).

Student Civil Liberties

An unintended consequence of enhanced school security that has generated much discussion is infringement on student civil liberties (Addington 2009; Berger 2003), which can be separated into two related concerns: suspicionless searches and privacy encroachments. Searches of students' persons, lockers, and belongings have been the subject of many court cases regarding the fourth Amendment, including several Supreme Court rulings. One landmark case, New Jersey v. TLO (1985), established that searches conducted by school administrators require a far lower standard of suspicion than police searches of citizens on the street, because the intrusion on students' privacy is deemed minor and is overshadowed by public health and safety concerns (Berger 2003). The rationale for this standard is the "special needs" doctrine that emerged from this case, stating that a special need exists such that schools must maintain discipline in order to have an environment conducive to learning. Therefore, it is not necessary for administrators to have probable cause before searching students and their belongings (Berger 2003), including the use of metal detectors and locker searches. Essentially, although students have the right to privacy, this right is counterbalanced by the "special need for an immediate response to behavior that threatens either the safety of schoolchildren and teachers or the educational process itself" (New Jersey v. TLO 1985, p.353). Another landmark case, Vernonia School District 47J v. Acton (1995), applied this doctrine to drug testing of student athletes; later, this was expanded to allow schools to drug test all students participating in any extracurricular activity (Board of Education v. Earls 2002). Thus, although students do not waive their fourth Amendment rights in school, the special needs doctrine offers school officials a large amount of discretion and flexibility in order to maintain a safe environment (Berger 2003).

Although these Supreme Court rulings applied the special needs doctrine to searches by school administrators for contraband in order to reduce or prevent drug use, lower court rulings have expanded the application to include searches by law enforcement personnel and security measures designed to prevent violence (Addington 2009; Berger 2003). Originally, searches allowed through New Jersey v. TLO and similar cases were limited to those conducted by school personnel rather than police officers, based on the rationale that the mission of school officials is to educate rather than collect evidence for a criminal prosecution. However, public anxiety over school crime and violence has led to a new view of student searches by police officers as acceptable under the special needs doctrine because these searches are seen as minimal, nonintrusive, and within the realm of reasonable suspicion (Berger 2003). In addition, decisions by lower appellate courts have also expanded this power to security searches designed to prevent violence, such as metal detector screenings (Addington 2009).

There is also a sense of these security measures infringing on students' privacy, even beyond the legal exploration of suspicionless searches (Addington 2009). This can be seen particularly with tactics that monitor student behavior in public areas, such as security cameras and the presence of SROS, which are also the measures that tend to be implemented most often. Concerns appear when these measures are used in ways for which they are not originally intended (Addington 2009). For example, if security cameras are originally installed for violence prevention, is it legitimate to then use them to thwart vandalism? Additionally, the use of cutting-edge technology to enhance security, such as webcams and radio frequency identification tags on ID badges, has the potential for even greater privacy infringement (Addington 2009).

The Impact on School Community

This invasion on student privacy and civil liberties may lead to another consequence of the intensification of school security: the altering of the school environment. Much research (summarized in the "School Social Organization, Discipline Management, and Crime" entry in this encyclopedia) has illustrated the importance of school climate and social organization. Schools with healthy supportive environments generally have more effective teachers who enjoy their jobs more and have more positive perceptions of the school administration (Gottfredson et al. 2005). In addition, students who attend these types of schools are more attached to teachers, more committed to school, and have stronger belief in school norms (Payne et al. 2003). This positive school community and subsequent student bonding, in turn, leads to a beneficial learning environment and less school crime and disorder (Gottfredson et al. 2005; Payne et al. 2003).

But what happens to the school community and subsequent student behavior when restrictive security practices are implemented? Restrictive measures may first lead to an oppositional relationship between students and staff, as students could protest these practices with petition drives and class boycotts (Berger 2003). Even without this type of adversarial response, aggressive security measures may negatively impact the school environment by interfering with the educational process, disrupting the learning environment, and wasting valuable class time (Berger 2003). For example, Devine (1996) described how teachers in a New York City school could not teach due to "loud noises coming from the walkie-talkies in the corridors" supervised by security staff (p. 89), while Glazer (1992) detailed how administrators in another New York City school took close to 3 h to "funnel all 3,000 students into the gym, where they are frisked with hand-held metal detectors and their book bags are probed" (p. 790).

In addition, the implementation of many of these intrusive security practices often creates a climate of fear and resentment, resulting in negative attitudes toward school (Addington 2009; Hyman and Peronne 1998). For example, (Hyman and Peronne 1998) detail how searches result in detrimental consequences for both students and staff, such as lower student morale, distrust for staff, and alienation for law enforcement authorities; other studies have shown similar student alienation and mistrust as a consequence of restrictive security measures (Noguera 1995). Metal detectors, security patrols, and lock-down drills make schools feel like prisons (Noguera 1995) and often make students more afraid rather than less (Devine 1996). As Devine (1996) describes, aggressive security measures in urban schools result in "a climate of fear that indoctrinates youth into a culture of violence and dictates that only those exhibiting a 'tough' demeanor will survive" (p.179). As fear increases, so does student resentment and hostility (Hyman and Peronne 1998), leading to lower student bonding and a negative school environment (Addington 2009). Thus, it is possible that intrusive security might have the opposite effect than intended, leading students to increasingly break school rules. Ultimately, there is a strong chance that the intensification of school security leads to students feeling as though they do not belong in their schools, which, in turn, may decrease learning and increase the likelihood of these students engaging in deviant and delinquent behavior.

The Future of School Security

Beyond a doubt, far more "evidence-based research is…needed to evaluate the costs and effectiveness of school security measures" (Berger 2003, p. 351). The lack of studies clearly shows that evaluations must be conducted to examine the impact of these practices on the levels of misbehavior and violence in schools. Further, the little research that has been done is severely limited in several ways. First, several studies examine perceptions of school community members as an outcome, rather than actual effectiveness on school crime and violence (for a full review, see Addington 2009). In addition, the few studies that do examine the impact of these measures on school disorder rely on cross-sectional data with no baseline measures of crime and deviance (Ginsberg and Loffredo 1993; Mayer and Leone 1999; Chen 2008). This makes it impossible to truly establish the temporal order of the relationship between restrictive school security and school disorder; that is, it is possible that these practices were implemented in schools that were already displaying high levels of crime, rather than leading to more crime after implementation, as suggested by Mayer and Leone (1999). This lack of research is surprising given the large amount of evidence supporting the use of other policies and programs designed to prevent student misbehavior (see "School-Based Interventions for Aggressive and Disruptive Behavior: A Meta-Analysis" entry in this encyclopedia). Future studies should use longitudinal data and include baseline measures of crime to examine the impact of restrictive measures on school disorder.

In addition, the financial costs of these practices need to be studied. Little data exist on the cumulative cost to schools of metal detectors, SROs, security cameras, and other such measures (Addington 2009). Along with a gathering of costs, cost-benefit analyses should be conducted to evaluate whether the financial price is worth the effectiveness. Included in this consideration should be the examination of the possibility of "budgetary trade-offs" that may happen in order to pay for the enhanced security; it is possible that the cost of these measures leads to fewer resources for actual learning, such as books and staff (Addington 2009, p. 1440).

Even if they are found to be both effective and cost-effective, the use of these restrictive security measures should be balanced against the costs to student civil liberties and the school environment. Although more research is needed, studies do suggest that these measures infringe upon student civil rights (Berger 2003). As Addington (2009) discusses, it appears as though no one is protecting the students' rights, as no one with power is questioning the impact of enhanced security measures on student privacy and civil liberties. Students may want to change polices but they do not have the ability to do so, while most parents believe this security keeps their children safe and school officials are likely to give in to the demand for strong school security. With the possibility of technology, such as radio frequency identification tags, enhancing security even further, it is imperative that the impact of these measures on students' rights is considered. While student safety is clearly important, school officials should work toward developing and implementing strategies that keep student safe without infringing on their fourth Amendment rights (Berger 2003).

It is also possible that enhanced security measures create a negative learning environment, filled with fear and hostility. The few studies that have been conducted suggest that implementing restrictive measures such as metal detectors, locker checks, and security personnel may lead to an "unwelcome, almost jail-like, heavily scrutinized environment [that] may foster the violence and disorder school administrators hope to avoid" (Mayer and Leone 1999, p. 349; Chen 2008). The findings suggest, instead, that more attention should be paid to communicating school rules and norms and fairly and consistently enforcing these rules with appropriate consequences (Mayer and Leone 1999), a practice that is well supported by previous research (Berger 2003; Gottfredson et al. 2005).

This leads to a broader discussion on what schools can do to effectively reduce disorder and violence. Fortunately, a large body of research exists that establishes effective strategies. These practices are discussed in two related encyclopedia entries: "School Social Organization, Discipline Management, and Crime" and "School-Based Interventions for Aggressive and Disruptive Behavior: A Meta-Analysis."

Conclusion

As the crime control model continues to guide security, "schools grow more like prisons than institutions of education" (Giroux 2003: 553). Reliance on this model has intensified security practices to the point of creating a picture of school prisonization and student criminalization, despite a clear decline in school crime and violence. The little research that has been conducted suggests that, although school officials appear to be pleased with enhanced security, these practices may not be effective for reducing student misbehavior. In addition, this intensification runs the strong risk of invading students' privacy and creating a negative school environment, both of which may, in fact, increase school disorder. Until evidence supporting the use of these practices is provided, schools would benefit from focusing on other evidence-based strategies to reduce school disorder and respond to student misbehavior, rather than continuing to use restrictive security practices that mirror the criminal justice system. If changes are not made, the school-to-prison pipeline may, ironically, ensure that certain students are found in that system in the future.

Overview

School violence, drug use, vandalism, gang activity, bullying, and theft are costly and interfere with academic achievement. Student misbehavior interferes with teaching and learning and is one of the primary sources of teacher turnover in our nation's schools. Gallup polls from the past 20 years show that the percentage of parents who report being concerned about the physical safety of their children while at school has ranged from 15 % to 55 %, with the highest percentages registering just after the infamous school shootings at Columbine High School in 1999. Reducing crime rates has become an increasingly high priority for America's schools.

There has also been an important trend in the official response to school crime. The response has become increasingly formal over the last 20 years, with greater recourse to arrest and the juvenile courts rather than school-based discipline. To some extent, this trend has been furthered by federal law that has imposed zero-tolerance rules for some offenses and has subsidized the hiring of uniformed officers to police the schools. The shift has been from administrative discretion to mandatory penalties and from in-school discipline to increasing use of suspension or arrest. At the same time, there has been a considerable investment in the use of surveillance cameras and metal detectors.

While the increasing formality in school response to crime has coincided with the declining crime rates, there is no clear indication of whether the new approach gets any of the credit. Indeed, the evaluation literature that we review here has very little to say about the likely effects of these changes. As so often happens, there appears to be a disconnect between policy and research.

There are alternatives to the get-tough approach with its reliance on deterrence and exclusion. We know that some schools do a much better job than others in controlling the behavior of their students. Characteristic of successful schools in this respect is that they are close-knit communities where rules of acceptable behavior are clearly communicated and consistently (if not harshly) enforced. In addition to good management practices, there is much that can be done in the classroom that has demonstrated effectiveness in improving behavior.

In this entry, we summarize evidence showing that how the school is organized and managed (in general) influences problem behavior and school safety. We then discuss two specific aspects of school organizational climate – discipline management and school culture, respectively – and how they can be manipulated to reduce crime and related problem behaviors. We conclude with recommendations to guide future evaluation research on school-based interventions. Throughout the entry, our focus is on how schools can and do influence the behavior of students while they are enrolled.

Does School Organization Matter?

How the school is organized and managed influences problem behavior and school safety. In an early national study of school disorder, Gottfredson and Gottfredson (1985) showed that even after controlling for input characteristics of students and communities in which schools were located, characteristics of schools accounted for an additional 12 % (junior high) and 18 % (senior high) of variance in teacher victimization rates. More recent national studies have replicated these findings and extended them to show that school characteristics account for a substantial amount of variance not only in teacher victimization but also in student reports of victimization and delinquency (Gottfredson et al. 2005).

Which aspects of the way schools are organized and managed influence crime and disorder? Cook et al. (2010) discuss school system decisions that influence the demographic composition of schools and the number and types of other students to whom a child is exposed. Schools and school districts have a good deal of control over the makeup of the student body. Schools can be based on neighborhood residential patterns or integrated across race and class. The grade span for elementary and middle schools can be adjusted. Truancy and dropout prevention programs can be pursued with more or less vigor, and troublesome students reassigned. Whether failing students are retained in grade or given a social promotion influences the extent of age homogeneity within classrooms. Students who are enrolled in the school can be tracked on the basis of academic potential or mixed together. These decisions influence the characteristics of other students to whom youths will be exposed. Importantly, these decisions determine the pool of youths from which highly influential peers will be selected as well as the dominant peer culture in the school.

School and school district decisions about curricular content and teaching methods are also important. These decisions determine student success in school and decisions to persist in school. As summarized in the Wilson entry elsewhere in this section, the use of specialized prevention curricula directly influences the level of problem behavior. Below, we discuss two additional characteristics of schools that influence crime and disorder: (1) policies and procedures governing discipline management that directly affect the extent to which formal sanctions are applied and the effectiveness of these sanctions and (2) aspects of the school social organization that affect the nature of interactions among teachers and students (and hence the application of social controls) and the school culture.

Discipline Management

Cook et al. (2010) summarize findings from 12 studies that looked at the association of discipline management practices with school crime. The results show remarkable consistency: when schools monitor students and control access to the campus, and when students perceive that school rules are fair and consistently enforced, schools experience lower levels of problem behavior. Inclusion of students in establishing school rules and policies for dealing with problem behaviors has also been found to be related to lower levels of problem behavior, most likely because students are apt to internalize school rules if they have helped to shape them. On the other hand, severity of sanctions is not related to a reduction in problem behaviors. These findings conform to the main findings from deterrence research that the certainty of punishment has greater deterrent effect than the severity of punishment.

Of course, there has been considerable policy attention to school disciplinary practices, especially in response to the spate of school shootings experienced in the 1980s and 1990s. Most schools employ security and surveillance strategies aimed at keeping intruders out and preventing weapons from coming into the schools. Common practices include controlled entry and identification systems, metal detectors, security personnel or volunteers who challenge intruders, or doors fitted with electromagnetic locks. Since the late 1990s, school resource officers (SROs) have also been especially popular in secondary schools as a way to prevent violence, encouraged by federal subsidies. The Payne and Eckert and Na and Gottfredson entries elsewhere in this section discuss what is known about the effectiveness of these practices.

A closely related discipline strategy is the use of zero-tolerance policies in schools – another “tough on crime” practice engendered by the epidemic of youth violence in the late 1980s and the school rampage shootings of that decade and the next. The US Congress adopted the Gun-Free Schools Act in 1994, mandating that students be suspended for 1 year if they brought a gun to school. A large majority of school districts adopted zero-tolerance policies for alcohol, tobacco, drugs, and violence. The use of suspension, especially long-term suspension, is thought to have disproportionate impact on minority and special education populations, whose behavior places them more at risk for suspension. Civil liberty advocates have argued that zero-tolerance policies rob youths of their right to a public education.

As with other security-related school polices, little high-quality evidence is available to guide decisions about which discipline management policies produce the most desirable outcomes. The issue is complex, requiring consideration of the trade-offs between in-school and out-of-school crime, the welfare of the youths who perpetrate the school-based offenses versus that of the other youths in the school, and long-term versus short-term outcomes. Clearly, removing troublemakers from school helps to maintain an environment more suitable for learning for these remaining students. But the costs of doing so for the offenders and society are not well understood. A complete analysis of the effect of zero-tolerance policies on youth crime would consider the displacement of crime from school to the community as well as the consequences for the suspended youths’ long-term criminal and academic careers. As youths lose more days of school to suspension, promotion to the next grade becomes less likely. And as youths fall further behind grade, they become much less likely to graduate, which is likely to increase subsequent crime. Clearly, although zero-tolerance policies benefit the classmates of troublesome youths, a rational discipline policy would also have to consider the broader consequences of such policies for the community.

More consistent with the research on effective crime deterrents are school discipline polices that emphasize the certainty of response to misbehavior over the severity of the response. Among the most effective school-based strategies for reducing youth violence, aggression, and problem behavior are behavioral interventions that target specific behaviors, systematically remove rewards for undesirable behavior, and apply contingent rewards for desired behavior or punishment for undesired behavior. These interventions are often applied to the high-risk youths who are most at risk for being suspended from school under zero-tolerance policies and as such could be incorporated into school routines for discipline management. Gottfredson et al. (2002) meta-analysis reported average effect size on measures of antisocial behavior and aggression of 0.34 ($p <.05$) across 12 studies of this type of behavioral intervention.

Examples of particularly effective behavioral interventions currently in use in schools are the "Good Behavior Game" (GBG; Kellam et al. 2008) and "home-based reinforcement" (Schumaker et al. 1977). The GBG is a classroom-based application of behavioral principles in which elementary school children are divided into small teams, and the teams are rewarded when the classroom behavior of the entire team meets or exceeds a preestablished standard. The GBG is played several times per week throughout the school year. The intervention was evaluated through a randomized trial involving 19 schools in Baltimore, with posttests conducted immediately following the intervention, as well as 6 and 14 years later. The results of this study indicate that participation in GBG is related to immediate reductions in aggressive behavior, rates of diagnosed antisocial personality disorder, and long-term effects (14 years later) on drug and alcohol use and smoking. Home-based reinforcement (HBR), applied to individual students displaying behavior problems, requires cooperation between teachers and parents in the management of the child's behavior. After agreeing upon specific child behaviors to be extinguished or encouraged and establishing a baseline for these behaviors, teachers systematically record data on the target behavior on a "daily report card" that goes home to the parents. The parents, who generally have access to a wider array of reinforcers and punishments than do the teachers, use the teacher's information to guide the application of rewards and punishments. As the desired behavior emerges, the frequency of reports for home is reduced, and the schedule of contingencies is relaxed. In the earliest research on HBR, application of this technique to junior high school students showed that school rule compliance, teacher satisfaction with the student, and academic performance improved as a result of participation in an HBR program (Schumaker et al. 1977). A recent review of 18 empirical studies of "school-home collaboration" interventions (Cox 2005) concluded that behavioral interventions using the daily report card strategy had the strongest effects on problem behavior. Lasting effects on crime are unknown.

These relatively simple and inexpensive behavioral interventions represent a potentially potent school-based prevention strategy that might be incorporated into routine school practice. The 1997 reauthorization of the Individuals with Disabilities Education Act (IDEA; P.L. 105–17) required functional assessment and behavioral intervention procedures to be implemented in the disciplining of students with disabilities. The evidence-based programs described here would meet these federal requirements.

Behavioral principles have also been incorporated into school-wide discipline management systems. These systems are typically designed to clarify expectations for behavior. They establish school and classroom rules, communicate these rules as well as consequences for breaking them clearly to parents and students, establish systems for tracking both youth behavior and consequences applied by the schools, and monitor the consistency of the application of consequences for misbehavior. School-wide discipline management efforts, most often implemented by a school-based team of educators, are highly consistent with the research summarized earlier suggesting that students' perceptions of school rules as fair and consistently enforced are related to reductions in problem behavior.

The meta-analysis described earlier (Gottfredson et al. 2002) also examined the effectiveness of this type of school-wide effort to improve discipline management and reported average effect size on measures of crime (0.27, $p < .05$) and alcohol and other drug use (0.24, $p < .05$). Among the studies included in the meta-analysis are two early studies of the effects of school-wide discipline management systems on problem behavior outcomes. Students in the intervention schools in the first of these efforts (Project PATHE implemented in nine Charleston, South Carolina, schools) reported less delinquent behavior and drug use and fewer punishments in school relative to the students in the comparison schools (Gottfredson 1986). A similar intervention was tested in a troubled Baltimore, Maryland, junior high school, with a special emphasis on replacing the school's reliance on out-of-school suspension with a wider array of consequences for misbehavior. This intervention, which added positive reinforcement for desired behavior to the mix of consequences routinely used, also showed positive effects on student delinquency and rebellious behavior (Gottfredson 1987a). This early research, although based on relatively small numbers of schools and lacking randomization to condition, suggested that behavioral principles could be incorporated into "normal" school disciplinary practices and that an emphasis on consistency of rule enforcement as opposed to severity of punishment provided an effective deterrent.

Contemporary approaches to discipline management incorporate behavioral principles into comprehensive systems that include school-wide discipline policies and practices as well as targeted behavioral interventions. One popular approach is School-Wide Positive Behavior Support (SWPBS). This system, adopted by over 5,600 schools throughout the United States, uses a school-team approach to apply behavioral interventions at different levels of intensity for students at different levels of need. Universal interventions focus on clarity of school and classroom rules and consistency of enforcement, and on screening for more serious behavior disorders. Group-based behavioral interventions are employed with the 5–10 % of youths who do not respond to the universal interventions. In addition, intensive, individualized behavioral interventions are employed to manage the behavior of the small segment of the population that is especially at risk. Unfortunately, the research on the effectiveness of SWPBS is not as sophisticated as it should be for such a widely disseminated program. Although dozens of studies have demonstrated that problem behavior decreases after the intervention is put in place, only one (Sprague et al. 2001) compared change in the intervention school(s) with the change that might be expected in the absence of an intervention. Even this study is not useful for isolating the effects of the behavior management strategies because it also included the introduction of a prevention curriculum along with the school-wide behavioral supports. Higher-quality research is needed to assess the effects of this promising approach on crime both in and out of school.

School Culture

School culture is potentially the most potent aspect of school climate because it involves proximal interpersonal influences on student behavior. *School culture* refers to the quality of human relationships in the school and includes both peer culture and the extent to which the organization is communally organized. All of these dimensions influence youth crime and can be successfully manipulated to reduce it.

Behavioral Norms

Cultural norms, expectations, and beliefs influence all behaviors. Recent research on school culture (summarized in Cook et al. 2010) concurs that norms and expectations for behavior, of both peers and adult, are powerful determinants of behavior, net of the individual's own beliefs.

Of course, school "inputs" are key determinants of the predominant cultural beliefs in the school. School desegregation and retention policies, as well as the grade span, of the school can influence school culture by altering the mix of students in the school. But several more programmatic attempts to alter school culture have also been studied. These programs have in common a focus on clarifying behavioral norms. That is, in contrast to the instructional programs described in the previous section that focus on teaching youths with specific social competency skills, these normative change programs focus on clarifying expectations for behavior. Some signal appropriate behavior through media campaigns or ceremonies; others involve youths in activities aimed at clarifying misperceptions about normative behavior; and still others increase exposure to prosocial models and messages.

Several studies of attempts to clarify norms for behavior have been reported. Gottfredson et al. (2002) summarized effects reported in 13 studies and concluded that such programs are effective for reducing crime, substance use, and antisocial behavior. Two of the better-known examples of programs in this category are the Bullying Prevention Program (Olweus et al. 1999) and the Safe Dates Program (Foshee et al. 1998).

Olweus's anti-bullying program includes school-wide, classroom, and individual components. School-wide components include increased adult supervision at bullying "hot spots" and school-wide discussions of bullying. Classroom components focus on developing and enforcing rules against bullying. Individual counseling is also provided to children identified as bullies and victims. A large-scale evaluation of this program in Norwegian schools demonstrated that it led to reductions in student bullying and victimization and decreases in the incidence of vandalism, fighting, and theft (Olweus et al. 1999). A very recent review of anti-bullying programs summarizing results from 59 studies conducted between 1983 and 2008 (Farrington and Ttofi 2009) confirmed that anti-bullying programs are effective for reducing bullying and student victimization and that Olweus's program is particularly effective.

The Safe Dates Program targets norms for dating violence among adolescents. The school portion of the intervention includes a theater production performed by peers; a ten-session curriculum addressing dating violence norms, gender stereotyping, and conflict management skills; and a poster contest. The community portion of the intervention includes services for adolescents experiencing abuse and training for community service providers. Foshee et al. (1998) found that intervention students reported less psychological abuse and violence against dating partners than did control students.

Based on these and other relatively rigorous evaluations, Gottfredson et al. (2002) concluded that interventions aimed at establishing norms or expectations for behavior can be effective in preventing substance use, delinquency, aggression, and other problem behaviors. It should be noted, however, that evaluations of these programs seldom provide clean tests of the proposition that culture matters, since the programs more often than not combine attempts to alter norms with other components aimed at increasing levels of supervision and enforcement (e.g., Olweus) or improving social competency skills (Foshee).

We would be remiss if we failed to mention that sometimes school-based practices seek to clarify norms for behavior backfire. One example is a peer counseling program that deliberately mixed delinquent and nondelinquent youths in counseling sessions in which youths were encouraged to share their problems. The intent was that the negative beliefs and attitudes voiced by the delinquent youths would be corrected through interaction with the nondelinquent youths. A randomized experiment testing this program as implemented in the Chicago Public Schools (Gottfredson 1987b) reported predominantly harmful effects for high school students: high school treatment youths reported significantly *more* delinquent behavior than controls. A more recent large-scale evaluation of the Reconnecting Youth program (Cho et al. 2005) also found negative effects for a group counseling program for at-risk high school students. This program sought to "reconnect" truant, underachieving high school students (and to reduce their deviance and substance use) by developing a positive peer-group culture. Students were grouped together in classes of 10–12 students for a full semester during which a trained group leader (following a standardized curriculum) attempted to develop a climate conducive to building trust. The evaluation reported only negative effects 6 months following the end of the intervention. Treatment students showed greater bonding to high-risk peers, lower bonding to school and conventional peers, lower grade point average (GPA), and higher anger than control students at the 6-month follow-up.

Communal Social Organization

A second aspect of school culture that has been studied extensively pertains to the affective bonds between students and teachers and among adults in the school. The concept of "communal social organization" (CSO) was first introduced as part of the effective schools debate in the 1980s and studied by Bryk and colleagues (Bryk and Driscoll 1988) mostly in the context of predictors of school achievement. Communally organized schools are schools characterized by high levels of social support, connectedness, common goals, and sense of shared purpose. Members of such schools are more likely to be involved and personally committed to the school. This aspect of school culture is especially important for school crime research because individual-level student affective bonds are an important predictor of delinquency, and it seems reasonable to hypothesize that schools high on CSO would produce higher levels of student bonding to school.

Research suggests that average student attachment to school and CSO more generally do inhibit student problem behaviors. The most comprehensive test of this linkage was provided by Payne et al. (2003) using data from the NSDPS. This study demonstrated that more communally organized schools experience less student delinquency and teacher victimization and that the effect of communal school organization on student delinquency is mediated by average student bonding.

This survey research dovetails nicely with an ambitious ethnographic study of school violence conducted for the National Research Council. In 2003, the Committee to Study Youth Violence in Schools of the National Research Council published its report on the circumstances surrounding several incidents involving extreme lethal violence that had occurred in the nation's schools (National Research Council 2003). The report was based on detailed case studies of six schools and communities that had experienced school shootings resulting in death. Among the committee's several insights into the factors leading to the incidents is the following:

> the sense of community between youth and adults in these schools...was lacking. In the worst example, the school allowed a school newspaper to print an article that humiliated one of the students who became a shooter. The adults involved may have been too distant from the students to prevent some social processes leading to the potential for violence or resulting in an intolerable humiliation from some potentially vulnerable youth. (p. 256)

This observation is consistent with the research on more mundane forms of school violence just summarized. It suggests that strategies that increase social bonds between students and others in their schools will reduce misbehavior by increasing informal controls. Students who care what adults in the school think about them will be less likely to act in ways that jeopardize their positive regard. More concretely, students who have close ties to the adults in the school will be more likely to report on rumors of impending attacks. But how can such bonds be built or maintained? Possibilities include organizing the school so that the typical teacher interacts with fewer students, reducing class size, and creating more "communal" social environments in which members are more tightly joined together by common goals and in which members are held in place by the support and positive regard of others in the organization. Reorganizing schools to create a smaller feel to the schooling experience is an effective strategy for increasing youths' sense of connection and that enhanced connectedness should hold criminal behavior in check.

A less drastic intervention with the same objectives is mentoring. Youth mentoring programs often target youths at risk of behavioral problems, assigning them to an adult mentor who spends time with the young person, provides support and guidance, and offers general guidance. Evaluations of such programs have been mixed, but often null or weak results can be attributed to implementation failure. As with any voluntary program, mentoring programs in practice are often not as intensive as intended (e.g., Karcher 2008). However, a recent meta-analysis of mentoring programs (Eby et al. 2007) demonstrated small but positive effects of mentoring programs on several behaviors of interest in this entry: withdrawal behaviors (e.g., school dropout, truancy – 18 studies), deviance (e.g., suspension from school, aggressive behavior, property crime – 15 studies), and substance use (7 studies). This review included a wide range of types of mentoring programs, but outcomes for youth mentoring programs were as strong on these outcomes as were the other types of mentoring programs (academic and workplace mentoring) included in the review.

One of the better-known models for adult mentoring, the Big Brothers Big Sisters program (BBBS), is a community-based program identified by BVP as a model primarily on the basis of evidence from a large-scale randomized trial that found that mentored youths were 46 % less likely than control youth to initiate drug use, 27 % less likely to initiate alcohol use, and almost one-third less likely to hit someone during the study period (Tierney et al. 1995). Community-based mentoring involves meetings between the mentor and mentee at times and places selected by the pair. Many schools now provide "school-based mentoring," (SBM), which involves meetings primarily in school during the school day. A recent evaluation of the BBBS SBM model, also involving random assignment of a large number of youths, shows that although it is not as effective as the community-based alternative, SBM does improve academic performance, reduce truancy, and reduce serious school infractions (Herrera et al. 2007) at least during the first year of mentoring. Consistent with results from smaller-scale randomized trials of SBM showing positive effects on connectedness and social support (Karcher 2008); Herrera et al. (2007) found that mentored youths reported more often than controls the presence of a nonparental adult in their life who provides social supports. At the end of the second year of the study during which minimal SBM was provided, the positive program effect on truancy was sustained but the other positive effects were not. Herrera et al. (2007) conclude that although the SBM model is promising, it needs to be strengthened to ensure longer and higher-quality mentor/mentee matches than are typically found in schools.

Discussion and Conclusions

In this brief essay, we summarized research on school discipline management policies and practices and showed that they are important determinants of school crime. Research consistently shows that in schools in which students report that the school rules are clearly stated, fair, and consistently enforced, and in schools in which students have participated in establishing mechanisms for reducing misbehavior, students are much less likely to engage in problem behaviors. We showed that evaluations of specific school-based programs that employ behavioral strategies to monitor and reinforce student behavior are effective both for controlling behavior in school and for reducing subsequent crime. Also, altering school-wide discipline management policies and practices to incorporate behavioral principles, clarify expectations for behavior, and consistently enforce rules reduces problem behavior. We discussed popular "get-tough" approaches to school discipline such as zero-tolerance policies. Although the effects of these polices on crime are not known, we argued that they might actually increase crime outside of school. There is a clear need for rigorous research on the effects of these policies.

Finally, we summarized research showing that perceptions of social norms for behavior are related as expected to problem behavior, net of individuals' personal beliefs. In schools in which the prevailing norm is to condone delinquent activities, students are more likely to do so regardless of their own personal dispositions to engage in these behaviors. But we showed that schools can intervene to change perceptions of norms and expectations for behavior and that doing so reduces delinquency, although attempts to do so sometimes backfire. We also reported on evidence suggesting that in schools in which students feel an emotional attachment to the adults in the school, their misbehavior is restrained. We discussed several strategies that might increase communal social organization and that show promise for increasing youths' sense of connection to the school. We reviewed research on school-based mentoring programs and showed that they also hold considerable promise for crime prevention. Although research documents positive effects of these programs on social relations outcomes, more work is needed to test the full potential of more potent models of school-based mentoring than have been tested to date.

Given the limitations of the evidence base, we are more confident in making recommendations about research priorities than about effective policy. Indeed, this field is burdened by a lack of timely policy research and a tendency to launch major initiatives without first (or ever!) doing a high-quality evaluation. Note in this regard the various "get-tough" policies that have been encouraged by the federal government and adopted nationwide since the 1990s, the widespread use of SROs, or the School-Wide Positive Behavior Support package that has been adopted by 5,500 schools.

We have several recommendations to guide evaluation research on interventions. The first recommendation is to actually do such research, as suggested above. An impediment to learning about the effects of many school reforms is that the reforms tend to be implemented in all schools in the affected jurisdiction at once. This hinders rigorous evaluation because it leaves no schools in which to measure what would happen in the absence of the reform. A smarter approach would be to randomly assign schools to different phase-in periods, allowing for comparison during the first few years of the schools who implement the reform early and those who will implement it in the future.

Other recommendations are to measure effects on crime and other forms of misbehavior in evaluations conducted of interventions intended to improve academic performance, to capture the most serious forms of crime in evaluations rather than only less serious misbehavior, and to assess effects of prevention practices and policies on the entire student population rather than only on the students who are targeted.

Finally, it is important to identify programs to create more cohesive, communal, personalized environments. Many approaches to creating such environments seem plausible, but no rigorous research has yet established that such changes can be accomplished and that doing so results in a reduction in crime. This appears to be the next large challenge facing research on school-based prevention.

Notes and Acknowledgments This entry is based on a more detailed chapter (Cook et al. 2010) on school crime control and prevention. Portions of this work are also included in a forthcoming chapter entitled "School-Based Crime Prevention" in the *Oxford Handbook on Crime Prevention* (Brandon C Welsh and David P. Farrington, editors).

Overview

Other essays in this encyclopedia summarize school-based prevention strategies that have been demonstrated to be effective for reducing crime and discuss the importance for schools of having close-knit communities where rules of acceptable behavior are clearly communicated and consistently (if not harshly) enforced. Schools' capacity to implement effective prevention strategies and to establish well-ordered communities is likely to be greater in schools that are not overwhelmed by having a high proportion of the students at risk. In this essay, we discuss decisions primarily made outside of the school building that influence the demographic composition of schools and the number and types of other students to whom a child is exposed. Externally determined factors (e.g., finances, physical features of building, school size, and student/teacher ratio) also determine resources available in the school and define patterns of interaction broadly speaking. Here we will focus on school-district policies influencing the student composition of schools and school size.

Specifically, we will consider the extent to which school or school-district decisions regarding how students are organized for instruction (e.g., academic or behavioral tracking or departmentalization) further narrow the characteristics of other students to whom youths will be exposed. Importantly, these decisions determine the pool of youths from which highly influential peers will be selected as well as the dominant peer culture in the school. These structural characteristics potentially influence crime-producing mechanisms.

We find that the concentration of different types of students in a school has important implications for the amount of crime in the school: The grade levels included in the school or average age of the students in the school, the percentage male students, the social class composition, and the racial and ethnic composition of the schools are related to measures of problem behavior. Further, some policies that alter the composition of classes, grades, or schools have been shown to reduce problem behavior: Keeping sixth graders in elementary schools as opposed to moving them to middle schools reduces disciplinary infractions, and retaining students in grade increases conduct problems both for the "old-for-grade" students and for non-retained students. We find little support for the idea that the size of the school per se matters for reducing school crime.

We begin this essay with a summary of research related to school size and student demographics as they relate to school crime and disorder. We then discuss school policies and practices that are likely to alter the types of students with whom a student is likely to be exposed. We end with a discussion of implications for policy and research.

School Ecology

One category of school structural characteristics is "school ecology." Very few studies have examined the influence of several potentially important aspects of school ecology including school finances and the physical features of the school building. By contrast, many studies include a measure of school size – number of students in the school or in the grade. Our discussion will therefore focus on school size, providing a summary of the literature and some new results.

School size is thought to have a major influence on the internal organization of schools and on subsequent student outcomes. Lee et al. (1993) suggest that larger schools are likely to have increased capacity to tailor programs and services to meet the diverse needs of students in the school. The extreme example of low specialization is a one-room schoolhouse in which one teacher teaches all students all day. In small schools, the typical teacher teaches a smaller number of different students and gets to know these students well. Students in such schools may develop a greater sense of trust in the adults and be more likely to communicate potentially dangerous situations to them. Large schools are likely to be organized more bureaucratically and to involve more formalized social interactions among members of the school population. As a result, communication may be less frequent or less direct, cohesiveness may be reduced, management functions (including the management of discipline) may become less nuanced, and individuals may share less of a common experience in the school. Alienation, isolation, and disengagement may result. All of these mechanisms are plausible but speculative.

As it turns out, school size has not received much focused attention in research on schools and crime. However, many studies have included a measure of school size as a control variable when focusing on the effects of other aspects of school climate. Cook et al. (2010) summarized the associations between measures of school size and problem behavior in school-level and multilevel studies. They found nine school-level studies based on data from seven different data sources. In the studies that reported an unambiguous association between school size and a measure of problem behavior, the conclusions differed depending among other things on the measure of problem behavior used. Positive associations between school size and measures of minor misbehavior were reported for the High School and Beyond high school data and the National Education Longitudinal Study [NELS] eighth graders, but the association with more serious forms of misbehavior was not statistically significant. In another data source (Safe School Study), school size was not significantly related to student victimization but was positively related to teacher victimization. That study also showed that the effect of school size on teacher victimization is mediated by aspects of the school social organization and culture. No significant relationship with school size was found in a study of middle schools in Philadelphia.

The multilevel studies summarized provided no support for the "smaller is better" viewpoint. Fifteen different research reports based on nine different data sources were summarized. In these studies, which generally controlled for community characteristics as well as characteristics of the students who attend the school, only one data source (NELS tenth graders, as reported in Stewart 2003) produced a significant positive association between school size and a measure of problem behavior, and the measure of problem behavior used in this study was unusual because it contained mainly school responses to misbehavior (e.g., being suspended or put on probation) rather that actual youth behavior. Hoffmann and Dufur (2008) also reported on the association of school size and a broader measure of problem behaviors including substance use, arrest, and running away using the NELS tenth grade sample and found no significant association. Reports from a sample of Israeli schools containing seventh and 11th grades documented a positive association between average *class* size and student victimization, but no significant association with school size. One of the multilevel studies reported a significant negative association between school size and student victimization, but this sample included only rural schools located in New Brunswick, Canada, whose average size was 39 and 53 students, respectively, for sixth and eighth grade. A recent study by Gottfredson and DiPietro (2011) found that, net of individual-level risk factors and confounding characteristics of schools and their surrounding communities, more students per teachers and a higher number of different students taught by the average teacher were related to higher student victimization rates, but larger school size was significantly related to lower student victimization rates. Cook et al. (2010) concluded that most of the multilevel studies suggest that school size is not reliably related to student problem behavior once characteristics of the students who attend the schools are controlled.

However, the studies summarized often reported on the association between school size and problem behavior from models that may provide too conservative a test. The student characteristics that are controlled in the multilevel studies are often exactly those student characteristics that Lee et al. (1993) hypothesized to be influenced by school size (e.g., school attachment, involvement, perceived positive social climate). Also, most of the associations with school size reported in the studies are from models that partial out influences not only of the communities in which the schools are located and the average demographic characteristics of the students attending the schools but also of other school climate characteristics such as school culture and the administration/management of discipline, hypothesized to mediate the influence of school size on student outcomes. For example, Hoffmann and Dufur's (2008) study reported a negative association between school size and delinquency in the NELS data, but the equation also contained measures of "school quality," a composite measure assessing youth perceptions of their school as fair and their teachers and fellow students as caring and trustworthy. Unfortunately, many of these reports did not report the association of school size with problem behavior in models that do not control for potential effects of school size.

New results. We analyzed data from the 2007–2008 School Survey on Crime and Safety

(SSCS; Neiman and DeVoe 2009) in an attempt to establish baseline descriptive results on how school size relates to school crime. Principals were asked how many incidents of various types of crime had occurred at school during the last school year. They were asked about violent crimes (rape, sexual battery other than rape, physical attack or fight with or without a weapon, threat of physical attack with or without a weapon, and robbery with or without a weapon) and about theft and larceny. We calculated rates per 1,000 students for each school. Because school size is highly related to location and level, it is necessary to look at the association of crime rates and enrollment while controlling for these factors.

Figure 1 shows median rates per 1,000 students for theft/larceny and violent crimes, according to school principals. The figures make clear that crime rates are not systematically related to school size within level and location. However, there is some suggestion that the association between size and principal reports of crime differs according to type of crime, level, and location: In urban locations, principals in smaller elementary and middle schools report more violent crimes. This is not the case in rural/suburban schools or in urban high schools.

We conclude that school size is not generally related to principal reports of school and that whatever differences observed favor larger schools over smaller schools.

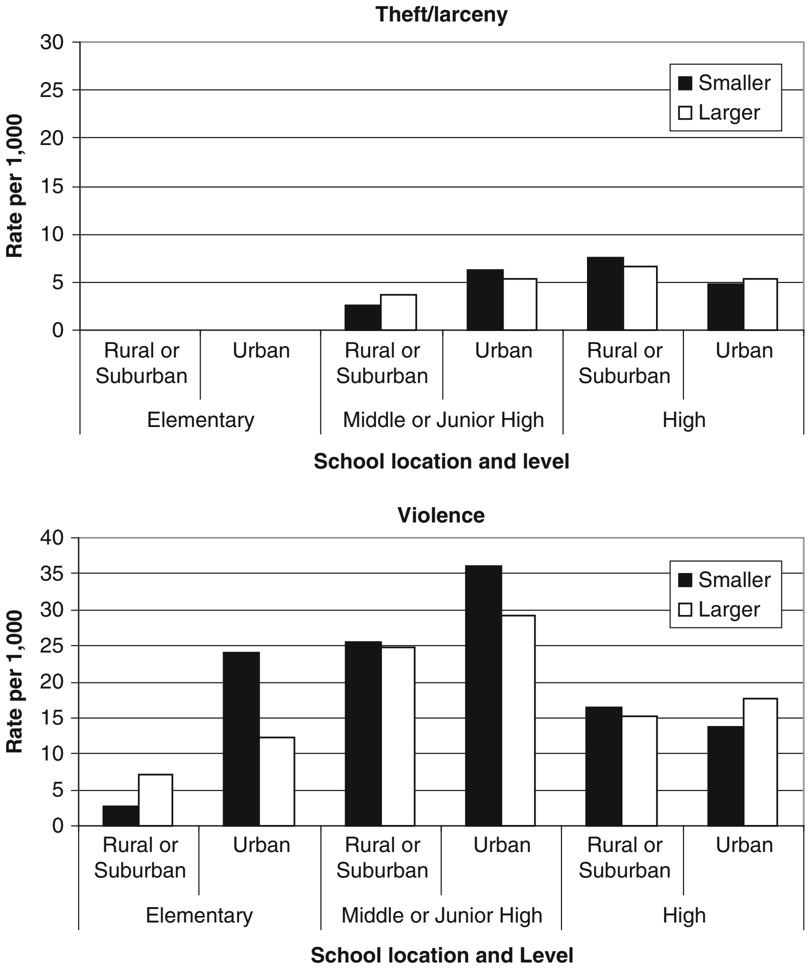
It is likely that the ratio of adults to students rather than the actual number of students in the school is related to problem behavior. Five of the studies summarized in Cook et al. (2010) looked at the association of problem behavior to student/teacher ratio. Only one of the five studies reported a significant relationship: Gottfredson and DiPietro (2011), in a multilevel study using data from the National Study of Delinquency Prevention in Schools, reported a positive association of student/teacher ratio and personal but not property crime victimization. That study reported that higher levels of social capital, as measured by student consensus about normative beliefs, partially mediated the effects of student/teacher ratio on personal victimization. We believe that a more sensitive measure of adult presence would be the ratio of all adults (rather than just teachers) to students. Many schools use parent volunteers and teacher aides in addition to teachers to help maintain order. The ratio of the total number of adults to students would reflect variability in the use of such auxiliaries. Unfortunately, no studies have reported on this association.

As far as we know, there are no intervention-based studies of how school size affects school crime. Case studies of instances in which an established school is divided in smaller units are available, but they almost never assess effects on crime, and they do not provide a clean test of the effects of changing school size because other factors (such as the curriculum, aspects of the physical space, and school finances) are always altered simultaneously.

Milieu

The SSCS data show that rates of problem behavior differ with demographic characteristics. Middle schools have higher rates of delinquency than elementary or high schools (the partial exception is substance use, which increases through high school). Schools with 50 % or more minority enrollment experience higher rates of violence than majority white schools (Nolle et al. 2007). Socioeconomic status of the student body is also associated with delinquency rates (Gottfredson et al. 2005).

More interesting from a policy perspective is the extent to which the mix of students in the school or the classroom influences the likelihood that any given student will misbehave. The mechanisms of deviant peer influence are both direct and indirect. The direct effects may arise as a result of deviant peer influence: learning and imitation, social reinforcement for deviant acts, and the creation of opportunities for deviant activities (Dishion and Dodge 2006). It may also be due to the presence of social norms that support (or at least appear to youth to support) delinquent behavior. All these mechanisms are



School Structural Characteristics and Crime, Fig. 1 Principal reports of crimes recorded by school, by school enrollment, location, and level – median rates per 1,000 students. Note: Size is split at the median total enrollment for each school level: 452, 585, and 885 for elementary, middle, and high, respectively. One outlier (a small alternative school for delinquent youths with a very high crime rate) is excluded. Violent crimes include rapes, sexual batteries other than rape, robberies with or without a weapon, physical attacks or fights with or without a weapon, and threats of physical attack with or without a weapon. Theft includes taking things worth over $10 without personal confrontation and includes pocket picking, stealing a purse or backpack (if left unattended or no force was used to take it from owner), theft from a building, theft from a motor vehicle or [of] motor vehicle parts or accessories, theft of a bicycle, theft from a vending machine, and all other types of thefts (Source: Original tabulation from data files. SSCS 2007–2008)

relevant for involvement with delinquency both in and out of school, including drugs and alcohol, and participation in gangs. The indirect effects may come about as a result of the dilution of authority – a teacher who can manage one or two disruptive students may lose control of the classroom when there are more than two. The same phenomenon can occur at the school level, where a high "load" of troublesome students may swamp the mechanisms of control in the corridors, cafeteria, lavatories, and grounds.

Given the real possibility of peer influence, the actual behavior of youths with a given propensity to deviant or criminal activity may well depend on whom they encounter in their classes and in the other locations in the school. A variety of policies are relevant to influencing the mix of students. At the level of the school district, the distribution of students among schools will be influenced by which grade spans are included in the middle schools, the extent to which low-performing students are held back, and whether school assignments are tied largely to place of residence or tailored to promote integration or parental choice. For a given pattern of assignments to schools, the number and characteristics of students who are actually in the building on a school day will depend on absenteeism and use of out-of-school suspension. And for a given population of students who are actually attending the school on any given day, social influence will likely be mediated by policies that influence the extent to which deviant students are concentrated, such as in-school suspension or academic tracking.

Cook et al. (2010) summarized the results from 18 multilevel studies based on 14 datasets showing associations between the milieu of the school and measures of problem behavior, controlling for individual-level demographics as well as for related characteristics of the communities from which the student body is drawn. These studies showed that the grade levels included in the school or average age of the students in the school, the percentage male of students, the social class composition, and the racial and ethnic composition of the schools are related to measures of problem behavior. These associations sometimes did not reach statistical significance, but they were nearly always in the expected direction. Here we discuss several of the strongest studies relevant to evaluating the impact of policy choices concerning grade span, grade retention, truancy prevention, racial segregation, and use of alternative schools.

1. *Grade span.* One recent study demonstrates that the grade composition in a middle school influences the rates of misbehavior of the students. A generation ago, most elementary schools included sixth grade, but now most sixth graders attend middle school. Using a quasi-experimental approach, Cook et al. (2008) compare the school records of North Carolina students whose sixth grade was located in a middle school with those whose sixth grade was in elementary school (the sample of sixth grades in middle school was trimmed to match the sixth grades in elementary school in several dimensions). While the two groups of students had similar infraction rates in fourth and fifth grades, those who moved to a middle school for sixth grade experienced a sharp increase in disciplinary infractions relative to those who stayed in elementary school. More interesting, perhaps, is that the elevated infraction rate persisted through ninth grade. A plausible interpretation of these findings is that sixth graders are at a highly impressionable age, and if placed with older adolescents, they tend to be heavily influenced by their inclination to break the rules. This example of negative peer influence is quite large and extends to all types of infractions, including violence and drug violations.
2. *Retention policies.* The age mix in a school is closely related to the grade span, but that is not the only determinant; the school district's retention policies also play a role. In response to high-stakes accountability programs (including No Child Left Behind), many school systems have ended social promotion for students who fail end-of-grade tests, thus increasing the number of old-for-grade students. Entry-level at-risk students are often held back for a year before making the transition to second grade. The effect of retention on behavior of the retained students has been extensively studied. Most studies have focused on academic outcomes: Meta-analyses of this literature conclude that the long-term effect on academic achievement is null or negative, with a greatly elevated risk of dropping out (Jimerson et al. 2006). Hence, given the robust general finding that students with academic difficulties are more prone to antisocial behavior (Nagin et al. 2003), it is not surprising that grade retention appears to increase conduct problems. One of the most sophisticated studies, using Richard Tremblay's longitudinal data on Montreal

school children, found that the effect of grade retention on classroom physical aggression (as measured by teacher reports) is conditioned by the developmental history of the child: Those showing no aggression or chronic aggression levels were not affected, whereas those whose trajectory of aggression was declining over time increased their aggression more so if retained than if not retained (Nagin et al. 2003).

There has been less attention to the contextual effect of having old-for-grade students in the classroom and school. One exception is a recent study that uses a comprehensive data set of North Carolina students. Muschkin et al. (2008) conduct a cross-sectional analysis of infraction rates by seventh graders, finding that the prevalence and incidence of infractions increase with the prevalence of retained students (students who were retained at least once in the previous 3 years) and the prevalence of old-for-grade students who were not retained during that 3-year period. These results hold after they controlled for various characteristics of the student body and the schools and the inclusion of district fixed effects. The authors also find evidence that susceptibility differs among types of students; in particular, the old-for-grade seventh graders were themselves especially susceptible to the influence of the concentration of other old-for-grade students in their school. Similar results were found when the outcome variable was the likelihood of being suspended.

3. *Truancy prevention*. The mix of students who are in the school building on any given day will be affected by absenteeism and tardiness. School attendance laws require that youths between specified ages (e.g., 7–16 in North Carolina and 5–18 in New Mexico) attend school, with possible exceptions for home schooling. This is a legal obligation for which both the child and parents are liable. In many school districts, however, these laws are widely flouted. For example, the absentee rate in DC public high schools in the 2006–2007 school year averaged 17 %.

   The rate of unexcused absence determines not only the number of students in the school building but also the behavioral propensities of those students. Chronic truants are not a representative sample of the student body but rather tend to come from dysfunctional families and be at risk for delinquency, violence, and substance abuse (McCluskey et al. 2004). It is also true that chronic truancy engenders academic problems and is associated with failure to graduate from high school and a variety of poor life outcomes, including involvement with serious crime. As a logical matter, then, programs that are effective in improving attendance rates may have several effects. First, if they get delinquent youths off the street and into school, the result may be reduced crime rates in the community. Indeed, communities concerned about the daytime crimes committed by truants have increasingly enlisted the police and the juvenile court to combat truancy. Second, effective truancy-prevention programs may come at the cost of higher crime rates within the school. And third, if at-risk youths are persuaded to attend school more faithfully, the long-term result may be to improve their chances of graduation and subsequent success.

   A number of school-based programs have been evaluated in part by their effect on school attendance. Unfortunately, there are no studies, insofar as we know, that evaluate the effect of attendance-promoting programs on school crime rates or overall (community plus school) crime rates.

4. *School desegregation*. In compliance with the 1954 Supreme Court ruling *Brown v. Board of Education*, federal courts issued a series of desegregation orders to public school districts. These orders forced a considerable increase in the extent to which African American students attended school with whites during the 1960s and 1970s. A vast literature on the effects of school segregation and desegregation has focused on academic outcomes. The results of this research offer support to the conclusion that integrated schools promote

black achievement and increase black high school graduation rates, college attendance and graduation rates, and occupational success (LaFree and Arum 2006). A persuasive quasi-experimental study of the effect of desegregation plans found that they reduced black dropout rates by 2–3 % points, with no detectable effect on whites (Guryan 2004). Given the tight link between academic success and school behavior, it is entirely plausible that the degree of segregation has a direct influence on delinquency in schools. But we are not aware of any direct evidence on the subject; segregation studies have not used school crime as an outcome variable. There have been two persuasive studies concerning the effects of segregation on crime outside of school. LaFree and Arum (2006) analyzed the incarceration rates for black males who moved to a different state following school. For any given destination state, they found that those who moved from a state with well-integrated schools had a substantially lower incarceration rate than those who moved from a state where the schools were more segregated. A more recent study (Weiner et al. 2009) utilizes a quasi-experimental approach in which the court desegregation orders serve as the experimental intervention: They report that these orders reduced black and white homicide victimization rates for 15–19-year-olds. The authors explore several mechanisms that may account for this result, including both the direct effects of changing the mix of students in the schools and indirect effects associated with police spending and relocation of some white students. In any event, since all but a handful of these homicides occurred outside of school, we are still waiting for direct evidence on crime in schools.

5. *Alternative schools.* A recent survey found that 39 % of public school districts administered at least one alternative school for students at risk of educational failure. As of October 2000, 613,000 students were enrolled in these schools, 1.3 % of nationwide total enrollment. Urban districts, large districts (those with 10,000 or more students), districts in the Southeast, districts with high minority student enrollments, and districts with high poverty concentrations were more likely than other districts to have alternative schools and programs for at-risk students. Despite the widespread use of these schools as a means of removing antisocial and violent students from the regular classrooms, there have been no systematic studies of the effects on school crime rates. The effects on the behavior of youths who are given alternative-school placements have been studied, with mixed results. Indeed, there is unlikely to be any generic answer, since effects will depend on the quality of the programming and on which students are selected. Best-practice judgments tend to rely on expert opinion rather than on evaluation studies with strong designs.

6. *Grouping within schools.* Academic tracking is nearly universal in US secondary education. The attraction of separating students into tracks that are more or less demanding academically is the belief that this is the best way to tailor coursework to the differing background, ability, and motivation of the students. Tracking tends to have the result of concentrating minorities and students from lower socioeconomic status households in certain classrooms. Given the strong association between academic success and delinquency involvement, it also has the effect of concentrating crime-prone students, setting the stage for negative peer influence.

As a device to improve academic progress, tracking has had more detractors than advocates among education specialists. The evidence base is thin: Most notably, Mosteller et al. (1996) identified only ten randomized experimental evaluations comparing the performance of students in tracked (homogeneous) and untracked (heterogeneous) classrooms. When these studies were combined, the best estimate was a zero difference in average academic performance. Still thinner is any evidence on how tracking affects misbehavior. Thus, we conclude that the possibility of deviant peer influence due to tracking is plausible but unproven.

Conclusion

School reform is typically shaped by theories of how to improve students' academic performance. But to the extent that school safety is an important goal, somewhat distinct from academic progress, the potential impacts on safety should be considered in any evaluation.

One of the most prominent reform efforts since 2001 has been the campaign funded largely by the Gates Foundation to create small high schools. While that effort was abandoned in 2008 as a result of disappointing results on academic progress, it would also be of interest to know the effect on school crime and juvenile delinquency. Given the fact, reported here, that small schools are not systematically safer than large schools (controlling for urbanicity and grade level), it appears doubtful that smaller is better in this domain.

There is very good reason to believe that the mix of students who are assembled in a school or any one classroom may influence the behavior of all. Two relevant mechanisms are deviant peer influence and "resource swamping," both implying that overall crime rates within school may increase in nonlinear fashion with the addition of deviant students to the mix (Cook and Ludwig 2006). This concern is relevant in evaluating policies regarding grade retention, truancy prevention, use of suspension and expulsion, use of alternative high schools, and even academic tracking. In each case, however, we found that relevant evaluations were lacking.

Implications for Research and Policy

Crime rates differ widely among schools. Experimental evidence suggests that the crime involvement of any given student at risk is influenced by the school that he or she attends. That fact motivates our scientific quest to find the school structural determinants of criminal activity by school-aged youths.

In another entry in this volume, we summarized findings from studies of school climate and crime and discussed numerous additional studies that reported on attempts to manipulate aspects of school climate. The school climate studies revealed sturdy associations between measures of school climate and measures of student delinquency, victimization, substance use, or other forms of problem behavior.

A starting point in accounting for interschool differences in crime is the criminal propensities of the students. Schools in which many of the students are active delinquents outside school start with a far greater challenge than those in which the students are largely law-abiding. The school crime rate of a student body with high crime propensity may be greater than the sum of the parts for two reasons. First, if the school lacks the adult resources to manage the "load" of misbehavior, then the school may become progressively more chaotic, spinning out of control. Further, delinquent and deviant youths may have a negative influence on each other and other students as well, further amplifying the problem. As noted in earlier discussion of the mechanisms involved in the production of crime and the features of schools that might influence these mechanisms, decisions that influence the demographic composition of schools are important because they determine the prevailing cultural beliefs in the school as well as the pool of youths from whom friends can be selected. In short, the crime rate in school is not just the sum of the parts but does reflect the ecological effects of the mix of students in the building.

Schools and school districts have a good deal of control over the makeup of the student body. Schools can be based on neighborhood residential patterns or integrated across race and class. The grade span for elementary and middle schools can be adjusted. Truancy and dropout prevention programs can be pursued with more or less vigor and troublesome students reassigned. Whether failing students are retained in a grade or given a social promotion influences the extent of age homogeneity within classrooms. Students who are enrolled in the school can be tracked on the basis of academic potential or mixed together and so forth. This array of policy choices has the potential to influence the "load" on teachers and other adults and the opportunity for deviant peer influence. Some of these policies have been evaluated for these ecological effects, but the evidence base is quite thin.

We also note that most of the evaluations of policies that affect the mix of students – truancy and dropout prevention, alternative schools, tracking, grade retention of failing students, and so forth – only consider the effect on the students who are targeted and fail to consider the ecological effects. But secondary effects on other students may be quite important and should be included when it is possible to implement a comprehensive study.

Finally, we noted that evidence does not support the conclusion that smaller schools are more effective for limiting problem behaviors than larger schools, but research reported in the "School Social Organization, Discipline Management, and Crime" entry of this volume suggests that conditions that make a school environment "feel" smaller and more communally organized are related to levels of problem behavior.

Notes and Acknowledgments This essay is based on a more detailed chapter (Cook et al. 2010) on school crime control and prevention.

School violence prevention

Overview

Schools are an important location for interventions to prevent or reduce aggressive behavior. They are a setting in which much interpersonal aggression among children occurs and the only setting with almost universal access to children. There are many prevention strategies from which school administrators can and do choose, including surveillance (e.g., metal detectors, security guards), deterrence (e.g., disciplinary rules, zero tolerance policies), and psychosocial programs. Indeed, over 75 % of schools in one national sample reported using one or more of these prevention strategies to deal with behavior problems (Gottfredson et al. 2000). Other reports similarly indicate that more than three-fourths of schools offer mental health, social service, and prevention service options for students and their families (Brener et al. 2001). Among psychosocial prevention strategies, a broad array of programs can be implemented in schools. These include packaged curricula and homegrown programs for use school-wide and others that target selected children already showing behavior problems or deemed at risk for such problems. Most psychosocial prevention programs address a range of social and emotional factors assumed to cause aggressive behavior or to be instrumental in controlling it (e.g., social skills or emotional self-regulation), and it is these psychosocial programs that are the focus of this meta-analysis.

Key Issues

Various resources are available to help schools identify programs with proven effectiveness. Among these resources are the Blueprints for Violence Prevention; the Collaborative for Academic, Social, and Emotional Learning (CASEL); and the National Registry of Evidence-based Programs and Practices (NREPP) administered by the Substance Abuse and Mental Health Services Administration (SAMSHA). There is, however, little indication that the evidence-based programs promoted to schools through such sources have been widely adopted or that, when adopted, they are implemented with fidelity (Gottfredson and Gottfredson 2002).

While lists of evidence-based programs can provide useful guidance to schools about interventions likely to be effective in their settings, they are limited by their orientation to distinct program models and the relatively few studies typically available for each such program. A meta-analysis, by contrast, can encompass virtually all credible studies of such interventions and yield evidence about generic intervention approaches as well as distinct program models. Perhaps most important, it can illuminate the features that characterize the most effective programs and the kinds of students who benefit most. Since many schools already have prevention programs in place, a meta-analysis that identifies characteristics of successful prevention programs can inform schools about ways they might improve those programs or better direct them to the students for whom they are likely to be most effective. Thus, the purpose of the meta-analysis reported here is to investigate which program and student characteristics are associated with the most effective treatments.

In 2003, we published a meta-analysis on the effects of school-based psychosocial interventions for reducing aggressive and disruptive behavior aimed at identifying the characteristics of the most effective programs (Wilson et al. 2003). That meta-analysis included 172 experimental and quasi-experimental studies of intervention programs, most of which were conducted as research or demonstration projects with significant researcher involvement in program implementation. Though not necessarily representative of routine practice in schools, those programs showed significant potential for reducing aggressive and disruptive behavior, especially for students whose baseline levels of antisocial behavior were already high. Different intervention approaches appeared equally effective, but significantly larger reductions in aggressive and disruptive behavior were produced by those programs with better implementation, that is, more complete delivery of the intended intervention to the intended recipients. In 2007, we published an updated version of that meta-analysis that included 249 studies of school-based prevention programs (Wilson and Lipsey 2007). For that analysis, we separated the programs into four mutually exclusive groups, characterized by the general service format and target population of the programs. The four program groups were universal programs, pullout programs for high-risk populations, comprehensive programs, and special school programs. In addition to being distinctive in terms of service format, programs in each of the groups had a number of methodological, subject, and dosage differences that made it unwise to combine them in a single analysis. Furthermore, school decision-makers typically make choices from within a format category, rather than across them. Thus, there was little utility in lumping all the school-based prevention programs into one larger set.

Results of the 2007 meta-analysis found positive overall intervention effects on aggressive and disruptive behavior and other relevant outcomes. The most common and most effective approaches were universal programs and pullout programs targeted for high-risk children. Comprehensive programs did not show significant effects and those for special schools or classrooms were marginal. Different program approaches (e.g., behavioral, cognitive, social skills) produced largely similar effects. Effects were larger for better implemented programs and for those involving students at higher risk for aggressive behavior.

Since the publication of our earlier work, the analytic methods for handling dependent effect size estimates in meta-analysis have improved. Multiple effect size estimates from a single study sample can now be included in a meta-analysis using robust standard errors that account for the statistical dependencies present when multiple effect size estimates are used (Hedges et al. 2010). This entry provides an opportunity to take the school-based prevention programs included in the 2003 and 2007 papers and reanalyze their results using these new statistical methods.

Method

Criteria for Including Studies in the Meta-Analysis

Studies were selected for this meta-analysis based on a set of detailed criteria, summarized as follows:

1. The study was reported in English no earlier than 1950 and involved a school-based program for children attending any grade, prekindergarten through 12th grade.

2. The study assessed intervention effects on at least one outcome variable that represented either (a) aggressive or violent behavior (e.g., fighting, bullying, person crimes), (b) disruptive behavior (e.g., classroom disruption, conduct disorder, acting out), or (c) both aggressive and disruptive behavior.
3. The study used an experimental or quasi-experimental design that compared students exposed to one or more identifiable intervention conditions with one or more comparison conditions on at least one qualifying outcome variable. To qualify as an experimental or quasi-experimental design, a study was required to meet at least one of the following criteria:
   - Students or classrooms were randomly assigned to conditions.
   - Students in the intervention and comparison conditions were matched and the matching variables included a pretest for at least one qualifying outcome variable or a close proxy.
   - If students or classrooms were not randomly assigned or matched, the study reported both pretest and posttest values on at least one qualifying outcome variable or sufficient demographic information to describe the initial equivalence of the intervention and comparison groups.

Search and Retrieval of Studies

An attempt was made to identify and retrieve the entire population of published and unpublished studies that met the inclusion criteria summarized above. The primary source of studies was a comprehensive search of bibliographic databases, including PsycINFO, Dissertation Abstracts International, ERIC (Education Resources Information Center), US Government Printing Office publications, National Criminal Justice Reference Service, and MEDLINE. Second, the bibliographies of meta-analyses and literature reviews on similar topics were reviewed for eligible studies. Finally, the bibliographies of retrieved studies were themselves examined for candidate studies. Identified studies were retrieved from the library, obtained via interlibrary loan, or requested directly from the author. We obtained and screened more than 95 % of the reports identified as potentially eligible through these sources. Note that a new search was not performed for this entry and that the literature reviewed here is current through 2004.

Coding of Study Reports

Study findings were coded to represent the mean difference in aggressive behavior between experimental conditions at the posttest measurement. The effect size statistic used for these purposes was the standardized mean difference, defined as the difference between the treatment and control group means on an outcome variable divided by their pooled standard deviation (Lipsey and Wilson 2001). In addition to effect size values, information was coded for each study that described the methods and procedures, the intervention, and the student samples. Coding reliability was determined from a sample of approximately 10 % of the studies that were randomly selected and recoded by a different coder. For categorical items, intercoder agreement ranged from 73 % to 100 %. For continuous items, the intercoder correlations ranged from 0.76 to 0.99. A copy of the full coding protocol is available from the author.

General Analytic Procedures

All effect sizes were multiplied by the small sample correction factor, $1-(3/4n-9)$, where n is the total sample size for the study, and each effect size was weighted by its inverse variance in all computations (Lipsey and Wilson 2001). The inverse variance weights were computed using the subject-level sample size for each effect size. Because many of the studies used groups (e.g., classrooms, schools) as the unit of assignment to intervention and control conditions, they involved a design effect associated with the clustering of students within classrooms or schools that reduces the effective sample size. The respective study reports provided no basis for estimating those design effects or adjusting the inverse variance weights for them, so cluster adjustments were not made in the analyses reported here. This should not greatly affect the effect sizes estimates or the magnitude of their relationships to moderator variables but does assign them somewhat smaller standard error estimates and, hence, larger inverse variance weights than is technically correct. A dummy code identifying these cases was included in the analyses to reveal any differences in findings from these studies relative to those using students as the unit of assignment. The effect sizes for cluster assigned studies were not statistically different from the student-assigned studies in any analysis.

Examination of the effect size distributions for each of the four program format groups identified a small number of outliers with potential to distort the analysis. Outliers were defined as values that fell more than three interquartile ranges (IQR) above the 75th percentile or below the 25th percentile of the effect size distribution. Outliers identified using this procedure were Winsorized to the next closest value. In addition, several studies used unusually large samples. Because the inverse variance weights chiefly reflect sample size, those few studies would dominate any analysis in which they were included. Therefore, the extreme tail of the sample size distribution was Winsorized using the procedure described above, and the inverse variance weights were recomputed for those effect sizes. These adjustments allowed us to retain outliers in the analysis, but with less extreme values that would not exercise undue influence on the analysis results.

In the original publications (Wilson et al. 2003; Wilson and Lipsey 2007) only one effect size from each subject sample was used in the analyses to maintain independence of the effect size estimates. When more than one was available, the effect size from the measurement source most frequently represented across all studies (e.g., teachers' reports, self-reports) was selected. We wanted to retain informant as a variable for analysis, so we did not elect to average across effect sizes from different informants; if there was more than one effect size from the same informant or source, however, their mean value was used. However, techniques for computing robust standard errors for dependent effect sizes have since been developed (Hedges et al. 2010) and are employed in the analyses reported below. Thus, when a study reported intervention effects for more than one aggressive or disruptive behavior outcome, all effect sizes were used in the analyses. Dummy codes indicating the type of aggressive behavior measured and/or the informant or source of the outcome measure were examined for their influence on the effect sizes in the analyses.

Finally, many studies provided data sufficient for calculating mean difference effect sizes on the outcome variables at the pretest. In such cases, we adjusted the posttest effect size by subtracting the pretest effect size value. This information was included in the analyses presented below to test whether there were systematic differences between effect sizes adjusted in this way and those that were not.

A small number of studies were missing data on the method, participant, or program variables used in the final analyses; missing values were imputed using an expectation-maximization (EM) algorithm in SPSS.

Analysis of the effect sizes was conducted separately for each program format (described below) and done in several stages. We first produced the random effects mean effect size for each group of effect sizes and examined the homogeneity of the effect size distributions using the Q-statistic (Hedges and Olkin 1985). Moderator analyses were then performed to identify the characteristics of the most effective programs using weighted mixed effects multiple regression with the aggressive/disruptive behavior effect size as the dependent variable. When the number of effect sizes and studies was sufficient, three models were produced in order to examine the added contribution of different sets of variables. In the first stage of these analyses, we examined the influence of study methods on the effect sizes. Influential method variables were carried forward as control variables for the next stage of analysis, which examined the relationships between student characteristics and effect size. The third stage in these analyses involved adding important treatment characteristics to the models. Because a large number of potential moderators were available from our coding manual, moderators were selected based on the size of their weighted zero-order correlations with the effect size while being mindful of collinearity among the different moderator variables. That is, if two potential moderators were highly correlated with each other and with effect size, the one with the largest correlation with effect size was selected for the meta-regression models. Random effects analysis was used throughout but, in light of the modest number of studies in some categories and the large effect size variance, statistical significance was reported at the alpha=0.10 level as well as the conventional 0.05 level.

Results

Program Format and Treatment Modality

The literature search and coding process yielded data from 283 independent study samples. Note that many studies reported results separately for different subgroups of students (most commonly, results for boys and girls were reported separately). We treated each subgroup as a separate study sample. The 283 study samples participated in a variety of prevention and intervention programs. For purposes of analyzing their effects on student aggressive/disruptive behavior, we divided the programs into four groups according to their general service format. Programs differ across these groups on a number of methodological, participant, and intervention characteristics that made it unwise to combine them in a single analysis. The four intervention formats are as follows:

- *Universal programs*. These programs are delivered in classroom settings to all the students in the classroom; that is, the children are not selected individually for treatment but, rather, receive it simply because they are in a program classroom. However, the schools with such programs are often in low socioeconomic status and/or high crime neighborhoods, and thus, the children in these universal programs may be considered at risk by virtue of their socioeconomic background or neighborhood context.
- *Pullout programs for high-risk students*. These programs are provided to students who are specifically selected to receive treatment because of conduct problems or some risk factor (typically identified by teachers for social problems or classroom disruptiveness). Most of these programs are delivered to the selected children outside of their regular classrooms (either individually or in groups), although some are used in the regular classrooms but targeted on the selected children.
- *Special schools or classes*. These programs involve special schools or classrooms that serve as the usual educational setting for the students involved. Children are placed in these special schools or classrooms because of behavioral or academic difficulties that schools do not want to address in the context of mainstream classrooms. Included in this category are special education classrooms for behavior disordered children, alternative high schools, and schools-within-schools programs.
- *Comprehensive/multimodal programs*. These programs involve multiple distinct intervention elements (e.g., a social skills program for students and parenting skills training) and/or a mix of different intervention formats. They may also involve programs for parents or capacity building for school administrators and teachers in addition to the programming provided to the students. Within the comprehensive service format, some programs are delivered universally while others are targeted toward high-risk groups. All but one of the programs in this subcategory includes services for both students and their parents.

General Study Characteristics

Nearly 90 % of the studies were conducted in the United States with over 75 % run by researchers in psychology or education. Table 1 shows additional characteristics of the studies, broken down by program format. Among universal programs, nonrandomized designs were most common. However, cluster randomization, in which schools or classrooms were randomly assigned to treatment conditions, was utilized with some

frequency for both the universal and comprehensive programs, as would be expected given how participants were typically recruited for such studies. Individual random assignment was the norm for the pullout programs and common for the special school programs, though cluster randomization and nonrandomized designs were also present for these formats. Overall, fewer than 20 % of the studies were conducted prior to 1980 and most were published in peer-reviewed journals (60 %), with the remainder reported as dissertations, theses, conference papers, and technical reports.

The student samples reflect the diversity in American schools (see Table 2). Most were comprised of a mix of boys and girls, but there were some all boy samples (19 %) and a few all girl samples (6 %). Formats targeting higher-risk children (i.e., pullout and special school programs) tended to have larger proportions of boys. Minority children were well represented with over a third of the studies having primarily minority youth; nearly 30 % of the included studies, however, did not report ethnicity information, making it difficult to examine differential program effects for different ethnic groups. Interestingly, missing information on ethnicity was more common among the special school and pullout programs, both of which tended to serve higher-risk groups of students. All school ages were included, from preschool through high school; the average age was around 9–10 for universal, pullout, and comprehensive programs and slightly older (about 13) for special school programs. A range of risk levels was also present, from generally low-risk students to those with serious behavior problems, and different risk levels were associated with the different program formats. Socioeconomic status was not widely reported, but a range of socioeconomic levels was represented among those studies for which it was reported.

Characteristics of the delivery and dosage of the programs, as well as the different program types, are shown in Table 3. Most studies were conducted as research or demonstration projects with relatively high levels of researcher involvement. Routine practice programs implemented by typical service personnel with less researcher involvement were less common. Program length varied by format, with comprehensive programs longest. Pullout and special school programs were the shortest, averaging 15 and 18 weeks, respectively. Universal programs averaged about 24 weeks. Service frequency also varied, with comprehensive and special school programs having larger proportions of daily contacts. Programs were generally delivered by teachers or the researchers themselves, though comprehensive programs tended to involve multiple types of

other delivery personnel. About 35 % of the reports mentioned some difficulties with the implementation of the program. This information, when reported, presented a great variety of relatively idiosyncratic problems, for example, attendance at sessions, dropouts from the program, turnover among delivery personnel, problems scheduling all sessions or delivering them as intended, wide variation between different program settings or providers, results from implementation fidelity measures, and the like. This necessitated use of a rather broad coding scheme in which we distinguished no problems indicated versus possible (some suggestion of difficulties but little explicit information) or definite problems with implementation.

The treatment modalities used in the four program formats varied. However, cognitive approaches and social skills training were common across all four service formats. Social cognitive strategies were cognitively oriented and focused on changing thinking patterns (e.g., hostile attributions) and developing social problem-solving skills (e.g., I Can Problem Solve; Shure and Spivack 1980). Anger management programs were also cognitively oriented but tended to focus on changing thinking patterns around anger and developing strategies for controlling angry impulses or coping with frustration (e.g., Coping Power; Lochman and Wells 2002). Social skills training focused on learning constructive behavior for interpersonal interactions, including communication skills and conflict management (Gresham and Nagle 1980). Also relatively common among the modalities were behavioral strategies that manipulated rewards and incentives (e.g., the Good Behavior Game, Dolan et al. 1993). Traditional counseling for individuals, groups, or families was also represented and tended to use a variety of therapeutic techniques (Nafpaktitis and Perlmutter 1998). The treatment coding was not mutually exclusive for any of the four program formats because many programs involved more than one

strategy. While many of the programs involved multiple program strategies, the comprehensive programs tended to have more strategies on average than the other three formats, and the selection of different components was distinctive for the comprehensive programs. The comprehensive programs tended to have multiple distinct components (e.g., a school-based cognitive component and a family-based component) and often had nonschool-based elements, while programs in the other three format categories that had multiple components tended to combine similar elements, like social cognitive and anger management components; they also tended to be solely school based.

The analyses reported below allow the 238 study samples to contribute multiple effect sizes with different characteristics, which are shown in Table 4. The aggressive behavior outcomes were grouped into six categories. Violence outcomes involved clear-cut violent behavior, including hitting. Delinquency was generally not aggressive or violent and included arrests, police contacts, and self-reported criminal behavior. Aggressive behavior outcomes were those that assessed clear physically aggressive behavior. Measures of aggressive behavior were similar to those for violence, but generally less serious. Ideally, we would have liked to examine program effects on relatively distinct groups of outcome constructs. However, very few of the measures that called themselves aggressive behavior focused solely on physically aggressive interpersonal behavior. Many included disruptiveness,

acting out, and other forms of behavior problems that are negative, but not necessarily aggressive. These measures were placed in the aggression and disruption mixed category. Externalizing measures generally involved disruptive and acting behaviors, but did not include physical aggression. Finally, the undifferentiated problem behavior category was comprised of those measures that included both internalizing and externalizing behaviors in the same score (e.g., the Child Behavior Checklist). Self-reports and teacher reports were the most common sources of information about aggressive and disruptive behavior, but observations, archival information, and parent reports were also used. Treatment effects were typically measured immediately after treatment, but some studies had longer follow-up periods. Effect sizes were generally computed directly from means and standard deviations, but other statistics were used in about 25 % of the cases. Direct computation from means and standard deviations or mathematically equivalent statistics was possible in over 80 % of the cases, and over 80 % of effect sizes had pretest effect sizes that allowed for adjustment. Attrition was moderate and averaged 10–18 % across the four program formats.

Overall Effects for School-Based Prevention Programs

The random effects weighted mean effect sizes and confidence intervals for the four program formats are shown in Table 5. The mean effect sizes for the universal, pullout, comprehensive, and special school programs are all positive and statistically significant, indicating that the participants in the school-based programs represented here had significantly lower levels of aggressive and disruptive behavior after the programs than students in comparison groups. The pullout

School-Based Interventions for Aggressive and Disruptive Behavior: A Meta-Analysis, Table 5 Random effects mean effect sizes and confidence intervals for each program format

	Mean ES	*95 %* *CI*	*n*	*k*	Q_E	τ^2
Universal programs	0.16	(0.11, 0.22)	175	89	233	0.03
Pullout programs	0.37	(0.28, 0.47)	272	128	392	0.20
Comprehensive programs	0.06	(0.02, 0.11)	72	21	40	0.01
Special Schools programs	0.13	(0.03, 0.23)	139	45	91	0.07

programs evidenced the largest mean effect size of the four groups. The comprehensive programs had the smallest mean effect size at 0.06. The homogeneity statistics for the four groups of programs suggest that there is greater variability in the distributions of effect sizes than would be expected from sampling error. This variation was expected to be associated with the nature of the interventions, students, and methods used in these studies. The next step, then, is to examine some of the method, subject, and program characteristics that may be associated with the variability in treatment effects using meta-regression models.

Results for Universal Programs

There were 89 studies of universal programs in the database, all delivered in classroom settings to entire classes of students. Many studies tested program effects on more than one relevant outcome. Thus, the universal programs contributed 175 effect size estimates to the analysis. The random effects weighted mean effect size for universal programs was 0.16 ($p < 0.05$) and the distribution of effect sizes evidenced heterogeneity. The moderator analysis focused first on the relationship between study methods and the intervention effects using random effects inverse variance weights estimated via the method of moments. As mentioned above, moderator variables were selected based on their weighted zero-order correlations with effect size. This analysis is shown as Model I in Table 6.

Neither informant nor type of outcome measure was related to the effect size, so these variables were not included in the final models. Most notable is the lack of significant relationships between the study design variables and effect size. Method of assignment, pretest adjustments and computations, and attrition were not significantly related to effect size.

Our next step was to identify student characteristics that were associated with effect size while controlling for method variables. The results of this analysis are presented as Model II in the table. Only two student variables were significantly associated with effect size: gender mix and socioeconomic status. Programs with larger proportions of boys showed larger effects from universal programming than those with larger proportions of girls. Since boys tend to be more likely to exhibit aggressive, disruptive, or acting out behavior, this result is not surprising. Students with low socioeconomic status achieved significantly greater reductions in aggressive and disruptive behavior from universal programs than middle-class students ($p < 0.10$).

Model III in Table 6 shows the addition of the program characteristics to the models. Again, moderators were selected based on their correlations with effect size. In Model III, nonrandom assignment becomes active when the program variables are included, indicating that some of the variability remaining after controlling for subject and program characteristics was associated with method of assignment. Gender mix and socioeconomic status were still influential and associated with effect size. Several other variables in this analysis were also significant. Teacher and researcher delivery of programs had a significant relationship with effect size, with programs delivered by teachers or researchers having larger effects than those delivered by other personnel. In general, the other personnel were not school affiliated and included laypeople, social workers, and counselors. Well-implemented programs showed significantly larger effect sizes than those experiencing implementation problems. Dummy codes for the most common program types were also included in the model and none of those were statistically

significant. The different program types all produced positive effects on the outcomes and were not appreciably different from each other in effectiveness.

Results for Pullout Programs for High-Risk Students

There were 128 studies of pullout programs that targeted interventions to individually identified children. These studies contributed 272 effect sizes. The overall random effects mean effect size for these programs was 0.37 ($p < 0.05$), nearly twice as large as the average effect size for universal programs. The homogeneity test of the effect sizes showed significant variability across studies, and our analysis of the relationships between effect size and methodological and substantive characteristics of the studies proceeded much the same as for the universal programs (see Table 7). First, Model I examined the influence of each method variable on the aggressive/disruptive behavior effect sizes. Here also the study design was not associated with effect size—random assignment studies did not show appreciably smaller or larger effects than nonrandomized studies. Note that for the pullout programs, the design contrast was primarily between individual-level randomization and nonrandomization; there were only 11 cluster randomized studies. The two method variables that did show significant relationships with effect size were the

**$p < 0.1$

outcome measures of undifferentiated problem behavior and attrition. Outcome measures that included both internalizing and externalizing problem behavior tended to produce larger effect sizes than the other outcomes (all more closely associated with aggressive behavior). Attrition was associated with smaller effect sizes.

Model II in Table 7 shows the addition of the subject characteristics to the analysis. One student characteristic had a significant relationship with effect size in this model. Higher-risk subjects showed larger effect sizes than lower-risk subjects though, with the pullout programs, very few low-risk children were involved. The distinction here is mainly between indicated students who are already exhibiting behavior problems and selected students who have risk factors that may lead to later problems. Nevertheless, programs with the highest-risk students tended to have larger effects.

Model III includes the characteristics of the intervention programs. In contrast to the universal programs, researchers and other non-teacher personnel as treatment delivery agents were less effective than teachers. Programs with higher-quality implementation were associated with larger effects. None of the different program types was significantly better or worse than any other.

Results for Comprehensive or Multimodal Programs

There were only 21 studies of comprehensive programs in the database, distinguished by their multiple treatment components and formats. These programs contributed 72 effect sizes indexing treatment effects on aggressive and disruptive behavior. The average number of distinct treatment components for these programs was nearly four, whereas the universal and pullout programs typically employed one or two treatment components. The studies of comprehensive programs tended to involve larger samples of students than the other program formats and a larger proportion of cluster randomizations as well. Thus, the statistical significance of the mean effect size of 0.06 is likely overstated. Comprehensive programs were generally longer than the universal and pullout programs. The modal program covered an entire school year and almost half of the programs were longer than 1 year. In contrast, the average program lengths for universal and pullout programs were 24 and 15 weeks, respectively.

Students who participated in comprehensive programs were slightly better off than students who did not, though the effect size was small. The Q has relatively low statistical power with small numbers of studies; therefore, despite the relative homogeneity in relation to the other program formats, we ran a single meta-regression model to examine the influence of some key study characteristics. This model is shown in Table 8. Because of the limited number of studies available in this category, only a few variables were tested. None of the method characteristics had correlations with effect size above 0.20 and were not tested. We also examined student risk level and found that it was not associated with effect size. Overlapping with the risk level variable was the variable we tested in the 2007 paper which compared universally delivered programs to those targeting higher-risk groups in a pullout format. Like the risk variable, this variable was not associated with effect size. Programs with implementation problems tended to have smaller effects than those without such problems, but the relationship was not significant. However, the frequency of treatment and the number of different treatment components were both associated with effect sizes. More frequent treatments produced larger effects on aggressive and disruptive behavior, while programs with more components produced smaller effects. The comprehensive programs with larger numbers of distinct components tended to be less effective than those with fewer components.

Results for Special Schools or Classes

There were 45 studies of programs delivered in special schools or classrooms. These programs generally involved an academic curriculum plus programming for social or aggressive behavior. The students typically had behavioral (and often academic) difficulties that resulted in their placement outside of mainstream classrooms. The mean aggressive/disruptive behavior effect size for these programs was 0.13 ($p < 0.05$). The Q-statistic ($Q_e = 91$) indicates that the distribution of effect sizes was heterogeneous. About 20 % of the studies of special programs assigned students to intervention and control conditions at the classroom level. As a result, there may be a design effect associated with the

clustering of students within classrooms that overstates the significance, though the overall effect size and the regression coefficients presented below should not be greatly affected.

The limited number of studies available for this program format necessitated that we examine fewer moderator variables in the meta-regression models (See Table 9). The two method characteristics with the highest weighted zero-order correlations with effect size were random assignment and delinquency outcomes. Studies employing individual randomization did not produce effect sizes that were smaller or larger than studies that did not use random assignment. When program effects were assessed on delinquency outcomes for the special school programs, effect sizes were significantly smaller than when any other outcome variable was used. Note that all of the other outcomes contained some form of aggressive, violent, or acting out/disruptive behavior, while the delinquency outcomes included arrests, police contacts, and self-reported crime.

In Model II, two subject characteristics were tested, average age and risk level. Neither age nor risk level were associated with effect size. These subject characteristics were dropped from Model III to allow us to test more different treatment characteristics. The length of the program did not have a significant relationship to effect size. In one form of the special school programs, students were assigned to special education classes or schools and the program was delivered entirely in the classroom setting. The other form involved students in special education classrooms who were pulled out of class for additional small group treatments. The programs delivered in classroom settings did not produce different effects than the pullout programs. Also, as in other analyses, better implemented programs showed larger effects. Three treatment modalities were tested in this model, anger management, social cognitive programs, and counseling. None were found to be significantly more effective than any of the other strategies.

Summary and Conclusions

The primary issue addressed in this entry is the effectiveness of programs for preventing or reducing such aggressive and disruptive behaviors as aggression, fighting, bullying, name-calling, intimidation, acting out, and disruptive behaviors occurring in school settings. The main finding is that, overall, the school-based programs that have been studied by researchers (and often developed and implemented by them as well) generally have positive effects for this purpose. A secondary purpose of this entry was to utilize new analytic techniques that allow for multiple dependent effect sizes from the same study to be included in an analysis (Hedges et al. 2010). Several differences from our original work are noteworthy. The mean effect size using the new techniques for universal programs was 0.16, while it was 0.21 in Wilson and Lipsey (2007). The mean effect size for the pullout programs was 0.37, quite a bit larger than the 0.29 published in Wilson and Lipsey (2007). It is well known that selecting a single effect size from each study is not ideal in meta-analysis; this reanalysis dramatizes how much difference such selections can make on results and conclusions.

The most common and most effective approaches are universal programs delivered to all the students in a classroom or school and pullout programs targeted for at-risk children who participate in the programs outside of their regular classrooms. The universal programs that were included in the analysis mainly used social cognitive approaches, anger management, and social skills training, and, like the original analysis, all strategies appeared about equally effective. In the 2007 meta-regression model for the universal programs, only SES was significant. The new analyses found that implementation quality and the type of delivery personnel were also important predictors of treatment effects.

Cognitively oriented approaches (both social cognitive programs and anger management) and social skills training were also the most frequent among the pullout programs, but many did use behavioral or counseling treatment modalities as well. In the original analysis, behavioral strategies were associated with larger treatment effects. However, differential use of the different modalities within the pullout format was not associated with differential effects in the new analysis. This suggests that it may be the pullout program format that is most important but does not rule out the possibility that the treatment modalities used with that format are especially effective ones. It is also possible that the larger effect size with the pullout programs was due to the generally higher-risk students participating in these programs. Higher-risk students generally achieve better outcomes from psychosocial programming than lower-risk students, so the larger effect size for the more targeted pullout programs may be partly due to the students with more serious behavior problems having greater room for improvement.

The mean effect sizes of 0.16 and 0.37 for the universal and pullout programs, respectively, represent a decrease in aggressive/disruptive behavior that is not only statistically significant but likely to be of practical significance to schools as well. Suppose, for example, that approximately 20 % of students are involved in some version of such behavior during a typical school year. This is a plausible assumption according to the *Indicators of School Crime and Safety*: *2005* which reports that 13 % of students age 12–18 were in a fight on school property, 12 % had been the targets of hate-related words, and 7 % had been bullied (DeVoe et al. 2004). Effect sizes of 0.16 and 0.37 represent reductions from a base rate prevalence of 20 % to about 14 % and 8 %, respectively, that is, 30–40 % reductions in aggressive and disruptive behavior. The programs of above average effectiveness, of course, produce even larger decreases.

The substantial similarity in effects across the different types of programs within the universal and pullout formats suggests that schools may choose from a range of such programs with some confidence that whatever they pick will be about as effective as any other choice. In the absence of evidence that one modality is significantly more effective at reducing aggressive and disruptive behavior than another, schools might benefit most by considering ease of implementation, compatibility with school culture, and teacher and administrator training and preferences when selecting programs and focusing on implementation quality once programs are in place. Our coding of implementation quality, albeit crude, was associated with larger effect sizes for all four treatment formats. A very high proportion of the studies in this meta-analysis, however, were research or demonstration projects in which the researchers had a relatively large direct influence on the service delivery. Schools adopting these programs without such engagement may have difficulty attaining comparable program fidelity, a concern reinforced by evidence of frequent weak implementation in actual practice (Gottfredson and Gottfredson 2002). The best choice of a universal or pullout program for a school, therefore, may be the one they are most confident they can implement well. In addition, for the universal programs, teachers and researchers as delivery personnel were generally more effective than nonschool personnel. Selecting programs that fit with teachers' interests, training, and existing curricula may help to keep implementation fidelity as high as possible.

Another significant factor that cut across the universal and targeted pullout programs was the relationship of student characteristics to program effects. Larger treatment effects were achieved with higher-risk students, even among the already higher-risk samples in the targeted pullout programs. For the universal programs, the greatest benefits appeared for students from economically disadvantaged backgrounds and for groups with larger proportions of boys. Universal programs did not specifically select students with individual risk factors or behavior problems, though many students were of low socioeconomic status and there were most likely some behavior problem students in the classrooms that received universal interventions. These findings reinforce the fact that a program cannot have large effects unless there is sufficient problem behavior, or risk for such behavior, to allow for significant improvement.

The programs in the category we called comprehensive, in contrast to the universal and pullout programs, were surprisingly ineffective. On the face of it, combinations of universal and pullout treatment elements and multiple intervention strategies would be expected to be at least as effective, if not more so, than less multifaceted programs. The small mean effect size for the comprehensive programs raises questions about their value. It should be noted, however, that there were few programs in this category and that most of these were long-term school-wide programs. It may be that this broad scope is associated with some dilution of the intensity and focus of the programs so that students have less engagement with them than with the programs in the universal and pullout categories. The comprehensive programs also suffered from implementation difficulties more frequently than the other formats (see Table 3), although implementation was not significantly associated with effect size in the reanalysis or in the original. However, the reanalysis found that the comprehensive programs with the largest number of treatment components were the least effective in this category, a finding that may be an indicator for implementation problems. This is an area that clearly warrants further study.

The most distinctive programs in our collection were those for students in atypical school settings. The mean effect size for these programs was modest, though statistically significant. As in the original analysis, implementation was important. The results also are somewhat anomalous. One of the signal characteristics of students in these settings is a relatively high level of behavior problems or risk for such problems; thus, there should be ample room for improvement. On the other hand, the special school settings in which they are placed can be expected to already have some programming in place to deal with such problems. The control conditions in these studies would thus reflect the effects of that practice-as-usual situation with less value added provided by additional programming of the sort examined in the studies included here. Alternatively, however, the add-on programs studied in these cases may have been weaker or less focused than those found in the pullout format, or the more serious behavior problems of students in these settings may be more resistant to change. Here too are issues that warrant further study.

A particular concern of our original meta-analysis (Wilson et al. 2003) was the smaller effects of routine practice programs in comparison to those of the more heavily represented research and demonstration programs. Routine practice programs are those implemented in a school on an ongoing routine basis and evaluated by a researcher with no direct role in developing or implementing the program. Research and demonstration programs are mounted by a researcher for research or demonstration purposes with the researcher often being the program developer and heavily involved in the implementation of the program, though somewhat less so for demonstration programs. In the present meta-analysis, somewhat more studies of routine programs were included, and it is reassuring that their mean effect sizes were not significantly smaller. The zero-order correlation between routine practice and effect sizes was only large enough to be included in the meta-regression models for the pullout programs, and it did not turn out to have a significant relationship with effect size in the model in which it was tested. However, only 35 of the 283 studies in this meta-analysis examined routine practice programs. This number dramatizes how little evidence exists about the actual effectiveness, in everyday real-world practice, of the kinds of school-based programs for aggressive/disruptive behavior represented in this review.

Notes and Acknowledgments The research reported in this entry was supported by grants from the National Institute of Mental Health, the National Institute of Justice, and the Centers for Disease Control and Prevention.

A bibliography of studies used in the meta-analysis is available from the first author.

Scientific Basis of the Forensic Process

William J. Tilstone
Centre for Forensic Science, University of Strathclyde, Glasgow, Scotland, UK

Overview

The chapter reviews the contributions to the History and Philosophy of Science (HPS) that impact on the scientific basis of the forensic process. There is a close parallel between the scientific method and the forensic process, in that each consists of hypothesis creation, testing and review based on observations and rigorous challenge. The leaders in HPS whose thoughts are most relevant are Popper, for his views on the limitations of inductive reasoning, Peirce, for introducing the concept of abduction, Kuhn for his view on "normal science" and the sociology of scientific developments, and Lakatos, for formalizing Popper's views into what he termed research programs.

Having established the scientific foundation of the forensic process, the chapter turns to how it is used to convert "science" into knowledge in the form of evidence arising from an investigation and of relevance to the determination of facts by a tribunal. The fundamental types of forensic evidence, classified by purpose, are described, leading to a taxonomy of forensic evidence based on the principles of rhetoric.

Is It Science?

There is no definition of "forensic science" that addresses the question of its scientific basis. Most definitions are constructed around the concepts of "science applied to the law" and "working carefully", but these beg more questions than they answer. Is parentage testing for immigration purposes forensic? What about dope testing of Olympic athletes, or race horses? Is investigation of environmental spills forensic? Where does pre-employment drug screening fit? And "working carefully" encompasses pilots, accountants, and surgeons, but that clearly does not make them forensic.

Adopting the approach that it is something conducted by scientists in the laboratory does not help much either. For example, aspects of a homicide investigation that could be classed as "forensic" may be conducted at the scene by personnel as diverse as those who are serving police officers and whose qualification consists of successful completion of high school together with in-service training, and by toxicologists and DNA analysts with a Ph.D. degree working in a university or private laboratory.

Not too long ago, such questions would have seemed too academic and abstract for a work on forensic science, the forensic literature was dominated by case reports and papers describing new or improved technical methods. That should never have been so and is certainly less so today. The relatively recently published report by the National Academies of Science on forensic science in the US was highly critical of forensic science in general, and aspects of crime scene-related criminalistics such as tool marks and fingerprints in particular, for not being well-founded in science. The UK too has embraced basic scientific philosophy in evaluation of forensic evidence, where proposed legislation on the admissibility of expert evidence requires that a trial judge may refuse to admit expert evidence that is based on a hypothesis which has not been subjected to scrutiny (including experimental or other testing) or has failed to stand up to scrutiny.

However, the main unanswered question, other than a superficial passing mention in the NAS report, is what exactly **is** science?

This chapter addresses these issues by first of all exploring what science really is, then defining and exploring the forensic process, and thereby demonstrating how the forensic process is indeed fundamentally a scientific endeavor, with all the advantages and limitations that arise from that. The chapter ends by addressing the question "does it matter whether or not it is based in science" and explores some consequences.

Science, Technology, and the Scientific Method

The word “science” is derived from the Latin verb *scire*, to know, and its noun *scientia*, knowledge. Although the principles of the scientific method can and have been applied to other areas including psychology and the social sciences, the accepted usage today is knowledge of the natural world. Hence the generally accepted perspective of forensic science as a source of unqualified and independent information, but the history of the scientific method and the writings of the philosophers of science tell us that science is not absolute.

The ancient Chinese and early Muslim societies contributed many discoveries and inventions relevant to natural laws, but “knowledge”, including scientific knowledge, in western societies is built on the foundations provided by the ancient Greeks and Romans. As a result, up until the early sixteenth century, philosophers formulated what they regarded as laws of nature based on the universal belief that the Earth was the center of the Universe. Thus it was “known” that the Earth was at rest in the centre of the universe. This was a natural and inevitable conclusion arising from the form of deductive logic that prevailed at the time, namely that having accepted certain propositions we can increase our knowledge by using those to predict outcomes, and so new propositions come into being.

This changed dramatically when Nicolaus Copernicus (1473–1543) decided to test the accepted knowledge by carrying out observations on the heavenly bodies to see if they behaved as predicted. They did not, and the scientific method was born.

The next century reinforced the importance of inductive logic in developing our knowledge of the natural world. Francis Bacon (1561–1626) described what is still today accepted as the essence of the scientific method, namely the cycle of observations to determine facts, followed by application of inductive reasoning to formulate a hypothesis that explains the observations, followed by further experimentation to test the hypothesis, resulting in its acceptance, refinement or rejection. Bacon’s ideas were central to the subsequent three centuries of scientific enlightenment, and stimulated interest in science as an area of study in its own right.

The core of Bacon’s scientific method is the role of the hypothesis. It is the link between observation and interpretation, and one that requires the utmost rigor in its application. Contrary to the popular expression, facts do not speak for themselves. The same observations can satisfy many interpretations, and many of the advances in what can be regarded as “scientific” are concerned with the relationship between observation, hypothesis, and interpretation. A fact is something known or proven to be true and may therefore be assumed to be the starting point or end point of the cycle, but “facts” themselves may indeed not be objective, proven, immutable entities, but may be subjective perceptions or interpretations of some consequence of a true fact.

The work of the American philosopher of science Charles Sanders Peirce (Peirce 1934) is central to the understanding of the strengths and weaknesses of the science that underpins forensic science, especially in regard to current controversies regarding contextual bias. Before Peirce, scientific enquiry was either *inductive*, that is, making inferences from a particular set of phenomena in order to predict and make propositions of more general character (empiricism), or *deductive*, that is, inferring from accepted truths and using general laws to deduce outcomes (rationalism). He introduced a third option, “abduction,” using the formulation and testing of hypotheses to explore possible explanations for a surprising event or occurrence, one in which there is no existing set of phenomena. Abduction therefore gives us an alternative entry point into the scientific method, and of course in this context criminal offences are almost always surprising events.

In practical terms the hypothesis is the scientist’s best guess of the character of phenomena that he or she is going to investigate. Intuitively, the validity or strength of any guess will be proportionate to the quality and extent of the information on which it is based. Abduction is therefore counter-intuitive but provides the most fertile although least secure mode of inference. The hypothesis, being based on a "surprise event" and lacking a foundation of pre-existing phenomena, needs to have practical implications that can be rigorously tested.

Peirce himself was aware of the limitations of abduction as well as its advantages. He expressed it thus: "Deduction proves that something must be; Induction shows that something actually is operative; Abduction merely suggests that something may be."

A functional definition of forensic science is that it is concerned with identifying objects at a crime scene that can be used to provide a credible reconstruction of the event (Tilstone et al. 2012), and induction, abduction and deduction are all essential elements of the process in deriving that reconstruction. The surprise event is the crime itself and trying to explain what happened begins with the formulation of an explanatory hypothesis, followed by its testing and refinement. However, the information available as a consequence of that one event, the crime, is an insufficient basis for the conventional inductive approach to hypothesis formulation. On the other hand abduction is an imaginative, "what if," process that enjoys exploring the unexpected, captures the intuitive actions of the crime scene investigator, and can lead to formulation of one or more credible hypothesis. Peirce established abduction as a legitimate element of the scientific method, but the imaginative beginning must be balanced by rigorous, objective, scrutiny of alternate hypotheses and testing of their validity.

How then can a hypothesis be evaluated with a view to establish whether it is a matter of fact and not just a possible explanation? The cycle of the scientific method demonstrates that science is not an absolute, but a continuous process of searching for the truth, and therefore cannot prove any hypothesis to the exclusion of everything else. Karl Popper (Popper 1970) was a key figure in the debate. He held that all observation is from a point of view, and therefore any conclusion drawn from observations will be colored consciously or sub-consciously by our existing understanding. This by the way was 40–50 years before the "discovery" of contextual bias in the forensic sciences.

Popper's critical rationalism challenged the prevailing thinking in science, which held that a theory could be verified and thus acknowledged as being true on the basis of direct observations in the natural world. At its simplest, Popper's view is that no amount of confirmation proves a theory but one reliable falsification disproves it.

This point was controversial in that the prevailing theory of science preceding Popper was one that relied on empirical observation as the basis of drawing scientific conclusions. If one could make direct observations in the world which supported one's theory – then the theory was believed to be verified and thus could be acknowledged as true.

Popper used a simple example to illustrate his disagreement. Everyone in Europe and North America knew that all swans were white, but the exploration of Australasia was accompanied by the discovery of black swans, thereby challenging the accepted situation and leading to refinement of the properties that define "swan." Using this and other examples, Popper successfully argued that using observation to verify a theory does not necessarily result in secure knowledge or empirical truth. He proposed that seeking to falsify theories rather than verify them was a much more reliable way in which to produce knowledge that could be trusted.

Falsification is a simple and powerful tool for testing scientific hypotheses. Sadly it is one that seems to have been beyond the wit of the then US Supreme Court Chief Justice, at the time of the Court's decision in Daubert –v- Merrel Dow. It is itself not absolute, however, and apparent falsifications have to be subject to the same scrutiny as any other element of a hypothesis. Observations may produce information that apparently falsifies a hypothesis, but further testing may provide an explanation that maintains the integrity of the law. Such was the case with the discovery of the planet Neptune. The development of better telescopes led to the observation that the orbit of the planet Uranus was not as predicted by Newton's laws. Rather than reject Newton's laws which had stood the test of time, astronomers searched for an explanation, the most likely of which was the presence of a hitherto undiscovered planet. And so it turned out when Neptune was observed in 1846, in exactly the predicted place.

These examples – the black swans and the discovery of Neptune – show that an essential element of a good theory is its ability to predict something or even better forbid it, and this is as true for the specific application of science in forensic investigations as it is for science in general.

Mention was made above of how Popper's falsification challenged the status quo of the scientific method at the time. This leads to an alternate approach to defining science, by focusing on the behaviors of scientists rather than seeking an explanation of "science" based on the methods used or framework within which they work.

This was the approach taken by Thomas Kuhn (Kuhn 1966) who argued that scientists work within a conceptual paradigm that strongly influences the way in which they see data. Kuhn was interested in the way that science advances, and differentiated between what he called normal science, which progresses incrementally, little by little, and revolutionary science, where no change occurs until there is overwhelming evidence to overcome the prevailing paradigm which is then cast aside and replaced by the new.

In conducting his research Kuhn had to grapple with the essential question of what "science" is in order to be able to discuss how changes come about in scientific theories. He concluded that it is defined by communities of practitioners sharing properties related to the manner in which they conduct the exploration of knowledge about some aspect of the physical world. It is the existence of these communities and their established norms that make the paradigm such a strong force, inevitably resulting in conservatism.

Imre Lakatos is the last of the scientific philosophers to be considered here, but by no means the least, certainly in considering the foundation principles of forensic science. Lakatos was concerned that a strict and unthinking interpretation of Popper's falsification concept meant a hypothesis would be rejected, but its core usefulness might still be valid but lost (Lakatos 1970). Any apparent falsification should not be accepted without question, but may instead point the way to further refinement and improvement of the apparently false hypothesis.

To remedy what he saw as a problem with Popper's theory Lakatos introduced the concept of "research programmes" as a solution. A research programme is the aggregate of several theories which share a core and that progress using a common set of methodologies. In Lakatos' approach, a scientist works within a "research program" that corresponds roughly with Kuhn's "paradigm." Whereas Popper rejected the use of ad hoc hypotheses as unscientific, Lakatos accepted their place in the development of new theories, as of course did Peirce.

The main contribution to forensic science made by Lakatos is his insistence on incorporating the concept of *ceteris paribus* into the evaluation of a hypothesis. Translated as "other things being equal," *ceteris paribus* provides a context in which the formulation of a hypothesis and its acceptance, rejection, or modification depend on the state of our knowledge at the time. Its significance can be summarized as "We don't know what we don't know" and future discoveries – either new and unsuspected information like black swans or apparent contradictions to a well-established theory like Newton's law – can alter the interpretation of observations.

In summary, a single exact definition of science has eluded philosophers of science, but whether it is defined in terms of the scientific method or the behaviors of scientists, one thing is certain: science is not absolute. At any given time the apparent facts revealed by observations and their interpretation are limited by many factors: the limitations imposed by the state of technology (the quality of telescopes, the ability to travel to the opposite side of the Earth); the influence of the paradigms within which scientists work (the behavioral norms of each sect within science); the danger of seeking to confirm rather than challenge; and the impossibility of dealing with things unknown – "we don't know what we don't know" but seldom qualify (or are allowed to qualify) judgment with an admission of *ceteris paribus*.

From Science to Knowledge to Evidence

Recognizing that science is not absolute is not the same as saying science is junk, to use a term currently in vogue among the detractors of forensic science. Bacon was a champion of science as a tool for the betterment of humankind, and our lives today are shaped by it, from the trivia of the entertainment industry, to the very practical and significant advances in medicine, and the seemingly arcane activities associated with increasing our understanding of the natural world, such as the Large Hadron Collider. In the criminal justice system, the value of science is that it provides evidence that is indisputably more reliable than eye-witness testimony and that provides significant information not otherwise available to the triers of fact. For example, the Innocence Project in the United States (Innocence Project 2011) has identified eye witness misidentification as a leading factor in 75 % of the wrongful conviction cases that it has successfully pursued.

The place of forensic science within the justice system is described by Hald, in the entry on "The Philosophical Basis of the Forensic Process," and the section that follows is to some degree complementary to her paper, as it demonstrates how applying the scientific method to the investigation of crimes produces knowledge that is expressed as evidence for the legal tribunal.

An understanding of the scientific method, and to an extent, how it can produce the knowledge inherent in forensic science, permits an analysis of the purpose of the forensic process, evidence. Although dictionaries define "evidence" in a legal context as something submitted to a court to assist it in arriving at a decision, crime laboratories in the US also use "evidence" synonymously with "exhibit," namely a physical entity recovered from a crime scene. This chapter avoids that usage, preferring the sequence that an exhibit is something presented before a court, the examination of which has produced evidence that may assist the tribunal in its determinations.

Types of Forensic Evidence

The legal process distinguishes between real and testimonial evidence, which are respectively evidence resulting from the examination of exhibits and evidence resulting from the direct narrative of a witness as to what he or she has done or observed. Real evidence can be further classified according to the use to which it is put, namely inceptive, exclusionary, corroborative, or associative.

Inceptive evidence is evidence that indicates a crime has been committed. Straightforward examples include detection of accelerant traces at a fire scene and identification of cocaine in someone's possession. Less straightforward is the finding of semen in samples taken from the vagina of a woman who states that she has been raped, as the evidence speaks to intercourse and not to absence of consent – perhaps a good instance around which to discuss the application of *ceteris paribus* to forensic science. Identifying semen in intimate samples from the alleged victim, and DNA profiling to link the semen to the alleged assailant is the first and core part of the forensic science investigation of a rape. But is it possible to have rape without semen – the use of a condom, or penetration without ejaculation for example, and possible to have semen identified as being from the suspect but without rape – if the court accepts that the intercourse was consensual or that the semen was from a different act of intercourse that occurred some time before the act of rape.

Exclusionary evidence is to identity in forensic science as falsification is to hypothesis testing in science in general. There are many techniques available that speak to individual identity: fingerprints; DNA profiles; facial recognition; acquired characteristics such as tattoos, restorative dentistry, and skeletal fractures; and voice. These may be ranked in ascending order of how well they approach the critical test of knowing the identity of someone: voice, facial recognition, acquired characteristics, DNA, and fingerprints. There is a continuum from transient and variable voice, through subjective facial recognition (although computer programs are changing this), to acquired characteristics which may not be individual and unique, to DNA and fingerprints. Even the DNA and fingerprinting may fall short of what could be accepted as indisputable knowledge. The DNA profile maybe partial, and the latent print may be limited in its data content. Even if they are both complete there is considerable debate at present as to the uniqueness of any individual fingerprint, with little information on population frequencies, and in regard to even the extremely rare DNA profiles, some statisticians will argue that if there is a finite probability of something happening then sooner or later, it will (Gettinby 2012).

And of course "we don't know what we don't know" – how were the fingerprint or biological fluid rendering the DNA profile deposited? It therefore may be more scientifically sound to follow Popper and to say that if there are differences in DNA profiles or fingerprints, then can safely be concluded that this excludes a given individual as being the source, and if none are observed, then the conclusion is that the target person or object cannot be excluded as being the source.

Some of the most compelling examples of exclusionary evidence have come from the Innocence Project (2011) in the United States. As of March 2011, there have been 267 post-conviction exonerations in the US arising from the application of DNA testing, the first being in 1989. The true suspects or perpetrators were identified in 117 of the cases.

Corroborative evidence is what remains when there is no exclusion. Corroborative evidence is very similar to *associative evidence*, which seeks to establish the relationship between things – people with other people, people with places, and objects with other objects. Hairs, fibers, paint glass, soil, some examples of impression evidence, are all examples of areas of forensic science that have traditionally contributed to corroborative evidence. They are also areas that are being encountered less and less frequently because of the difficulty of attaching a weight to them, due to the absence of databases to provide reliable frequencies of the different kinds of corroborative evidence in the population.

The difference between exclusionary evidence and corroborative evidence is mirrored in another way of looking at some forensic evidence, namely identification and class characteristics. Everyday language uses identity and its derivative "identification" to mean "uniqueness" and the act of "assigning a unique identity" to something or someone. This usage does not correspond however to that found in forensic science, which distinguishes between "identification" and "individualization" thus: identification means that items share a common source or possess the same properties, and individualization means coming from a unique source.

The Latin roots of the two clarify the difference: the root of identify (identification) is *idem*, which means "the same" whereas the root of individualize is *individus* meaning "not divisible." However, the distinction is not absolute and just when "same" becomes "unique" can be unclear. For example the mechanisms used to fire a bullet and to extract the spent cartridge case from a gun impart markings on the case; imperfections left on the lands of the gun barrel during manufacture and the relationship of the lands to the grooves can be used to associate spent bullet cases and recovered projectiles with the weapon that fired the round. Some of these such as the number of lands and grooves and their twist are characteristic of all examples of a particular model of gun. Others such as the imperfections created by tools when machining the barrel will be specific to an individual gun of that model. However, wear and tear and further imperfections created by dirt in the barrel mean that the features specific to a particular gun will change in the course of time.

It may be of value to refer back to some of the classic scientific activities of the nineteenth and early twentieth centuries, where some of the advances in science were related to classifications within the natural world, that is, with taxonomy. The taxonomy of forensic science can be reduced to two levels: What? and Which or Who? The question "what is this" together with the question of "who is this" (which one of all of the higher taxonomic level) can be simplified into just one – identity. The answer to the WHAT question will be the correct identification of something as being *one of a specified group* of things and the answer to the WHO (or which) question will be the correct identification of a *unique member* within that group.

This differentiation can be illustrated by returning to Popper and his swans. If there is sufficient agreed information to define what a swan is – the highest forensic taxonomic level – then it is possible to test the hypothesis of whether or not something is a swan.

Popper's example uses one property of "swanness," color. Note that Popper does not argue that all white birds are swans, but rather that one of the properties of being a swan is to possess white plumage. If the proposition is extended to be "a large waterbird with a long flexible neck, short legs, webbed feet, a broad bill, and all-white plumage" the finding of a bird with all but one of these would have three possible outcomes: the bird would be classified as other than a swan; the bird could be classified as a new species within the Cygnus (swan) genus; or the variant would be dismissed as an anomaly.

The second taxonomic level is to identify which swan – no two will be identical (birds don't have identical twins), and to do this requires information beyond the core properties. The conclusions are contextual and depend on the question being posed. If the question is "WHAT" is this, then the object is a swan if it possesses the agreed core properties. If the question is akin to "WHO" is this, which swan, then something other than the core properties is required to confirm its individual identity. How much more is one of the major issues in forensic science.

This approach makes it apparent that the question of identity is a matter of graduation on a continuum between identification of class to unique individualization. Between these two points there are an infinite number of degrees of identification, and many opportunities for these to vary with time.

As an example, a tire - print is located in the snow at a scene in northern Denmark. A cast is made and the size and general brand of the tire determined. The tread pattern shows uneven wear and an area of damage, probably a cut. Some months later investigators identify a suspect whose car has tires of the same make, and one of which has similar wear and damage patterns. However, because of the amount of driving in the time interval and the problems of capturing fine detail in marks made in snow, there will be differences, at the same time as areas of correspondence between the tire and the print. It is therefore not always possible to conclude that the suspect car is the vehicle involved in the incident, but neither can it be concluded that it is not. This is an example of corroborative evidence that is positioned at an intermediate point in the continuum from what to who.

The above discussion leads to the conclusion that the characteristics of good forensic evidence are:

- It should be stable and not change with time.
- It should have well defined core attributes and known population statistics.
- The basis of variations in non-core attributes should be known and scientifically justifiable.

The above discusses the examination of exhibits in the context of the goal of identifying, usually as "WHAT" or "WHO." There is another framework that is widely used in practice, namely the Locard Exchange Principle and the use of comparison testing. The Locard exchange principle, summarized "as every contact leaves a trace", is the foundation of traditional associated evidence based on microscopy. The concept is simple and can be illustrated as follows: Mr. A met Miss B in a bar one evening: they knew each other slightly because Mr. A was a friend of a distant relative of hers. The conversation was amicable and Miss B had no problem with accepting Mr. A's offer to escort her home when the bar closed. The next morning Miss B's body was found in a river that ran through the park that was on the way between the bar and her home. She had been strangled and raped. This happened some years before the introduction of DNA testing and although blood grouping on the semen from her vagina showed it to be the same as Mr. A's, it was a group O which is found in 50 % of the population. Mr. A was detained on suspicion and his clothing examined microscopically along with that of Miss B. Fibers found on her coat could have come from the jacket of Mr. A and fibers found on Mr. A's underpants could have come from the skirt worn by Miss B.

This two-way exchange of fibers is exactly what is entailed by the Locard exchange principle. In considering the weight to be attached to the findings the exchange from the outer clothing is of very little significance given the known and admitted social contact in the bar. However the exchange between the skirt and the underpants is an entirely different matter.

This simple and to some extent simplistic example is taken from a real case in which the author was involved. The complexities of the Locard exchange principle and the reason why it is now not so significant in most laboratory investigations, relate to the dynamics of fiber exchange, loss, and redistribution, to the difficulty of attaching an objective meaning to the relatively few possibly transferred fibers recovered compared to the many orders of magnitude more present from the background population, and to the lack of sound databases regarding the frequencies of the types of fibers encountered.

The question was posed earlier of how much information is required in regard to the move of identity from "WHAT," or class, to "WHO," or individualization. The same issue of how much is enough applies to comparison testing. However, the fundamental aspect of individualization is that the core properties that define "WHAT" are known and if they are not present then the person or thing is not a member of the class of interest. Comparison testing does not hinge around these core properties, and professional judgment has to be employed to decide if two items could have come from the same source. This is a major shortcoming in comparative identity.

Beyond What and Who: The Science Behind the Forensic Process

The European Network of Forensic Science Institutes (ENFSI 2002) has defined the Forensic Process by means of a set of standards covering activities from the time of the initial actions at the scene to reporting the results of the investigation and testifying in court. They are:

(a) Undertaking initial actions at the scene of crime
(b) Developing a scene of crime investigation strategy
(c) Undertaking of scene of crime investigation
(d) Assessment of scene of crime findings and considering further examination
(e) Interpreting and reporting findings from the scene of crime
(f) Laboratory examination, testing and presumptive testing
(g) Interpretation of the result of examinations and tests
(h) Reporting from examinations and tests including interpretation of results

The standards involve planning, identifying and preserving potential exhibits, conducting tests, and, at (e) and (g), evaluation and interpretation of what has been done. Considering whether or not these are scientific activities, requires consideration of parts of the section discussing what science is. As discussed by Hald, even though they followed the highly deductive and anthropocentric model of advancing knowledge based on a foundation of accepted societal beliefs, the ancient Greeks and Romans developed the skills of rhetoric to the point at which logic, evidence and argument became refined and effective tools for decision-making. The integral process, due to the Greek rhetorician Hermagoras but described in Latin by St Augustine, is building the argument round the questions *quis, quid, quando, ubi, cur, quem ad modum, quibus adminiculis* (who, what, when, where, why, how, in what way and by what means/which aids). These are questions that cannot be answered "Yes" or "No" but demand that explanations based on evidence be given.

Lying at the opposite end of the time frame from the ancients, Thomas Kuhn's concept that science can be defined as something that scientists do provides a link between social behavior, facts, and rhetoric. Accepting that there is indeed an activity called "forensic science" and that it is conducted by crime scene examiners and chemists and biologists working in places called "forensic laboratories" (and the equivalents of these in the several other subgroups of forensic science described in the introduction), then what happens in forensic science can be measured against the requirements of the scientific method, and the evidence-based objectivity of Hermagoras' questions, or, simply "The 6 Ws":

- WHAT has happened
- WHERE did it take place
- HOW did it happen
- WHO was involved
- WHEN did it happen – at what time and in what sequence
- WHY did it happen

The principle underlying the maxim is that each question should elicit a factual answer. What is important is that none of these questions can be answered with a simple "yes" or "no." They therefore present the incident as a problem to be solved. Solving the problem by providing factual answers to each dimension – each question – is the purpose of investigative inquiry.

The 6Ws define a process (of inquiry) to be used within a process (the ENFSI forensic process), and can be related back to the discussion on the types of evidence that forensic science can furnish. The examples below are from scene examination, because this is the place where Peirce's surprising event begins, and abduction is a necessary part of the process. However, the same principles apply in all stages of the forensic process.

Inceptive evidence was discussed in relation to information regarding specific crimes (arson and drug possession). The first of the 6Ws – What? – is a broader exposition of inceptive evidence. Was a crime committed or not, and if so, was it planned or accidental? In many cases this may appear to be a trivial matter – a body concealed in a shallow grave, with a gunshot wound to the temple. Or a husband calls, pretty agitated. His wife has fallen from the fourth floor window. Ambulance and police are dispatched to the scene and find her lying dead on the footpath, wearing underwear, socks, pants, sweater and rubber gloves of the type normally used for household cleaning activities. She had several injuries that could have been due the fall from the window.

Applying *ceteris paribus* to these cases suggests that the first demands to be treated as murder and the second as accident. But "we don't know what we don't know," and have to challenge the hypotheses. In the apparent murder, the questions of how did the body get there, who else was involved, and why all had to be pursued and led to the discovery that it was a case of suicide and concealment of the body. The murder hypothesis was falsified by exclusionary evidence, when it was shown that the blood patterns and bullet trajectory at the scene where the shooting occurred – not where the body was found – could only have arisen from a self inflicted shot. The accident hypothesis in the other case was firstly challenged by finding blood inside of the gloves – a surprising event – that led to the discovery of widespread residues of blood in the shower in the house, providing corroborative evidence to the conclusion of murder and not accident. The woman had been bludgeoned to death by her husband.

The murder/suicide case also demonstrates one aspect of the second of the 6Ws – Where? Knowledge of where the incident took place is essential in any investigation. It establishes the boundaries within which to search for evidence and can lead to other layers of interest, for example to the primary scene in the first case above.

The 6 W question of "How did it happen" is both obvious and hidden in the murder case, obviously by a fatal gun shot but hidden that it was self-inflicted. The case of the fallen wife illustrates a different aspect of "How" since the injuries themselves could be explained by the fall, and it was the additional information from the blood inside in the glove – exclusionary or falsifying information in regard to the accident hypothesis – that led to the correct conclusion.

"Why" is the most intangible of the 6Ws. It is perhaps less valuable in recreating events than in bringing a sensible closure to a case. In the suicide/concealment case, the deceased shared a house with others who like him were illegal migrants. His friends found him dead when they returned from work and feared the consequences of reporting the death, hence the concealment of the body.

If It Is Science, Does It Matter?

The development of a sustainable description of what science is – the scientific method and its modern refinements – together with the rigorous scrutiny of the steps in the forensic process using the ancient tool of rhetoric transcribed into the 6Ws, establishes forensic science as being a well-grounded scientific discipline. The question was not properly addressed in the NAS report but set aside in favor of a discourse on methodologies and statistical interpretations. Unlike the NAS committee, the US Supreme Court did try to come to terms with "science" in Daubert –v-Merrel Dow, as did others. However, both made the mistake of assuming that "scientific" somehow meant "reliable and absolute."

This paper is about the scientific basis of forensic science. The first part shows how science is not absolute but is ever-evolving and contextual. Lakatos remains the thought leader in both areas. The limitations that *ceteris paribus* places on the formulation and evaluation of hypotheses have been described, but Lakatos was also a strong proponent that taking a broader view of Popper's ideas of falsification is a vital part of the advancement of science. He created the concept of research programs to describe how exploration of real and apparent falsifications strengthen by providing a framework for the continuous iteration of ideas and refinement of knowledge. And so it should be with forensic science, the formulation of a hypothesis and its challenge, and the understanding that falsification of the initial hypothesis is not an end but a beginning, as new testing and a new examination of the existing information leads to a better hypothesis that perhaps approaches knowledge.

However, two vital parts of the work of the forensic scientist are the reliability of the testing methods and the validity of conclusions drawn from observations and tests. These have nothing to do with science any more than the quality of the prosecution or defense in a trial have. Quality assurance in chemical, biological and physical testing is a well-worked topic (Tilstone 2012), not covered here, but are dealt with in the NAS report somewhat (but not entirely) better than it dealt with science.

A more subtle issue is that of confirmation bias. It has long been a tenet of forensic science that findings based on observation, that is, findings that are subjective, must be confirmed by an independent observer to add a degree of objectivity. The matter of objectivity has been dealt with as an element in quality assurance, by the definition of "Objective test" and a description of how to ensure objectivity in the guidance document for forensic accreditation (ILAC 2002), but recent work shows that the confirmation itself can be subjective, and systems approaches have been proposed to overcome the problem (NIST 2012). Aside from subjectivity and the breakdown (or lack of implementation) of quality assurance procedures, bias is an inevitable consequence of an inductive approach based on asking a question that can be answered "Yes" or "No" and a rigorous implementation of the 6Ws together with effective quality assurance and a more systems approach to observer-dependent testing should resolve the problem.

Scientific Evidence Before International Criminal Tribunals

Melanie Klinkner
Business School, Bournemouth University,
Bournemouth, Dorset, UK

Overview

Over the past decades, a number of international tribunals and courts have been created to help bring international human rights and humanitarian law violators to justice, thus complementing the role of domestic courts. Substantive international criminal law comprises categories of crimes such as war crimes, crimes against humanity, genocide, the crime of aggression, torture, and terrorism (Zahar and Sluiter 2008). For an accused to be found guilty of any of these crimes, the alleged perpetrator must be found criminally liable either through having materially committed the crime or through their engagement in other forms of relevant criminal behavior.

International criminal prosecutions are often exceedingly complex, as evidenced by the overambitious prosecution approach taken in the case of former Serbian President Slobodan Milošević who was charged with over 7,500 crimes committed during three wars spanning 8 years. Expert witness testimonies can be paramount in providing specialist knowledge and contextual information. In international criminal trials, as in domestic English proceedings (??x-ref Roberts), expert witnesses "are normally allowed to testify on issues about which the judges themselves, based on their personal knowledge and experience, cannot be expected to reach an opinion alone" (Schabas 2006: 480). As the extensive experience of the International Criminal Tribunal for the Former Yugoslavia (ICTY) demonstrates, scientific expertise, especially relating to mass grave evidence, has been used successfully to prosecute the categories of crimes falling under its jurisdiction, and it is fair to assume that for future international criminal proceedings, the use of expert witnesses will continue to be imperative.

There are two aspects in particular that distinguish the presentation of expert evidence before international criminal tribunals from domestic proceedings. Firstly, investigations crucially rely on state cooperation, since international criminal institutions have no enforcement agency of their own (Del Ponte 2006). A delay in investigations can mean that much of the evidence, especially physical evidence, has vanished or deteriorated in condition (McGrath 2002). Witness testimony can be lost through death, intimidation, murder, or flight from an ongoing war zone, and access to war-torn countries can be both dangerous and difficult if international and domestic support is not forthcoming. Secondly, and more relevant to the discussion here, the mixed procedural model containing civil law and common law traditions produces a unique blend with few provisions relating to evidence presentation, creating a novel – and, to some, controversial (Murphy 2008) – environment for presenting and evaluating expert evidence. The following discussion provides an overview of the rules governing expert evidence presentation at both the ICTY and the International Criminal Court, before turning to consider how scientific expertise has assisted the ICTY in its fact-finding.

Expert Evidence Provisions at the ICTY and the ICC

Informed by the development of evidentiary rules, proceedings, and jurisprudence from previous international criminal tribunals, the ICC adopts a flexible approach to the admissibility of evidence. Article 69 of the Rome Statute states that "[t]he Court shall have the authority to request the submission of all evidence that it considers necessary for the determination of the truth" (Rome Statute, Art 69.3). The court adopts the affirmative, as opposed to exclusionary, method of evidence admission, taking into account in particular the probative value of the evidence and whether it is prejudicial to fair trial requirements (Rome Statute, Art 69.4).

Likewise, the ICTY's procedural law does "not contain a detailed set of technical rules" (*Prosecutor* v *Delalić* 1998: [15]). Rule 89 of the ICTY's Rules of Procedure and Evidence (RPE) states that evidence is admissible if it is relevant, of probative value, not to the detriment of a fair trial and not otherwise excluded as being obtained through methods that would be detrimental to its reliability or might damage the integrity of the proceedings (ICTY RPE, Rule 95). While the Trial Chambers may thus be inclined to admit scientific evidence, it does not follow that expert evidence will be afforded much, if any, weight in the court's deliberations. In fact, at the ICTY it has been decided that initial admissibility rulings may be reversed at later stages in the proceedings, as and when further information relating to the validity or reliability of evidence becomes available (*Prosecutor* v *Orić* 2004).

Expert Witness Status

To the dismay of some (Derham and Derham 2010), neither the ICC nor the ICTY has specifically defined "expert witness." The ICTY Trial Chamber in *Popović* described an expert witness as someone who possesses the relevant specific knowledge, experience, or skills to help the Trial Chamber come to a better understanding and conclusion on a technical issue (*Popović* 2007a). The qualifications of an expert, summarized in the expert's curriculum vitae submitted to the court, authorize the expert – unlike an ordinary witness of fact – to state opinions, inferences, and conclusions on matters within the realm of her expertise.

At the ICC, pursuant to Regulation 44(1), the registry holds a list of experts whose qualifications have been verified and "have undertaken to uphold the interests of justice" (*Prosecutor* v *Dyilo* 2007a: [24]). Where possible, the parties are expected to rely on this list for expert instructions. To facilitate efficient trial management, joint instructions (including by victim representatives) of expert witnesses are preferred.

While qualifications are regarded as formal prerequisites for a witness to qualify as an expert, objectivity and independence are not. Rather, “the questions of objectivity, impartiality and independence become relevant to assess the weight to be accorded to that opinion evidence” (*Prosecutor* v *Popović* 2007a: [26]). Affiliation with a party, which has been commonplace in relation to ICTY investigations, does not in itself constitute grounds for disqualification. Indeed, scientific experts were routinely employed by the ICTY’s Office of the Prosecutor, and without this arrangement, little scientific expertise or original physical evidence would have been available to the ICTY. The joint instruction procedure at the ICC should serve to ameliorate perceptions of witness bias, as the opposing parties will be bound to rely on the same expert. Neither the ICTY nor the ICC have Codes of Practice for expert witnesses, but one would expect any scientific expert to be independent and to act in good faith.

Pretrial Chamber and Expert Reports

Standard practice at the ICTY is to tender and admit expert reports through Rule 94 *bis* on the testimony of expert witnesses, which provides a timetable for disclosure and other preliminaries (*Prosecutor* v *Blagojević* 2003: [20]). At this stage, the opposing party is required to indicate whether it intends to accept the expert witness statement, desires to cross-examine the expert witness, disputes her qualifications, or challenges the relevance of the witness statement. Expert evidence can be denied admissibility on three grounds. It must be excluded firstly, if it has been “obtained by methods which cast substantial doubt on its reliability” (ICTY RPE, Rule 95); secondly, if it jeopardizes the fairness of the trial (ICTY RPE, Rule 89(D)); and thirdly, evidence may be excluded pursuant to Rule 89(C) because it lacks probative value. Of these three grounds for exclusion, Rule 95 has the greatest relevance for the work of scientific experts, as it directly addresses the expert’s methods of data collection and whether, in light of the way the scientific inquiry was conducted, its results are reliable.

Provided that no objection is made by the other side, a scientific report can be admitted into evidence without hearing testimony from the expert, so long as the Trial Chamber is satisfied as to the evidence’s relevance and probative value (*Prosecutor* v *Blagojević* 2003). In *Popović*, the ICTY elaborated on the application of the general requirements of relevance and probative value to expert reports, in terms of

> (1) whether there is transparency in methods and sources used by the expert witness, including the established or assumed facts on which the expert witness relied; (2) whether the report is reliable: and (3) whether the contents of the report falls [sic] within the accepted expertise of the witness. (*Prosecutor* v *Popović* 2007a: [30])

Qualification as an expert does not automatically guarantee the admissibility of the expert’s report. The burden lies on the party tendering the evidence to convince the tribunal that it satisfies Rule 89(C).

At the ICC too, the Trial Chamber has an important role to play regarding expert witnesses. A chamber not only can instruct an expert proprio motu (ICC Regulations of the Court, Reg. 44.4.), but the chamber can also determine the subject of an expert report, number of experts in the case, the way experts are instructed, and how they are to present evidence and within what time limits (Reg. 44.5). In *Prosecutor v Jean-Pierre Bemba Gombo*, the ICC Pretrial Chamber issued detailed instructions for the disclosure of all evidence, to ensure that the defendant receives the evidence to be disclosed by the prosecutor (ICC RPE, Rules 76 and 77) and has adequate time and facilities to prepare a defense. Only evidence that is of true relevance to the case should be disclosed. In addition, the prosecutor must supply “sufficiently detailed legal analysis relating the alleged facts with the constituent elements corresponding to each crime charged” (*Prosecutor* v *Gombo* 2008: [66]). This general requirement naturally applies to scientific evidence. Pages and paragraphs of expert reports or testimonies as well as photographs, physical evidence, and maps must be analyzed in the same way, contributing to a summary table of evidence. The Trial Chamber ultimately rules on the admissibility and relevance of evidence, including scientific evidence.

Admissibility of Summary Reports and Transcript Testimony

The ICTY Rules of Procedure and Evidence contain provisions to facilitate expeditious presentation of complex scientific evidence. Rule 92 *bis* RPE authorized, for example, the presentation of summary reports by investigators in relation to mass grave excavations and examinations. These summary reports are compilations, derived from multiple sources, containing background evidence of the forensic examinations, contextualizing and reducing the complexity of the findings (e.g., Manning 2000). While summary reports can save precious trial time, they may be challenged as hearsay evidence, which is generally admissible in international criminal proceedings but may be accorded little probative value (*Prosecutor* v *Milošević* 2002: [2](i)–(ii)). That said, investigator Manning's report on physical evidence recovered from Srebrenica execution points and mass graves used in *Krstić* was subsequently also found to be "highly relevant to the case and admissible under Rule 89" in *Prosecutor* v *Blagojević* (2003: [30]).

Similarly, Rule 92 *bis* (D) authorizes the admission of trial transcripts of evidence previously given by a witness, including expert witnesses, provided the evidence does not relate to the acts and conduct of the accused. In *Blagojević* statements and transcript testimony of numerous experts relating to mass grave, investigations were admitted in this way. The Trial Chamber was satisfied that the transcript testimonies submitted under Rule 92 *bis* (D), along with the expert reports received pursuant to Rule 94 *bis*, were relevant, probative, and together provided "a complete picture of the expert evidence" (*Prosecutor* v *Blagojević* 2003: [35]).

At the ICC, Article 69.2 of the Rome Statute and Rule 68 RPE govern the use of recorded testimony, including transcripts or other documented evidence as long as the measure is not "prejudicial to or inconsistent with the rights of the accused" (Rome Statute, Art 69.2). Where the witness is not present before the Trial Chamber, both the prosecutor and the defense must have had an earlier opportunity to examine the witness. Where the witness has consented for the materials to be used and is present before the chamber, the prosecutor, the defense, and the chamber must have the opportunity to examine the witness during the proceedings if they so wish.

Expert Witness Proofing

At the ICTY, prior to giving evidence in court, experts may review their testimony with the party calling them. Lawyers and expert witnesses may discuss the relevance of the scientific evidence to eliminate any misunderstandings. Such "proofing" may assure the expert witness as to their role in court, help recollect important elements of the evidence, and assist the lawyer in using the evidence effectively. While "rehearsing, practicing, or coaching" is not permitted, it was held that "reviewing a witness' evidence prior to testimony is a permissible practice under the law of the Tribunal and, moreover, does not per se prejudice the rights of the Accused" (*Proecutor* v *Milutinović* 2006: [22]).

In contrast, the ICC's Victims and Witnesses Unit (VWU) is considered the most appropriate organ of the court to help witnesses become familiar with the experience of giving evidence. The VWU is tasked, firstly, with reminding the witness to tell the truth; secondly, to provide the witness with a copy of their original statement as a memory prompt; and thirdly, to obtain copies of any other statements made by the witness and to ensure that witnesses do not discuss their evidence with the parties. In fact, the Trial Chamber in *Dyilo* emphasized that "the ICC Statute and Rules do not expressly provide for the possibility of parties preparing witnesses for testimony, and further finds no provision in the texts to justify the practice" (*Prosecutor* v *Dyilo* 2007b: [36]). This was in marked contrast to the ICTY's more relaxed approach to witness proofing.

However, in a January 2013 decision on witness preparation, Trial Chamber V ruled differently, suggesting that the silence of the Statute does not automatically imply that witness preparation is forbidden. The judges found that witness preparation is likely to "enhance the efficiency, fairness and expeditiousness of the present trial" (*Prosecutor v Ruto and Sang* 2013: [35]).

Testing Scientific Evidence

Fairness demands that the opposing party in an adversarial proceeding must be given the opportunity to test the evidence presented to the fact finder. This is enshrined in Art 67.1(e) of the ICC's Rome Statute giving the accused the right "to examine, or have examined, the witnesses against him or her and to obtain the attendance and examination of witnesses on his or her behalf under the same conditions as witnesses against him or her." Within the general framework of victim representation at the ICC, legal representatives for victims may also question an expert witness subject to Trial Chambers' decisions on what questions may be put to the witness.

In general, testing the reliability and credibility of scientific evidence may involve some or all of the following related issues: (a) the expert's qualifications and status as an expert, (b) the scientific methods adopted, (c) norms of practice, (d) acceptance within the scientific community and validation of methods through publications and peer review, (e) whether and how the science is produced for litigation, and (f) the novelty of the scientific evidence presented (Edmond 2000). Evaluations of expert evidence in international criminal proceedings tend to focus on professional competency, methodologies, and the credibility of the findings in context (Schabas 2006: 480). Rule 140.2(b) of the ICC's RPE specifies that both the prosecution and the defense have the right to question an expert witness about the reliability of the testimony provided, the credibility of the witness, and "other relevant matters."

The following pattern is commonly observed when expert evidence is given in court. After the solemn declaration, examination in chief begins with a discussion of the expert's education and qualifications, employment record, and relevant experience, before substantial matters relating to the scientific report are queried to demonstrate the credibility of the witness and the reliability of her evidence. This is followed by cross-examination by the opposing party and, if necessary, reexamination by the party who initially called the expert. In light of the technical nature of the evidence, the accused can request the presence of her own expert during such testimony to assist with cross-examination (*Prosecutor* v *Karadžić* 2011a). Judges at the ICTY may ask questions at any stage, while ICC judges may ask questions only before or after the witness is examined by a party. The defense has the right to be the last to examine the witness (ICC RPE, Rule 140.2(c) and (d)). Challenges to the credibility of experts have been frequent before the ICTY. Experts, such as Dr Haglund in *Prosecutor* v *Popović* (2007b), have been attacked on a personal level rather than being called upon to defend the substance of their evidence (Klinkner 2009). However, if the ICC's procedural mechanism for joint instruction of expert witnesses becomes well established, one would expect there to be little strategic incentive in trying to discredit an expert whose appointment has been agreed to by all the parties.

In terms of weighing the evidence, Sluiter and Zahar observe that "[c]ross-examination, giving evidence under oath, and the direct perception of the witness's demeanour are key factors in attaching weight to live testimony" (2008: 393). Fact finders will consider whether an expert witness appears honest, independent, and impartial, and must try to establish whether the scientific examinations were conducted according to appropriate scientific standards. Qualification as a bona fide "scientific expert" does not necessarily guarantee the quality of the work conducted in any particular case.

False Testimony and Misconduct

Like all witnesses, expert witnesses are under the obligation to tell the truth. False testimony under oath may result in an investigation, preparation of an indictment for willfully giving false testimony, and, ultimately, prosecution under Rule 91 of the ICTY's RPE or Article 70 of the Rome Statute. To convict an expert witness of false testimony or an offense against the administration of justice "requires the necessary mens rea and not a mere wrongful statement" (*Prosecutor* v *Akayesu* (1998: [140])). At both institutions, conviction may entail imprisonment or fines. Misconduct can also be charged under Article 71 of the Rome Statute, potentially resulting in interdiction by the court or a fine.

Needless to add, any of these sanctions would incidentally exact a huge reputational cost for the expert's professional standing.

Weighing Expert Evidence: Scientific Evidence from Mass Graves Before the ICTY

Experience from the ICTY demonstrates that scientific evidence, especially in relation to mass grave investigations, has been mostly uncontroversial and generally accepted. First and foremost, scientific evidence recovered from mass graves provides useful corroboration for eyewitness testimony. In Srebrenica, for example, evidence derived from execution points and graves matched accounts of the events by those lucky enough to escape. In the case of Dražen Erdemović, one of the first defendants at the ICTY, who pleaded guilty to murder as a crime against humanity, it was the accused himself who led the investigations to execution and burial sites which were not previously known to the Office of the Prosecutor (*Prosecutor* v *Erdemović* 1996: [135]). Excavations that took place at the Branjevo Military Farm revealed that there were 132 male victims in the grave, 130 of whom had died from gunshot wounds, and 83 ligatures were found in the grave. Furthermore, analysis showed that the Branjevo Military Farm mass grave had been disturbed. Individuals had been removed and placed in secondary graves (Manning 2000), indicating belated attempts at concealment.

Corroboration of evidence can assist with witness selection, especially as witnesses' memories may have faded or been affected by posttraumatic stress disorder and the passage of time. It is conceivable that some witnesses will suffer from memory loss or alteration by adding to their own painful memories details they heard from fellow sufferers, which poses challenges for the investigation. Furthermore, studies on eyewitness testimony have found that "recall of details from a violent incident was significantly worse than recall of a nonviolent incident" (Clifford and Scott 1978: 356). Contrary to the common sense assumption that most people would never forget the face of an individual who had physically confronted and threatened them, large numbers of participants in one empirical study were unable to identify the person responsible for their ordeal. This research provides "robust evidence that eyewitness memory of persons encountered during events that are personally relevant, highly stressful, and realistic in nature may be subject to substantial error" (Morgan et al. 2004: 274).

Scientific evidence in general, and forensic science in particular, helps to clarify the context surrounding the crimes and contributes towards proving what crimes were committed and how they were perpetrated.

War Crimes

Grave breaches of the Geneva Conventions (ICTY Statute, Art. 2) fall within the subject matter jurisdiction of the ICTY, while Article 3 provides the tribunal with the power to prosecute "violations of the laws or customs of war," including cruel treatment, torture, and murder. Scientific evidence can assist in confirming these charges. Findings presented in *Prosecutor* v *Mrkšić* (2007) from forensic examinations of the bodies retrieved from the Ovčara mass grave in Croatia showed that 198 were male and two were female, with an age range from 16 to 72 years. The cause of death in 188 cases was attributable to single or multiple gunshot wounds. Seven individuals were believed to have died from trauma, while the cause of death is still unknown for the remaining five victims. Postmortem examinations revealed that 86 individuals had suffered from injuries prior to their death on 20/21 November 1991. In 1997, it was possible to identify 192 of the victims buried at Ovčara. With the help of forensic science, the ICTY prosecutor had little difficulty in proving the crimes that had occurred at Vukovar. The tribunal was also satisfied that the victims who were taken from the Vukovar hospital on the morning of 20 November 1991 were at that time not taking part in hostilities and therefore could not be considered legitimate military targets.

Genocide

To constitute the crime of genocide (ICTY Statute, Art. 4), the accused must have deliberately intended to destroy a protected group in whole or part (Cassese 2008). Where direct evidence of genocidal intent is absent, the requisite intent may be inferred from the factual circumstances of the crime. Perhaps the most interesting case to date where a defendant was indicted for genocide partly on the basis of scientific evidence is *Krstić*. Radislav Krstić stood accused for his actions as Deputy Commander of the Bosnian Serb Army during the Srebrenica massacre between 10 and 19 July 1995. During the trial the prosecution called six forensic experts and two ICTY investigators to give evidence in relation to the mass grave investigations. The Trial Chamber found that the forensic evidence corroborated "important aspects of the testimony of survivors from the execution sites" (*Prosecutor* v *Krstić* 2001: [71]) and was sufficiently credible and compelling to confirm the *actus reus* of genocide.

The judges concluded that "following the take-over of Srebrenica, thousands of Bosnian Muslims were summarily executed and consigned to mass graves" (*Prosecutor* v *Krstić* 2001: [73]). The investigations suggested that most of the deceased had not been killed in combat, leading the judges to infer that some 7,000 missing persons had been executed and buried in mass graves. The Trial Chamber reasoned that the disappearance of generations of men showed an intent to physically destroy Bosnian Muslims as an ethnic group. Further indication of the intent to destroy the group, as such, was provided by a "well-established pattern" (*Prosecutor* v *Krstić* 2001: [68]) of executions. Bodies were not only concealed in mass graves, but were at a later time excavated in an attempt to hide the crimes. Expert examinations of seven secondary graves found commingled and mutilated body parts rendering identification efforts, repatriation, and appropriate burials extremely difficult, causing further distress to the survivors. The fact that all located and examined gravesites associated with the Srebrenica massacre were within the Drina Corps area of responsibility contributed to the Trial Chamber's overall belief that Krstić shared the intention to commit genocide (*Prosecutor* v *Krstić* 2001). The Trial Chamber was satisfied that Krstić had participated in the joint criminal enterprise, sharing the genocidal intent to kill Bosnian Muslims, and duly convicted him of genocide. On appeal, however, this verdict was overturned as the Appeals Chamber felt that the necessary intent to commit genocide was not proven beyond reasonable doubt.

In this case, scientific evidence helped to determine that (a) a specific group was targeted; (b) the killings and burials were systematic; (c) many civilians were amongst the dead; (d) demonstrable attempts had been made to conceal the crimes; and (e) a high level of cooperation was required to undertake such executions and burials.

The *Krstić* judgments and the forensic evidence presented during that trial have since been relevant to other Srebrenica cases, especially *Blagojević*, *Popović* et al., and *Milošević*. In December 2011, three of the forensic experts that appeared in *Krstić* gave evidence before the *Karadžić* proceedings with more experts scheduled to testify in early 2012 (*Prosecutor* v *Karadžić* 2011b).

Crimes Against Humanity

Numerous defendants have been charged with crimes against humanity (ICTY Statute, Art 5), mostly in relation to attempted "ethnic cleansing" of particular regions. In the *Popović* trial, where five of the defendants stood accused of extermination as a crime against humanity, the defense was keen to clarify whether those found in mass graves had been killed legitimately in combat or whether they were identifiable as civilians whose murder would constitute a crime against humanity. An expert witness, for example, was asked whether some victims from mass graves could have died as a result of combat as opposed to execution and whether military clothing was found on the bodies (*Prosecutor* v *Popović* 2007c). According to the expert, the evidence suggested that the dead had not been killed in combat as (a) they were not wearing military clothing; (b) the deceased were of all ages, some with physical disabilities; (c) blindfolds and ligatures were found in some graves; (d) many victims had been killed from behind by a single shot to the head; and (e) there was little indication of previous injuries consistent with combatant status. While it could not be fully excluded that some had been killed in combat, the majority of dead could not be accounted for in that way (also see *Prosecutor* v *Popović* 2007d). The Trial Chamber accepted these findings and was "satisfied with the reliability of the conclusions in relation to the cause of death reached in the Prosecution expert reports" (*Prosecutor* v *Popović* 2010: [619]).

In *Prosecutor* v *Milutinović* (2007, 2009), the accused were allegedly responsible for deportation, forcible transfer, murder (as a crime against humanity and a violation of the laws or customs of war), and persecution of Kosovo Albanians. Volume two of the judgment reviews the evidence relating to the alleged crimes, relying on much of the forensic evidence gathered from investigations conducted in Kosovo during 1999. In light of these findings, the Trial Chamber concluded that over 700 bodies originally buried throughout Kosovo during the NATO bombing campaign were secretly exhumed and transported to Serbia in an attempt to conceal them from citizens of the former Yugoslavia and from the international community (*Prosecutor* v *Milutinović* 2009). These clandestine operations led the Trial Chamber to believe "that the great majority of the corpses moved were victims of crime, as opposed to combatants or people who perished during legitimate combat activities" (*Prosecutor* v *Milutinović* 2009: [1357]). Forensic science evidence thus underpinned the Trial Chamber's conclusion that some of the deceased (who included women and children) were victims of crimes against humanity.

The Future of Scientific Evidence in International Criminal Proceedings

Critics say that the amalgam of civil law and common law approaches to the rules and procedures of evidence creates an "uncertain, obscure, and unworkable body of law that does not expedite proceedings, but offers numerous possibilities for parties to submit motions for the exclusion of evidence" (Zahar and Sluiter 2008: 394). Others contend that judicial liberality results in the admission of dubious evidence which prolongs proceedings and complicates the tasks of adjudication (Murphy 2008). A flexible approach to the reception of scientific evidence does, however, mean that judges are not required to assess scientific validity when ruling on issues of admissibility.

This uncluttered approach to determining the admissibility of expert evidence at the ICC and the ICTY in no way detracts from the critical importance such evidence may play in international criminal proceedings. In such complex cases, the probative value of scientific evidence is highly contextual. Questions of scientific methodology, of reliability, and of experts' credibility, objectivity, and impartiality are addressed on a case-by-case basis through the process of testimony in court and tested through cross-examination. It is then the judges' role to weigh the evidence presented and to arbitrate between reliable and unreliable, as well as scientifically valid and invalid, evidence. The slender body of procedural rules governing expert witness testimony reflects an implicit faith that effective communication between scientific expertise and the law is possible and that traditional legal procedures will facilitate accurate fact-finding in international criminal proceedings.

Scientific Evidence in Criminal Adjudication

John D. Jackson
School of Law, University of Nottingham,
Nottingham, UK

Overview

The different functions of science and law have long led to tensions between methods of investigation deployed within the sciences and the various methods of legal fact-finding that are deployed for determining legal disputes. These tensions become particularly acute in relation to scientific evidence in criminal adjudication. On the one hand, the courts have become increasingly reliant on scientific evidence; on the other hand, they cannot for the sake of their own legitimacy be seen to hand over the evaluation of such evidence entirely to scientists. The traditional "adversarial" and "inquisitorial" models of adjudication have each adopted different approaches towards the gathering and evaluation of scientific evidence which have come under critical scrutiny. The use of scientific evidence in "adversarial" systems would seem to have been particularly susceptible to miscarriages of justice while its use in "inquisitorial" systems has led to human rights violations. Against this background, it may be suggested that one way forward is to realign existing procedures in the direction of a participative model of criminal adjudication whereby *both* parties *and* adjudicators play a role in ensuring that scientific evidence is effectively prepared, presented, and tested.

Scientific Evidence in Criminal Adjudication

The growth in the use of expert or scientific evidence in legal disputes poses challenges to the traditional manner in which legal claims have been resolved. It is noteworthy how many issues of fact are increasingly coming within the domain of expert or scientific evidence (Redmayne 2001). This "creeping scientization of factual inquiry" (Damaška 1997: 143) has arisen as a result of science's ability to generate knowledge by means of sophisticated technical instruments well beyond the knowledge of laypersons. Equally significant has been the growth in the sciences of the mind which has led to the recognition of new forms of psychological evidence such as post-traumatic stress disorder, battered woman's syndrome, and recovered memory syndrome. Even the task of assessing the credibility of witnesses which has long been considered best left to the common sense of the lay judge or jury has been challenged by the growth of experts willing to testify on witness credibility and by such "scientific" techniques as polygraph evidence.

This increasing intrusion of scientific evidence into both civil and criminal adjudication can conjure up a somewhat apocalyptic vision of legal fact-finding processes being replaced altogether by scientists and experts. There are certainly instances where challenges have been made. Challenges to the traditional common law methods of eliciting testimony by means of examination and cross-examination were to be seen in the work of early twentieth century experimental psychologists (see Muensterberg 1908). Although, more recently, legal systems have refined their approaches towards certain kinds of witness testimony, such as the evidence of children and other vulnerable witnesses, behavioral science challenges have not prompted any fundamental review of legal procedures (Greer 1971). Indeed the need for testimony to be tested orally by means of cross-examination would seem to have gained rather than diminished in importance in criminal adjudication, not only in common law processes but in civil law processes as well – partly as a result of the human rights fairness requirement that everyone charged with a criminal offense has the right "to examine or have examined witnesses against him" (see Art. 14(2)(f) of the International Covenant on Civil and Political Rights, Art. 6(3)(d) of the European Convention on Human Rights).

This illustrates that scientific procedures or "scientific method" can never dictate how fact-finding should be conducted in the course of criminal adjudication, even though the same processes of inductive reasoning may be used to reach conclusions in both domains (Twining 1982; Jackson 1988). However dependent legal processes become on scientific evidence, fundamental differences between the scientific enterprise (the pursuit of truth) and the legal enterprise (the resolution of disputes through justice) mean that different methods are required to produce the desired results in each field, scientific discoveries, or legal verdicts. It is in the nature of the scientific endeavor constantly to seek better evidence, to be prepared to revise even the most entrenched claim in the face of unfavorable evidence (Haack 2004; and for the different values within science and law see Schuck 1993 and Goldberg 1994). This spirit of inquiry is incompatible with the constraints of legal inquiry where decisions have to be reached in the interest of finality (Redmayne 1997; Jackson 2004). As a former English Law Lord, Lord Scarman, once said, Justice cannot wait upon the truth; as the famous legal maxim goes, "justice delayed is justice denied."

This means that legal procedures cannot simply replicate scientific modes of inquiry. Irrespective of the accuracy of legal procedures, errors will inevitably occur and political decisions which may be highly contestable need to be reached as to how the risk of errors should be distributed. In criminal adjudication there is a consensus across the common law and civil law traditions that proof of guilt must be established beyond reasonable doubt (*in dubio pro reo*, as the principle is known in continental jurisdictions) which reflects a bias in favor of false negatives (acquittals of the guilty) over false positives (convictions of the innocent), although there are differences across the traditions as to how formidable the evidentiary barriers should be for prosecutors seeking to establish guilt (Damaška 1973). The need for finality, which can have profound consequences for those who are found guilty, correspondingly engenders expectations of fair and transparent procedures allowing defendants to contest the charges against them in an open forum and requiring that decisions are fully justified by an independent and impartial tribunal. Because of the "tragic choice" inherent in legal proceedings, whereby decisions need to be sufficiently appeal-proof even when they may be wrong in order to withstand continuing uncertainty (Nobles and Schiff 2000), the process of reaching decisions becomes a vital legitimizing tool in determining their social acceptability. Although different models of criminal adjudication have developed across legal systems expressing varying societal conceptions of adequate proof, there is a consensus across western countries that they must not only provide for accurate procedures but must also secure public acceptability through fair and open procedures.

The ambivalent attitudes that continue to be displayed towards science and technology suggest that it will be some time before "men and women in white coats" are trusted to replace lay decision-makers in the making of final decisions (Roberts 2008: 324). Scientific evidence needs to be carefully regulated and evaluated so that its probative benefits can be harnessed to assist the lay decision-makers who make final determinations in individual cases.

Adversarial and Inquisitorial Models of Adjudication

Comparative literature on criminal procedure and evidence has been dominated by a tendency to describe different criminal justice systems as either "adversarial" or "inquisitorial," with the term "accusatorial" often being used synonymously with "adversarial." Although these labels have enjoyed long currency, they have tended to be used as caricatures which often obscure rather than enlighten how different legal processes might be best understood. It is misleading, for example, to use the terms "accusatorial" and "adversarial" interchangeably to describe Anglo-American systems of criminal justice as the old accusatory forms of justice (characterized by spitting off the prosecutorial function from the final adjudication) have very little in common with contemporary "adversarial" trials, where accused persons are properly equipped through legal representation to contest the charges against them in an effective manner (Vogler 2005). Similarly, the term "inquisitorial" with its overtones of secret procedures dominated by authoritarian judges is hardly an apt description of the modern systems of justice to be seen on the European continent which replicate many of the "adversarial" features of Anglo-American trials.

Rather than use the terms as abbreviated descriptions of actual procedures, they have more helpfully been used as models to idealize opposing features to be found within the generality of Anglo-American and continental procedures. Although there is some difficulty in determining exactly which features should fit within the respective models, the essence of the contrast between adversarial and inquisitorial models of proof seems to boil down to this. Adversarial proceedings are organized around the notion of a dispute or contest between two sides – prosecution and defense – in a position of theoretical equality before a court which must determine the outcome, whereas inquisitorial procedures adopt the notion of an official and thorough inquiry driven by court officials. Thus, in the "contest" model, the prosecution prepares the case, brings the charge, and is responsible for presenting the evidence and proving the offense. The defendant either pleads guilty or attempts to rebut the charge by presenting evidence and arguments against the prosecution. The proceedings are presided over by a neutral adjudicator whose function is to see that the parties play by the rules of the contest but not to take an active part in the presentation of the evidence. In order to ensure that the parties play fair, there is a complex body of rules ensuring that relevant evidence is disclosed, particularly by the prosecution to the defense, in advance of the trial and that evidence is only admissible at the trial if it has sufficient probative value. In the "inquest" model court officials take center stage in the handling of the evidence. The prosecution may first decide the charge but officials of the court then have the responsibility for gathering, testing, and evaluating the evidence. A case file is built up containing all the documents relating to the proceedings and all the evidence that is gathered. This file can be consulted by the parties, but any role the prosecution and defense play in the proof process is incidental and subordinate to the court's primary function of finding the truth. The trial that follows the proof-gathering phase is largely based on material already in the file and this phase of the proceedings is also dominated by the court rather than the parties.

Although these models are considered to be a valuable heuristic tool for theorizing about different features of Anglo-American and continental processes of proof, more and more "real life" systems have been moving away from the models' classic features and (on some accounts) converging towards a "middle position" mixing features of both "adversarial" and "inquisitorial" traditions (Markesinis 1994: 30). For example, in the Swiss system, which is commonly perceived to fall within the inquest model, judicial authorities no longer take center stage in the handling of evidence. In Switzerland the investigating judge is now the prosecutor and, in common with a number of other continental systems, the position of the investigating judge has been abolished altogether. In the pre-trial process the prosecutor arranges confrontation hearings and is responsible for conducting them. There is no impartial third party present – just the prosecution and defense – and the defense has the chance to question the witnesses. Another novel feature in many "inquisitorial" systems is that the prosecution and defense may now reach an agreement over the outcome of the case, with the result that the court no longer plays any meaningful role in fact-finding at all (Weigend 2008). One distinguishing feature of common law systems, by contrast, is that for all the possibilities for plea bargaining, the trial is still generally the only forum where evidence can be effectively challenged by the defense. Within civil law systems, on the other hand, the defense has the opportunity and is expected to challenge evidence before trial in the various pre-trial phases, even though in many instances there may not be a judge present to oversee fairness in the process. This suggests that the contrast between criminal procedure systems is better found at the stage of the process at which "adversarial" evidence-testing takes place, rather than in any fundamental or wholesale difference between "adversarial" and "inquisitorial" proceedings.

For all this, the two models appear to retain some explanatory force if they are broadened out to include different political structures of authority and different legal cultures, for they can then be viewed as two different procedural traditions that have dominated the common law and civil law worlds, respectively, encompassing different normative expressions of how legal proceedings *should* be organized (Langer 2004; Field 2009). Jurists and practitioners within common law and civil law systems tend to identify strongly with idealized procedural models expressing different values. For example, there is a long-standing tradition of anti-inquisitorialism in American law which has acted as a kind of "negative polestar" for American criminal procedure (Sklansky 2009), while "anti-adversarialism" has tended to dominate debates surrounding many criminal justice reforms in France, such as those strengthening defense rights, the movement towards plea bargaining, and the role and function of the *juge d'instruction* (Hodgson 2005).

The Role of Scientific Evidence Within the Adversarial and Inquisitorial Procedural Systems

With the caveat that the adversarial and inquisitorial models may be more useful in reflecting beliefs about how procedural systems *should* be organized than as descriptions of how they actually *are* organized, we can begin to detail how scientific evidence is treated within each of the dominant procedural families (see generally Champod and Vuille 2011). Within the adversarial model, experts are employed by the parties in the pre-trial and trial phase of the criminal process and the court does not become involved in the appointment and use of experts except during the sentencing phase when it does make use of experts whom it appoints to assist in determining risk factors relevant to imposing penalties on convicted defendants. Before this phase, the parties employ experts to gather scientific evidence and write reports. If experts give evidence at trial, they are called as party-instructed witnesses.

The principle of party presentation by which parties call "their" own witnesses at trial extends to expert as well as lay witnesses, although no party has any exclusive property right in the evidence or any right to prevent another party from calling any witness (*Harmony Shipping Co SA* v *Saudi Europe Line Limited* [1979] 1 WLR 1380). Scientific evidence is tested in the same manner as other evidence is tested, through cross-examination at trial by counsel. Experts are treated like any other witness in this respect. However, expert witnesses are entitled to somewhat more leeway than ordinary witnesses in being allowed to state their opinion on matters within their expertise, and also to give hearsay evidence of scientific knowledge. Expert reports are often admitted as well by way of exception to the hearsay rule.

Although it is open to both sides to appoint experts, in practice defendants who are legally aided have to make a case to the legal aid authorities for scientific assistance. Even when this is forthcoming, defense experts have to overcome the structural and practical disadvantages of arriving late on the scene after prosecution experts have received items for analysis and conducted their tests and they may have to rely heavily on prosecution experts for information (Roberts 2002). Increasingly, prosecution experts are required to disclose all relevant information to the defense, while the defense is usually only obliged to disclose the scientific evidence it intends to adduce at trial.

In contrast with adversarial process, scientific experts in inquisitorial systems are in theory appointed by, and work under the supervision of, an examining judge or the court. They occupy a unique position in the criminal process, as they are neither witnesses nor judges. Increasingly, however, scientific expertise is called into the case by the police or by the prosecutor in cases where investigating judges are not involved. In reality, experts have often reached their conclusions in conjunction with the police investigation before the case reaches a judge (Nijboer 1993). The experts are usually appointed from lists or from accredited laboratories and have a status superior to that of witnesses. When they have completed their research and inquiries, experts submit a written report to the court and may be called to give oral evidence to explain their findings under questioning, which is mainly conducted by the court rather than by the parties, although counsel may be given permission to put questions directly to experts. Although the court must freely evaluate the expert evidence for itself, in practice expert opinions are afforded considerable deference.

The defense has traditionally had a limited input into the forensic process in inquisitorial systems, but the defense role has been expanding in more recent years. Defense lawyers sometimes request that particular questions are put to the expert or that certain tests are carried out (see e.g., Art 165 CPP France, Art 184 CPP Switzerland). They may comment on the expert's report once it has become part of the case file and they may request the appointment of another expert for a second opinion, although the courts can deny such petitions (see e.g., Art 167 CPP France, Art 244(4) CPP Germany). In certain systems, such as Italy (see Art 230 CPP), the defense may be able to appoint their own experts to work with the official expert but these party experts usually have inferior status to the official expert and permission may have to be sought before they are instructed (Champod and Vuille 2011: 21–22).

Miscarriages of Justice in Adversarial Systems

Although the use of scientific evidence has the potential to provide a more reliable evidential basis for verdicts than many traditional categories of evidence such as witness testimony and confessions, a litany of miscarriages of justice caused by faulty scientific evidence across a range of different forensic fields has come to light during the last 30 years, especially within the common law world. These have prompted criticism, not only of scientific evidence itself but also of systematic weaknesses in the "adversarial" model of proof. Various cognitive errors can arise when scientific evidence becomes so dependent on the parties (see generally Roberts 2002, Champod and Vuille 2011). First of all, there is the question whether it is wise to permit the parties to choose which experts to bring into the case. As one judgment over a century ago reflected: "A man may go and does sometimes to half a dozen experts . . . He takes their honest opinions, he finds three in his favour and three against him; he says to the three in his favour will you be kind enough to give evidence? And he pays the three against him their fees and leaves them alone . . . the result is that the court does not get the assistance from the experts which if they were unbiased and fairly chosen, it would have a right to expect" (*Thorn* v *Worthington Skating Ring Co*. LR 6 ChD 414, 416, 1876). Within the criminal process, the parties may not have the luxury of such a wide choice of experts, but this suggests a further problem. The parties need proper resources to be able to employ good experts which may not be available, in particular, to the defense relying on over-stretched legal aid budgets to secure expert evidence.

The traditional way in which adversarial systems have sought to protect themselves from partisan sources of evidence is by developing strict admissibility tests to screen out unreliable evidence and to give each party an opportunity to challenge the sources of evidence presented by their opponent. These approaches, however, have only had limited success in respect of expert evidence. Adversarial systems have developed a number of rules to restrict the admission of expert evidence. English law has traditionally taken a fairly deferential approach towards experts by allowing them to express expert opinions provided the subject matter of the opinion is beyond the knowledge, skill, or experience of the tribunal of fact and the expert has sufficient expertise in the field (Redmayne 2001). Although the position may now be changing, there is no established requirement that any specific threshold be met to ensure the reliability of expert evidence (Dennis 2010: 895). In practice this has meant that if an expert is accredited or has the necessary qualifications, and the subject matter of the expert's evidence is relevant to the case before the court, his testimony will be admitted (Alldridge 1999).

In 1923 in *Frye* v *US* (1923) 293 F.1013 a US federal district court appeared to impose stricter gate-keeping responsibilities on judges when it agreed that the trial court had been correct to exclude a polygraph technique because it had not achieved general acceptance in the relevant scientific community. This seemed to put a reliability threshold on the evidence by deferring to scientific consensus in the relevant field. A majority of courts in the US applied this standard and it appeared to creep into other jurisdictions as well (see, e.g., in Australia *R* v *Bonython* (1984) 38 SASR 45, *R* v *Parenzee* [2007] SASC 143). The difficulty with this approach was that it led to uneven application in practice. Courts applied varying degrees of rigor to the standard, with little indication as to which facts of the expert testimony had to be generally accepted and how widely or narrowly the relevant scientific community was to be defined (Redmayne 2001: 113; Ligertwood and Edmond 2010: 7.51–2). In *Daubert* v *Merrell Dow Pharmaceuticals, Inc.*, 509 US 579 (1993), the US Supreme Court considered that the *Frye* test had been superseded by the Federal Rules of Evidence in 1975 which made no mention of the *Frye* test but implied that a judge had to ensure that any and all scientific testimony or evidence admitted was not only relevant but reliable. *Daubert* is commonly considered to have replaced the *Frye* test in the US federal and many state jurisdictions with a reliability test involving consideration of five factors: (1) whether a theory or technique can be (and has been) tested; (2) whether the theory or technique has been subjected to peer review and publication; (3) the known or potential error rate; (4) the existence and maintenance of standards controlling a technique's operation; and (5) general acceptance in the scientific community.

The scope and application of the *Daubert* criteria have been clarified in later Supreme Court decisions. A sixth criterion was added in *General Electric Co* v *Joiner* 522 US 136 (1997) which entails examining the extent to which general findings are applicable to the instant case. In *Kumho Tire Co.* v *Carmichael*, 526 US 137 (1999) the Supreme Court broadened the applicability of these criteria to all expert evidence including that which is not strictly, or at all, "scientific." But *Daubert* remains the leading case and is now applied in federal courts in the US and has been cited with approval in certain other jurisdictions as well. In the UK, for example, the England and Wales Law Commission (2009) has recommended that *Daubert*-style criteria be introduced into the English courts.

The difficulty with requiring judges to take on an effective gate-keeping role in relation to expert or scientific evidence is that this depends for its success on judges having a sufficient understanding of the science involved. Although the test would seem to put explicit responsibilities on judges to test the validity of scientific evidence, it has been claimed that within the realm of forensic science many courts have continued to admit bite mark analysis, microscopic hair analysis, voiceprint evidence, and handwriting analysis despite the absence of any demonstrable theoretical basis, population databases, standardized methodology, or empirical data on error rates for this kind of evidence (Beecher-Monas 2007). A comprehensive report into the state of forensic science in the US concluded from reported opinions in criminal cases that, despite *Daubert*, trial judges rarely excluded or restricted expert testimony offered by prosecutors and that appellate courts routinely deny appeals contesting trial court decisions admitting scientific evidence against criminal defendants (National Research Council 2009). Judges are not helped in this endeavor by criminal defense lawyers who rarely have any background in relevant scientific expertise, whilst prosecutors have little responsibility in an adversary system to vouch for the reliability of the expertise they place before the court.

The other means of ensuring reliability of evidence in the adversarial system is to permit opposing parties to make an effective challenge to the evidence adduced. But this is only possible where the parties are properly resourced and there is sufficient disclosure of all the relevant evidence in the case. In certain notorious miscarriages of justice in England and Wales arising out of IRA terrorism in the 1970s, scientists failed to disclose important scientific information even to the prosecuting authority. The English Court of Appeal responded by requiring scientists advising the prosecuting authority to disclose material known to them which may have some bearing on the case (see *R* v *Maguire* (1992) 94 Cr App R 133). The difficulty is that, in the absence of effective oversight, investigators and forensic scientists are left to discharge these duties themselves and there may be little incentive for them to do so. Even if scientists are sufficiently objective in their approach, they may have received instructions which are incomplete and may not be alerted to all the relevant evidence in the case. When it comes to communicating their results and opinions, the requirement that they submit to examination and cross-examination by the parties means that questioning is focused on one direction or the other and expert witnesses may not be able to give as complete a picture to the court as they would like. The fact that experts are treated as witnesses also means that they are prevented from entering into open dialogue with decision-makers in the case, potentially frustrating the important educative role that experts have to explain their findings to the court (Allen and Miller 1993).

Human Rights Challenges in Inquisitorial Systems

Inquisitorial systems may be thought better able to withstand some of the cognitive weaknesses of adversarial criminal procedure. Under the inquisitorial trial model, scientific investigations are carried out under the supervision of an impartial court thereby facilitating the production of more impartial and reliable reports. Experts are also able to communicate the results of their findings to the court, whether in reports or by oral evidence, without being hampered by the artificial adversary process of examination and cross-examination. Problems of disclosure between the parties are pre-empted by having a case file made freely available to both the prosecution and the defense. Experts have full opportunity to respond to any issues raised by the parties or to call for a second opinion. Such a procedural model, however, is heavily dependent on the integrity and competence of "impartial" forensic experts. Scientific experts are perceived to be impartial because they act for the court rather than being instructed by adversarial parties, but in practice many experts work exclusively with the prosecuting authorities and this may put the defense at a considerable disadvantage. In some legal systems, such as that of the Netherlands, government forensic institutes are only permitted to investigate cases when requested to do so by the police or justice authorities (Jakobs and Sprangers 2000). If the defense wishes to commission expert evidence, it must usually pay for it and may encounter difficulties recruiting willing and able experts, particularly if it intends to challenge the findings of the experts appointed by the judicial authorities. Even if the defense is able to commission its own expertise, there is no guarantee that the court will afford the same weight to this evidence as to that produced by the official forensic scientists.

In a string of cases arising from inquisitorial systems, the European Court of Human Rights (ECtHR) has ruled that there was a violation of the right to a fair trial on the grounds that the defense had been disadvantaged under the principle of the "equality of arms" which requires that the prosecution and defense are put on an equal procedural footing. In *Bönisch* v *Austria* (1987) 9 EHRR 191 the applicant was prosecuted for preparing meat which contained an excessive concentration of benzopyrene on the basis of a report prepared by the Director of the Federal Food Control Institute who was appointed later as an expert by the court. The ECtHR considered that as it was his report that had led to the charges being brought, the Director of the Institute was more likely a witness against the accused than an independent court expert. The principle of equality of arms inherent in the concept of a fair trial required equal treatment as between the hearing of the Director and the hearing of persons who were or could be called in whatever capacity by the defense. Yet since the Director had been heard as an "expert" his statements must have carried greater weight than those of an "expert witness" called by the accused. As a formally recognized expert, the Director had enjoyed a privileged position in being allowed to attend throughout the hearings, put questions to the accused and witnesses with the leave of the court, and comment on their evidence. It followed that there had been a violation of the right to a fair trial (see also *Eggertsdottir* v *Iceland*, App. no. 31930/04, 5 July 2007; *Stoimenov* v *Former Yugoslav Republic of Macedonia*, App. no. 17995/02, 5 April 2007).

Bönisch is often contrasted with *Brandstetter* v *Austria* (1993) 15 EHRR 378, where the expert whom the court appointed was not the person who filed the report leading to the applicant's prosecution but was employed by the same Institute as the expert who had filed the report. The ECtHR held that, in this case, doubts about the neutrality of the expert could not be objectively justified and the Austrian courts had not breached the principle of equality of arms in refusing the applicant's request to appoint another expert. A court apparently does not have to appoint further experts at the request of the defense just because the opinion of the court-appointed expert supports the prosecution case. A second expert must be appointed to satisfy the requirements of the right to a fair trial only where there is some objective ground for suggesting that the expert was biased or, alternatively, some external factor suggesting that the expert's testimony may have had a distorting impact on the tribunal of fact (*GB* v *France* ECtHR 2 October 2001).

Apart from falling foul of the requirement of equality of arms, inquisitorial systems have also run up against the European principle of "adversarial procedure." This does not imply that European systems adopt fully fledged adversarial modes of proof (Jackson 2005). Instead the principle requires that the parties are given the opportunity to have knowledge and comment on the observations filed and the evidence adduced by the other party (*Brandstetter* v *Austria* (1993) 15 EHRR 378, *Rowe and Davis* v *UK* (2000) 30 EHRR 1, [60]). In *Mantovanelli* v *France* (1997) 24 EHRR 370 the ECtHR considered that the principle was violated because the applicants were not informed in advance of the dates on which an expert appointed to report on the circumstances of the death of the applicants' daughter interviewed witnesses and examined documents. The Court considered that there was no general right to be present during an expert's investigative activities. What was essential, however, was that the parties should be able to participate properly in the proceedings before the tribunal. Although the applicants could have made submissions to the court on the contents and findings of the report after having received it, the ECtHR was not convinced that the arrangement "afforded them a real opportunity to comment effectively on it." The question the expert was instructed to determine was identical with the one the court had to determine and pertained to a technical field that was not within the court's knowledge. Thus, the expert's report was likely to have a preponderant influence on the assessment of the facts by the court. In these circumstances the applicants could only have expressed their views effectively before the expert report was lodged. Since there would have been no practical difficulty in allowing them to do this, failure to provide advance notification constituted a violation of their ECHR Article 6 right to a fair trial.

Strasbourg case law has established a "two-pronged test" to ensure that criminal proceedings involving expert evidence are fairly conducted (Van Kampen 2000: 201). First of all, national courts must ensure that both parties are able to have knowledge of, and comment on, the evidence adduced by the opposing party and that they are able to question and challenge any court-appointed expert. According to one of the latest cases, *Mirilashvili* v *Russia* (2008) App no. 6293/04, 11 December 2008, [190], "if the court decides that an expert examination is needed . . ., the defence should have an opportunity to formulate questions to the experts, to challenge them and to examine them directly at the trial." This still falls short of any requirement that the defense be allowed to appoint its own expert to mount an effective challenge. If, however, objectively justified fears exist that the expert appointed by the court is not in fact acting with the presumed impartiality and neutrality, a second requirement is that national courts need to ensure that the defendant is provided with the opportunity to secure the attendance and examination of experts and/or witnesses on their behalf under the same conditions as the experts against them. This may require that the court appoints a counter-expert to ensure that the statements of the experts for the prosecution and defense are treated as probative equals.

Future Directions: A Participative Model

A recent report commissioned by the Council of Europe on the state of forensic science both globally and in the European Union has concluded that accusatorial and inquisitorial models alike do not lend themselves to the sound management of scientific evidence (Champod and Vuille 2011: 31). In those systems which give the parties prime responsibility for finding evidence, defendants who are already disadvantaged in the criminal process are penalized still further. Defense lawyers are ill-equipped to scrutinize prosecution expert reports. They may attempt to secure experts themselves but they frequently face difficulty in finding experts working in equivalent conditions to prosecution experts and even when defense experts can be found, they become involved at a comparatively late stage when critical samples have already been taken and they have to rely on information provided by the prosecution experts. The adversarial trial then requires judges and juries to assess scientific evidence in the "worst conditions imaginable" where the principle of "contradiction for contradiction's sake" holds sway (Champod and Vuille 2011: 31). Inquisitorial systems, by contrast, place too much trust in court-appointed experts who are complacently supposed to be both neutral and competent and given the misplaced status of a "judge in white" (Volk 1993: 45). The expert's work is rarely called into question and even when it is, the evidence is not assessed on its scientific merits but on the basis of exogenous factors, such as the expert's reputation, employment, or official status.

Against the failure of legal systems across the common law and civil law traditions to provide a reliable system for gathering and assessing scientific evidence, it is hardly surprising that much of the focus of recent debates has been on improving standards within forensic science itself (see, e.g., National Research Council 2009; Champod and Vuille 2011). If we extend our gaze beyond the constraints of the adversarial and inquisitorial models of proof, however, improvements might also be made to the legal process within which scientific evidence must be gathered and assessed. The principles of equality of arms and adversarial procedure developed by the ECtHR provide the basis for realigning traditional proof systems, in accordance with a new model of proof better characterized as "participative" than as "adversarial" or "inquisitorial" (Jackson 2005). The participation model is predicated on the notion that although the main actors in the criminal process – prosecutors, defense lawyers, and adjudicators – each have separate defined roles in adjudication, processes of proof should be constructed to provide all these actors with as much relevant evidence as possible, as early as possible in the process so that it can be assessed, challenged, and evaluated in a spirit of positive participation. When it comes to scientific evidence, this would mean that the parties should ensure that scientific experts are fully informed during the course of their investigations and that the experts themselves are encouraged to share and examine information between themselves. Opportunities for effective challenge and testing should be maximized. This may be better achieved by way of written exchanges before trial than in the full glare of an adversarial trial. Traditional methods of oral examination and cross-examination developed to test cognitive capacities or the good faith of ordinary witnesses are less suited to scrutinizing scientific methodology.

In common with other generalized models of adjudication, it may be that the positive participation model is most useful in expressing values that should be embedded in adjudication than as a detailed "one-size-fits-all" blueprint for conducting all cases. There are also procedural values at work that tend to detract from active participation. The defense has no obligation in Anglo-American systems to put forward any positive theory of its case and is entitled to play a passive role throughout the process. Here the defense may be more inclined to play a negative role of demolishing the prosecution case than a positive role in the generation of specific theories and hypotheses. One commentator has claimed that adversarial systems, in which two parties dance a "tango" with each other to settle for an "interpretive" truth, are ill-suited to the more interactive or collective enterprise of searching for substantive truth which resembles a "rumba" performed by coordinated troupes of dancers moving in time to a shared rhythm (Grande 2008). Where scientific evidence is involved, however, it may be argued that all the lay participants have to try to understand what the evidence means in order to assess its value. Since legal systems cannot rely on scientists themselves to validate scientific theories and techniques, lay participants have no choice but to make the necessary epistemological inquires for themselves and this suggests that, at least in exchanges between the parties and the scientists, a more positive participative exchange should be encouraged and facilitated (see Imwinkelried 2011).

Expert evidence; Expert witnesses; Forensic evidence; Forensic science evidence

Overview

There is no doubt that forensic science today makes an enormous contribution to the detection and proof of crime in modern legal systems. Scientific evidence is often useful, and sometimes vital, in proving offenses and bringing perpetrators to justice who might otherwise evade detection or conviction. Strong scientific evidence implicating the accused often induces guilty pleas without the need for a contested trial. Scientific evidence simultaneously plays an important role in excluding innocent suspects from further official inquiries or surveillance. Yet scientific evidence can also be a potent source of injustice when errors are made.

This entry explores the role of scientific evidence in criminal prosecutions, particularly with regard to common law jurisdictions such as those in the UK and the USA. It highlights challenges for criminal process actors and indicates issues of on-going controversy and concern. Prosecutors play a pivotal role in the use of scientific techniques of detection and in providing scientific evidence to the court. Common law prosecutors are instrumental in instructing expert witnesses and, in consultation with trial counsel, in adducing scientific reports and testimony in cases proceeding to trial. While the entry focuses primarily on prosecutors' professional responsibilities within an institutional legal framework informed by particular ideals of justice, the final section briefly addresses a more socio-legal issue: the impact on prosecutions of the "CSI Effect."

Scientific Evidence as Proof of Crime

The use of scientific techniques and expertise in the investigation and prosecution of crime is not a new phenomenon. The appliance of cutting-edge technology in the administration of criminal justice goes hand-in-hand with the Enlightenment and modernity's scientific revolution. Indeed, English law cases addressing issues surrounding expert evidence, such as *Buckley* v *Rice Thomas* (1554) 1 Plowden 118, CB, (which is still occasionally cited today), date back to the Renaissance. However, the twentieth century is properly regarded as the century of forensic science. This is when the early practical experimentation of the nineteenth century, immortalized by Sir Arthur Conan Doyle in the figure of Sherlock Holmes and his avowedly scientific methods of criminal detection, truly bore fruit. First pathology and fingerprinting, then blood-typing (serology) and a raft of comparison "sciences" (handwriting, ballistics, toolmarks, glass, hairs, fibers, footwear marks, dentition, facial-mapping, voice analysis, etc.), and most recently CCTV cameras, mobile phones, digital forensics, and – above all – DNA profiling have transformed criminal investigation, prosecutions, and trials around the globe.

Forensic science has become an integral part of modern criminal justice systems. Scientific evidence routinely features in high-profile serious crimes of murder, robbery, and sexual assault, but also plays an important role in relation to more mundane offending lower down the criminal calendar. Empirical research indicates that relying on DNA evidence in prosecutions of high volume crimes such as burglary yields many more identifications of perpetrators than more traditional methods of detection, including fingerprinting, at apparently reasonable cost (Roman et al. 2008: but cf. Williams and Johnson 2008: Chap. 6). It is not surprising that governments have invested heavily in the development of forensic science technologies, notably including the UK's DNA expansion program and the creation of a large National DNA Database (NDNAD) (Williams and Johnson 2008: Chap. 5) – although the Coalition Government's highly controversial recent decision to close the British Forensic Science Service (FSS) is regarded by many as a retrograde step (see House of Commons Science and Technology Committee 2011).

Acknowledging that the development and proliferation of forensic science over the course of the twentieth century has been a marvelous boon for the administration of criminal justice is not to say that it comes without any risks or drawbacks, much less to encourage complacency about it. Like any powerful tool, forensic science gets the job done efficiently and with impressive results but it is equally capable of doing appalling damage if it is not handled carefully and treated with respect. Precisely because scientific evidence has a – generally speaking, well-merited – reputation for objectivity and reliability, it is prone to be highly misleading in cases where it is either inherently unsound or put to improper uses. This is why forensic science is often implicated in miscarriages of justice. In a National Registry of Exonerations recently launched by Michigan and Northwestern law schools in the USA, "bad forensic science" features in 24 % of 891 confirmed false convictions since 1989 (Gross and Shaffer 2012: 63–65). It is often suggested that, whatever defects scientific evidence might suffer from, it has to be more reliable than other forms of evidence traditionally relied on in criminal adjudication, such as eyewitness identifications and confessions by suspects, which have often produced false convictions in the past and have been repeatedly torn to shreds by behavioral science researchers. While it might well be true that scientific evidence is comparatively more reliable than other forms of criminal proof, this is no reason not to strive to improve its performance and to make every effort to safeguard against errors, to the extent that this might be possible.

Prosecutors play a pivotal role in the use of scientific techniques of detection and in providing scientific evidence to the court. In many continental jurisdictions prosecutors direct criminal investigations, including recourse to scientific testing, and judges seek further technical advice, as required, from their own court-appointed experts. In common law jurisdictions, criminal investigations have traditionally been run by police detectives with substantial operational autonomy and comparatively little input from prosecutors. But this is changing. For example, many state prosecutors in the USA today adopt a proactive approach to participating in major criminal investigations, and even in England and Wales – where strict separation between the police and the Crown Prosecution Service (CPS) used to be an article of faith – there is far greater emphasis on interagency dialogue and cooperation between what is now, revealingly, described in official documents as "the prosecution team" (Moreno and Hughes 2008). Prosecutors are instrumental in instructing expert witnesses and, in consultation with trial counsel, in adducing scientific reports and testimony in those cases that proceed to trial.

Scientific Evidence in Adversarial Criminal Process

Reliance on scientific evidence in particular criminal prosecutions is the outcome of a deliberate, self-conscious process, comprised of a series of reasonably distinguishable, though often overlapping, temporal phases. Forensic science evidence is just as much a product of police case-building, structured by a hypothesized "theory of the case," as any other type of evidence. Research conducted for the Royal Commission on Criminal Justice identified nine key phases in the production of scientific evidence (Roberts and Willmore 1993; Roberts 1994), suggesting the following, somewhat stylized, model of "the typical case" to which real proceedings conform to a greater or lesser extent.

(1) Investigators must first of all decide to utilize scientific expertise. The initial decision is made by police and prosecutors and therefore answers to investigative, rather than strictly scientific, imperatives. This creates an observable tension between investigators' needs and expectations, and the ability of science to satisfy them. In recent times attempts have been made to educate investigators about the possibilities and limitations of scientific evidence, harnessing technological innovation to financial imperatives driving "cost-effective" policing (Lawless and Williams 2010). Police officers have been encouraged to turn to science in the investigation of "routine" volume crimes such as burglary and theft, where the potential for scientific assistance has often been overlooked in the past, but progress is uneven across the regions. It remains the case that scientific evidence is produced only when investigators think they need it, which is not necessarily when science might in fact be of most – or indeed, of any – assistance to the prosecution.

(2) Having elected to employ scientific assistance, the first task for police or prosecutors is to locate an appropriate expert. In the UK, until very recently, the FSS has been on hand to provide what was generally acknowledged to be a world-class service in a range of forensic specialisms, including DNA profiling. With the closure of the FSS, reliance must now be placed on market provision by a range of commercial suppliers, some of which – like LGC Forensics, the old Lab of the Government Chemist – were formerly state-run but subsequently privatized. Effective regulation, validation of techniques and processes, and accreditation of laboratories is vital to the integrity of this market-based system. In England and Wales, much of this responsibility has been invested in the newly created post of Forensic Science Regulator, with the assistance of the Forensic Science Advisory Council. For other types of expertise, including clinical, medical, and the more esoteric forensic sciences, investigators have to look to the hospitals, universities, research institutes, and private consultancies to locate an appropriate expert. Although these arrangements seem to

work out in the majority of cases, the process of hiring experts is surprisingly informal, and sometimes fails to produce the best evidence. It remains to be seen whether a post-FSS world of free-market provision will continue to supply an adequate range of high-quality forensic science expertise to the administration of criminal justice, with appropriate investment in quality control and research and development (Lawless 2011; Roberts 1996).

(3) Once an appropriate expert has been engaged, the next step is to supply the expert with relevant crime scene material (or other raw data) for analysis. Crime stain samples or material recovered from suspects or complainants must be identified, preserved, and transmitted to the laboratory free from contamination and protected from (further) degradation. Police and prosecutors must ensure that chain of custody is properly documented, since physical evidence is worthless unless the court can be confident about its provenance and integrity. For example, samples should be collected in "temper-evident" packaging (Lynch et al. 2008: Chap. 4). These simple administrative measures make an essential contribution to ensuring that justice is not only done, but also manifestly seen to be done.

(4) Another crucial aspect of the process of generating forensic science evidence concerns the nature of the instructions received by the expert. Scientists are inevitably influenced by the type and extent of background information provided to them by investigators, and even possibly by the form and wording of the police request for assistance. Researchers have drawn attention to the risks of unconscious biases creeping into scientific judgments through suggestive contextual information, leading forensic experts to "see," and report to prosecutors and courts, what the information they were given has led them to expect (Risinger et al. 2002). One way to respond to the risk of "contamination" by such extraneous influences would be to insist that items must be sent to the laboratory without any accompanying background information and with a request for assistance in scrupulously neutral terms. At one time the FSS considered this best practice. Yet that approach, and the language employed in its justification, betrays a fundamental misconception about the nature of forensic science. Following from the essentially applied nature of their discipline, most forensic scientists prefer to be told as much background information as possible, in order to be able to tailor their approach to the needs of the investigation. There is, most obviously, little point in a scientist wasting time and energy on matters that are not disputed in the proceedings. Background information is not so much, on this view, an external source of "contamination" or "bias," but an essential part of the scientist's data for analysis. Nonetheless, the continued risk of inappropriate, and possibly unconscious, influence suggests that – to the extent that it can reliably be identified – irrelevant and potentially prejudicial material should be filtered out of the information provided to forensic scientists, at least until they have conducted relevant tests and produced their preliminary findings.

(5) The scientist next proceeds to conduct whatever testing or examinations are judged appropriate. (6) The results of the scientific investigation are then written up into a report. Both testing and reporting reflect investigators' instructions and expectations, within the broader framework of criminal proceedings and the conventional practices of forensic science. The rules of substantive criminal law structure police investigations, which in turn influence the questions scientific experts are asked to consider, the tests they undertake, and the nature and content of the reports they write. For example, scientists asked to produce a DNA profile from blood-stained clothing in order to establish identity would not routinely comment on a self-defense theory of the case, or any other conceivable hypothesis such as provocation, mistake, or accident. But if specifically invited to do so, the expert could consider how blood spatter patterns, DNA mixtures or secondary transfer, etc., might bear on potential defense arguments and report any relevant findings or advice to prosecutors. According to one police training manual, "forensic awareness… involves the prosecution team providing the forensic scientist with all essential information in the case from the outset, keeping

them continuously updated and asking them the right questions to progress the case and get the best results" (Moreno and Hughes 2008: 25). When producing reports detailing their results and conclusions, experienced forensic scientists are conscious of the instrumental role of science in criminal proceedings, and of a report's intended audience. Investigators expect scientists to help them prove, or disprove, criminal charges against a suspect, and the style and language of expert reports is directed to that end. There are generalized pressures to work quickly and produce definite conclusions. Even if scientists were always paragons of the ideals of impartial and objective inquiry, which most of them espouse and the law demands, their work product would still remain a highly selective, constrained, stylized, and instrumentally orientated form of science. Unfortunately, forensic scientists have occasionally been seduced, or corrupted, by the institutional pressures inherent to an adversarial criminal process, allowing themselves to become partisan instruments of the prosecution rather than impartial purveyors of objective scientific facts and considered expert opinions to the courts (see Erzinçlioglu 1998; Giannelli 1997).

The production of a scientific report often effectively signals the end of particular criminal proceedings, either because the accused is induced to plead guilty in the face of compelling incriminating evidence, or because the prosecution is too weak to proceed in the absence of scientific corroboration. Scientific evidence plays an important – and possibly somewhat overlooked – role in exonerating innocent suspects from continued suspicion, in cases where DNA profiling indicates that the suspect could not, in fact, have been the perpetrator after all. In those minority of cases that do proceed to trial, the production of scientific evidence typically involves three further key stages.

(7) Defense lawyers sometimes appoint their own experts, occasionally to follow up exculpatory leads, but more often just to double-check the work already conducted by a prosecution expert. The appearance of a defense expert may present opportunities for communication, or even cooperation and the exchange of ideas, between experts on opposite sides of the adversarial divide. Forensic scientists seldom share the adversarial culture of the police and lawyers who hire them, and some scientists treat their notional adversaries as colleagues. On the occasions when scientists meet in the laboratory to review test results, defense experts have been known to persuade scientists working for the prosecution to undertake further tests or to reinterpret their results in the light of a different perspective or new information (Roberts and Willmore 1993: 56–57). Scientific investigations undertaken by the defense, in conjunction with prosecution scientists or independently, do occasionally produce significant exculpatory evidence. In the majority of cases, however, the defense examiner simply confirms the prosecution expert's data and conclusions.

(8) Expert witnesses may attend a pretrial conference with counsel. This is potentially an important meeting, at which counsel can review the expert's evidence and ensure that the expert is prepared to stand by the conclusions expressed in the expert's report. Empirical research conducted in England and Wales in the early 1990s found that pretrial conferences between experts and counsel were frequently short or nonexistent (Roberts and Willmore 1993: 57–61). This was partly due to time pressures, but also reflected a deeply held aversion on the part of some barristers to meeting any witnesses prior to trial, for fear of attracting accusations of "witness coaching." That fear seems misconceived with regard to expert witnesses, not because experts are immune to pressure and undue influence, but because counsel are unlikely to lead scientific evidence successfully if they do not themselves understand the expert's evidence. Lack of pretrial communication between experts and counsel was said on occasion to have adversely affected the presentation of scientific evidence at trial. By contrast, witness preparation is a standard feature of criminal litigation in the USA. No US prosecuting attorney would proceed to trial, in any serious matter, without first having reviewed the evidence of key prosecution witnesses, including scientific experts, in person.

Over the ensuing years, the novel idea of conducting pretrial conferences with expert witnesses has become more familiar and culturally acceptable to barristers in England and Wales, too. More significantly still, English courts have adopted a general policy of proactive judicial trial management within the framework of the Criminal Procedure Rules (CrimPR), which were introduced in 2005. The CrimPR make explicit provision for clarifying, and if at all possible resolving, scientific issues prior to trial through conferences of experts and joint reports. The Court of Appeal has repeatedly emphasized the importance of these provisions, and constantly encourages trial judges to enforce them on the parties. It has come to be widely appreciated that adversarial trials involving "battles of experts" tend to obscure genuine scientific disagreements and sometimes give the impression of scientific dispute or uncertainty where none truly exists. The prevailing philosophy among the senior judiciary is consequently to try to deal with scientific aspects of the case outside the courtroom, while still preserving the determination of genuinely contested issues for the jury at trial.

(9) Although only a very small percentage of criminal cases results in a contested trial in any adversarial jurisdiction where guilty pleas and bargains are the norm, these are disproportionately serious and important cases. Scientific evidence features in many of these contested trials, to a greater or lesser extent. Such evidence is often uncontroversial, and may be agreed – possibly as a result of successful pretrial discussions between the parties and their experts. When not disputed, the expert's report can simply be read out as documentary evidence, and is likely to be accepted at face-value by jurors (albeit that the jury is always at liberty to form its own view, and must be so directed by the trial judge in England and Wales: see e.g. *R* v *Allen* [2005] EWCA Crim 1344; *R* v *Hookway and Noakes* [2011] EWCA Crim 1989). Where the defense or, more infrequently, the prosecution wants to challenge scientific evidence, however, the expert will usually be called to court to testify in person by the party instructing the expert. There is formal provision for court-appointed experts in many common law jurisdictions. However, judges tend not to utilize court experts, in deference to the adversarial precept that the parties run their own cases at trial, with the judge adopting a relatively passive role as neutral "umpire" to ensure "fair play" and litigants' adherence to the rules of criminal procedure. (The "umpireal" model of judging in adversarial trials is an overstated and increasingly anachronistic simplification, but still serves to encapsulate a deep-seated cultural difference between "adversarial" and "inquisitorial" conceptions of the trial judge's role.)

Scientific experts testify in the courtroom like any other witness, through a series of answers to questions put by counsel. The expert witness is first taken through examination-in-chief (in the USA, direct examination) by the advocate calling the witness, and then undergoes cross-examination by counsel for the other party or parties in a multi-handed trial. If thought necessary to clear up any matter raised in cross-examination, a third phase of questioning ("reexamination" in the UK, "redirect" in the USA) may be conducted by the side calling the expert. Needless to say, this is a highly artificial way of presenting scientific evidence to the court. Its success depends in large part on the skill and scientific understanding of counsel, which cannot always be relied upon, especially if pretrial preparation has been inadequate. It might be preferable, from the point of view of communicating scientific evidence effectively, if experts could present their evidence in a more direct and less constrained fashion. As things stand, counsel may through incompetence or as a deliberate strategy distort the intended meaning of an expert's evidence, and the effect may be compounded where experts called by the prosecution and defense disagree, or appear to disagree, with each other. The evident limitations in this context of traditional oral trial procedure, whatever its efficacy or cultural significance in relation to ordinary witnesses of fact, underscore the wisdom of making more extensive use of pretrial mechanisms to fully and fairly exploit the potential of forensic science in criminal proceedings.

The Common Law Prosecutor's Role and Responsibilities

In many continental legal systems prosecutors are formally part of the magistracy. As a matter of jurisprudential theory, they are unequivocally regarded as acting in the pursuit of justice and they are supposed to be objective and nonpartisan. In common law countries, too, prosecutors are required to be "ministers of justice" who select and pursue appropriate charges against those suspected, on the basis of pertinent and reliable evidence, of having committed particularized criminal offenses. "Prosecution counsel has to exercise independent judgment throughout, with the objective not of obtaining a conviction at any cost, but of ensuring that justice is done" (Buxton 2009: 427). English prosecutors, it is said, prosecute but do not persecute. The special responsibility that prosecutors owe to justice may be rather less self-evident and unequivocal in an adversarial procedural system, in which criminal trials can sometimes take on the appearance of a gladiatorial contest. But it is no less fundamental to the legal system's claims to justice and legitimacy. There is a world of difference between a tough-minded lawyer who prosecutes firmly and fairly, and an ethically cavalier show-boater who tries to win cases and secure convictions at almost any cost.

Another important difference between civilian and common law jurisprudential theory is that, whereas many continental systems adopt some version of the "principle of legality" requiring compulsory prosecution in every serious case in which there is solid evidence of criminality, common law prosecutions are fundamentally discretionary. Of course, a suspect cannot be prosecuted in the absence of evidence capable of demonstrating his guilt. But incriminating evidence alone is not automatically enough to justify, let alone mandate, a prosecution in common law jurisdictions. Prosecution in the instant case must also be judged to be in the public interest more broadly conceived. This principle is encapsulated in the two-step test for prosecution specified by the Code for Crown Prosecutors in England and Wales (CPS 2010). The first part of the test poses the question of evidential sufficiency: is there a "reasonable prospect of conviction" of specified charges on the available evidence? This is generally understood to mean that the reviewing prosecutor must judge that conviction is more likely than not, on the balance of probabilities (ibid: para. 4.6). Otherwise, more evidence must be sought by the police; and the prosecution may ultimately have to be abandoned if better evidence is not forthcoming. Only if the evidential sufficiency test is satisfied should the Crown Prosecutor proceed to consider the second limb of the two-part Code test: is prosecution also justified in the public interest? The Code for Crown Prosecutors contains lists of public interest factors supporting or detracting from the case for prosecution, albeit that offense seriousness is always a weighty consideration and will often be dispositive in practice. Crown Prosecutors in England and Wales are under a duty of continuous review to ensure that the Code Test is satisfied in any case proceeding to trial. Since 2004, Crown Prosecutors have also been responsible for framing the initial charges in serious cases – a task formerly allocated to the police, on the traditional theory that common law prosecutions are initiated by private parties. Selection of appropriate charges likewise requires an (earlier) assessment of evidential sufficiency. Charging and evidential review are among the prosecutor's prime responsibilities in all common law jurisdictions, though detailed doctrinal arrangements and the institutional micro-dynamics of police-prosecutor relationships will naturally differ from one legal system to another.

As forensic science and other kinds of technical expertise have become increasingly prominent features of modern criminal investigations, they have also inevitably presented prosecutors with new challenges and opportunities. Some cases are effectively impossible to prosecute without scientific or medical evidence; in others, expert testimony plays a vital supporting rule. Prosecutors must grasp scientific fundamentals in order to make informed assessments of evidential sufficiency. For example, if an expert

DNA report states that the accused's DNA profile matches a crime stain partial profile with a random match probability of 1 in 30,000, the prosecutor needs to be able to make sense of this jargon in order to assess the probative value of the DNA evidence, within the evidential context of the case as a whole. Or again: if a medical expert report states that the pattern of a child's injuries is "consistent with nonaccidental trauma," does this constitute strong evidence of child abuse? Or does it simply fail to rule out abuse as one among myriad other possibilities that could be "consistent with" the injuries observed? In short, widespread use of scientific evidence in criminal prosecutions demands at least a basic level of scientific literacy from prosecutors (as well as from other relevant criminal justice professionals, including defense lawyers and judges). Ideally, prosecutors should also be equipped to spot the potential for developing lines of scientific inquiry that the police might have initially overlooked or regarded as unnecessary. This implies that prosecutors cultivate reasonable familiarity with the range of scientific specialisms and technologies potentially available to support criminal investigations, and should know how to identify and instruct suitably qualified experts, in consultation with police investigators and trial counsel where appropriate.

There are various lists of forensic practitioners produced by professional associations such as the UK Forensic Science Society, the British Psychological Society, and the Society of Expert Witnesses. National prosecution services like the CPS and state District Attorneys offices in the USA might further assist individual prosecutors by building up local intelligence on the range and quality of forensic scientific assistance available for consultation. These largely invisible, office-based processes have rarely been studied by empirical researchers, but what little we do know tends to suggest that identifying and instructing scientific experts is a rather *ad hoc* affair, heavily influenced by the motivation and personal experience of individual prosecutors. As well as failing to capitalize on opportunities to develop better evidence in the instant case, failure to share experiences more systematically may allow poorly performing experts to remain in circulation long after their consulting forensic practices should have been closed down. It is difficult to believe that this curiously unscientific approach to drawing on scientific expertise is beyond practical improvement – though it has to be said that developments over the last several decades (including the short life and ignominious demise of the UK Council for the Registration of Forensic Practitioners) provide little grounds for optimism.

The CPS in England and Wales has adopted various topic-specific policies pertaining to scientific evidence. One significant interagency document provides guidance on charging in cases involving DNA evidence (The Prosecution Team 2004), including the important principle that "[a] suspect should not ordinarily be charged solely on the basis of a match between his own profile and a DNA profile found at the scene of the crime" (ibid 11.1). This effectively introduced an informal corroboration requirement for DNA profiles in relation to suspects first identified through a speculative search of the NDNAD. It attempts to forestall the embarrassment experienced in several early DNA cases in which suspects who, viewed objectively, could not possibly have committed the crime in question were nonetheless charged purely on the basis of an adventitiously matching DNA profile. This was an object lesson in the dangerous fallacy of treating DNA evidence as though it supplied infallible proof of guilt and an invaluable reminder that, just occasionally, DNA matches can occur purely by chance (if not through contamination, analytical discrepancy, or interpretational error). CPS charging policy in England and Wales now sensibly proceeds on the assumption that, if the suspect is truly guilty, there should be more evidence linking him to the offense than an unexpected "hit" on the DNA database. Yet unjustifiably late decisions to discontinue prosecutions involving DNA matches evidently still do occur (see, most recently, Dodd and Malik 2012).

CPS training and policy specifically draw Crown Prosecutors' attention to the potential for utilizing scientific or medical evidence in a number of priority areas. In relation to domestic violence prosecutions, physical evidence of assaults backed-up by medical testimony may be vital in continuing with a prosecution if the complainant later – for whatever reason – withdraws her complaint (Dempsey 2004), by all accounts a frustratingly common occurrence. Scientific evidence can be important in building up the prosecution's case in rape and sexual assault prosecutions, partly because it can help to deflect the perception that such cases often involve "one person's word against another's," inducing the jury to acquit because it cannot be sure that the accused is guilty, despite jurors' suspicions that he probably is. At the limit, expert testimony can sometimes effectively constitute compelling evidence of guilt or innocence by itself. However, prevailing scientific opinion can and does change over time, making it risky to base a prosecution primarily on expert evidence, at least where the relevant science is rapidly evolving. This dilemma was presented starkly in England and Wales by a recent series of criminal prosecutions of mothers for murdering their children, based in part on the alleged improbability of multiple innocent cot deaths in the same family.

R v *Clark* [2003] EWCA Crim 1020 was one notorious case in which the prosecution expert testified that the probability that both of the defendant's children could have died from Sudden Infant Death Syndrome (SIDS) was 1 in 73 million. This opinion was invalid when given, since it improperly assumed that serial cot deaths are independent events when in fact they could be caused by the same underlying pathology or genetic predisposition (with the further implication that multiple SIDS might run in families). In *R* v *Cannings* [2004] 2 Cr App R 7, a case in which three of the accused's infant children had died, the Court of Appeal observed:

> Experts in many fields will acknowledge the possibility that later research may undermine the accepted wisdom of today.... That does not normally provide a basis for rejecting the expert evidence. With unexplained infant deaths, however ... in many important respects we are still at the frontiers of knowledge.... In cases like the present, if the outcome of the trial depends exclusively or almost exclusively on a serious disagreement between distinguished and reputable experts, it will often be unwise, and therefore unsafe, to proceed. (ibid. 111)

Standing alone, this statement might have been interpreted as giving a strong hint to prosecutors that they should discontinue prosecutions in cases of suspicious infant death whenever there was disputed medical evidence. In *R* v *Kai-Whitewind* [2005] 2 Cr App R 3, however, the Court of Appeal said that it would be a "startling proposition" if "whenever there is a conflict between expert witnesses the case for the prosecution must fail unless the conviction is justified by evidence independent of the expert witnesses" (ibid. 480). The Court proceeded to elucidate an essential distinction:

> In *Cannings* there was essentially no evidence beyond the inferences based on coincidence which the experts for the Crown were prepared to draw. Other reputable experts in the same specialist field took a different view about the inferences, if any, which could or should be drawn and hence the need for additional cogent evidence. With additional evidence, the jury would have been in a position to evaluate the respective arguments: without it, in cases like *Cannings*, they would not. (ibid.)

Coincidence, in other words, cannot prove murder beyond reasonable doubt, if expert opinion is divided on whether the circumstances justify an inference of foul play. But the mere fact of expert disagreement will not block a prosecution supported by other evidence.

The Court of Appeal reiterated in *R* v *Henderson* [2010] 2 Cr App R 24 that conflicts in expert evidence are in principle to be resolved by juries just like any other conflict of factual testimony. *Henderson* concerned three consolidated appeals involving allegedly "shaken babies," prosecutions which have provoked much controversy in both the UK (*R* v *Harris* [2006] 1 Cr App R 5) and the USA (Tuerkheimer 2011). Prosecution evidence in these cases often almost amounts to an uncorroborated medical diagnosis of murder.

Doctors have testified repeatedly that babies exhibiting a particular combination of symptoms (known as "the triad") were definitely injured intentionally, and even sometimes claiming that the temporal pattern of symptoms pinpointed the culprit. However, recent developments in medical research and scientific thinking have cast serious doubt on such diagnoses. In *Henderson* the Court of Appeal stated unequivocally that "the triad" is not to be treated as conclusively diagnostic of nonaccidental head injury. This is something else that Crown Prosecutors must now take into account in exercising their charging and prosecutorial discretions in cases of alleged child abuse. Current CPS policy states that prosecutions based only on the triad are unlikely to be brought or continued, in the absence of "appropriate supporting evidence (which in certain circumstances can be found in the absence of certain factors)" (CPS 2011).

Sexual assault cases based on physical examinations of the alleged victims have also posed difficulties for prosecutors. In the past, medical experts have sometimes been willing to infer intercourse from physical marks or injuries, e.g., a ruptured hymen or anal tearing. However, a recent report by the Royal College of Paediatrics and Child Health (2008) called into question the extent to which such examinations could warrant positive findings of abuse, prompting the Court of Appeal to quash a conviction of child sexual assault in *R* v *PF* [2009] EWCA Crim 1086. Medical evidence led by the prosecution at trial was also criticized for being too dogmatic by the appeal court in *R* v *Martin T* [2008] EWCA Crim 3229, but on this occasion the conviction was upheld on the strength of the complainant's testimony. In these delicate situations, involving disputed allegations of sexual abuse or assault, prosecutors must balance their duty to present as strong a case as possible today, against the possibility that changes in medical opinion might tomorrow undermine the safety of any conviction secured at trial. Recent experiences of dramatic reversals in prevailing medical opinion will predictably make prosecutors more reluctant to pursue cases built upon the shifting sands of scientific knowledge (O'Brian 2011).

These observations and illustrations prompt a more general question: to what extent should prosecutors be responsible for assessing the quality and validity of scientific evidence (as opposed to assessing its probative value on the assumption that scientific evidence is valid)? Of course, if a prosecutor knew or strongly suspected that a particular expert witness was incompetent or a charlatan it would constitute a gross breach of professional responsibility to present that person to the court as a witness of truth. Such faulty evidence could not legitimately contribute towards satisfying the evidential sufficiency test for prosecutions in England and Wales. But this is presumably – to put it no higher – a very unusual scenario. Prosecutors are not themselves trained scientists or forensic experts. When any indications to the contrary are absent, why shouldn't the prosecutor simply take at face value the validity of scientific evidence produced by ostensibly well-qualified experts? After all, scientific experts are called upon to assist in criminal proceedings precisely because they contribute knowledge and skills otherwise unavailable to the justice system. Expert evidence comprises scientific findings, interpretative judgments, and expressions of opinion which prosecutors are presumptively ill-equipped to second-guess.

Two mutually aggravating considerations belie this superficially plausible rationalization of the legal status quo. First, recent years have witnessed a growing realization that many of the traditional forensic sciences routinely employed in criminal prosecutions and trials actually lack formal, rigorous scientific validation. A report published in 2009 by the highly respected National Research Council of the National Academy of Sciences in the USA concluded that "[i]n a number of forensic science disciplines, forensic science professionals have yet to establish either the validity of their approach or the accuracy of their conclusions, and the courts have been utterly ineffective in addressing this problem" (National Research Council 2009: 1–14). Even the reliability of fingerprinting has been called into question by high-profile controversies and inquiries in the USA (see ibid: 5–7 to 5–14) and the UK (The Fingerprint Inquiry: Scotland 2011). The point is not to induce blanket skepticism about scientific evidence and the thousands of convictions based on it, which would be a counterproductive and unwarranted overreaction to these revelations. A more measured approach demands continued vigilance and scrutiny of scientific evidence's methodological and epistemic credentials, a task to which prosecutors should arguably contribute through searching pretrial evaluations of evidential sufficiency.

Less initiative might be expected of prosecutors in this regard if the validity of scientific evidence were sure to be thoroughly investigated at trial. But herein lies the second cause for concern. Common law courts have not traditionally imposed exacting admissibility requirements on scientific evidence. To the contrary, the general attitude has been that relevant scientific evidence should be admitted, leaving any (rare) challenges to validity to be resolved as questions of fact for the jury in the course of the trial. In recent decades, many common law jurisdictions have introduced somewhat more rigorous approaches to scientific validity, requiring trial judges to undertake some measure of "gatekeeping" scrutiny, at least in relation to novel techniques or applications. The best known of these tests is the admissibility standard elucidated by the US Supreme Court in *Daubert* v *Merrell Dow* 113 S Ct 2786 (1993) and subsequently adopted in many US state procedural codes. The success, or otherwise, of such interventions is still hotly debated. Commentators have noted a tendency (not necessarily restricted to US judges: Beecher-Monas 2007: 94–121) for *Daubert* to be applied quite stringently to disqualify claimants' scientific evidence in civil tort suits, while a far more relaxed and indulgent standard is applied to admit scientific evidence adduced by the prosecution in criminal proceedings.

In the meantime, there is no equivalent admissibility test for scientific evidence in England and Wales, albeit that the Law Commission (2011) has proposed legislation to introduce a locally adapted (and rather elaborate) version of the *Daubert* standard. One might argue that prosecutors' professional responsibility to inquire into the scientific validity of expert evidence they propose to adduce at trial is all the greater in the knowledge that scrutiny in the courtroom is likely to be minimal. Lay jurors can hardly be relied upon to detect unacknowledged weaknesses in prosecution scientific evidence that lawyers and judges have failed, or disdained, to notice. On the other hand, it is probably unrealistic, in terms of institutional culture and personal psychology, to expect prosecutors in adversarial proceedings to adopt an overly critical attitude towards scientific evidence which, on the face of it, supports their case and would easily satisfy the law's undemanding admissibility requirements.

Prosecution and Defense

In *R* v *Ward* (1993) 96 Cr App R 1, 51, the English Court of Appeal observed:

> [A] forensic scientist conjures up the image of a man in a white coat working in a laboratory, approaching his task with cold neutrality, and dedicated only to the pursuit of scientific truth. It is a somber thought that the reality is sometimes different. Forensic scientists may become partisan . . .. Forensic scientists employed by the government may come to see their function as helping the police. They may lose their objectivity.

Consciously partisan scientific evidence is antithetical to the expert witness's primary duty to the court. The judges in *Ward* were in no doubt that "the clear duty of government forensic scientists [is] to assist in a neutral and impartial way in criminal investigations. They must act in the cause of justice" (ibid. 52). This most basic of the expert witness's duties has been reiterated many times (e.g. *R* v *Harris*, [2006] 1 Cr App R 5; *R* v *B (T)*[2006] 2 Cr App R 3), and is now embodied in rule 33.2 of the Criminal Procedure Rules, which states unequivocally that:

> An expert must help the court . . . by giving objective, unbiased opinion on matters within his expertise. This duty overrides any obligation to the person from whom he receives instructions or by whom he is paid.

In the United States, Standard 3–3.3(a) of the ABA *Standards for Criminal Justice: the Prosecution Function* states to similar effect, but with the emphasis on the *prosecutor's* duty:

> A prosecutor who engages an expert for an opinion should respect the independence of the expert and should not seek to dictate the formation of the expert's opinion on the subject. To the extent necessary, the prosecutor should explain to the expert his or her role in the trial as an impartial expert called to aid the fact finders . . ..

Impartiality and objectivity are indubitably laudable ideals for scientific evidence and expert witness testimony. Whether it is entirely realistic to expect the parties to adversarial litigation to interpret their respective roles with a primary emphasis on achieving justice, viewed objectively and impartiality, is another question. The expert witness's abstract "duty to the court" and to justice provides useful, but very incomplete, guidance for ethical professional practice. Prosecutors and defense lawyers also owe duties to the court, but this hardly settles myriad difficult questions of legal ethics and strategic decision-making in adversarial trial proceedings.

It is accepted as axiomatic in all modern systems of criminal justice that the accused must have a fair opportunity to put his side of the case and adequate time and facilities to mount a defense. Justice is unlikely to be done, and certainly will not be seen to be done, if the accused is muzzled or unreasonably hampered in conducting his defense. However, active defense participation in the proceedings takes on additional functional and symbolic significance in adversarial systems. Adversary theory assumes that the trier of fact will best be able to discern the truth of contested events by hearing each side advance its best case at trial and adjudicating between them (Roberts and Zuckerman 2010: 46–65). There is no overriding duty on the court to discover the truth, as there would be in inquisitorial proceedings. It would consequently undermine not only the normative legitimacy, but also the epistemic efficacy of adversarial criminal trial procedure, if the trier of fact were allowed to hear only the prosecution's side of the story. In fact, the common law jury is always presented with at least two versions of events in any contested criminal trial, even if the defense "story" is reduced to a blanket denial of the allegations advanced primarily through cross-examination of the prosecution's witnesses.

Adversarialism has broad ramifications for defense participation in criminal trials. Specifically in relation to scientific evidence, the most obvious implication is that the defense should have appropriate access to high-quality forensic science assistance, to retest and verify the prosecution's scientific evidence, and to pursue further scientific inquiries of its own (Giannelli 2004; Roberts and Willmore 1993: Chap. 3). This is partly a question of providing adequate resources, which in practice means legal aid funding for work that the uninitiated might regard as wasteful reduplication. Criminal legal aid is virtually always squeezed in times of austerity. In addition, there is the related question of adequate defense access to evidential material, data, test results, and government labs and technicians (to the extent that these public goods survive free-market provision; wherein commercial confidentiality becomes a further potential barrier to access). This brings us to the more general, and perennially controversial, topic of pretrial disclosure by the prosecution to the defense.

Contrary to what simplistic models of adversarial "contests" might lead one to expect, trial by ambush is largely a thing of the past and is deprecated by modern courts and judges. Most common law procedural systems today require extensive pretrial disclosure by the prosecution, and many jurisdictions also demand more circumscribed disclosure by the defense. (The presumption of innocence preempts fully reciprocal pretrial disclosure in criminal litigation.) Moreover, late or inadequate disclosure by the prosecution has been exposed as a potent cause of miscarriages of justice, not least in relation to scientific evidence.

The extent of the prosecution's common law duty to disclose scientific evidence was clarified in *Ward*, in which the Court of Appeal stated:

> An incident of a defendant's right to a fair trial is a right to timely disclosure by the prosecution of all material matters which affect the scientific case relied on by the prosecution, that is, whether such matters strengthen or weaken the prosecution case or assist the defence case. This duty exists whether or not a specific request for disclosure of details of scientific evidence is made by the defence. Moreover, this duty is continuous: it applies not only in the pretrial period but also throughout the trial. The materiality of evidence on the scientific side of a case may sometimes be overlooked before a trial. If the significance of the evidence becomes clear during the trial there must be an immediate disclosure to the defence.

In *Ward* itself, negative test results seemingly contradicting the prosecution's case were withheld from the prosecutor, and consequently were neither disclosed to the defense nor adduced at trial, an outcome which particularly infuriated the Court of Appeal because the jury had been kept in the dark about potentially significant information:

> The consequence is that in a criminal trial involving grave charges three senior government forensic scientists deliberately withheld material experimental data on the ground that it might damage the prosecution case. Moreover [in their testimony at trial, two of them] misled the court as to the state of their knowledge about the possibility of contamination occurring from the debris of an explosion. No doubt they judged that the records of the firing cell tests would forever remain confidential. They were wrong. But the records were only disclosed about 17 years after Miss Ward's conviction and imprisonment. (ibid. 49)

Pretrial disclosure in England and Wales is now governed by the Criminal Procedure and Investigations Act 1996, as amended, and the Criminal Procedure Rules. Although the principle of full and timely pretrial disclosure by the prosecution is accepted beyond question in English criminal proceedings, disputes can still arise over its precise requirements in individual cases, especially regarding "unused material" not forming part of the prosecution's affirmative case. Defense lawyers and academic commentators continue to express skepticism about levels of compliance in practice with the prosecution's disclosure requirements (see Lord Justice Gross 2011), possibly indicating deep cultural resistance to full disclosure in an adversarial system (Quirk 2006).

If it emerges at trial that the prosecution has failed to discharge the full extent of its disclosure duties in relation to scientific evidence, the proper course will normally be for the judge to consider granting an adjournment to allow the defense time to deal with new information. The defense would not necessarily require extra time in every case: it all depends on the precise nature of the evidence and the way in which the trial is being run by both sides. It is conceivable, however, that the evidence would have to be excluded altogether, in cases where the defense position has been irreparably damaged, for example, because the opportunity to conduct further testing on perishable samples has been lost. In the event that material nondisclosure of scientific evidence comes to light after the trial has been concluded, the Court of Appeal may determine that a conviction is no longer "safe," in the terminology of the Criminal Appeal Act 1968, and must be quashed. Retrial might be a practical option in some, but by no means all, such cases. Viewed in this light, conscientious compliance with the prosecutor's pretrial disclosure duties is calculated to safeguard the reliability and legitimacy of well-founded convictions of the guilty, at the same time as ensuring the defense has a fair opportunity to present its side of the story to the jury in an adversarial criminal trial.

A "CSI Effect"?

The "CSI Effect" has generated some anxious practitioner and academic discussion, predominantly in the USA (see Cole and Dioso-Villa 2009). The basic idea is that jurors weaned on a concentrated TV diet of the *CSI: Crime Scene Investigation* franchise, *Law & Order*, *Bones*, *Silent Witness*, *Waking the Dead* and similar top-rated serials may have come to entertain hopelessly inflated expectations of scientific evidence. The worry is that jurors in thrall to these cultural fantasies might effectively "punish" the prosecution by voting for an acquittal in any case entirely lacking in scientific proof, or in which the more banal reality of expert evidence fails to live up to the glamorous fictional portrayals driving jurors' expectations. A handful of US prosecutors claims to have experienced the CSI Effect in cases in which the outcome has been, in their eyes, disappointing (e.g. Thomas 2005).

It is a perfectly plausible conjecture that fact-finding by lay jurors in criminal trials is influenced by a range of social and cultural factors, including expectations generated by crime fiction (Tyler 2006). But such cultural influences are doubtlessly diffuse and operate in concert with countless other complementary and confounding perceptions and motivations. The empirical basis for positing a genuine CSI Effect is exceedingly thin. Most academic commentators who have addressed the issue are highly skeptical, starting with the rather protean and ill-defined concept of "the CSI Effect" itself. In most of the shows in question police and forensic scientists are portrayed as civic heroes and forensic science itself invariably wins the day and puts the bad guys behind bars where they belong. One might equally posit that jurors immersed in these predictable narratives will be only too ready to accept the truth of the prosecution's case and, in particular, to defer to scientific proof of guilt whenever it is adduced (Godsey and Alao 2011).

Whatever the empirical truth of the matter, the theoretical possibility of a CSI Effect serves as a useful reminder that scientific evidence, for all its undoubted potency as a weapon in the armory of law enforcement, is neither infallible nor necessarily free from any conceivable drawbacks, downsides, or unanticipated side-effects. Part of the price of our increasing social investment in scientific proof may be eternal vigilance (not least on the part of prosecutors) to ensure that forensic science serves to promote, and not to thwart, the values and ideals of criminal justice.

Overview

Offending is commonly measured by asking people to admit whether they have committed each of a specified number of delinquent acts such as burglary, theft, robbery, assault, and vandalism. A key question is: How reliable and valid are these admissions? Given that people may conceal, exaggerate, or forget their offenses, how accurate are self-reports as a measure of actual delinquent behavior? This entry will focus on self-reported offending (SRO) surveys of large community samples (at least several hundred), to address this question. The extent to which these reports are differentially valid by gender and race will also be explored. There is no space to review self-report surveys of prisoners or the literature on self-reported drug use.

Self-reports of offending have been used for a number of years, initially to uncover "hidden delinquency," but more recently as a complementary measure to indexes of official offending (such as arrests or convictions). Self-reports of offending are reliable, since measures administered at different times produce similar results. The validity of self-reports is usually measured by comparing them with official arrests or convictions. Individuals who self-report offenses are more likely to have official records than those who do not report offenses, and individuals with officially recorded crimes usually admit these crimes. Crucially, self-reported offenses predict future arrests and convictions for the same crimes, even among people with no official record. Overall, the research suggests that self-reports provide a valid measure of offending for white males. Validity is sometimes lower for other demographic categories (e.g., females, Asians, and African-Americans), but these findings are far from consistent. More methodological research on self-reported offending is needed, especially on the differential validity of self-reported offending (SRO) by various demographic categories.

History of the Use of SRO

For many years, people in surveys have been asked to report offenses that they have committed that have not necessarily been detected by the police, in order to obtain information about "hidden delinquency." For example, Burt (1929) in England and the Glueck and Glueck (1968) in the United States obtained this information from their interviewees and from other informants such as parents and teachers. However, the use of structured SRO questionnaires began in the 1940s. One of the most influential early studies was by Wallerstein and Wyle (1947), who distributed a 49-item mail questionnaire to nearly 1,700 adults in New York. The main finding of this research was that offending was very common: 99 % of adults admitted at least one offense, and even ministers of the church admitted an average of 8 offenses each. Reflecting on this, however, Wallerstein and Wyle (1947) concluded that acts that were technically offenses in this study were often quite trivial.

The major influence of SRO research on criminology really began in the 1950s with the research of Short and Nye (1958). Perhaps the main reason why their SRO survey was influential was because they found no relationship between socioeconomic status (SES) and self-reported delinquency. However, when they compared training school boys with high school boys, they found that the institutionalized delinquents came from much lower SES backgrounds. The implication, therefore, was that official processing was biased against low SES people – a finding that fitted well with the prevailing theorizing at the time. This result is credited with triggering the "self-report revolution," with criminologists enthusiastically embracing the self-report method, often using the same items as Short and Nye.

Gold (1970) carried out a very important SRO survey in Michigan. This study is noteworthy because of the care taken in addressing methodological issues such as random sampling, efforts to reduce attrition, and the comparison of self-reports with informant reports of offending. The major findings of this study were that three-quarters of offenses were committed with others (most commonly peers) and that getting caught by the police was followed by an increase in offending (in agreement with labeling theory). Hirschi (1969 was the first to use the self-report method to test a theory about the causes of delinquency, and this seminal and highly cited study inspired a number of similar cross-sectional surveys designed to investigate causes using self-reports.

National SRO surveys quickly followed in the United States (e.g., Williams and Gold 1972), and these provided an alternative measure of juvenile crime rates to the official arrest records. These surveys were in turn followed by the ambitious longitudinal US National Youth Survey (NYS), beginning in 1977 and continuing to the present day (Elliott et al. 1985). This survey is one of the most important sources of self-report data on criminal careers and the causes of offending, but there are numerous other influential American prospective longitudinal studies which have used the self-report methodology, such as the Causes and Correlates projects in Pittsburgh, Denver, and Rochester; the Seattle Social Development Project; and the Oregon Youth Study (for details about all these surveys, see Farrington and Welsh 2007, Chap. 2). SRO surveys have been used in many other countries, with the Pan-European International Self-Report Delinquency Study (Junger-Tas 2010) being particularly noteworthy. The most comprehensive methodological work on these surveys has been conducted in the United States and England.

History of Research on Reliability and Validity

The first attempt to review the reliability and validity of SRO surveys was in a conference report by Hardt and Bodine (1965). They noted (p. 15) that little was known about these topics because sociologists preferred substantive research to methodological examination. The first systematic assessment of SRO surveys on standard psychometric criteria such as questionnaire construction, administration procedure, objective scoring, norms for various populations, internal consistency, retest stability, and concurrent and predictive validity was completed by Farrington (1973). He published the first demonstration that an SRO survey had predictive validity. The next important methodological and substantive assessment of SRO surveys was completed by Hindelang et al. (1981), who concluded that the reliability and validity of SRO surveys was quite good in comparison with other methods and did not vary much with the method of administration (questionnaire or interview, anonymous or not). Unfortunately, this influential and highly cited book caused a great decrease in methodological SRO research, because it was now assumed that the validity of SRO surveys had been established for all time and that methodological research was not needed. From then on, the focus was on obtaining substantive results, using self-reports as the main outcome measure in criminology.

Reliability of SRO Surveys

Reliability refers to the consistency of a measure in providing similar results under similar conditions, but this concept is generally more relevant when attempting to assess attitudes or other difficult-to-observe social constructs, as opposed to the recall of actual behavior. However, there are two criteria by which the reliability of SRO surveys can be assessed: test-retest stability (the degree to which results are consistent from one questionnaire administration to the next) and internal consistency (the degree to which items on a questionnaire all measure the same underlying construct), with the former arguably being more important than the latter. This is because it would reflect poorly on SRO surveys if the same person reported a different profile of offending during a specified time period when asked on two separate occasions (low test-retest reliability). When evaluating the test-retest reliability of SRO surveys, the time lag between the two administrations is important. If this time period is too short (e.g., a few days), participants could simply be recalling what they had said previously, whereas if the time lag is too long (e.g., several weeks), participants may forget the offenses that they had committed or may report new offenses committed in the interim.

A number of studies have evaluated the test-retest reliability of SRO measures (with various time lags). Although the results varied depending on the number and types of offenses enquired about (and the methods of scoring), they suggest that these measures are at least as reliable as measures of attitudes (Thornberry and Krohn 2003). For example, Huizinga and Elliott (1986 reinterviewed a random selection of 177 participants from the NYS 4 weeks after the initial completion of the SRO survey. They found that crime index offenses (which are more serious and less frequent) had very high reliability, while less serious and more frequent offenses (e.g., public disorder offenses) had lower but still acceptable reliability. They also did not find any consistent variation in test-retest reliability over gender, race, social class, or involvement in delinquency.

Validity of SRO Surveys

The key question for SRO surveys is validity: To what extent do self-reports produce an accurate estimate of the true number of offenses committed? And how accurately do self-reports measure the prevalence, frequency, and seriousness of offending? Setting aside the less important issues of content and construct validity, the validity of self-reports is usually assessed by comparing them with some external criterion of offending. The comparison can be concurrent (measure and criterion at the same time) or predictive (measure before criterion).

The main problem centers on what to use as an accurate external criterion of offending. Unlike drug use, for example (Harrison and Hughes 1997), there are no physical traces of burglary or shoplifting in hair, blood, or urine. Some researchers have compared SRO in the usual conditions and when people are told that their lying will be detected physiologically, and generally admissions increase in these physiological conditions. There is some evidence that admissions of problematic behavior are also greater in anonymous conditions, with audio computer-assisted interviews yielding the highest response rate (Tourangeau and Smith 1996).

Notwithstanding the fact that self-reports were intended to overcome some of the perceived deficiencies of official records, SRO results are usually validated against arrests or convictions. It is possible to compare self-reports with parent, teacher, or peer reports of offending and also to compare reports of offending with direct behavioral measures of actual offending, but there have been relatively few of these types of studies (see Farrington et al. 1980). Generally, the most important validity checks are in relation to official records.

There are two general ways in which the concurrent validity of SRO has been evaluated. The first is to compare self-reported offending (e.g., reporting breaking into a house with the intention of stealing) with official records (e.g., an arrest or conviction for burglary). The second is to examine the fraction of those who are known to have an official record who self-report official offending or to compare self-reported arrests or convictions with official records of arrests or convictions.

The level of correspondence between SRO and official records is influenced by the severity and frequency of the delinquent behavior, with the expectation that more severe and more frequent behaviors would be more likely to result in an official record and more likely to be self-reported. For example, Maxfield et al. (2000) found that 59 % of those with one arrest self-reported that they had been arrested, compared with 73 % of those with 2–4 arrests and 85 % of those with five or more arrests (vs. 21 % of those with no arrests).

Concurrent Validity of SRO

Overall, the correlations between self-reports of offending and official records of arrests or convictions are generally substantial and statistically significant. However, correlations are not very good assessments of the validity of SRO surveys because most self-reported offenses will not result in an official record. The correspondence between self-reported offending and official records (both dichotomized) can be illustrated using a 2 × 2 table (Table 1).

In cell a (SR Yes, OR Yes) and cell d (SR No, OR No), the two measures of offending correspond, and this is treated as accurate responding. Cell b (SR No, OR Yes) is usually treated as concealment of offending by the individual and as such is commonly referred to as underreporting. There are of course other reasons why someone might not report an offense that was officially recorded, including forgetting and being innocent of that particular offense (e.g., because of plea bargaining). Cell c (SR Yes, OR No) represents one of the key purposes of SRO surveys, to identify offenders and offenses that have not been officially recorded. A lack of correspondence here can therefore not necessarily be attributed to a lack of validity, although this cell count might be influenced by exaggerated reporting. However, when self-reports of arrests or convictions are compared to official records, cell c might indicate overreporting (or faulty records).

Self-Reported Offending: Reliability and Validity, Table 1 Self-reports versus official records

	Self-report		
		Yes	No
Official	Yes	a	b
Record	No	c	d

When examining the validity of SRO, it might be expected that the probability of an arrest or conviction would increase with the intensity (e.g., frequency or seriousness) of self-reported delinquency. For example, Jolliffe et al. (2003) investigated the validity of self-reports by comparing these to the court referrals of over 800 boys and girls (age 11–17) in the prospective longitudinal Seattle Social Development Project (SSDP). A total of 626 youths self-reported at least one offense during this age range, and 230 of these (37 %) had a court referral. In contrast, 101 reported that they had not committed any offense, and only 16 of these (16 %) had a court referral. This comparison was statistically significant and suggested that court referrals were much more common among those who self-reported an offense than among those who denied offending. This measure of concurrent validity was highest for those who self-reported burglary (a serious offense) or drug offenses (the most frequent). A number of other studies have also demonstrated the concordance between SRO and official records.

Some researchers have questioned, however, whether self-reports of offending are equally valid across demographic categories. Generally, male/female and black/white ratios in American SRO surveys are lower than in official records. One possible reason for this is that male and black youth are more likely to conceal their offenses than females and white youths, but there are also a number of other potential explanations. Since the prevalence of offending is usually much greater in self-reports than in official records, there may be a "ceiling effect"; for example, if 50 % of white youth self-reported offending, the maximum possible black/white ratio in self-reports would be 2:1, whereas if 20 % of white youth were convicted, the maximum possible black/white ratio in convictions would be 5:1. In addition, self-reported offenses may not be comparable to (may be less serious than) official offenses.

Methods of scoring may influence race and gender ratios. Elliott and Ageton (1980) found that these ratios were much greater when the scoring allowed for large numbers of admitted crimes, rather than the maximum category being "three or more," for example. They concluded (p. 107) that race and gender differences were "more extreme at the high end of the frequency continuum, that part of the delinquency continuum where police contacts are more likely." Another possibility is that official records may reflect police and court bias against male and black youth, and more recorded male and black youth might in fact be innocent. Alternatively, male and black youth may be disproportionately arrested because of their aggressive demeanor. In a validity test, Hindelang et al. (1981) investigated how many offenses known to the police were self-reported and found that white males failed to report 20 % of serious offenses, compared with 57 % for black males, 50 % for white females, and 59 % for black females.

Similar findings on differential validity of SRO have been reported in other studies, but the pattern is far from consistent. For example, using data from the Pittsburgh Youth Study, Farrington et al. (1996) discovered that, although the self-reports of both Caucasian and African-American boys were significantly associated with their court referrals, the relationship was stronger for Caucasians. However, in the SSDP, Jolliffe et al. (2003) found that concurrent validity was lowest for Asians and females and that African-American males had the highest concurrent validity.

The comparison between SRO and official records has also been studied for racial and ethnic minorities in other countries. In a longitudinal study in New Zealand, Fergusson et al. (1993) found that children of Maori or Pacific Island descent were 2.9 times more likely to have a police record than children of European descent, but were only 1.7 times more likely to offend according to parent and self-reports. The researchers attributed these findings to ethnic biases in citizen reporting and police recording. In a national SRO survey in the Netherlands, Junger (1989) discovered that Moroccan and Turkish boys with police records were less likely to admit delinquency than indigenous Dutch boys or Surinamese boys. She pointed out that concurrent validity was not necessarily lower for ethnic minorities, because the Surinamese boys were black.

Another measure of the concurrent validity of SRO is the percentage of those with a court record for a particular offense who admit committing the same offense. For example, of those with a court referral for burglary, what percentage admit that they have committed a burglary? The association between self-reports and official records in this type of comparison is generally quite high. For example, in the SSDP, Jolliffe et al. (2003) found that, of the 246 youth referred to court, 94 % admitted committing at least one offense. The probability for specific offenses was lowest for robbery (38 %) and highest for marijuana use (100 %). Figures ranging from 54 % to 90 % have been discovered in similar studies, suggesting that most officially identified offenders self-report their particular offenses, but some differential validity by gender and race has been found. For example, in the study by Jolliffe et al. (2003), males were more likely to admit than females, and Asians were less likely to admit than either African-Americans or Caucasians. There were no differences in concurrent validity between African-Americans and Caucasians.

Concurrent Validity of Self-Reports of Arrests or Convictions

A more direct method of investigating validity is to compare self-reports of arrests or convictions with official records of arrests or convictions. For example, West and Farrington (1977) found that, at age 18, 94 % of convicted boys admitted that they had been convicted, while only 2 % of unconvicted boys claimed to have been convicted. Of offenses leading to conviction, 53 % were reported accurately, 34 % were reported but minimized, 7 % were reported but exaggerated, and 6 % were not reported. The probability of arrested or convicted offenders admitting their crimes is also high in other studies, with those who have a greater number of convictions being generally more willing to self-report offenses (e.g., Brame et al. 2004).

Again, there is some indication of differential validity by gender and race in the self-reporting of official contacts. Hindelang et al. (1981) found that 76 % of white male official delinquents reported that they had been picked up by the police, compared with 52 % of white females, 50 % of black males, and only 30 % of black females. These results fostered the widespread belief that the self-reports of black youths (especially those who were the most delinquent) were less valid because of concealment. Other studies, however, have not found race differences in reporting arrests. Maxfield et al. (2000) discovered that 75 % of convicted white youths admitted being arrested, compared with 70 % of black youths (not significantly different), and 76 % of convicted males admitted being arrested, compared to 60 % of convicted females (significantly different). More recently, in a large sample of Dutch adolescents, Van Batenburg-Eddes et al. (2012) found that 62 % of those with official police contacts self-reported a police contact (interrogation in the police station), but this was somewhat higher for older (age 14–15) adolescents compared to younger (age 12–13) ones: 65 % compared to 57 % (significantly different). They also found that indigenous Dutch (65 %) and Surinamese (70 %) boys and girls were significantly more likely than Moroccan boys and girls (46 %) to report their police contacts.

The differential validity of the self-reporting of arrests was explored by Krohn et al. (2013) using data from the Rochester Youth Development Study. Overall, 61 % of arrests were admitted. Arrested males (64 %) were more likely to admit their arrests than arrested females (46 %). Caucasian males were likely to overreport arrests, while African-American males were likely to underreport arrests. However, Krohn et al. (2013) also demonstrated that those who were arrested more frequently were least likely to report each arrest, regardless of race or gender. It could be that frequently arrested offenders had more difficulty in remembering all of their arrests.

There have been relatively few studies of how concurrent validity varies with age. However, Kirk (2006) compared age-crime curves based on official and self-reported arrests. The two curves were generally similar, but the self-report curve had a higher and earlier peak (at ages 18–19) than the official curve (at age 21). Kirk also found that the black/white prevalence ratio was higher for official arrests (2.3–1) than for self-reported arrests (1.3–1), but this was because whites overreported their arrests; 21 % self-reported an arrest compared to 13 % who had an official arrest.

Predictive Validity

Predictive validity is more impressive than concurrent validity, because being convicted may itself lead to an increase in the probability of admitting delinquent acts (Farrington 1977), perhaps because a person may assume that the researcher will know about convictions and therefore that concealment is futile. It is to be expected that current self-reported offending (of past acts) will predict future convictions, because many current self-reported offenders are also convicted and because future convictions are of course predicted by past convictions. A better test of the predictive validity of SRO surveys is to investigate the extent to which self-reports predict future convictions *among currently unconvicted people*.

There have only been four investigations (using three prospective longitudinal studies) of the predictive validity of SRO. In the Cambridge Study in Delinquent Development (a survey of over 400 London boys), Farrington (1973) showed that, for unconvicted boys, a measure of self-reported variety of offending at age 14 significantly predicted their probability of conviction in the following 3 years. Farrington (1989) later repeated this analysis for specific types of offenses. For example, among boys not convicted of burglary up to age 18, significantly more of those who self-reported burglary up to age 18 were subsequently convicted of burglary up to age 32, in comparison with the remaining boys who denied committing burglary up to age 18 (20 % as opposed to 2 %). Similar results were obtained for vehicle theft, assault, vandalism, and drug use, but not for shoplifting.

In the first test of predictive validity using American data, Farrington et al. (1996) classified the self-reported offending of Pittsburgh Youth Study boys into four categories based on seriousness of offending and compared this with their later petitions to court. For both samples, the predictive validity of self-reports was high and statistically significant (except for drug offenses in the oldest sample). Of the boys who reported the most serious forms of delinquency, 29 % were petitioned to court for Index Violence, compared to only 7 % of the boys who reported no delinquency. This difference was statistically significant, again showing that SRO had predictive validity. Farrington et al. (1996) also examined the extent to which predictive validity varied according to race, but found that predictive validity was similar for Caucasians and African-Americans. Perhaps the most important finding with regard to the validity of SRO was that there was a substantial increase in predictive validity by combining the reports of the boys with those from other sources (mothers and teachers).

Jolliffe et al. (2003) examined the predictive validity of SRO for males and females of different racial backgrounds. In the SSDP, they found that predictive validity was high and statistically significant for most offenses (except robbery and vehicle theft). It was generally higher for males than for females and highest for Caucasians and lowest for Asians (predominantly Chinese and Filipinos). The self-reports of Asian and African-American females had the lowest predictive validity.

Summary and Future Directions for Research

Self-reports of offending were initially developed to reveal the dark figure of crime, but they have evolved to be one of the most common outcome measures used in criminological research. On psychometric criteria, self-reports provide a reliable measure of offending. In addition, most research suggests that self-reports are concurrently valid, in that those who self-report offenses or arrests are more likely to have official records than those who do not self-report, and those who have been officially recorded tend to admit their offenses. Importantly, self-reports have predictive validity; among those with no official record, those who self-report offenses are more likely to be officially recorded in the future than those who do not self-report. This is good news for criminological researchers. The bad news is that the overall validity of self-reports conceals the fact that they appear to be more valid for some demographic categories than for others. Self-reports are clearly valid for white males, but they are less consistently valid for females, for Asians, and for African-Americans. Little is known about validity at older ages. That said, there are indications that other factors (e.g., number of arrests) might be more relevant to validity than demographic categories. More research is needed on the validity of self-reports of offending, and of self-reported arrests and convictions, to establish the optimal conditions for enquiring about these topics. Randomized experiments, such as that conducted by Enzmann (2013), are needed to study the effects of different methods of administration on the reliability and validity of different demographic categories. It is also important to establish to what extent differential validity might reflect biases in official processing. Since most criminological research is based on self-reports, it is very important that their reliability and validity should be measured.

Sentencing as a Cultural Practice

Overview

Most of the scholarly literature on sentencing is written from a legal or philosophical perspective. Legal scholarship analyzes sentencing law. Philosophical work analyzes the normative debates about the aims of punishment in a liberal democratic society. This chapter examines sentencing as a cultural practice. Culture refers to sets of shared meanings or collective representations. To study culture is to examine the ways in which meanings are defined, enacted, mediated, communicated, and shared by a range of actors and audiences. A cultural analysis of sentencing is a study of how certain important meanings are represented. These include representations of moral boundaries, of justice, and of legitimate decision-making processes. David Garland argues that penal institutions have important cultural dimensions and consequences which shape penal policies and practices.

> Cultural categories, habits and sensibilities are embedded in and constitutive of our political and economic institutions. (Garland 2006)

A cultural understanding of sentencing seeks to understand sentencing as a collective practice which involves nonjudicial actors as well as judges. Garland distinguishes between different uses of the term “culture” in the sociology of punishment. On the one hand, “culture” describes a particular web of meanings which can be found empirically, for example, the local court culture of a particular jurisdiction which is shared and reproduced by the regular court actors. In this sense a culture is a more or less bounded set of customs, values, habits, and beliefs. On the other hand, “culture” can also be used analytically to describe ways of making meaning in a social setting, for example, how the sentencing process defines what it means to make just decisions about the allocation of punishment. In this sense cultural analysis is distinct from other forms of analysis, for example, political. A cultural analysis focuses on the creation of meaning, and a political analysis will focus on how a particular meaning becomes powerful and silences other potential meanings. This chapter focuses on the latter use of the concept; it provides a cultural analysis of sentencing rather than describing a particular sentencing culture (Yanow 1996).

There are three important ways in which a cultural approach provides a better understanding of sentencing.

First sentencing articulates the moral boundaries of society. In allocating different sorts of punishment to different sorts of offender, sentencing defines the boundaries between order and disorder, between the respectable and the disreputable, between the pure and the polluted, between good and evil, and between reason and emotion. Whatever particular forms punishment takes, it always performs this cultural task of ordering, separating the sacred from the profane (Smith 2008; Douglas 1966). Thus, sentencing helps to promote social solidarity.

Second, sentencing decision making performs and defends a particular definition of "justice." A distinctive narrative of justice underpins sentencing decision making in most common law jurisdictions, even in those US states with sentencing guidelines. This narrative both purports to describe how judges reach their sentencing decisions and also provides a normative justification for these decisions. This narrative, which is commonly known as "individualized sentencing," is described below.

Third, sentencing reproduces shared sets of meanings. It is a social practice and not just the action of an individual judge. Sentencing decision making, like other social action, is largely habitual, taken for granted, and unreflective. This does not mean that sentencers have anything less than a thoroughly professional, conscientious, and serious-minded approach to their work. But like all professionals, they work within a framework of meanings, perceptions, values, and motives that for most of the time are unquestioned. They are the taken-for-granted assumptions on which the challenging job of sentencing is based. Bourdieu calls this the "habitus" (Hutton 2006). Individualized sentencing forms the habitus for judges; it refers to the unquestioned, taken-for-granted cultural framework which defines both the way that decisions are made and also the way that these decisions are justified.

The chapter proceeds by looking at each of these three cultural tasks and in the final section analyzes the challenges to the dominant cultural approach to sentencing.

Boundaries of Moral Tolerance

From a broader Durkheimian perspective, sentencing decision making enacts deeper cultural meanings about moral boundaries which both bind society together and at the same time identify fractures and divisions (Smith 2008). Punishment expresses ideas about the sacred and the profane, about moral pollution, and about atonement and evil. As Philip Smith argues, "we can understand these basic, protean, cultural categories running through and under what appear to be more rational modern scientific instrumental or bureaucratic tendencies." Sentencing performs an "othering" function in all communities. There cannot be a community, "people like us," without people who are not like us. Sentencing therefore both includes and excludes. For Smith, following Durkheim, all societies have crime and punishment but the cultural meanings of these vary. They are invoked and put into practice in a political context and are always contested and contestible.

In allocating punishment, sentencing performs the job of defining these moral boundaries. In a broad sense, this involves invoking binary classifications such as good/evil, sacred/profane, pure/polluted, safe /dangerous, and insider/outsider. Sentencing decision making involves drawing these black-and-white distinctions, but it also involves more subtle shading which blurs the apparently sharp binary division and produces distinctions which are not as clear-cut in practice as they may appear in cultural theory.

Criminalization and the decisions of police officers and prosecutors about whether to proceed further with a reported incident patrol the boundaries between criminal and noncriminal. Sentencing is really about the shape and gradation of the negative side of this binary divide and also sometimes about the potential for an offender to shift back across to the positive side. Sentencing is about separating the good guys from the bad guys. It is also about establishing just how bad the bad guys are, about the possibility or impossibility of bad guys transforming themselves into good guys, and about what opportunities may be offered to help them to change.

In sentencing, the distinction between prison and the community is symbolically crucial. In those jurisdictions where the death penalty has been abolished, prison is the most severe sanction now available. In both England and Wales and Scotland, legislation provides that custody should only be used as a last resort where no other sanction would be appropriate Padfield (2011), Tombs (2004). The removal of the individual from the community by the State signifies both the power of the state and the subjugation of the body of the individual offender. The decision to imprison has therefore a qualitatively different significance from those other sanctions which deprive the offender of limited amounts of time, money, or association.

Aside from the custody/community tension, there are other important meanings being generated in sentencing. At the most serious end of the scale, there is a debate about how long serious offenders need to be imprisoned and the relativities both within offences (e.g., how to define different levels of seriousness of rape) and between offences (e.g., a rape and a serious assault). At the lower end, there are decisions about the boundary between fines and community sanctions (which have received less attention because of the symbolic and fiscal implications of custodial sentences) and the debates about whether fines are simply a form of economic regulation which carry little of the stigma of the other sanctions. The fine delivers pain while impacting minimally on the freedoms of movement, speech, association, and political participation that we call "liberty." The regulation of conduct virtually through automated bank transfers may be seen as a dystopian nightmare by some (Aas 2005), but it could also be the desirable freedom of a consumer society where we choose whether or not to conform and pay the price if we decide not to, literally the price of freedom (O'Malley 2009).

While it is true to say that the implementation of the criminal law performs the function of dividing conduct into acceptable and unacceptable, in practice the boundary is more accurately described as a sloping shelf, than a clearly defined wall. The boundary relates strictly speaking to actions, people can move from one side to the other. However, in practice we tend to think about criminals rather than criminal acts, and the label of criminal may persist independently of particular actions. Sentencing plays the important cultural function of defining the shape and texture of the boundary between "them and us" which turns out not to be a sharp binary distinction but a much more amorphous and liminal territory. The prison population is clearly visible "out there," but there are crowds milling around the prison walls.

In this section we have seen that punishment is about drawing distinctions between insiders and outsiders and that sentencing is the performance of this cultural process of ordering. So sentencing is not about exclusion or inclusion but about both. Sentencing can support discourses of redemption, desistance, and rehabilitation, but it also needs to support discourses of punishment, pain, and exclusion. Sentencing therefore cannot choose between rational and emotional responses to offending; it has to be able to sustain both of these approaches.

The Discourse of Individualized Sentencing

The discourse of individualized sentencing may be summarized as follows. In reaching their decision, judges take into account all of the facts and circumstances of the individual case. Each case is composed of a very large number of relevant factors and is therefore held to be unique. No two cases are exactly the same. Judges reach their decision by an "instinctive synthesis" (R v Williscroft [1975]VR292 at 300) of these myriad factors. By defining each case as unique, this approach is able to remain silent about consistency, another important feature of liberal definitions of justice. So individualized sentencing performs a particular sort of "justice" which privileges the specificities of an individual case over the demands of consistency. Judges use the discourse of "individualized sentencing" to defend a particular approach to making just decisions. "Individualized sentencing" therefore performs a particular cultural logic which both produces "justice" in sentencing and defends this definition against its potential critics, primarily those who argue that it is possible to determine similarities between cases and that it is ethically important to treat similar cases in a similar way. "Instinctive synthesis" has a transcendent quality because it is not susceptible to further rational explanation. There is thus an element of the sacred in the discourse of individualized sentencing. Intuitive synthesis presents sentencing decision making as being beyond the control of human agency, a function which can only be performed by those holding the office of judge.

Sentencing as a Social Practice

Sentencing is collective action made possible by shared cultural meanings and understandings. The actions of other criminal justice actors in the process play a part in shaping the judicial sentencing decision and are also shaped by this approach to decision making. Sentencing is a stage in the criminal justice process. Judges deal with cases which have been constructed by other actors. Each case proceeds through several processes of translation. The term "translation" (Latour 2005) is used here to make the point that what constitutes a "case" changes, as it passes through each stage of the process. Actors interpret information which is presented to them by others, act on this information in pursuit of their professional requirements, and pass this information on to the next set of actors in the next stage of the process. Cases are therefore constructed out of witness accounts, police reports, prosecutors' professional practices, reports written for the court by social workers, medical professionals, forensic scientists, psychologists, psychiatrists, and defense pleas in mitigation (Castellano 2009; McNeill et al. 2009; Sudnow 1965; Tata 2007; Yngvesson 1989). When judges pass sentence, their understanding of the case comes from reading documents and sometimes listening to evidence and argument. They have no unmediated access to the event that gave rise to the case. Thus, by the time that the case has reached the sentencing stage, it is defined in a particular way which already limits the options open to the judicial decision maker. The case is a more or less familiar narrative which prompts a more or less familiar ending.

So sentencing is not simply about judges nor is it solely about individual cases nor about individual decisions. Sentencing is a social practice and also a cultural practice.

Sentencing is the social and cultural performance of a particular definition of justice. The term "performance" is chosen deliberately to emphasize the importance of action. Justice is not something which only exists in philosophical debates or in sentencing texts. Justice has to be enacted every day in the decision-making processes of actors working in the criminal justice system. One of the most important cultural tasks of the sentencing process is to persuade audiences that sentences passed by the court are just. Sentencing is therefore about the creation of meaning performed by an interpretive community. Sentencing is a means of communicating, persuading, convincing, justifying, and providing an account of decisions which have a profound impact on individual offenders and carry powerful messages both about the kind of society we live in and the kind of society we might want to create.

Philosophical Aims of Sentencing

From a philosophical perspective, the main issue related to sentencing is the moral question of how punishment can be justified and what should be the aims of punishment (Honderich 1989). The infringement of individual liberty and/or the imposition of pain by the state requires to be both lawful and morally justifiable. Debates range about whether punishment should be backward looking and impose punishment proportionate to the seriousness of the offence ((just deserts) or whether punishment should be forward looking and seek to have an impact on reducing crime by deterring individuals or the general population, by making reparation to the community or the victim, by rehabilitating the offender, or by protecting the public. Most jurisdictions adhere to these aims at a general systemic level, but in terms of sentencing decision making, it is not clear what impact, if any, the pursuit of aims plays in selecting the type and severity of sentence in individual cases. This "cafeteria" approach (Ashworth 2010) offers great flexibility as any sentence can be fitted into one or more of these justifications. It enables sentences to be justified on a case-by-case basis. However, the flexibility of this suite of aims is also a weakness.

A sentence which appears to be fair in comparison with sentences for similar cases may not be an appropriate sentence for protecting the public or for enabling the rehabilitation of the offender. The cafeteria approach does not encourage any systematic or general policy approach to sentencing which makes it difficult to provide a more general rationale for sentencing to the public. Decisions are made on a case-by-case basis and if necessary justified post hoc with an account which can include any philosophical justification or combination of justifications. From a cultural perspective, the definition of justice is controlled by the judiciary. The mode of accountability is the public trust in the office of the judge.

Thus, although sentencing is a collective social and cultural practice, the way in which decisions are justified and defended is located at the level of the individual judicial decision maker. The following section describes the cultural framework of sentencing. It shows how individualized sentencing, seen as an approach to making and justifying decisions about justice, promotes particular values, allocates the power to define what is to count as justice to particular agencies and processes, and adopts particular rhetorical devices to persuade audiences of its propriety and legitimacy.

Sentencing as the Performance of Justice

Sentencing decisions perform justice. They define what counts as a "just" decision. These decisions also need to be justified. The discourse of individualized sentencing needs to explain how decisions are just and also needs to demonstrate that the process by which these decisions were reached was legitimate and persuade audiences of the propriety and correctness of this decision-making process. In this sense sentencing shares much in common with administrative decision making. Recent work in the cultural sociology of administrative justice provides a useful framework with which to analyze the ways in which sentencing seeks to construct just decisions and defend these decisions.

Sentencing is a legal decision in so far as decisions are made by judges, have the authority of the court, and are therefore legitimate. However, the way in which sentencing decisions are made accountable and justifiable has as much in common with administrative decision making as it does with judicial decision making. Although sentencing decisions are made by judges, the procedural form and mode of justification through which these decisions are made and defended are, in important ways, quite unlike other judicial decisions. Kagan (2010) argues that the characteristic function of an administrative decision is to get the work of society done while the characteristic function of a legal decision is to establish the legal coordinates of a situation in light of preestablished legal rules. In terms of Kagan's typology, sentencing decisions look more like administrative decisions than legal decisions.

Individualized sentencing is more about doing the job of making a "just" decision in an individual case than it is about applying rules to facts. "Rules are based on generalisations" (Kagan 2010, p. 11). A rule says that if A and B and C obtain, then the appropriate decision is X because X will advance the policy goals of the organization. In the choice of a type and amount of sentence, there are no rules which specify that if circumstances A, B, and C exist, then the judge must pass amount Y of sanction X (with the exception of mandatory life sentences in some jurisdictions). For example, there might be a well-known customary practice whereby offenders convicted of injury with a weapon which causes permanent disfigurement will receive a prison sentence, but this is a custom not a rule. The judicial decision about the appropriate type and severity of sanction is not rule governed, and thus the accounts provided to justify these decisions cannot be rule based.

Administrative decision making requires the decision maker to respond to complex and rapidly changing social circumstances which are not susceptible to the generalizations applied in fixed legal rules. Administrative decision making requires experience, expertise, and specialization to enable outcomes to be adjusted to meet the peculiarities of each individual case. Judicial sentencing decision making is based on the exercise of discretion in individual cases to deal with complex and multiple facts and circumstances. It is in this sense that sentencing more resembles administrative decision making than legal decision making. This is not to argue that sentencing is an administrative decision but rather that the style of decision making employed and its modes of accountability have more in common with the processes commonly employed to defend "just" decisions in an administrative context. "Individualized sentencing" thus serves as an important means of justifying decisions but not necessarily as an accurate account of the empirical process of making decisions.

Mashaw has argued that administrative justice refers to

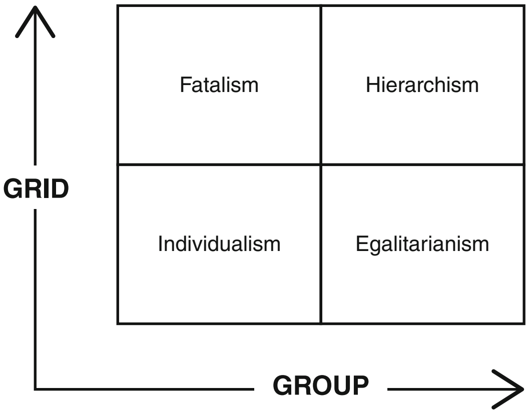
> "the qualities of a decision process that provide arguments for the acceptability of its decisions". (Mashaw 1983, p. 16)

Justice, in this context, is about the decision maker being able to provide an account of the decision process that enables the public to make a judgement about whether or not the decision is a fair and reasonable decision (Tata 2002). Members of the public may disagree with the substantive decision, but still be satisfied that it was reached by a fair and reasonable process. Individualized sentencing serves a similar purpose for sentencing. A "just" sentencing decision is reached by taking into account all of the facts and circumstances of the individual case and coming to a judgement about the type and level of sanction required.

Christopher Hood has produced a cultural analysis of administrative justice which is employed here to help understand how "individualized sentencing" defines and puts into practice a particular concept of "justice" and also to identify the challenges to this discourse based on an understanding of its weaknesses (Hood 1998).

Legitimacy and Accountability

Mary Douglas famously proposed that social relations between individual actors and the institutional arrangements for managing these individuals could be classified along two variables which she called group and grid (Douglas 1982 quoted in Halliday and Scott 2010) (Fig. 1).



Sentencing as a Cultural Practice, Fig. 1 Grid-group analytical framework of cultural biases (From Halliday and Scott (2010))

In the context of decision-making processes, grid refers to the level of externally imposed prescriptions experienced by a decision maker. High grid means the decision makers are relatively strictly bound by rules/prescriptions over which they have little or no control, and low grid means the opposite: that decisions makers have wide-ranging discretion and are relatively unconstrained by rules. Group refers to the extent to which individuals see themselves as being incorporated into bounded units, as sharing a sense of the collective. In terms of justice, a high-grid approach believes that "justice" is most effectively delivered through a closed and controlled process and a low-grid approach implies greater openness and flexibility. A high-group approach attempts to deliver collective values, a low-group approach prioritizes individual self-interest. Group addresses questions about political legitimacy, that is about who is authorized to make decisions. Grid addresses questions about modes of accountability, about what processes make decisions transparent. So this refers to how individuals both perceive their social world and how they are able or not able to understand, challenge, and participate in decision making. It refers to the relationship between the state and the individual, a fundamental concern of political theory and law.

Examining behavior across these two dimensions gives four ideal types which can be used to exhaustively classify decision-making processes: hierarchism (high grid high group), individualism (low group high grid), egalitarianism (high group low grid), and fatalism (low group low grid). These are normative ideal types which prioritize different values in decision making. Hierarchism emphasizes expertise and skills; egalitarianism emphasises citizen participation; individualism prioritises competition; and fatalism favours stoicism and/or serendipity. As with all ideal type analysis, these are highly unlikely to exist in their pure forms in the observable world. Rather, particular decision processes will exhibit varying degrees of some or indeed all of the types, usually one being predominant.

Individualized sentencing exhibits high-group features. Authority over sentencing decision making is shared between the legislature and the judiciary. The legislature set the legal framework which judges implement. Judges are entrusted to act on behalf of the collective. In practice, the legislature leave the judiciary with wide discretion to make sentencing decisions. Individualized sentencing provides a persuasive account of how just sentences are made in order to promote the collective good.

The issue of grid is more complex. At first sight, the relative paucity of rules might suggest that sentencing is low grid, but a closer examination of the discourse of individualized sentencing suggests that it is more accurately classified as high grid. The discourse of individualized sentencing effectively restricts access to decision making to the judiciary. Individualized sentencing presents itself as the single correct way to make just sentencing decisions, an approach which can only be implemented by judges and experts by virtue of their education, knowledge, and experience and which is thus inaccessible to ordinary members of the public. Sentencing decisions are justified on a case-by-case basis. There is no set of rules which can be applied to provide a justification for the sentence chosen in each case. Judges are expected and entrusted to exercise their skill and judgement for public benefit. Citizens are not expected to participate. Individualized sentencing may not have the transparency of a grid, but it has the rigidity and stability of a grid. Individualized sentencing is thus firmly a hierarchist form of decision making.

In an individualized sentencing regime, sentencing is controlled by the judiciary. Other agents and officials play a part in the decision-making process. Defense agents have the opportunity to make a plea in mitigation. Reports provided for the court by probation or social work staff provide an opportunity for these professional groups to contribute to the decision-making process. However, ultimately the decision is made by the judge. Sentencing is "owned" by the judiciary (Tata et al. 2008). Individualized sentencing is thus substantive rather than formal, irrational rather than rational, and hierarchical rather than participatory. Hierarchical, in so far as the judge controls the process and standards for decision making and yet informal in so far as the authority of the decision, rests with the power of the decision maker and not with detailed legal rules.

Challenges to Hierarchism in Sentencing

Egalitarianism

In most late modern societies, confidence in authorities and experts is diminishing (Garland 2001). The judiciary are no exception. Judges seem to be losing public trust and may no longer be able to rely on their education, status, and tradition to sustain public confidence (Hough and Roberts 2004). The perceived monopoly of the judiciary as the "owners" of sentencing is being challenged. Kagan (2010) argues that political leaders will be comfortable with an expert judgement system so long as the electorate displays high levels of trust in the experts. However, where there is evidence that trust is in decline, leaders are likely to seek to impose a more formal and legalistic decision system with clearer accountability.

There is evidence of an increasing desire amongst citizens to have a greater input into sentencing decision making. Single-interest groups in many jurisdictions particularly those representing victims of crime and their families seek to have a greater influence on sentencing decision making. Some US states have a strong populist tradition which enables more direct citizen involvement in sentencing (California's public initiatives). A variety of sentencing institutions, usually known as councils or commissions, have been introduced in many common law jurisdictions (Hutton 2008). Some of these have the power to establish sentencing guidelines; others provide public information, education, and advice. Most of these institutions offer citizens an opportunity to influence sentencing decisions, but the discourse of individualized sentencing has proved highly resistant to change because of the powerful cultural messages that it communicates.

The history of the sentencing guidelines movement (Tonry 1996) is the story of attempts to provide a more structured approach to sentencing which allocates greater significance to the pursuit of consistency in sentencing rather than the delivery of a just sentence in each individual case. This also makes sentencing decision making more transparent and accountable and therefore more susceptible to rational debate. Individualized sentencing invites challenges about who makes sentencing and policy and what the aims for such a policy should be.

Individualism

It is hard to imagine sentencing being operated by the market, although there is increasing private sector involvement in the administration of punishment. However, it is not so hard to imagine a market approach being used to assess sentencing. In most areas of government spending such as health or education, the executive is responsible and accountable for setting budget priorities for the expenditure of public funds to manage activities in these areas. Ministers are responsible for ensuring that their officials make their decisions in a just manner, ensuring, for example, that appropriate processes have been observed and that the decisions are fair and reasonable. In common law jurisdictions where there are no comprehensive sentencing guidelines, the aggregate of sentencing decisions is, de facto, the sentencing policy for these jurisdictions. In this sense sentencing may be seen as a decision-making process which effectively allocates scarce penal resources in a particular way and provides a form of public justification for these decisions.

In an individualized sentencing approach, justice is defined with reference to an individual case and wider policy considerations about how sanctions might be allocated in a more cost-effective manner are not relevant. Decisions about justice are made by judges not policy makers although the allocation decisions of judges have significant public policy impact. Many US states are seeking to exert greater regulatory control over judicial decision making in sentencing to enable the government to exercise greater control over penal expenditure (National Conference of State Legislatures 2011). These pressures are being felt across Western jurisdictions. Politicians are keenly aware that justice clearly has a price and that for many jurisdictions, the current price is no longer affordable.

Fatalism

Fatalism is the belief that decision making is an unpredictable lottery. It can lead to cynicism and populist anger or it can lead to quietism and tolerance. There is also a strong element of fatalism in so far as citizens feel unable to influence sentencing policy and practice which is widely perceived to belong to the judiciary rather than the province of elected governments.

The strength of fatalism as a cultural bias should not be underestimated. It almost goes without saying that governments and judges need to see themselves as making positive and constructive decisions, as both being able to and having a duty to "make a difference." At the same time individuals judges, ministers, and policy makers will from time to time feel that their job is impossible. Crime will never go away and it is hard to find evidence of effective ways of dealing with crime. The media hold politicians responsible and it is not hard for them to find instances of failure. This is a cultural perspective, not an objective fact. The inevitability of crime and the apparent limitations of punishment to control crime need not lead to despair or cynicism, but rather to different ways of defining the issue and different modes of action to develop higher-group identification.

From a cultural perspective, decisions about justice in sentencing are justified by a hierarchist approach which is based on public trust in the discretionary decision making of individual judges on a case-by-case basis. This approach prioritizes particular values, most significantly those of professional expertise and experience and intuitive moral judgement. The inherent weaknesses in this approach are challenged by approaches which want to give a higher priority to different values, for example, a more rational and transparent form of accountability and a greater involvement of citizens and interest groups in decision making.

Conclusion: Why Is the Cultural Analysis of Sentencing Decision Making Useful?

Cultural analysis is useful to examine both stability and change in sentencing. In cultural terms, individualized sentencing has proved exceedingly durable and resistant to criticism. The discourse allows judges to retain control over the ways in which sentencing decisions are made and, perhaps more significantly, over how decision making is justified. The idea of fitting a sentence to the particularities of each individual case is fundamental to common sense conceptions of justice, and individualized sentencing deploys classic rhetorical devices to persuade audiences that it is the only process which can guarantee the production of justice in sentencing. To that end, justice is held to depend on scrupulous consideration of the detailed facts and circumstances of each case. The decision is made by judges and members of a respected, principled, and almost sacred profession, located above the compromised, pragmatic, world of politics. Their method is archaic, mysterious, and sacerdotal. Concerns about consistency, accountability, and rationality are presented as misguided attempts to objectify something which is inherently subjective. This representation of sentencing chimes with our common sense understandings of crime as a matter of individual responsibility, attributable to bad moral decisions made by individual offenders. It reflects the narratives of crime and punishment that form the basis of crime fiction, television crime drama, and Hollywood movies. At least part of the explanation for the resilience of individualized sentencing as an approach to sentencing lies in its insistence that "just" punishment is about the right punishment for an individual offender.

At the same time, like all justice discourses, the discourse of individualized sentencing contains the seeds of its own potential demise. As its strength is dependent on public trust in the judiciary, so it is vulnerable as this trust is perceived to be waning. Hood (1998) argues that cultural change always emerges from the perceived weaknesses of an existing state of affairs as opposed to being driven by utopian theoretical proposals premised on the possibility of starting with a blank sheet of paper. A cultural understanding tells us that any approach to decision making has both strengths and weaknesses. Change often results from the perceived failure of a process being attributed to its inherent weaknesses and solutions being sought in processes which exhibit strengths in these areas. Thus, the "problem" with individualized sentencing is its lack of transparency and limited capacity to hold judges accountable for their decisions, just as the problem with systems of sentencing guidelines is their perceived inability to take proper account of the distinctiveness of each individual case (Aas 2005).

A cultural analysis allows a better understanding of the traditional common law approach to sentencing. It shows that individualized sentencing is a political choice, not an inevitability, and that it is susceptible to challenge by approaches which offer a different version of what it means to produce justice in sentencing, for example, approaches which give a higher priority to consistency, accountability or effectiveness, and value for money. It shows that the approach to sentencing decision making in a jurisdiction arises out of political contest between politicians, administrators, judicial officers, third sector organizations, and other groups, all of which is conducted in a particular time and place and which is represented in various forms of media. It shows that there is no single objective definition of justice but rather a range of definitions over which there is continual contest.

Sentencing Commissions

Michael M. O'Hear
Marquette University Law School, Milwaukee, WI, USA

Overview

Sentencing commissions and sentencing guidelines were the preeminent institutional expressions of the sentencing reform movement that emerged in the United States in the 1970s and touched most American jurisdictions by the end of the twentieth century. This entry focuses on the history, design, and operation of American sentencing commissions. More than half of the American states have established sentencing commissions at one time or another, although several proved short-lived. At least a few commissions are believed to have played important roles in their states in advancing such ideals as uniformity, proportionality, and cost-effectiveness in sentencing policy and practice. Commissions are able to exercise influence through at least three distinct functions: collecting and analyzing sentencing-related data, advocating for or against new policy proposals in the legislature, and developing guidelines for use by sentencing judges.

The topics of sentencing commissions and sentencing guidelines are inevitably intertwined. Indeed, the core functions of many of the leading commissions have included developing and superintending guidelines. Any history or assessment of these commissions must therefore at least touch upon questions of guidelines design. However, a detailed treatment of such questions lies beyond the scope of this entry and is presented elsewhere.

Similarly beyond the scope of this entry is the history and function of sentencing commissions outside the United States, which include, for instance, commissions past or present in England, Canada, and Australia.

This entry's primary theme is the relationship between sentencing commissions and legislatures. Although sentencing commissions are predominantly legislative creations, commissions have often struggled to maintain their relevance in the face of ongoing legislative policymaking in the sentencing area, which frequently takes the form of harsh statutory responses to the "crime du jour." A secondary theme is the relationship between commissions and judges – another relationship that has sometimes proven quite challenging for the commissions to manage effectively.

Fundamentals

This section describes an early, influential articulation of the sentencing commission concept, presents case studies of two of the longest-functioning and most carefully studied commissions, and then more briefly surveys the history and design of commissions in other states.

Development of the Sentencing Commission Concept

United States District Judge Marvin E. Frankel is often credited with first proposing the idea of a sentencing commission in the early 1970s. Indeed, in his most well-known work, *Criminal Sentences*: *Law Without Order* (1973), Frankel himself characterized the sentencing commission as "the most important single suggestion in this book" (119). In particular, he saw a permanent sentencing commission as a way to mitigate systemic problems with legislative oversight of sentencing policy: "[T]he subject of sentencing is not steadily exhilarating to elected officials. There are no powerful lobbies of prisoners, jailers, or, indeed, judges, to goad and reward. Thus, accounting in good part for our plight, legislative action tends to be sporadic and impassioned, responding in haste to momentary crises, lapsing then into the accustomed state of inattention" (119).

Frankel envisioned three distinct roles for his commission. First, the commission would function as a sort of sentencing think tank, both collecting and synthesizing scholarly work in the field and designing and conducting its own studies. This function reflected Frankel's view that "the subject [of sentencing] will never be definitively 'closed,' that the process [of sentencing reform] is a continuous cycle of exploration and experimental change" (118–119). Second, putting its research and expertise to practical use, the commission would serve "as a kind of 'lobby'" with regard to sentencing issues (122). Frankel seemed to think that the commission would, in particular, represent the interests of prisoners and jailers. Indeed, he made a point of emphasizing that former or present prison inmates ought to serve as members of the commission (along with social scientists, legal professionals, business people, and artists) (120). Third, and finally, the commission would itself have some power to enact rules. Frankel did not precisely delineate the commission's jurisdiction relative to the legislature's, but suggested that the commission "could prescribe in rules of general application the factors to be considered in individual sentences, the weight assignable to any specific factor, and details of sentencing and parole procedures" (123). Thus, it seems that Frankel contemplated that the commission would promulgate what we would now call sentencing guidelines.

Minnesota's Sentencing Commission

It did not take long for Frankel's idea to achieve practical realization. In 1978, the Minnesota legislature created a sentencing commission as part of a broader package of reforms that also included the abolition of discretionary parole and the authorization of sentencing guidelines.

In broad outline, Minnesota's commission has performed each of the three roles described by Frankel. First, as to the think tank role, the commission's enabling statute directs that it "shall serve as a clearinghouse and information center for the collection, preparation, analysis and dissemination of information on state and local sentencing practices, and shall conduct ongoing research regarding Sentencing Guidelines, use of imprisonment and alternatives to imprisonment, plea bargaining, and other matters relating to the improvement of the criminal justice system" (Minn. Stat. § 244.09(6)). In furtherance of this role, the commission has gathered a "huge inventory of sentencing and corrections information," which is said to be "one of the most comprehensive and detailed databases ever assembled by any state" (Frase 2005a, b). Of particular importance has been the commission's research on pre-guidelines sentencing practices, which informed the development of the guidelines; on the corrections impact of the guidelines and proposed amendments; and on changes in sentencing practices since the implementation of the guidelines (Knapp 1987).

Second, as to the lobbyist role, the commission has participated regularly and sometimes quite successfully in legislative processes since 1978. This is not to say, however, that the commission's positions have always prevailed. For instance, a commission initiative in the 1990s to reduce the impact of plea bargaining on sentences ran into legislative resistance and proved only partially successful (Frase 2005a, b). It should also be noted that, while the commission has added an expert, well-informed voice on sentencing policy to the legislative process, it has not been quite so broadly representative a body as Frankel envisioned, at least based on its formal composition. Under the terms of its original enabling statute, the commission was to be comprised of three judges, a public defender, a prosecutor, a corrections representative, a parole board representative, and two members of the public. The commission has since been expanded to include a crime victim and a police officer. Missing, though, are social scientists, business people, artists, and (perhaps most significantly from Frankel's perspective) former or present prisoners.

Finally, as to the lawmaking role, the commission was statutorily required to promulgate sentencing guidelines for felony cases and authorized to make later amendments as necessary, subject to legislative override. The legislature initially gave the commission wide latitude in deciding which purposes and factors to emphasize in the guidelines. Notable decisions made by the commission in developing the initial guidelines, which took effect in 1980, included decisions to adopt a "prescriptive" instead of a "descriptive" approach (i.e., to seek to selectively change, rather than merely perpetuate, existing sentencing practices); to treat prison capacity as a firm constraint on guidelines severity (which implied that increasing severity levels for one offense would require corresponding severity decreases for other offenses); and to emphasize desert and offense-based considerations as primary determinants of sentence length. (Because it also gave significant weight to criminal history, the Minnesota approach was sometimes referred to as "modified desert" (Frase 1997)).

Since 1980, although the commission has retained lawmaking authority, the legislature has periodically pared back the wide policymaking discretion originally given to the commission and asserted its own lawmaking authority in the sentencing area. Often, these legislative interventions were of the type that seemed of greatest concern to Frankel: "sporadic and impassioned, responding in haste to momentary crises." For instance, in 1989, in response to a spike in violent crime, including a recent series of high-profile sexual assaults, the legislature adopted new mandatory minimum sentences for violent, sexual, and drug offenses, effectively overriding the commission's more restrained response to the crime wave (Frase 2005a, b). The legislature also amended the commission's enabling act to specify that "public safety" should be the "primary consideration" in establishing and modifying the sentencing guidelines – an implicit rebuff of the commission's emphasis on desert and prison capacity. Similarly, in 1992, after the rape and murder of two female college students, the legislature doubled the guidelines' presumptive sentences for sex offenses and imposed new mandatory minimums. In short, if an important objective of sentencing commissions is to preempt "sporadic and impassioned" penal legislation, the Minnesota commission has hardly been an unqualified success.

Yet, despite its periodic marginalization in the policymaking process, there are good reasons to regard the history of the Minnesota commission as a demonstration of the merit of Frankel's original vision. Indeed, the bare fact that the commission has survived and remained institutionally relevant for 35 years – operating in a deeply politicized field that has been repeatedly buffeted by waves of public outrage and wild swings in intellectual fashion – must itself be counted a notable success. With a half-dozen professional staffers, the commission continues to produce a detailed annual statistical report for the legislature, as well as ad hoc reports on issues of particular concern. The commission also regularly adjusts the guidelines in light of new legislation and other considerations, reports on the projected fiscal and racial impact of legislative proposals, and offers training and technical assistance for guidelines users (Minnesota Sentencing Guidelines Commission 2012). Through such activities, the commission has likely contributed to uniformity, rationality, and cost-effectiveness in Minnesota's sentencing policies and practices (Frase 2005a, b).

The commission may thus deserve some credit for Minnesota's remarkably low incarceration rate and success in avoiding the extreme prison overcrowding that has plagued so many other American states. On the other hand, Minnesota's incarceration rate was already quite low at the time the commission was formed, which suggests that preexisting aspects of the state's legal or political culture may have played an even more important role than the commission in restraining penal excess during the "get-tough" era of the 1980s and 1990s. Moreover, Minnesota's prison population has grown dramatically since 1978, even if the rate of growth has been somewhat below American norms. The commission appears to have been especially ineffective in resisting upward severity pressure in the politically charged areas of sex and drug crimes; this ineffectiveness has arguably resulted in sentences in these areas that are markedly out of step with the "just deserts" philosophy that originally animated the Minnesota guidelines (Stuart and Sykora 2011). Additionally, it should be noted that Minnesota has one of America's highest levels of racial disparity in its prison population. While these disparities seem to result largely from a complex interaction of social disadvantage, behavioral differences, and policing strategies, the commission's decisions on calculating and weighing criminal history in the guidelines may also play an important, if unintentional, role in exacerbating the disparities (Frase 2009).

United States Sentencing Commission

Although the Minnesota sentencing commission may claim the title as America's oldest, the federal commission has undoubtedly been the nation's most prominent and intensely scrutinized. Enmeshed in a political culture that seems far more polarized than Minnesota's, the federal commission has endured repeated, vociferous attacks from the both the left and the right. Perhaps even more than the Minnesota experience, the federal experience casts considerable doubt on the capacity of sentencing commissions to cure the political pathologies that Frankel associated with penal lawmaking.

As with Minnesota, proposals for a federal commission and guidelines date to the 1970s, although enabling legislation was not enacted until 1984. Once created, the federal commission faced a statutory mandate very similar to Minnesota's: gather and analyze data, make recommendations to Congress, and promulgate (and as necessary amend) sentencing guidelines (28 U.S.C. § 994). The federal commission was to be more robe-heavy than Minnesota's (three of seven voting members must be judges), but the federal statute was otherwise less prescriptive as to composition, leaving the matter to the dynamics of Presidential nomination and Senate confirmation.

One might imagine that appointment by a single president would result in a cohesive initial group of commissioners. It turned out, however, that the first commissioners were deeply divided philosophically, and one of them even publicly dissented from the guidelines the commission eventually promulgated. These divisions seem to have had important consequences for the guidelines' structure and may have contributed to perceptions that the guidelines embodied a set of unprincipled compromises (Stith and Cabranes 1998). In fairness to the first federal commission, though, it must be noted that the federal enabling statute, unlike Minnesota's, included a long list of directives regarding the content of the guidelines, many of which seemed to point in different directions (O'Hear 2006). In any event, notable decisions made by the federal commission in developing the initial guidelines, which took effect in 1987, included decisions not to endorse an overarching purpose of sentencing (in contrast to the Minnesota commission's embrace of desert); to employ the descriptive approach (except in the several important areas in which the enabling statute expressly favored harsher sentences); and to measure offense severity based not merely on the formal offense of conviction, but on a plethora of "real-offense" factors. The latter decision resulted in a set of guidelines marked by an extraordinary degree of complexity, which (along with their aggressive implementation of Congress's severity-enhancing directives) has been one of the chief sources of their unpopularity.

Since the guidelines' promulgation, the federal commission's path has paralleled that of the Minnesota commission: a strong record of data-collection and analysis has been accompanied by a more mixed record of resisting legislative interference with the integrity of the original guidelines system. With a staff of about 100, the federal commission's basic activities are similar to those of its Minnesota counterpart (publication of reports, amendment of guidelines, technical support for guidelines users, and so forth) but on a considerably larger scale.

Many commentators have effectively documented the troubled relationship between Congress and the commission, especially Congress's tendency to override the commission's policy choices in areas of particular public concern (e.g., Friedman and Supler 2008; Bowman 2004). One illustration may suffice for present purposes. In 1986, in response to a public outcry over crack cocaine and without waiting to see how the commission would deal with drugs in its pending guidelines, Congress enacted new mandatory minimum sentences for drug offenders. The law was especially tough on crack offenders: it only took 5 g of crack to trigger a 5-year minimum and 50 g for a 10-year minimum. Importantly, the corresponding weight thresholds for powder cocaine were 100 times greater, resulting in a wide disparity in the treatment of powder and crack defendants who were trafficking in similar volumes. Although not expressly required to follow suit, the commission nonetheless chose to incorporate the 100:1 ratio into its drug guidelines, thus extending the disparity across the full range of covered quantities, including those below the mandatory-minimum thresholds. Subsequent analysis by the commission, however, casts doubt on earlier assumptions that the crack form of cocaine was intrinsically more dangerous than the powder form, and also identified troubling racial disparities that arose from the 100:1 ratio (crack defendants were disproportionately black, while powder defendants were disproportionately white). Accordingly, in 1995, the commission promulgated an amendment in order to equalize the guidelines' treatment of crack and powder. Congress, however, rejected the amendment. In a series of reports over the following dozen years, the commission continued to urge Congress to soften the 100:1 ratio but to no avail. Finally, in 2007, the commission was permitted to reduce the ratio in the guidelines without congressional interference, and Congress itself then followed suit by reducing the statutory ratio to 18:1 in 2010. Although the commission eventually had some success in achieving legal change, the protracted nature of the process hardly demonstrates a high level of congressional deference to the commission's expert judgments.

In a thorough assessment of the first 15 years of sentencing under the federal guidelines, the commission claimed credit for an increase in transparency and predictability in sentencing, as well as a decrease in inter-judge disparity (United States Sentencing Commission 2004). The commission observed that it had developed "huge" databases, representing the "richest sources of information that have ever been assembled on federal crimes, federal offenders, and sentences imposed," and that its prison impact model had proven reliable in projecting prison bed and supervision needs. And those needs had become considerable; the commission noted a large increase in sentencing severity over the guidelines era. Not only were a larger percentage of federal defendants receiving prison terms, but those who were sent to prison were facing terms that were twice as long, on average, as they had been before the guidelines. Some of the increase in severity was due to congressional policy choices, such as the 1986 mandatory minimums for drug offenders, but the commission's policy choices also played a role, as in the initial decision to integrate the statutory 100:1 ratio into the guidelines. Moreover, the increase in severity was borne disproportionately by black and Hispanic defendants; the gap in average sentences between white and minority defendants grew rapidly in the guidelines era. Much of the black-white disparity was attributed to the then-prevailing 100:1 ratio.

Shortly after the 15-year report, the United States Supreme Court, in its 2005 decision in *United States v. Booker*, transformed the federal guidelines from mandatory to advisory. (Note that this decision affected only the federal guidelines, leaving intact the mandatory or presumptive character of the sentencing guidelines in Minnesota and a number of other states.) *Booker* fundamentally changed the role of the federal commission, which could no longer simply dictate policy to sentencing judges; rather, if the commission wished to maintain judicial compliance with the guidelines, it had to persuade judges that its policy choices actually merited deference. The Supreme Court made this clear in its 2007 decision in *Kimbrough v. United States*, in which the Court held that sentencing judges were no longer bound by the guidelines' 100:1 ratio. In so holding, the Court observed that the crack guidelines did not exemplify the commission's exercise of its "characteristic institutional role" because the commission relied on the statutory minimums and did not take account of "empirical data and national experience." The lesson seems to be that the commission's efficacy as a policymaking body in the future may depend in large part on its conformity to Frankel's vision of an independent, data-driven, expert agency.

Other State Sentencing Commissions

Although the Minnesota and federal sentencing commissions have been among the longest continually functioning and most carefully studied American sentencing commissions, they have hardly been alone. More than 30 other states have had sentencing commissions at one time or another (Barkow and O'Neill 2006). In some states, such as South Carolina and Alaska, the commissions were designed as temporary bodies. In other states, such as Wisconsin and Florida, the commissions were supposed to be permanent but were later abolished. In addition to Minnesota, some of the other states with well-regarded, long-established, still-functioning sentencing commissions include Kansas, North Carolina, Pennsylvania, and Virginia.

As of this writing, the National Association of Sentencing Commissions lists 22 active state sentencing commissions on its website (including a commission in the District of Columbia), although at least two of these have much broader mandates than just sentencing and at least one has recently been legislatively abolished. It is possible that states will be encouraged to develop a new wave of sentencing commissions in coming years by the American Law Institute's Model Penal Code: Sentencing project. The MPC: Sentencing "recommends to all American jurisdictions that they establish a permanent sentencing commission . . . as an essential agency of the criminal-justice system" (American Law 2007, 47).

As the Minnesota and federal case studies illustrate, sentencing commissions are often formed in connection with the abolition of parole and initially tasked with developing mandatory sentencing guidelines; in such jurisdictions, superintending the guidelines then typically becomes a core, ongoing function of the commission. A number of states, however, have not followed the Minnesota-federal model in all of these respects. In Florida and Michigan, for instance, the judiciary initially developed sentencing guidelines; commissions were only created later (Little Hoover Commission 2007). In some states, including Alaska and Tennessee, guidelines were maintained after the commission expired or was abolished. Also, in some commission states, such as Wisconsin and Virginia, the guidelines were advisory (as they now are in the federal system). In still other states, such as Louisiana and Massachusetts, commissions have operated without any guidelines at all (American Law 2007). Nor does having a commission necessarily imply the elimination of discretionary parole; both institutions existed for a time in Delaware, Pennsylvania, Virginia, and Wisconsin (Frase 2005b).

Although they vary widely in size, composition, and budget, state commissions typically have a larger and more diverse membership than the federal commission (Frase 2005b). The North Carolina commission, for instance, has 30 members, and the Virginia commission 17.

In states in which they were abolished, commissions failed for a variety of reasons. Often, the difficulties stemmed from either the resistance of judges to efforts to control their sentencing discretion or from the legislature's marginalization of the commission in making sentencing policy (Little Hoover Commission 2007).

Key Issues and Controversies

Have Sentencing Commissions Succeeded in Lessening Legislative Tendencies to Excessive Harshness?

Judge Frankel proposed the sentencing commission as a response to the problem of "sporadic and impassioned" legislative action. In this era of punitive populism, such legislative action has typically been on the harsh side, contributing to an increase in the American incarceration rate from 93 per 100,000 in 1972 to 500 per 100,000 in 2010 (Bureau of Justice Statistics 1982, 2012). Many critics contend that this ballooning incarceration rate reflects policies that "are too severe, waste lives and money, and often produce unjust results" (Tonry 2004, 3).

As Frankel's analysis suggested, a sentencing commission might bring about greater rationality and restraint in a state's criminal-justice system in at least three ways: by producing data to help policymakers better understand the costs and benefits of different policy options, by advocating on behalf of sound policies, and by creating sentencing guidelines that embody such policies. And there is some anecdotal evidence supporting the hope that commissions do sometimes succeed in reining in legislative excess (Barkow 2012; Wright 2002). Indeed, at least one multistate study finds a statistically significant, inverse relationship between the presence of a commission and growth in corrections spending (Barkow and O'Neill 2006).

Yet, it is plain that commissions are not always successful; the Minnesota and federal case studies both provide illustrations of commission marginalization. Having a commission does not ensure either a low or a stable incarceration rate. Minnesota's prison population was the nation's second-fastest growing in the first decade of the twenty-first century, while the federal system was tied for sixth-fastest (Bureau of Justice Statistics 2012). Moreover, two sentencing commission states, Alabama and Louisiana, are among the top five by incarceration rate. Commission states with low incarceration rates, such as Minnesota (notwithstanding its recent growth spurt) and Massachusetts, tend to be places that had relatively low rates even before their commissions were created; it is hard to say whether and to what extent the commissions deserve credit, as opposed to preexisting aspects of the states' political and legal culture.

It is even possible that some commissions may be counterproductive. The federal commission, for instance, is criticized for sometimes amplifying, rather than muting, ill-advised legislative policy choices, as with the 1986 drug mandatory minimums (Barkow 2012). Moreover, as Bowman argues, a complex guidelines system, like that of the federal commission, may invite, rather than discourage, legislative intervention; the federal commission, he observes, "created a mechanism that permits endless legislative tinkering in response to the crime du jour" (Bowman 2005, 250). Indeed, even a commission's data-collection and reporting activities present risks; as Wright notes, "A system that monitors sentencing practices carefully also keeps criminal justice closer to the top of the public agenda. Growth [in the prison population] may be built into this system" (Wright 2002, 90).

In the end, we cannot know for certain which commissions, if any, have truly made a long-term difference in reining in legislative excess. We cannot replay history with and without a commission, or randomly assign states to a commission or no-commission condition. States with well-financed sentencing commissions are a self-selected lot; we should not be surprised to see that these states also tend to pay greater attention to their commissions and to display greater penal restraint than other states. Whether and to what extent commissions serve to reinforce preexisting, positive tendencies in these states – although theoretically plausible and anecdotally supported – seems beyond conclusive determination.

Why Do Legislatures Create Sentencing Commissions?

In a notable series of entries, Barkow has considered the sentencing commission, not through the lens of penal policy (as it is usually considered), but through the lens of administrative law theory. One interesting question that she has posed, along with her coauthor Barkow and O'Neill (2006), is why legislatures create sentencing commissions in the first place. Although Frankel supplied good reasons to think that a commission would be in the public interest, public-choice theories suggest that legislatures are not likely to enact laws purely on the basis of public interest. In the standard explanatory model of legislative delegation of authority to an administrative agency, the legislature does so in order to avoid making a difficult decision that will inevitably offend one powerful interest group or another; legislators can then claim credit for addressing a matter of public concern without actually risking interest-group support. Sentencing, however, does not seem to fit the model: no powerful interest group opposes longer sentences, so legislatures seem free to adopt tougher sentencing laws without fear of reprisal.

Barkow and O'Neill empirically tested a number of possible explanations for commission-creation. They found statistically significant relationships between a state's likelihood of having a commission and such independent variables as a narrow partisan margin in the state, a high incarceration rate, and a high rate of corrections expenditures. In these findings, they see support for a cost-centered account of sentencing commissions: legislators support commissions in states in which corrections spending is sufficiently high so as to threaten other legislative priorities (such as keeping taxes low) and in which a close partisan divide makes it especially difficult for politicians to exercise restraint in sentencing policy and thereby risk appearing "soft on crime." In such states, delegating sentencing policy to a commission may indeed help legislators to avoid making politically risky choices.

What Actors and Activities Should Sentencing Commissions Regulate?

If, like Barkow, we think about sentencing commissions in relation to conventional government regulatory agencies, we might ask what actors and activities are regulated by sentencing commissions (Barkow 2005). Based on the example of the Minnesota commission and others that have followed in its footsteps, the answer seems to be that sentencing commissions regulate judges and, particularly, the decisions that judges make about whether and for how to long to incarcerate convicted felons. However, a sentencing commission's regulatory mission might be conceived much more broadly along both the "who" and the "what" dimensions. Indeed, if the fundamental objectives of a commission are understood to be something like achieving uniformity and proportionality in punishment or allocating criminal-justice resources in the most cost-effective fashion, then the narrowly focused approach of the Minnesota commission may be less than optimal or perhaps even counterproductive.

Consider, for instance, what may be the most perilous "third rail" for sentencing commissions: the regulation of prosecutorial plea bargaining. Plea bargaining is without question an important source of unwarranted disparities in the criminal-justice system. In jurisdictions with unregulated judicial sentencing discretion, judges could, in principle, offset some of these disparities. Depending on the overlap of statutory sentencing ranges, for example, a defendant who was able to negotiate an unusually generous reduction in charges might nonetheless ultimately receive the same sentence as other similarly situated defendants who were less fortunate in their negotiations. Sentencing guidelines, however, can impede such corrective measures, thus potentially resulting in even more prosecutor-created disparity at the same time that judicial disparity is being controlled. Indeed, the federal commission adopted "real-offense" sentencing in its guidelines precisely in order to limit the significance of prosecutors' charging and plea-bargaining decisions. Yet, federal prosecutors have proven remarkably adept at manipulating the guidelines so as to achieve desired sentencing results (Bowman and Heise 2002), which may or may not be consistent with such ideals as uniformity, proportionality, and efficiency. Indeed, in its 15-year report, the federal commission itself identified prosecutor-created disparity as an important, unresolved issue in the federal criminal-justice system. In any event, if real-offense sentencing has proven disappointing as an indirect means of regulating plea bargaining – and whatever its benefits, real-offense sentencing has undoubtedly created large complexity costs for the federal system – then more direct means might seem in order, such as the adoption of plea-bargaining guidelines. But this would put a sentencing commission at odds with a politically powerful interest group, prosecutors. Commissions have generally avoided such confrontations, and even modest commission efforts to address plea bargaining, such as the Minnesota commission's initiative in the 1990s (Frase 2005a, b have drawn strong resistance.

A thorough examination of all of the other things that commissions *might*, and in a few cases actually *do*, regulate lies beyond the scope of this entry. A few examples will serve to illustrate the range of possibilities. The North Carolina sentencing commission, for instance, has addressed misdemeanors and non-prison sentences in its guidelines (Wright 2002). Washington created a special commission to oversee juvenile sentencing in 1977, and then later transferred its responsibilities to the state's adult sentencing commission (Boerner and Lieb 2001). Hoping to better coordinate sentencing and release decisions, Chanenson (2005) has proposed a "Super Commission" that would promulgate both sentencing and parole release guidelines. A commission might also seek to regulate what sanctions are imposed for violations of the terms of probation or supervised release, as the federal commission does. Indeed, the federal commission has promulgated guidelines concerning a wide range of subjects that many state commissions have not tackled, including sentencing and plea-acceptance procedures, fines, restitution, and organizational sentencing.

Why don't commissions regulate more broadly? In part, this reflects limitations on their statutory authority. However, commissions have not always taken full advantage of what authority they do have. The Minnesota commission, for instance, could have, but did not, regulate the conditions of non-prison sentences (Frase 2005a, b). Moreover, even when statutory authority is lacking, commissions could request amendments to their enabling acts. However, as suggested by the discussion of plea bargaining above, another important constraint has doubtless been a desire by commissions and legislatures alike to avoid interagency turf battles; commissions have had enough political difficulty when their regulatory targets have been limited to sentencing judges that it is understandable why they might be less than enthusiastic about tackling prosecutors, juvenile courts, parole boards, probation offices, and so forth. And, even when it comes to regulating adult sentencing judges more fully (e.g., addressing misdemeanors and non-prison sentences), commission restraint likely reflects some combination of concerns regarding judicial resistance and resource limitations. Then, too, a commission focus on prison sentences is perfectly consistent with the Barkow-O'Neill hypothesis that commissions are formed primarily to prevent corrections costs from interfering with other legislative fiscal priorities; given the high cost of imprisonment relative to community corrections, preventing overutilization of prison seems the most direct and effective way to put a lid on state corrections spending.

How Can the Integrity of Commission Policy Choices Be Preserved From Legislative Incursions?

Although legislators may create sentencing commissions in the hope of relieving political pressures to adopt costly new sentencing laws, legislators do not seem able to keep their hands entirely off sentencing policy afterwards, even when the commission has created a comprehensive guidelines system. Legislative incursions threaten the coherence of state sentencing policy and may severely impair a commission's ability to achieve such objectives as proportionality and uniformity in punishment and stability in the size of the state prison population. Although ongoing legislative engagement with sentencing policy seems unavoidable – and, in light of democratic values, is probably even desirable at some level – a pressing question for commission design and operation is how to minimize the likelihood that the legislature will simply ride roughshod over commission policy choices; ideally, legislative engagement should be informed by commission data and expertise and should avoid large-scale disruptions to commission-created sentencing systems in the absence of some justification stronger than public outrage over the crime du jour.

Although no state seems to have found a foolproof formula, a number of devices seem potentially helpful. First, commission membership may help to strengthen the commission's relationship with the legislature or otherwise to enhance its political standing. Thus, the American Law (2007) recommends that sentencing commissions actually contain sitting members of the state legislature. Harkening back to Judge Frankel's ideas about commission membership, the ALI's model legislation also contemplates a broadly inclusive commission with representation from a range of stakeholder groups; such an approach may enhance the commission's political legitimacy. By contrast, the relatively small and judge-heavy composition of the federal commission may be one source of its political weakness.

Second, Barkow (2012) observes that reliable cost-forecasting has played a particularly important role in raising the political standing of some state commissions with their legislatures and in helping these commissions to head off costly legislative proposals with low crime-reduction benefits. This experience underscores the need for commissions to develop strong data-collection and analysis capabilities, as well as the value of statutes requiring a fiscal impact analysis of sentencing bills as part of the regular legislative process. At the same time, Wright (2002) offers an important cautionary note:

although commissions may find their greatest success by playing the role of corrections accountant, this orientation may come at the expense of promoting and contributing to public debate on some of the deeper ethical questions raised by sentencing policy.

Finally, Bowman (2005) suggests that a commission should cultivate a good relationship with judges; they are, he observes, "natural allies" in checking legislative excess in the sentencing area. He notes that some of the political weakness of the federal commission may be attributed to the adversarial relationship that developed between the commission and the judiciary in the first few years of the guidelines era. This poor relationship may seem counterintuitive, given the prevalence of judges among the commission's members. However, the judge-members were not selected by the judicial branch itself and were not necessarily reflective of mainstream judicial perspectives; the original commissioners, for instance, were tilted toward the appellate courts and had little actual sentencing experience (Stith and Cabranes 1998). By contrast, for instance, one version of the ALI proposal provides for selection of judge-members by the chief justice of the state supreme court and requires that three of five judge-members be trial-court judges (American Law Institute 2007). In any event, whether strengthened or weakened by the federal commission's membership, many judges quickly developed various negative impressions of the commission: that it was overly concerned with controlling sentencing judges and not sufficiently concerned with achieving just outcomes, that its guidelines were too harsh and too rigid, and that it was oblivious to courtroom realities and disinterested in feedback from the judges "in the trenches." This federal experience suggests that a commission wishing to maintain a good relationship with its "natural allies" should try to preserve a substantial measure of flexibility and discretion in the sentencing system, engage in regular dialogue with the trial bench, and demonstrate a willingness to modify guidelines based on judicial feedback.

How Can Sentencing Commissions Remain Relevant in an Advisory Guidelines System?

With Minnesota establishing the model, many commission jurisdictions gave their commissions the authority to promulgate and/or amend sentencing guidelines that had some level of legally binding force. In such jurisdictions, the commission has an obvious and important policymaking role (assuming the legislature does not routinely override commission policy choices). However, some commission jurisdictions chose to adopt advisory, instead of mandatory guidelines, which raises the question of whether a commission can be relevant when judges are free to ignore the commission's guidance. This question has taken on greater urgency in the wake of *United States v. Booker* (2005), which shifted the federal guidelines from mandatory to advisory, and a related line of constitutional decisions that led at least four other states to make the same transition (Pfaff 2009).

Of course, regardless of its policymaking authority, a commission may have an impact through the other two roles envisioned by Frankel, those of think-tank and lobbyist. But there are good reasons to think that a commission may also affect sentencing practices through advisory guidelines. One statistical study, for instance, found that the adoption of advisory guidelines in some states led to reduced variation in the length of sentences; although the effects were not as strong as those associated with the adoption of binding guidelines, they were nonetheless substantial (Pfaff 2006). Likewise, the *Booker* decision did not immediately render the federal guidelines irrelevant; since the Supreme Court's decision, most federal sentences have continued to be imposed within the guidelines range. Even when they are not required to follow it, some judges apparently (and understandably) appreciate and rely on expert guidance in discharging what many regard to be the most challenging responsibility in the judicial portfolio.

This is not to say, however, that advisory guidelines will inevitably succeed. Wisconsin and Louisiana, for instance, both tried and abandoned experiments with advisory guidelines

(Pfaff 2009). Moreover, since *Booker*, there have been persistent calls for Congress to reinstitute mandatory federal guidelines, prompted in part by steadily declining rates of within-guidelines sentences.

Procedural rules may enhance the relevance of advisory guidelines (and by extension of the commissions that superintend them). Following *Booker*, for instance, the Supreme Court made clear that guidelines ranges (though advisory) must still be calculated in each case; that determining the guidelines range should be the *first* step in the sentencing analysis; and that sentences within the range may be treated as presumptively reasonable on appeal. When the sentencing judge invests considerable effort in determining a guidelines range, it seems likely that the range will tend to condition the sentence imposed, even if the range is not regarded as controlling – all the more so if the range constitutes a safe harbor of sorts from the threat of appellate reversal.

Apart from such procedural rules, the commission in an advisory system may enhance the impact of its guidelines to the extent that they are persuasively grounded in sound cost-benefit research and reflect an appreciation of judicial perspectives. The commission might think of its "lobbyist" role as not merely limited to legislative policymaking decisions, but also extending to judicial sentencing decisions. This way of framing the commission's role in an advisory system underscores the importance of the commission's standing with the judiciary and the strength of the justifications it offers in support of its guidelines. In this spirit, a number of the suggestions made in the previous section regarding commission design and operation (e.g., strong representation by *trial* judges on the commission) may also be pertinent to the goal of maximizing compliance with advisory guidelines.

Future Directions

This concluding section briefly describes three important challenges that some commissions are beginning to face, and that may fundamentally alter the role of sentencing commissions in the coming years.

First, although many sentencing reformers hoped that sentencing commissions and guidelines would lessen the effects of racial discrimination in the criminal-justice system, wide racial disparities in incarceration have persisted or even grown worse in some commission jurisdictions, including Minnesota and the federal system. It does not seem that commissions have engaged in purposeful discrimination, but they have sometimes made policy choices with important racially disparate effects, such as the federal commission's original approach to crack sentencing and the Minnesota commission's treatment of criminal history. In any event, whatever the source of disparities, they seem to present an increasingly urgent threat to the legitimacy of the criminal-justice system. Commissions that concern themselves broadly with the system's fairness and effectiveness ought to pay heed. Indeed, in a few states, the legislature has prodded the commission to do so, for instance, by requiring the commission to prepare racial impact reports on sentencing bills along with a fiscal analysis (Barkow 2012). In addition to such participation in the legislative process, commissions that superintend guidelines might also do well to undertake a systematic examination of the racial impact of their own policy choices and to consider amendments so as to minimize unjustified disparities. The federal commission was a pioneer of sorts; its persistent efforts to address the 100:1 ratio were largely motivated by concerns regarding racial impact.

Second, commissions have traditionally communicated information to sentencing judges in a general way and at periodic intervals, in the form of reports, manuals, guidelines, training seminars, and so forth. In recent years, though, there has been growing interest in systems that would provide judges with real-time data at the bench or in chambers to assist with individual sentencing decisions as they arise. Such a "sentencing information system" would allow a judge to enter certain basic data about an offense and an offender, and then receive information about sentences and/or outcomes in similar cases (Miller and Wright 2005). This might include, for instance, a precisely calculated recidivism risk for an offender, or information about what probation conditions have been imposed on similar offenders in other cases. In jurisdictions in which a sentencing commission is already collecting a great deal of case-level data, the commission seems the natural agency to develop a SIS. However, putting a database created for one purpose –informing policy-level decisions by the commission and the legislature – to new uses by new users presents significant technical challenges at a minimum. The challenges would be even greater if, as some hope, different jurisdictions linked their systems and pooled their data. But the challenges may not be merely technical. For instance, one category of information that sentencing judges might like to have is cost data: what is the estimated expense to taxpayers of various sentencing options? The Missouri sentencing commission has, in fact, already attempted to make such information available (Flanders 2012). However, some critics object that cost data should not be shared with judges; this may invite a cold-blooded, cost-benefit decision that loses sight of the needs of victims or the demands of justice. Another challenge is presented by the calculation of recidivism risk. Assuming that risk forecasts may be made more accurate when data like race, sex, ethnicity, family relationships, education, income, mental health, and so forth are taken into account, difficult questions arise concerning the fairness and legality of basing sentencing decisions, even indirectly, on personal characteristics over which a defendant has little or no control, particularly when there is a history of invidious discrimination associated with those characteristics.

Finally, there is the challenge of effecting fundamental reform to an established guidelines system. Minnesota introduced the basic, widely imitated template for sentencing guidelines with the development of its two-dimensional grid more than 30 years ago. Sentencing knowledge has progressed considerably in the interim, and both public and expert beliefs seem to have shifted on a number of fundamental questions, such as the feasibility of achieving, and the desirability of attempting, offender rehabilitation in the criminal-justice system. Although commissions routinely amend their guidelines, these amendments are usually narrowly focused and rarely involve anything like a fundamental reworking of the guidelines architecture. Once a system is in place, the normal pattern seems to be that the commission becomes invested in the system's basic approach and shows little interest in reopening discussion on the big questions that had to be answered at the outset in creating the guidelines. This is all perfectly understandable, but it may become increasingly problematic as the basic models of the 1970s and 1980s fall further behind current knowledge and values. Attempts to address racial disparities and to develop sentencing information systems may exacerbate the perceived obsolescence of traditional approaches. Shifts from mandatory to advisory, and vice versa, may also necessitate structural changes in order to maximize guidelines effectiveness. Yet, fundamental change requires institutional will, political capital, and other resources that may be in short supply on many commissions. In some guidelines jurisdictions, the current systems emerged from multiyear deliberative processes and painstakingly crafted compromises among antagonistic stakeholder groups. It is hard to imagine a successful replication of such efforts. Yet, it is almost as hard to imagine that sentencing commissions and guidelines will remain viable institutions for another 30 years if they do not prove capable of periodic fundamental reform.

Sentencing Guidelines in the United States

Steven L. Chanenson
School of Law, Villanova University,
Villanova, PA, USA

Overview

Sentencing guidelines have been a central part of criminal law reform efforts in the United States since the late 1970s. Through sentencing guidelines, many American jurisdictions have attempted – with varying degrees of success – to improve their criminal justice systems by combating judicial disparity; increasing fairness, honesty, and transparency; and, in some cases, controlling costs. While a majority of states do not have them, the presence of guidelines in the federal system and a substantial percentage of high-profile states have provided sentencing guidelines with considerable visibility.

Sentencing is where the rubber meets the road in the criminal law. All of the niceties of a criminal trial, in the statistically unlikely event there was one, are over. The defendant is guilty. The system must now choose how to respond and which actor or actors should have what degree of discretion. Sentencing guidelines are a popular American tool for helping to inform and implement those choices. Depending on the method of counting, there are at least 53 full criminal justice systems in the United States, one in each state plus the federal government, the District of Columbia, and the military. Each system must decide, within the constraints of the United States Constitution (and its own Constitution if applicable), how to punish convicted offenders. Sentencing guidelines, as befitting a tool used by different sovereigns reflecting different political and legal cultures, vary quite a bit from jurisdiction to jurisdiction. There are, however, some common questions that many drafters of sentencing guidelines – whether the judiciary, the legislature, or a sentencing commission – face.

This entry will explore some of the fundamental aspects of sentencing guidelines, their structure, breadth, and challenges. This entry will not examine sentencing guidelines or their analogues outside of the United States, nor will it focus more than necessary on the sentencing commissions that often promulgate sentencing guidelines as those bodies have their own entry in this series. It will also not address capital sentencing.

This entry will, however, explore selected attributes and challenges of sentencing guidelines through the lens of some of the key sentencing guideline jurisdictions.

Fundamental Background of and Structures for Sentencing Guidelines

How Should Sentencing Systems Be Described?

Terminology describing sentencing systems is frequently confusing. A common language is thus essential. Sentencing systems are either determinate or indeterminate. "Indeterminate systems use discretionary parole release while determinate systems do not. Determinate and indeterminate sentencing schemes can take various forms. Either sort of system may be discretionary or nondiscretionary [as to sentencing]. Discretionary systems – be they determinate or indeterminate – may be guided or unguided" (Chanenson 2005, pp. 382–383). Sentencing guidelines are a popular way to provide guidance to sentencing judges, especially in discretionary, determinate sentencing systems. As noted below, sentencing guidelines can have varying degrees of force and may be best conceived of as occupying a continuum of enforceability. Common, although necessarily imprecise, terms for the relative power of the guidelines include "presumptive" and "advisory."

Why Do Some Jurisdictions Choose to Have Sentencing Guidelines?

Before the 1970s, the dominant approach to sentencing in the United States reflected a rehabilitative model and placed broad discretion in judges and parole boards. Judge Marvin Frankel and others questioned and criticized this highly discretionary approach as lawless and unfair. Academic commentators highlighted a "gross disparity in sentencing, with different sentences imposed upon similar offenders who have committed similar offenses by the same judge on different days, different judges on different days, different judges on the same day, and different judges in different jurisdictions" (Singer 1978, p. 402). US Supreme Court Justice O'Connor noted that unguided sentencing discretion "inevitably resulted in severe disparities in sentences received and served by defendants committing the same offense and having similar criminal histories. Indeed, rather than reflect legally relevant criteria, these disparities too often were correlated with constitutionally suspect variables such as race" (*Blakely v. Washington*, 542 U.S. 296, 315 (2004) (O'Connor, J., dissenting)).

Starting in the 1970s, as a result of these criticisms and other, sometimes local, concerns, various American jurisdictions reformed their approach to sentencing by implementing different forms of guidance. "One way to describe sentencing reform over the past half century is that law came to sentencing" (Miller 2004, p. 121). Some jurisdictions – most notably Minnesota and the federal government – abolished discretionary parole release and implemented a determinate system with sentencing guidelines. Other jurisdictions – most notably Pennsylvania – retained an indeterminate system but added sentencing guidelines. As the Pennsylvania Supreme Court has noted, sentencing guidelines "were promulgated in order to structure the trial court's exercise of its sentencing power and to address disparate sentencing" (*Commonwealth v. Mouzon*, 812 A.2d 617, 620 n.2 (Pa. 2002) (plurality)). Federal sentencing reform was the product of years of discussion, debate, and political compromise. Some scholars have asserted that the final product, the Sentencing Reform Act of 1984, reflected a "subtle transformation of sentencing reform legislation: conceived by liberal reformers as an anti-imprisonment and antidiscrimination measure, but finally born as part of a more conservative law-and-order crime control measure" (Stith and Koh 1993, p. 223).

Sentencing guidelines reflect the legal and policy choices of the jurisdiction. Thus, popular attitudes and opinion can play a significant role. Sentencing guidelines can spark intense debate in part because they are transparent. This law-based transparency "forces the resolution of issues of sentencing policy – and enforces the particular resolution – and thus makes the fact of resolution clear. This society is not of one mind on what values sentencing should embody and thus the resolution of these disputed issues means the values of some will prevail while those of others will not" (Boerner 1993, p. 174).

What Kinds of Structural Choices Do Legislatures Make When Starting This Process?

There are different ways to structure a sentencing system. Each jurisdiction must confront at least three common structural choices. First, should sentencing be determinate or indeterminate? Many commissions and guidelines – including in the Minnesota and federal systems – emerged as part of a package of legislation that abolishes discretionary parole release, which transforms the system from an indeterminate one to a determinate one. Other guidelines – like Virginia – began within an indeterminate structure, but the legislature transitioned to a determinate approach later for reasons similar to those motivating the Minnesota and federal systems. Finally, there are a couple of jurisdictions – most notably Pennsylvania – that continue to have both an indeterminate structure (meaning discretionary parole release) and well-developed sentencing guidelines.

Second, which actor in the system should promulgate the guidelines? In part because of their popularity and specialized expertise, permanent sentencing commissions have captured the lay imagination concerning guideline creation and maintenance, but they are not the only approach. It is possible for the legislature or the judiciary to create guidelines either themselves or through temporary bodies established for that purpose. Even when it creates a sentencing commission, the legislature often reserves for itself the power to formally create the guidelines or at least a veto power over the guidelines promulgated by the commission. A popular approach, exemplified by the federal and Pennsylvania systems, involves the sentencing commission issuing guidelines which take effect after a predetermined amount of time unless the legislature and executive affirmatively block them. This power-sharing arrangement is often described in a positive light as allowing the commission to act on its expertise with less political pressure than elected officials might feel while still respecting principles of democratic accountability.

Third, how much binding force should the guidelines have? Not all guidelines have the same amount of binding force. As exemplified by the original Minnesota and the federal approaches, powerful guidelines were initially a popular approach. Many felt that anything less binding would not rein in judicial discretion. Before a new interpretation of the Sixth Amendment to the United States Constitution emerged in the early 2000s, the federal guidelines were very binding (often called "presumptive") and judges would frequently have difficulty successfully justifying sentences that diverged from the presumptive guideline range, a process called "departing." In fact, the rigid nature of the federal guidelines – and the associated relative lack of judicial discretion – attracted severe and persistent criticism.

Terminology here can be challenging as labels like "presumptive" and "advisory" can mask many variations. Indeed, "there are an infinite number of stops between a purely advisory approach and a completely mandatory framework" (Reitz 2005, p. 157). However, a jurisdiction can influence how much power the guidelines (and, at times, functionally the prosecutor) have as opposed to the judge. One indication of a more voluntary guideline regime, exemplified by Virginia, is the absence of appellate review. The presence of appellate review generally reflects more binding guidelines, but the intensity of that review can vary widely. Releasing judge-specific sentencing information may also have an impact on guideline compliance as well as reflect a commitment to transparency (Bergstrom and Mistick 2003). It is interesting to note that Pennsylvania, a state in which judges run for election and stand for retention, releases judge-specific information while the federal government, in which judges are appointed for life, does not.

More binding or presumptive guidelines are arguably desirable because they have sufficient teeth to meaningfully limit judicial discretion. However, more advisory, and thus less binding, guidelines are arguably desirable because they provide sufficient judicial flexibility to promote fairness in a particular case. Just as there can be unwarranted disparity, there can also be unwarranted uniformity. Professor Doug Berman observed that "reformers believed that sentencing guidelines, by codifying standards which would direct judges' sentencing decisions in most but not all cases, could reduce sentencing disparities and maintain sentencing flexibility, while promoting the development of principled sentencing law and policy" (Berman 2000, p. 35). Ultimately, each jurisdiction has to find its own balance between individualization and uniformity of sentences.

How Do Sentencing Commissions Create Sentencing Guidelines?

Guideline drafters have a myriad of choices to make, and the American constitutional structure affords them substantial latitude within which to work. There are at least six decisions that can be characterized as critical:

1. What Philosophical Goals Should Animate the Guidelines?

   The legislature and/or the sentencing commission should address what philosophical goals of sentencing should be reflected in the guidelines. The standard debates about purposes of punishment play out in this process. While the rehabilitative model had been dominant, people like criminologist and law school Dean Norval Morris successfully urged that punishments should be limited by principles of just deserts. Morris argued that desert is "an essential link between crime and punishment. Punishment in excess of what is seen by that society at that time as a deserved punishment is tyranny" (Morris 1974, p. 76). Most systems have embraced Morris' idea of "limiting retributivism," pursuant to which the offender's desert defines the upper and lower limits of acceptable (not unjust) punishment and within that range other utilitarian goals can be pursued (Frase 2005, pp. 76–77).

   Although most modern American sentencing systems are now largely retributive, guideline drafters often struggle with how to articulate their views and integrate competing ideas. The United States Sentencing Commission officially sidestepped the question at the macro level when it promulgated the first set of federal guidelines in 1987. It noted that, "[a] philosophical problem arose when the Commission attempted to reconcile the differing perceptions of the purposes of criminal punishment.... Adherents [to both "just deserts" and "crime control" approaches] urged the Commission to choose between them, to accord one primacy over the other....

A clear-cut Commission decision in favor of one of these approaches would diminish the chance that the guidelines would find the widespread acceptance they need for effective implementation. As a practical matter, in most sentencing decisions both philosophies may prove consistent with the same result" (U.S. Sentencing Commission 1987, Ch 1A 1.3–1.4). Nonetheless, some scholars of federal sentencing have argued that the federal guidelines reflect a "modified just desert" theory in which "the greatest weight in determining sentences is given to matching the severity of punishment to the seriousness of the present offense," and the second most significant consideration is "the need to incapacitate for longer periods the more dangerous offenders" determined by criminal history (Hofer and Allenbaugh 2003, p. 24). This seems to be consistent with, if not a variant of, "limiting retributivism."

Putting these pieces together is not easy. Professor Frase summed it up by noting that "early guidelines reforms attempted to narrow the focus of sentencing to strongly emphasize uniformity and 'just deserts,' and to promote more rational sentencing policy. The much broader range of contemporary sentencing goals demonstrates an important underlying truth, which early guidelines reforms (and some recent proposals) seem to have overlooked: sentencing policy is very complex, requiring compromise and careful balancing of numerous, often-competing goals" (Frase 2000, pp. 435–436).

2. Should the Guidelines Be Descriptive or Prescriptive?

Sentencing guidelines can be designed primarily to reflect past judicial practices which can be described as a "descriptive" approach. This has the benefit of more likely acceptance by the judiciary as it will seem familiar in most cases, but it may not always produce the most desirable results. When the Virginia guidelines were promulgated, they enjoyed strong judicial support in part because they were largely descriptive. On the other hand, sentencing guidelines can be designed from the ground up to reflect what the sentencing commission believes is the best path even if it diverges from past judicial practice. This can be described as a "prescriptive" approach. Minnesota used a more prescriptive strategy in part to encourage incarceration for violent offenders and discourage it for property offenders. The prescriptive path may have the benefit of a more rational approach, but could encounter opposition from lawyers and judges who are accustomed to the old ways. As with so many things, the common responses can be plotted along a continuum with the bulk of guidelines avoiding the extremes.

3. Should the Guidelines Be Based More on a "Real" or a "Charge" Offense Model?

Which crime(s) should matter when sentencing a defendant? At first blush, it may seem like an odd question to ask. Should the defendant only be sentenced on the crime(s) for which he has been convicted? Does that mean that the judge must ignore compelling evidence of other criminal acts that, for whatever reason, were not the subject of the jury's guilty verdict or the defendant's guilty plea? On the other hand, should the defendant be sentenced based on every bad thing that the government alleges – and supports with proof at less than the beyond a reasonable doubt level – the defendant has ever done? Does that mean that the judge must factor in the amount of cocaine allegedly involved in a second drug charge on which the jury returned a verdict of not guilty? The restrictive approach is, at the extreme, described as "charge offense" sentencing while the inclusive approach is, at the extreme, described as "real offense" sentencing.

Charge offense sentencing runs the risk of the judge being prevented from sentencing based on everything known about the offender and the offense. It is also criticized for perhaps making it even easier for prosecutors to control the system by bringing more charges against some defendants and fewer charges against others. Real offense sentencing runs the risk of the defendant being punished on the basis of weak allegations that a jury either rejected or was never even given the chance to consider. While the extremes of both approaches may strike many people as preposterous, jurisdictions do stake out positions leaning toward one side or the other. Pennsylvania, for example, is largely a charge-based system, although judges may consider information about other behavior in exercising sentencing discretion. The federal system, in contrast, enshrines a fairly aggressive real offense scheme in its guidelines. Judges must calculate the guidelines on the basis of "relevant conduct," which encompasses acts similar to the offense of conviction. This relevant conduct must be included as long as it is proven by a preponderance of the evidence even if the government never charged those acts or the jury, employing the beyond a reasonable doubt standard, acquitted on them.

4. How, If at All, Should the Guidelines Address Multiple Convictions?

   Guideline systems struggle to deal with multiple convictions. Many people would agree that multiple offenses usually deserve greater punishments than a single offense of the same nature. But how much more? Should the increase be geometric? Is a "volume discount" appropriate for the multiple burglar? Some guidelines require consecutive sentences for certain types of offenses, such as violent crimes, but mandate concurrent sentences for other offenses, such as property crimes. Other jurisdictions, like Pennsylvania, do not speak to multiple convictions at all and thus afford the judge nearly unfettered discretion to impose sentences concurrently or consecutively. Then-Judge (now US Supreme Court Justice) Breyer criticized that discretionary model by observing that "[a] moment's thought suggests, however, that this approach leaves the prosecutor and the judge free to construct almost any sentence whatsoever" (Breyer 1988, p. 26). The federal system tries to avoid those extremes by creating a "system that treats additional counts as warranting additional punishment but in progressively diminishing amounts" (Breyer 1988, p. 27). While this federal approach may be more satisfying in theory, the practical result is a fairly byzantine process with nearly algebraic calculations that itself has been the subject of significant criticism.

5. How Should the Guidelines Deal with Mandatory Minimum Sentences?

   Despite the existence of sentencing guidelines which are designed to take a nuanced approach, many legislatures continue to create mandatory minimum provisions. Mandatory minimum sentence laws are often criticized as being crude, inconsistently applied, and in tension with the idea of sentencing guidelines. US Supreme Court Justice Breyer, who was an influential member of the original US Sentencing Commission, noted that mandatory minimum sentences "prevent the Commission from carrying out its basic, congressionally mandated task: the development, in part through research, of a rational, coherent set of punishments.... Most seriously, they skew the entire set of criminal punishments, for Congress rarely considers more than the criminal behavior directly at issue when it writes these provisions..." (Breyer 1999, p. 184). Many sentencing commissions have to decide how to respond to such conflicting legislative directives. For example, Congress created both the federal sentencing guidelines system and a series of gun and drug mandatory sentences in close succession. In fact, the mandatory sentences were passed before the new commission could even promulgate the first set of guidelines.

   There are two broad responses available to a sentencing commission. First, it could ignore the mandatory minimum sentences when crafting its guidelines. This allows the guidelines to reflect the views of the sentencing commission and simply be trumped by the mandatory minimum sentences when they apply. Doing so has the potential of creating a sentencing "cliff," which is a point where a small change in offense behavior prompts a large change in the sentence. For example, the commission may set relatively modest weight-based guidelines for a drug offense. If the amount of the drug involved reaches the level that triggers the mandatory minimum sentence, however, the defendant's sentence may increase precipitously. Sentencing cliffs are frequently criticized because of the perceived unfairness of the sharp increase in sentencing severity in response to the incremental increase in offending severity. Alternatively, the commission could accommodate the mandatory minimum scheme by integrating it into its guideline recommendations. This approach, largely followed in the federal system, avoids the "cliff" problem but requires the guidelines to be driven by the mandatory minimum sentences in a way that may diverge from what the sentencing commission would have otherwise done. The result may be greater severity for a wider swath of offenses and offenders. The Pennsylvania guidelines, providing another example of how broad labels can conceal variations, have largely declined to accommodate mandatory minimum sentences for its core recommendations. However, the guidelines have engaged with and attempted to provide alternatives to mandatory minimum sentences by providing such things as advisory sentence enhancements for conduct that might otherwise trigger mandatory minimums. It is interesting to note that Pennsylvania adopted a guideline system in part to "avoid mandatory minimum legislation that would severely restrict judicial discretion" (Kramer and Ulmer 2009, p. 15).

6. How Should the Sentencing Recommendations Be Communicated?

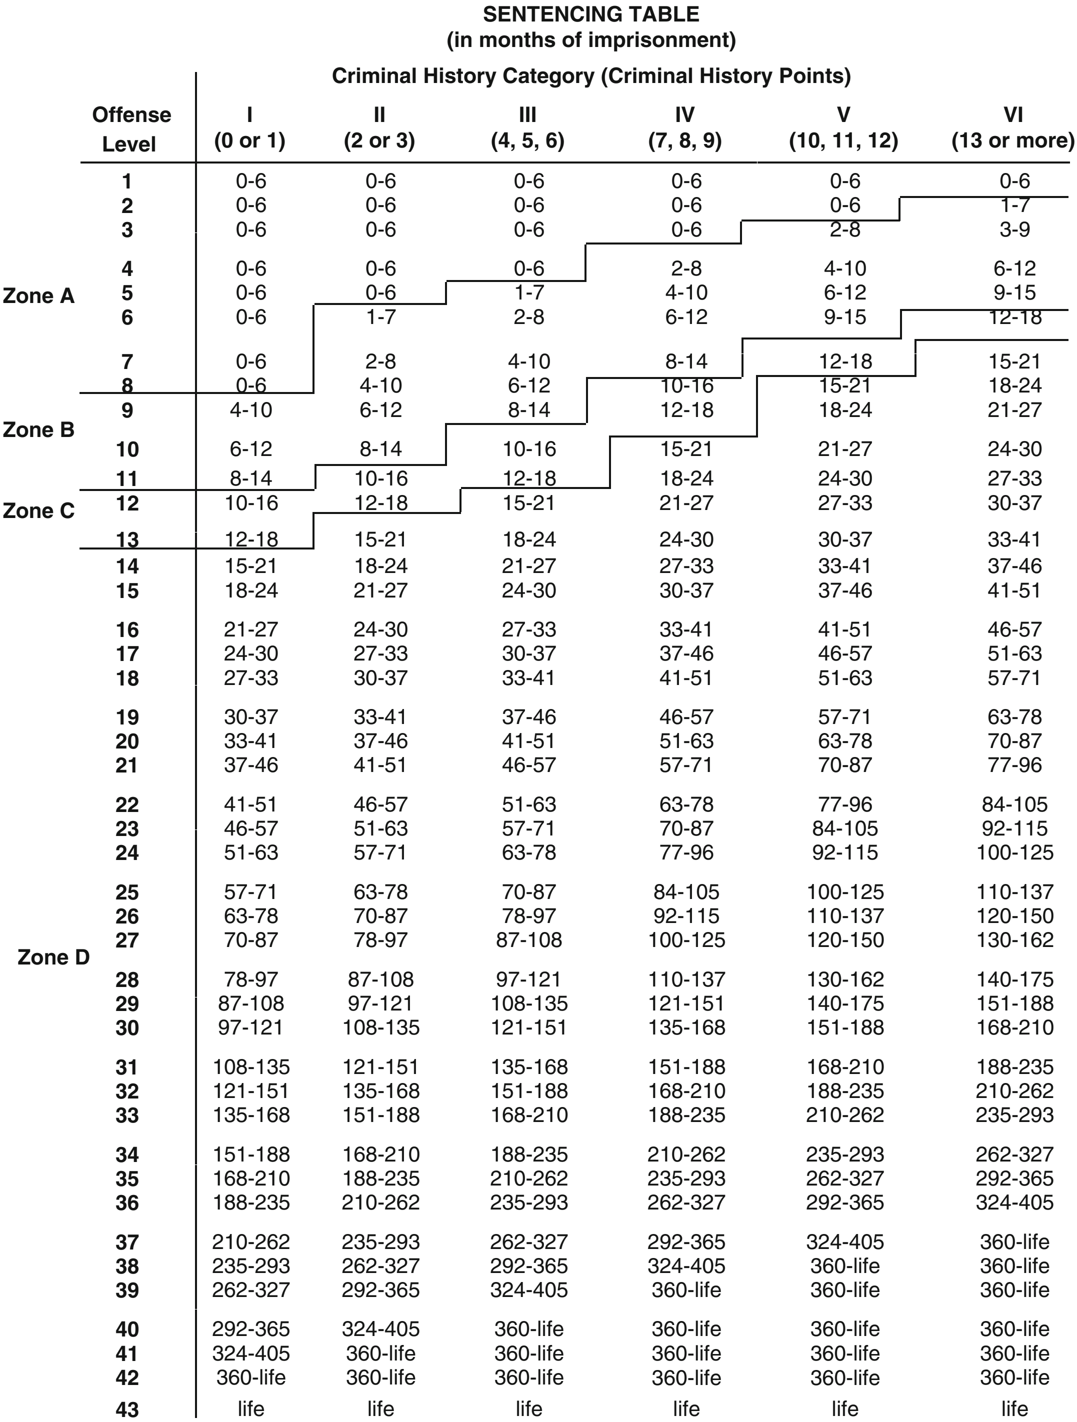
   The most common way to reflect the jurisdiction's sentencing choices and recommendations is through a simple two-axis grid, although there are other approaches such as narratives. This two-axis grid commonly reflects the defendant's criminal history along the horizontal axis and the severity of the crime along the vertical axis. Where those two paths intersect is the box or cell containing the guidelines' recommended sentence or sentencing range, which is often expressed in months of incarceration (*see* Fig. 1).

   Some jurisdictions, including Minnesota and Pennsylvania, have different grids for certain crimes (like sex offenses) or different ways in which crimes are committed (like with the possession or use of a deadly weapon). These separate grids are often explained as a way to reflect the particular seriousness of the targeted behavior without skewing the recommended sentences for the majority of offenses. This approach has been praised for limiting the impact of popular pushes for severity to the target offenses/offenders and has also been criticized for allowing that push for severity concerning those offenses/offenders to proceed more easily by bifurcating it from the bulk of cases.

The Mechanics of the Federal Sentencing Guidelines

Sentencing guidelines require the judge and lawyers to engage in a series of calculations that yield a particular recommendation, often as represented by a box or cell on the guideline grid. Guideline calculations vary in complexity depending on the jurisdiction. The federal system is widely viewed as the most complicated and is often criticized on that basis. Despite its distinctive federal complexities, a review of the kinds of calculations a federal judge needs to make before imposing a sentencing may afford a useful window on guideline sentencing generally.

There are 43 levels of what the federal guidelines call "offense seriousness" (US Sentencing Commission). In order to determine the ultimate offense level, the judge starts with the "base offense level" for the offense of conviction. Logically, offenses the Commission deems to be more serious are assigned a higher base offense level. The judge must then consider "specific offense characteristics," which are factors related to the offense such as the amount of money taken in a robbery or the quantity of drugs trafficked. The more the judge finds as taken or trafficked, the greater the increase in the offense level. At this point, the federal system's modified real offense feature can sweep in conduct for which there was no conviction. Next, the judge must determine whether



SENTENCING TABLE
(in months of imprisonment)

	Offense Level	Criminal History Category (Criminal History Points)

Sentencing Guidelines in the United States, Fig. 1 Sentencing table, United States sentencing guidelines any "adjustments" apply. Adjustments are not offense-specific and include such matters as the defendant's role in the offense (as a major or minor participant) and whether the defendant obstructed justice. Adjustments often increase a defendant's offense level, but they can reduce it as well, as in the case of a minor participant. The judge then must consider whether there are multiple counts of conviction. As noted above, the federal system employs a complicated formula to give an incremental increase for multiple offenses. Next, the judge evaluates whether the defendant has "accepted responsibility" for his offense. This often correlates with a guilty plea. If the defendant has accepted responsibility, his offense level will be reduced by either two or three offense levels. The resulting number is the defendant's offense level, which is represented on the vertical axis in the Sentencing Table (*see* Fig. 1). The horizontal axis reflects the defendant's criminal history. The judge assigns criminal history points for previous convictions of various types and whether the defendant was under judicial supervision at the time of the offense. These points translate into a "Criminal History Category." There are six Criminal History Categories. Where the offense level and the Criminal History Category intersect is the defendant's guideline range.

The US Sentencing Commission recaps the process this way. "The final offense level is determined by taking the base offense level and then adding or subtracting from it any specific offense characteristics and adjustments that apply. The point at which the final offense level and the criminal history category intersect on the Commission's sentencing table determines the defendant's sentencing guideline range" (US Sentencing Commission, p. 3). An offense level of 19 and a Criminal History Category of I, which is where a first-offender would be classified, yields a guideline range of 30–37 months. If the defendant was in Criminal History Category VI, which is the highest possibility, the guideline range would be 63–78 months.

Despite having calculated the guideline range, the judge is not ready to impose a sentence. Next, the judge must evaluate whether this is an unusual case warranting a different sentence under the guidelines. "[I]f an atypical aggravating or mitigating circumstance exists, the court may 'depart' from the guideline range. That is, the judge may sentence the offender above or below the range" (US Sentencing Commission, p. 3). For years, the availability of departures under the federal guidelines was a topic of frequent litigation and vigorous debate. Many critics argued that the appellate courts and the federal sentencing commission took an inappropriately crabbed view of these kinds of departures and that the fairness of the sentences often suffered. Yet judges did depart at times and could do so either up or down the offense level axis or left or right along the Criminal History Category axis. Since the Supreme Court of the United States made the federal guidelines "effectively advisory" (*see* below), judges must also consider whether the guidelines are appropriate in this case in light of the authorizing statute which invokes the traditional purposes of punishment as well as a parsimony provision. The judge may impose a completely different sentence if the judge believes that the guideline range does not meet the dictates of the statute, although the sentence is subject to appellate review for "unreasonableness."

The Sixth Amendment's Shifting Sands

Until approximately 2004, several guideline systems – especially the federal system – relied on facts that judges found at sentencing by a preponderance of the evidence in order to determine the presumptive sentencing range. "The top of the presumptive range was below the traditional statutory maximum for the offense of conviction. The actual sentence imposed might be higher or lower than the presumptive range, in part because of judicially found aggravating or mitigating facts" (Chanenson 2005, p. 378). In a series of decisions (including *Blakely v. Washington* and *United States v. Booker*) interpreting the Sixth Amendment to the United States Constitution, which guarantees the right to a trial by jury, the Supreme Court of the United States functionally invalidated crucial aspects of these presumptive guideline systems. The Court held these schemes unconstitutional because judges were allowed "to impose sentences higher than the presumptive guideline range based on facts found by the judge, using the preponderance of the evidence standard, instead of by the jury, using the beyond a reasonable doubt standard" (Chanenson 2005, p. 378). The key, according to the Court, was that a judge could not impose a sentence that exceeds the statutory maximum which, for these purposes, it defined as the "maximum sentence a judge may impose *solely on the basis of the facts reflected in the jury verdict or admitted by the defendant*" (*Blakely v. Washington*, 542 U.S. at 303). The Court emphasized that "the relevant 'statutory maximum' is not the maximum sentence a judge may impose after finding additional facts, but the maximum he may impose *without* any additional findings" (*Blakely v. Washington*, 542 U.S. at 303).

This could have been a mortal blow to federal sentencing guidelines, which was a heavily presumptive system and relied on significant judicial fact finding. However, the Supreme Court provided an escape hatch. These presumptive systems had two primary options. First, juries could be asked to find all of the facts beyond a reasonable doubt that judges had been finding by a preponderance of the evidence. This would then authorize the judge to impose a sentence in the same guideline range as in the past. While some jurisdictions went in that direction, many did not in part because of the factual and logistical challenges of asking juries to decide such sentencing facts as a defendant's role in the offense. This expanded role for the jury would have been particularly difficult for the federal sentencing system to adopt because it was both highly presumptive and required judges to make numerous factual determinations at sentencing, which now juries would have to make. The second option involved recasting the formerly presumptive guidelines as advisory. If the guidelines are just advisory, the judge has the ability to ignore the guidelines' advice and the power to impose a sentence up to and including the traditional statutory maximum, which is almost always higher than what the guidelines recommend. This is the path the federal system followed. However, neither the US Sentencing Commission nor the Congress made that change. Rather, it was the Supreme Court itself that recast the federal guidelines in this way. The Court construed the federal guidelines as "effectively advisory" in order to avoid the need to strike down the system as unconstitutional (*United States v. Booker*, 543 U.S. 220 (2005)). In doing so, it also broadened many people's conception of what it means for a system to be "advisory," as federal judges must still consider the guidelines and the sentences they impose are still subject to appellate review, albeit under a less stringent standard of review.

Broader Questions and Emerging Practices

Intermediate Punishments and Misdemeanors

Intermediate punishments have been the subject of discussion – and practice – for many years. Norval Morris and Michael Tonry have argued:

> We are both too lenient and too severe; too lenient with many on probation who should be subject to tighter controls in the community, and too severe with many in prison and jail who would present no serious threat to community safety if they were under control in the community. (Morris and Tonry 1990, p. 3)

It is thus unfortunate and somewhat surprising given the size and scope of community corrections programs that guidelines relating to intermediate punishment are not common. Some jurisdictions – like Pennsylvania and North Carolina – have addressed this issue to various degrees, but it remains an underdeveloped area (Frase 2000, pp. 439. –442; Frase 1999, pp. 77–78).

It is also interesting to note that relatively few guideline systems apply to both misdemeanors and felonies (Frase 2000, p. 429).

Guideline "Effectiveness"

The "effectiveness" of sentencing guidelines is often a topic of intense discussion and disagreement. Part of the disagreement flows from differing definitions of success and varying methodological views on examining the relevant issues. Overall, many believe that sentencing guidelines can be and have been effective along particular metrics, including disparity reduction, in certain circumstances (U.S. Sentencing Commission 2004, xiv–xvi, 135, 141; Frase 2000, p. 443). For example, Professor Michael Tonry has written that "[g]uidelines promulgated by commissions have altered sentencing patterns and practices, reduced sentencing disparities and gender and race effects, and shown that sentencing policies can be linked to correctional and other resources, thereby enhancing governmental accountability and protecting the public purse" (Tonry 1993, p. 713). To be sure, not every jurisdiction succeeds on every metric all the time, but if one accepts that an increase in transparency and a decrease in judicial disparity were key goals of sentencing guidelines, there are reasons to be encouraged.

Sentencing guidelines have also had some success in the realm of controlling costs. At a minimum, many sentencing commissions have become trusted sources of information for legislatures as they debate broad penal strategies. Some commissions, particularly Minnesota and North Carolina, have tried to respect financial restraints as they promulgate guidelines. More recently, Missouri started providing information about the financial consequences of particular sentencing decisions to judges in individual cases.

However, if one is focused more on controlling prosecutorial discretion (and the disparity that may flow from that discretion) sentencing guidelines have not been effective. As some predicted early on, there is a widely held view that prosecutorial power has increased after the introduction of sentencing guidelines. "Since guidelines limit the range of sentences available for a given offense, the power to drop or not drop charges is the power to select the sentence range available to the court (that is, what 'box' on the grid the case ends up in). Thus, any disparity in charging translates into disparity in sentencing" (Frase 1999, p. 77). It must be recognized that most sentencing guidelines do not speak to the prosecutorial role directly and were never intended to do so, despite the wishes of some.

Similarly, if one is focused on controlling prison populations, sentencing guidelines have not been particularly effective. The incarceration rate in the United States has risen precipitously in the last 30 years. Some jurisdictions have succeeded in curbing the growth of their prison population, but it is more than debatable whether the existence or nonexistence of guidelines is the dispositive feature. Sentencing guidelines are tools to implement broad policy in a manner that promotes systemic rationality and individual fairness. To that extent, there is reason to believe they can be – and often are – "effective." Sentencing guidelines are not inherently severe or lenient any more than fire is inherently a force for good (warmth and cooking) or evil (arson and destruction). "The experience in Minnesota and Washington, progressive states generally regarded as having the most successful guidelines systems, teach that while those systems were effective at restraining the growth of prison populations when that was the policy of those states, they were equally effective at implementing policy judgments that more punitive sentences were appropriate" (Boerner 1993, p. 176).

Evidence-Based Practices and Risk

Selected jurisdictions have started to consider how, if at all, they should incorporate evidence-based practices, including risk assessment, in their sentencing systems. While there are some echoes from the pre-guidelines era's interest in rehabilitation, the emphasis today is quite different. The focus now is on how reliable social science evidence can inform sentencing determinations – at the level of the guidelines and/or the individual sentencing judge – in a way that will reduce recidivism and thus improve public safety. Former Missouri Chief Justice Mike Wolff, who facilitated the inclusion of risk assessment information in Missouri's Sentencing Assessment Reports (its version of presentence investigation reports), has argued that, "We must acknowledge that the reason for sentencing is to punish, but if we choose the wrong punishments, we make the crime problem worse, punishing ourselves as well as those who offend" (Wolff 2008, p. 1395).

Virginia is the undisputed pioneer in integrating risk assessment into sentencing guidelines. Pursuant to a 1994 legislative directive, the Virginia Criminal Sentencing Commission explored whether an empirically based risk assessment tool could help judges divert "25 % of the lowest risk, incarceration-bound, drug and property offenders for placement in alternative (non-prison) sanctions" (Kern and Farrar-Owens 2004, p. 165). At the legislature's request, the Virginia commission later broadened the eligibility to additional low-risk offenders. If the risk instrument indicates that the qualifying offender is of sufficiently low risk, the Virginia guidelines, which are advisory and without appellate review, recommend the offender for an alternative sanction. The judge remains free to accept or reject that recommendation. A few years later, the Virginia legislature asked the commission to develop a risk assessment tool for sex offenders with the goal of identifying those with the highest risk of reoffending. In 2001, this instrument was integrated into the Virginia guidelines by increasing the upper end of the recommended range by varying amounts for higher risk offenders (Kern and Farrar-Owens 2004, p. 167). Again, the judge retains discretion and may, but need not, impose a sentence that takes advantage of the expanded sentencing range while remaining in compliance with the guidelines.

Pennsylvania is also weaving risk assessment into its sentencing guidelines. Under Pennsylvania's guidelines, the duration and intensity the recommended non-incarcerative sentence for certain drug-involved offenders has long reflected the treating of professional's judgment concerning treatment needs. Pursuant to a 2010 legislative directive, the Pennsylvania commission is now working to integrate an actuarial risk assessment instrument into the guidelines. While Pennsylvania may not follow the precise path blazed by Virginia, it is also trying to use risk assessment "to assist in the transparent – and thus accountable – decision-making by both the Commission at the policy level and judges... at the individual level" (Hyatt et al. 2011, p. 748).

There are many reasons to be cautious about risk assessment, and many policy makers and judges are quite wary, if not suspicious, of this approach. By definition, risk assessment deals with predictions and not certainties. No actuarial instrument will ever be 100 % accurate. Yet, policy makers and judges have long engaged in predictions of risk based on their clinical judgment – or gut instinct – which itself is not only imperfect, but research indicates is often less accurate than actuarial instruments (Gottfredson and Moriarty 2006). Sentencing remains deeply normative and predictions about recidivism will never – and should never – be the only consideration. Actuarial risk assessment is simply a tool that guideline systems can use to help inform judicial discretion.

Not only does risk assessment raise crucial questions concerning how to distribute punishment, but it also can prompt reflection on the severity of punishments. If a less severe sentence does not diminish – and may even improve – public safety in certain situations, was society's initial punitive judgment sound? There are no immutable answers, but the questions themselves can be important.

Concluding Observations

Sentencing guidelines have helped to refashion the landscape of American criminal justice, and they are continuing to do so. Even jurisdictions that do not yet have guidelines may be attracted by their promise of a more rational, transparent, and just approach to punishment. Indeed, the American Law Institute seems likely to recommend that all American jurisdictions adopt guidelines. Sentencing guidelines, however, remain very much a work in progress. All guidelines systems have flaws and many of them are glaring, but those same flawed systems often provide a mechanism for experimentation and, one hopes, positive refinement (Frase 2000, p. 445). Professor Michael Tonry summed it up this way:

> Like all calls for just the right amount of anything, not too much and not too little, a proposal for sentencing standards that are constraining enough

> to assure that like cases are treated alike and flexible enough to assure that different cases are treated differently is a counsel of unattainable perfection. Nonetheless, that is probably what most people would want to see in a just system of sentencing... (Tonry 1996, pp. 185–186).

Sentencing guidelines offer a real opportunity to strive for that “unattainable perfection.”

Overview

Research on sentencing has been an active field of inquiry for several decades. The 1980s, 1990s, and 2000s were particularly noteworthy. These decades saw advances in the quality of data, the sophistication of research methods, and improvements in theory. This entry provides a conceptual survey of research on noncapital sentencing outcomes since 2000. The entry first looks backward at the research agenda posed by reviews in the early 1980s and in 2000. Theoretical developments in the study of sentencing in the 1990s and 2000s are then discussed. An overview is next provided of recent sentencing research focused on the following: (1) court organizational and social contexts, (2) individual courtroom workgroup members, (3) disparity conditional on intersecting defendant characteristics, (4) victim characteristics, and (5) earlier case processing events and decisions.

The central focus of this entry is *noncapital sentencing decisions* as focal dependent variables. However, it is recognized that sentencing decisions are conditioned by and interdependent with a chain of earlier and later criminal justice processing decisions that are embedded in organizational and broader contexts. This entry also primarily focuses on research since 2000, discussed in the context of earlier reviews of sentencing research and theory in the 1980s and 1990s.

Sentencing Research in the 1990s: Responding to Issues and Opportunities

By far, the biggest development in the 1980s and 1990s was the availability of data collected by sentencing commissions in sentencing guideline states and the federal system. For the first time, researchers had at their disposal high-quality post-conviction, jurisdiction-wide data for very large numbers of cases. These data were disseminated by sentencing commissions with legal mandates to collect and make such data available. These data enabled progress on the following issues, raised by the important 1983 National Academy of Science assessment of sentencing research by Blumstein et al. (1983) and by Hagan and Bumiller in that report:

1. *The need for better measurement of legally relevant variables*: Sentencing commission data enabled substantially improved measures of offense severity and criminal history, which had often been measured crudely in earlier research.
2. *The need to study different sentencing outcome variables*: The Blumstein et al. (1983, p. 273) report called for "…more adequate treatments of the complexity of the dependent variable, sentence outcome."
3. *The need for larger samples from more varied jurisdictions* was particularly identified by Hagan and Bumiller (1983). Guideline data from states and the federal system provided very large samples drawn from large numbers of contextually diverse counties (for states) or district courts (with federal data).
4. *The need to investigate the effects of social contexts on sentencing and disparity* was noted by Hagan and Bumiller (1983) among others. As noted above, sentencing data from a relatively wide range of local jurisdictions enabled research on local variation in sentencing severity and disparity.

Several chapters of the Blumstein et al. (1983) report and others called for consideration of sentencing in the contexts of earlier criminal justice decisions, particularly pretrial detention, charging, and conviction. It has long been recognized that sentencing is conditioned by selection processes in earlier justice system decisions. For all their benefits noted above, guideline sentencing data are limited to convicted offenders and do not include preconviction information such as the type and number of original charges (and rarely include pretrial detention). Datasets that include preconviction data for large numbers of cases and multiple local jurisdictions have traditionally been difficult to obtain. The years since the Blumstein et al. (1983) report have seen comparatively few studies that examine sentencing in the context of earlier decisions.

Relatedly, the Blumstein et al. (1983) report called for sentencing research to examine the effects of defendant socioeconomic status variables on sentencing outcomes and to disentangle the potential influence of race and ethnicity versus socioeconomic factors in sentencing. In addition, the Blumstein et al. (1983) report and others called for studies that examine sentencing variation between criminal justice actors, especially judges and prosecutors, and the effects of decision maker characteristics in explaining variation in sentencing. But, only a handful of studies since then have examined sentencing variation between judges, and the effect of judge characteristics, and even fewer studies have examined between-prosecutor variation. Also, defendant socioeconomic data and/or data on individual court actors has generally been hard to come by in the most widely used guideline datasets. Thus, studies that disentangle socioeconomic factors from other defendant characteristics (especially race or ethnicity) have not been as common.

Reviews of the 1990s

Two comprehensive reviews (Spohn 2000; Zatz 2000) summed up research on sentencing up to 2000, primarily focusing on studies of disparity based on defendant social characteristics. Both reviews noted that research had improved in quality since the 1983 report. Both reports also highlighted research that went beyond simply assessing whether "race/ethnicity mattered" or "gender mattered" to investigating *when* and *how* such social statuses matter in sentencing – that is, investigating how the influence of race, ethnicity, and gender mutually conditioned one another and were also conditioned by other factors. Spohn's (2000) review in particular provided a quantitative summary of racial/ethnic disparity studies with an eye to conditional influences.

Regarding the incarceration decision, Spohn (2000) found that 55 % of 45 effects in 31 state court studies she reviewed, and three of seven effects in eight federal court studies, showed significant black disadvantages. More importantly, Spohn (2000, see p. 462) found that eleven studies had looked at whether race and/or ethnic effects were conditioned by other social statuses or characteristics, especially gender and/or age. All eleven found evidence of such effects. In particular, four studies found sentencing disadvantages for young black and/or Hispanic *males*, four found sentencing disadvantages for unemployed young black or Hispanic males, one found disadvantages for poor minorities, and one found disadvantages for low-education minorities.

In addition, several studies in the 1990s showed that race or ethnicity effects on sentencing were conditional on criminal history, offense type or severity, case processing factors, or victim characteristics. Eight 1990s studies found that blacks or Hispanics with more serious criminal histories were sentenced more severely. Ten studies found that race/ethnic differences were conditioned by type or severity of crimes. Three found that racial disadvantages were greatest in less serious crimes, and six found that racial disadvantages were pronounced in drug offenses. In addition, six studies found that race/ethnicity effects were conditioned by case processing factors. Two studies found that blacks were sentenced more severely if they were detained prior to trial, one found that blacks were sentenced more severely if represented by a public defender rather than a private attorney, and three found that blacks were sentenced more severely if they were convicted by plea rather than trial. Finally, one study found that blacks who victimized whites received more severe sentences than other victim-offender combinations.

These reviews also spelled out directions for further research that they hoped would be undertaken in the ensuing decade. Several of these directions called for further progress on earlier recommendations from the Blumstein et al. (1983) report. Among other directions, these reviews called for (1) investigations of how the effects of race and ethnicity on sentencing vary by social context and over time and how the effects of race and ethnicity might be conditioned by other factors, (2) more investigations of the sentencing of Latinos, (3) research that utilized better measures of defendant socioeconomic status factors and disentangling the effects of socioeconomic status from race and ethnicity, (4) research on how court social and organizational contexts shaped sentencing severity and disparity, (5) investigations of sentencing and disparity in the context of earlier criminal justice (particularly prosecutorial) decisions, and (6) qualitative research that illuminated sentencing processes.

Theoretical Perspectives on Sentencing

Hagan and Bumiller (1983) as well as other contributors to the Blumstein et al. (1983) report noted that at that time there was little theoretical development in the sentencing literature. Spohn (2000, p. 458) also noted that most pre-1990s sentencing studies were based on "an overly simplistic version of conflict theory." However, the 1990s and 2000s saw the emergence of new theoretical frameworks and the refinement of older theoretical propositions from conflict and labeling theories. These theories seem to be more complementary than competing, and some of them have mutually influenced each other. Below are brief sketches of these theoretical frameworks (readers seeking full treatments should consult the original works cited below).

Individual Cases and Actors

Celesta Albonetti articulated an *uncertainty avoidance* and *causal attribution* (1991) perspective on sentencing and court decision making. Albonetti applied insights from organizational theory to argue that sentencing suffers from operating in a context of bounded rationality in that court actors make highly consequential decisions with insufficient information, which produces uncertainty. Albonetti (1991) particularly stressed uncertainty and insufficient information regarding the recidivism risk and rehabilitative potential of offenders. Albonetti drew from attribution theory in social psychology to argue that, as a means of reducing uncertainty, decision makers fall back on attributions about reoffending risk and/or rehabilitation potential that can be linked to race and gender and other social status stereotypes. This can then result in extralegal sentencing disparity connected to these statuses.

Similarly, Farrell and Holmes (1991) presented an *interpretive theory of legal decision making*, in which they emphasized the situational role of stereotypes linked to defendant social statuses in case processing. Farrell and Holmes (1991) generated ten propositions about the conditional, situation-specific role of status-linked stereotypes for routine and nonroutine cases and defendants. A related idea is the *liberation hypothesis* which has sometimes been applied to sentencing discretion (Spohn and Cederblom 1991). The liberation hypothesis implies that as the seriousness and/or visibility of the offense or case increases, sanctioning discretion is tightened and legally relevant variables are decisive, leaving little room for extralegal influences. By contrast, in less serious/visible cases, opportunities for discretion are greater and extralegal variables can influence outcomes more than in serious cases.

Because the sentencing guidelines movement of the 1980s transformed the sentencing landscape, the 1990s saw important treatments of sentencing discretion and guidelines, which involves the management of several dilemmas: between flexible discretion and rule-bound control, between uniformity and individualization, and between centralization and decentralized localism. Joachim Savelsberg (1992) helpfully conceptualized sentencing and sentencing guidelines as an attempt to impose a regime of what founding early sociologist Max Weber called formal rationality onto a traditionally "substantively rational" process. *Substantive rationality* refers to an individualized decision process governed by criteria that are in service of ideological goals external to the law. The flexibility inherent in substantive rationality, however, permits the possibility of bias, discrimination, and unwarranted disparity.

The *focal concerns perspective* emphasizes particular kinds of substantively rational criteria at work in sentencing decisions. A recent review and statement of the focal concerns perspective in proposition form can be found in Kramer and Ulmer (2009). The focal concerns perspective argues that court actors' subjective definitions of offenders and offenses in relation to three focal concerns of punishment – blameworthiness, protection of the community, and practical constraints – determine punishment decisions. The focal concerns perspective argues that both legal and extralegal considerations affect the interpretation and prioritization of focal concerns through local substantive rationality (Kramer and Ulmer 2009). The influence of race, for example, may be conditional on defendant's gender, age, social class, legally relevant factors, and especially local contexts (see below).

Rational choice approaches have also been applied to sentencing in the times since the 1983 report (Piehl and Bushway 2007). Proponents of a rational choice approach to sentencing research would call for researchers to identify the formal and informal incentive structures of different court actors involved, make theoretical predictions about what sentencing outcomes would look like if actors acted rationally in pursuit of those incentives, and then compare these predictions to real-world data. Actors' incentives, of course, are strongly influenced by the organizational environments of prosecutors' offices, bench, and defense bar.

Court Organization and Multilayered Environments

It has long been recognized that sentencing practices varied between jurisdictions, even within states or the federal court system. Myers and Talarico (1987), Eisenstein et al. (1988), Ulmer (1997), and others drew attention to the localization of sentencing. The *court community perspective* views courts as communities based on participants' shared workplace; interdependent working relations between key sponsoring agencies such as the prosecutor's office, judges' bench, and defense bar; and the court's relation to its larger sociopolitical environment (Eisenstein et al. 1988; Ulmer 1997). These court communities are said to foster their own locally varying sentencing norms which influence sentencing as least as much as formal policies and legal structures (Ulmer and Kramer 1996).

Interest in social contexts that foster negative racial/ethnic-based stereotypes and perceptions of threat has been fostered by *racial threat theory*. This theory argues that as minority racial groups grow in size relative to whites, they are likely to develop greater power, economic resources, and political influence in the community and are better able to compete with whites for power. In the context of sentencing, racial group threat theory implies that when perceptions of minority group threat are more pronounced and when courtroom actors perceive particular racial/ethnic groups as more dangerous or morally disrespectable, such minorities may receive harsher sentences.

Finally, *organizational efficiency/maintenance models* of sentencing have long been recognized (Dixon 1995; Engen and Steen 2000). In fact, the focal concerns model would also recognize organizational efficiency as a potentially important practical constraint faced by court actors (Kramer and Ulmer 2009). These organizational efficiency model views emphasize leniency for those who plead guilty and avoid time- and resource-intensive trials as an effort by courts to keep cases moving smoothly. Relevant to rational choice theory, an organizational efficiency proposition would suggest that rewarding guilty pleas and punishing trials is an organizationally rational response to the need to move cases efficiently. Furthermore, this differential punishment would be conditioned by caseload pressure – the greater the caseload pressure, the more courts would rely on such costs and incentives.

Research Since 2000

These theoretical developments have been instrumental in five broad and interrelated areas of empirical inquiry discussed below.

Social Contexts and Sentencing

The 2000s saw a burst of studies on contextual effects and variation and how the influence of individual-level factors was conditioned by court or social context factors. Overall, the recent literature on contextual variation in sentencing shows that local variation permeates many aspects of sentencing, both under sentencing guideline jurisdictions and non-guideline jurisdictions. Studies typically find that most sentencing outcome variation exists at the individual level and is most strongly predicted by individual-level factors. However, not only does sentencing severity (and related outcomes such as guideline departures) vary between local courts and their contexts but so too sometimes do the effects of other important legally relevant and extralegal sentencing predictors.

Racial/Ethnic Population Composition

Some of this research has investigated the role of local racial/ethnic composition in conditioning racial and ethnic sentencing disparity, drawing from both racial group threat theory and the focal concerns perspective. Many multilevel sentencing studies find that the effects of race and ethnicity in sentencing decisions do indeed vary significantly across courts. However, results have been decidedly mixed regarding racial threat theory's ability to explain this variation. That is, race/ethnic effects on sentencing tend to vary across contexts, but not always in ways predicted by racial threat theory. Some studies have found that the percentage of blacks in local populations has been found to increase racial/ethnic disparities in sentencing. Other studies reveal either no support for racial threat or evidence contrary to racial threat hypotheses (see Ulmer 2012).

Local Organizational Constraints

Other research has examined how local practical constraints such as caseloads or local criminal justice resources (i.e., jail space) affect sentencing, research relevant for the organizational efficiency hypothesis, as well as the focal concerns and court communities' perspectives. Pennsylvania court caseloads were negatively related to sentencing severity (see in Kramer and Ulmer 2009). Local jail space in Pennsylvania counties affected the probability of incarceration and found that local jail space predicted the choice of county jail versus state prison (Kramer and Ulmer 2009).

Sociopolitical Influences on Sentencing Decisions

Though less common, studies have examined other sociopolitical influences on sentencing, including crime rates, political climate, neighborhood disadvantage, and local religion (see review by Ulmer 2012). Crime rates and broad political climate measures (such as percent Republican voters) have generally not been found to be strong predictors of sentencing patterns or to strongly and consistently condition individual-level predictors (an exception is Johnson 2006). Fearn (2005) and Ulmer et al. (2008) found evidence that local religious contexts may affect sentencing patterns. Fearn (2005) found that prison sentences were more likely in jurisdictions with greater proportions of evangelical Christians. Ulmer et al. (2008) found that local religious homogeneity fostered greater use of incarceration in Pennsylvania. Unlike Fearn (2005), Ulmer et al. (2008) did not find that evangelical Christian prevalence influenced sentencing but rather that local religious homogeneity interacted with percent Republican voters, in that counties that were religiously homogeneous *and* strongly Republican were most likely to incarcerate offenders.

Court Community Racial/Ethnic Composition

Farrell et al. (2009) studied the effects of federal district court community racial composition on variation in the effects of race on sentencing. They found that district US Attorney's Office's black representation was associated with significantly smaller racial disparities in incarceration, and interestingly, greater black Federal Probation Office representation was associated with greater black/white sentencing outcome disparity. In addition, studies have found that greater black representation among county attorneys attenuated local black/white sentencing disparity (see in Ulmer 2012).

Court Personnel

Earlier research had investigated the race and gender of judges on sentencing, and this was reviewed in Spohn (2000). Johnson (2006) examined court contextual and inter-judge variation in sentences in Pennsylvania. He found that black and Hispanic judges sentenced all offenders, and particularly minority offenders, more leniently than white judges. Furthermore, male judges sentenced female offenders more leniently. Studies have also examined inter-judge variation in sentencing and also found wide variation between judges in the effects of race, gender, or financial means on their sentences. It has also been found that judges considered legal and extralegal factors quite differently in their sentencing decisions (see in Ulmer 2012).

Conditional Disparity

In addition, a key theme of Spohn's (2000) and Zatz's (2000) summaries of the 1990s literature was that the influence of social status factors such as race, ethnicity, and gender was conditional and mutually contingent. Dozens of studies in the 2000s have continued to confirm this insight. Many of these studies are noted above and below in the discussions of research on court contexts, courtroom actors, victim characteristics, and earlier case processing decisions. In sum, there appears to be substantial evidence that the effects of such extralegal social statuses are conditioned by court contextual factors and provocative evidence that disparity varies across individual court community actors. Furthermore, most studies that examine the issue find young black, and to a lesser extent Hispanic, male defendants to be sentenced more severely (see reviews by Mitchell 2005; Ulmer 2012). Also, the effects of defendant social statuses may interact with case processing, offense characteristics, and criminal history.

Victim Characteristics

It should be noted that existing studies that utilize data from sentencing guideline jurisdictions actually implicitly consider victim harm, financial loss, and often victim age and vulnerability. These factors are commonly included in creating guideline offense severity rankings. Thus, the strong effects of offense severity typically found in such studies in part incorporate victim impact and vulnerability. Such research, however, does not tell us about the effects of other specific victim attributes. Curry (2010) found that Texas offenders who victimized females received longer sentences, and females who victimized males received sentences about 10 months shorter than males who victimized females. Curry's research also found that violent offenders who victimized white and Hispanic females received longer sentences, and Hispanic and black homicide offenders who victimized whites got longer sentences than other combinations. Other studies have uncovered similar findings (see in Ulmer 2012). They found no race of victim/offender combination effects, but found that males who killed females received the longest prison sentences and that females who killed males received shorter sentences than males who killed females. Overall, there is mixed evidence that victim characteristics may matter in noncapital violent crime sentencing.

Sentencing in the Context of Earlier Case Processing

A comparatively smaller set of studies has examined sentencing as related to earlier case processing events, such guilty pleas versus trial convictions, as well as charging decisions and pretrial release. This research provides some, albeit limited, insight into prosecutorial discretion as well as other joint courtroom workgroup outcomes, such as differentially punishing those convicted by trial relative to those who plead guilty.

Charging Decisions

Other researchers have investigated prosecutors' charging decisions and their impact on eventual sentencing. Studies have found that the number of indictment charges filed by federal prosecutors significantly increased federal sentence lengths, and decreased the likelihood of substantial assistance or other downward departures. Shermer and Johnson (2010) examined the likelihood of federal prosecutors reducing charges for defendants. They found that while about 12 % of federal cases in their sample involved charge reductions, race/ethnicity and gender (along with offense severity and criminal history) influenced the likelihood of those charge reductions in drug and violent offenses. These charge reductions, in turn, resulted in lower sentences for those who received them and charge reductions-mediated race/ethnic effects on sentences.

Pretrial Detention/Release

Though not as plentiful as studies of sentencing outcomes, there is a literature focusing on the consequences of these decisions for defendants' sentencing. Studies have found that defendants subject to pretrial detention were more likely to receive more severe sentences than defendants who had been released before case disposition. Other studies have Spohn examined federal offenders in three district courts and found that both legal and extralegal factors predicted pretrial status and that pretrial status significantly impacted sentencing. These found that race and gender had indirect effects on sentence severity through their effects on pretrial status.

Mandatory Minimums

Sentencing involving mandatory minimums has proved useful for understanding how earlier decisions shape and constrain sentencing choices. Bjerk (2005) found that prosecutors used their charge reduction discretion to circumvent three strikes mandatories for some defendants. He found that such circumvention of three strikes mandatory minimums was moderately less likely to occur for men, Hispanics, and to a lesser extent, blacks. Multilevel analyses of prosecutorial discretion in applying mandatory minimums among mandatory-eligible offenders sentenced for drug crimes or as "three strikes" offenders (see in Kramer and Ulmer 2009). They found that prosecutors' decisions to apply mandatory minimums were significantly affected by mode of conviction (negotiated guilty pleas greatly assisted defendants in avoiding mandatories), the type and characteristics of offenses and guideline sentence recommendations (the greater the difference between the mandatory and the applicable guideline sentence, the less likely the mandatory was applied), prior record, and gender. In addition, Hispanic males were substantially more likely to receive mandatory minimums.

Federal Substantial Assistance Departure Motions

Some studies have examined prosecutorial discretion in decisions to file motions for substantial assistance guideline departures in federal court crack and powder cocaine sentences in 2000. These found that the likelihood of substantial assistance motions increased with offense severity and criminal history and that having multiple concurrent charges reduced the likelihood of such motions for crack cocaine cases. In powder cocaine cases, black and Hispanic males had the lowest odds of receiving substantial assistance departures, while white females and males had the greatest likelihoods. The results were similar for crack cocaine cases, except that Hispanic females had the greatest odds of substantial assistance departures.

In addition, Johnson et al. (2008) examined interdistrict variations in the application of both substantial assistance and other downward departures among a variety of offense types in federal sentences from 1997 to 2000. Findings indicated considerable between-district variation in the probability of these prosecutor-initiated substantial assistance departures. This variation was explained, in part, by organizational court contexts such as caseload pressures and by environmental considerations such as the racial composition of the district.

Spohn and Fornango (2009) examined variation between federal prosecutors in three districts in their likelihood of moving for substantial assistance departures. They found substantial interprosecutor variation in the likelihood of substantial assistance departures, net of the influence of individual case and defendant characteristics. Specifically, about 24 % of the variation between prosecutors in the likelihood of substantial assistance departures was unaccounted for by case or defendant factors, and even more between-prosecutor variation was unexplained in nondrug cases.

Mode of Conviction

Finally, several studies have examined how mode of conviction affects sentencing; that is, sentencing differences between types of guilty pleas and types trials. This research exhibits some limitations in that studies typically use data on convicted offenders only, which presents issues of selection and potential missing-variable bias absent data on the likelihood of acquittal (see Bushway and Piehl 2007). Still, one overarching lesson from the recent studies below is that sentencing guidelines seem to provide a discretionary framework within which to differentially reward guilty pleas and punish trials.

Some studies have found that mode of conviction moderated the role of race/ethnicity in predicting guideline departures, with blacks and Hispanics experiencing different odds of receiving downward or upward departures, depending on their modes of conviction. Studies have looked at trial penalties for serious violent offenders and less serious offenders using hierarchical models with cases sentenced under Pennsylvania's guidelines (Kramer and Ulmer 2009). They found that defendants were substantially penalized if they were convicted by trial relative to those with negotiated or open guilty pleas. Furthermore, this jury trial penalty varied depending on the seriousness and type of offense (more severe offenses had lesser trial penalties), defendant criminal history (offenders with more substantial criminal histories actually experienced less of a trial penalty), race (blacks experienced greater trial penalties) and court contextual characteristics such as court community size (larger trial penalties in larger courts), local violent crime rates (the higher the crime rate, the greater the trial penalties), and the size of local black populations (greater trial penalties in counties with larger black populations). Studies have also found that federal trial penalties could not be fully explained by US Sentencing Guideline factors that were relevant to mode of conviction. They also found that higher district court caseload pressure was associated with greater trial penalties, while higher district trial rates were associated with lesser trial penalties (see in Ulmer 2012).

New Methodological Extensions

The past decade has seen the application of new statistical methods to sentencing research questions, and several useful quantitative modeling alternatives now confront sentencing researchers. Bushway et al. (2007) present a very useful discussion of the merits and demerits of two-part models (modeling incarceration and sentence length separately), tobit, and Heckman two-step corrections with ordinary least squares regression in addressing problems of censoring and/or selection surrounding the incarceration and sentence length decisions. Several researchers have also demonstrated the usefulness of using multinomial logistic regression to predict different types of incarceration, such as county jail versus state prison, either in an individual level (see review in Ulmer 2012). In addition, Britt (2009) proposes *quantile regression* as an interesting alternative for assessing variation in the effects of predictors of interest (legally relevant, extralegal, case processing, etc.) across the distribution of sentence length/severity. That is, the quantile regression approach allows the researcher to separate the sentence length distribution into quantiles and examine how the strength of predictors' effects varies across those quantiles. Finally, propensity score methods appear to be a promising alternative for examining sentencing disparity in a way that attempts to create balanced, comparable samples of offenders that differ only on a "treatment" or characteristic of interest (e.g., race or mode of conviction). This therefore allows the construction of useful counterfactuals, for example, "what would the sentence be if this case involved a white rather than a black defendant."

The Need for More International Research

Most sentencing research is limited to the contemporary North American – particularly the US – context. However, particularly useful overviews of the comparatively small amount of international literature on sentencing disparity that does exist can be found in Tonry and Frase (2001). Also, Johnson et al. (2010) studied 1,613 Dutch homicide offenses from 1993 to 2004 and found that homicide offenders that victimized youth under 18, elderly people, women, and Dutch (vs. foreign) victims were sentenced more severely than those victimizing other types of victims. Some other suggestive information on ethnic disparity comes from Canada and Australia (see reviews in Tonry and Frase 2001; Dawson 2006).

Comparatively little research exists on sentencing in non-Western contexts, particularly, in Asian countries, which are growing in global prominence. Lu and Kelly (2008) provide a useful summary of research on courts and sentencing in China. Two studies focus on sentencing in South Korea, a country which very recently adopted sentencing guidelines. These found that female drug offenders were sentenced more leniently than their male counterparts, though this gender difference disappeared among those with prior criminal records. Also, research has found that legal factors connected to the offense and past criminal behavior primarily determined the length of sentences for Korean marijuana and methamphetamine offenders but that males and older offenders received longer sentences. They also found that admitting guilt in court resulted in shorter sentences (see review in Ulmer 2012).

Finally, a great deal of research has been done on sentencing under sentencing guidelines, particularly, the US Sentencing Guidelines, and state guideline systems in Minnesota, Pennsylvania, Washington, and to a lesser extent Florida (see reviews by Spohn 2000; Zatz 2000; Kramer and Ulmer 2009; Ulmer 2012). More recently, research has examined the extent to which US federal sentencing and disparity changed in the wake of important Supreme Court decisions that rendered the federal guidelines advisory (see Ulmer et al. 2011). This research is mixed regarding whether racial disparity has increased under the advisory guidelines – the US Sentencing Commission's analyses argue that racial disparity increased, but independent researchers have disputed their findings, arguing that overall, the data do not support the notion that advisory guidelines have aggravated racial disparity (see Ulmer et al. 2011). Research has examined sentencing disparity, patterns, and trends within guideline systems, but relatively little research has compared differences in sentencing disparity between guideline systems (Engen 2009). Very little research has examined differences in sentencing between guideline and non-guideline jurisdictions, likely because of the lesser availability of comparable sentencing data from non-guideline systems and because of the methodological difficulties of comparing measures of key variables such as offense severity and criminal history across guideline and non-guideline contexts.

In sum, since 2000, research has made some progress on certain issues identified by the Blumstein et al. (1983) report and the Spohn (2000) and Zatz (2000) reviews. For example, in many sentencing studies published since 2000, researchers have moved beyond examining the traditional incarceration and length to look at more refined outcomes, such as distinctions between types of incarceration (e.g., probation, county jail, state prison). Also, studies have examined the imposition of mandatory minimums, which are tightly linked to prosecutorial discretion, adjudication waivers, first-time offender waivers, and special sex offender sanctions, and different types of sentencing guideline departures (see Ulmer 2012). Further, research in the 2000s generally heeded the call to include Hispanic defendants, and many, if not most, of the recent studies on US racial sentencing disparity include black, white, and Hispanic comparisons. Other directions, such as examining sentencing in the context of preconviction decisions and prosecutorial discretion, as well as research on sentencing in non-US and non-Western contexts, have seen comparatively less progress.

Sex Offender Treatment

Jo Thakker
School of Psychology, University of Waikato,
Hamilton, New Zealand

Overview

This entry provides a brief summary of three key aspects of the treatment of sexual offenders. It begins with a description and critique of the two of the most influential treatment models, namely, the Risk Needs Responsivity (RNR) model and the Good Lives Model (GLM). It then provides a discussion of some of the relevant process issues, namely, whether treatment should be conducted in groups, and the problems of confrontation and coercion. The entry concludes with a description of the primary components of group treatment approaches and a discussion of treatment efficacy.

Treatment Models

In order to fully understand contemporary sex offender treatment, it is useful to first summarize the models which underlie treatment. Obviously, it is not possible to describe all of the relevant models herein; thus, two models which are considered to be especially influential will be discussed, namely, the Risk Needs Responsivity model (Andrews and Bonta 2003a) and the Good Lives Model (Ward and Stewart 2003).

The Risk Needs Responsivity Model

Andrews and Bonta's (2003a) Risk Needs Responsivity (RNR) approach has been important in guiding treatment across a variety of offender groups, including sexual offenders. Since its development in the late 1990s, it has played a significant role in the way that treatment has been conceptualized and delivered. As indicated by the name of the model, there are three main components. The risk aspect of the model refers to the type and degree of risk that an offender poses and suggests that the risk level should determine the intensity of treatment. Thus, low-risk offenders should receive less intensive treatment, and high-risk offenders should receive higher intensity treatment. As explained by Andrews and Bonta, intensity essentially refers to the duration of treatment.

The need aspect of the RNR model refers to the offender's specific rehabilitative requirements, which are variously termed criminogenic needs or dynamic risk factors. Essentially, these are the psychological characteristics and/or behaviors of the individual which require treatment. According to the model, treatment should target the specific characteristics that contribute to the individual's offending so that the likelihood of reoffending will be reduced. As outlined by Andrews and Bonta, some common examples of these sorts of characteristics include antisocial attitudes and beliefs, substance abuse, and relationship problems.

The third part of the RNR model is the responsivity principle which is concerned with the actual delivery of treatment. As stated by Andrews and Bonta, the responsivity principle acknowledges the significance of the therapeutic relationship and assumes that an offender's response to treatment will be dependent on this, as well as a range of other variables. Also, the model takes the view that in order for treatment to be effective, it needs to identify and manage barriers to treatment and build on the individual's unique strengths. Furthermore, the responsivity principle espouses that in order for treatment to be successful, it needs to be designed according to best practice guidelines; in other words, it is important that there is evidence that a particular therapeutic approach is effective in treating the offender's unique range of needs.

According to Ward et al. (2008, p. 180), the RNR model has "constituted a revolution in the way that criminal conduct is managed in Canada, Britain, Europe, Australia, and New Zealand." While the model is general, insofar as it has been applied to a range of offender types, it is nonetheless pertinent to this discussion as it has been widely used in the design of treatment of sexual offenders. One of the key strengths of the model is the ease with which it can be translated into treatment. It provides clear guidelines in terms of selecting appropriate treatment for offenders, and it assists in the identification of treatment targets. Also, it encourages the therapist to consider the offender's strengths and weaknesses and to design treatment accordingly. Furthermore, it emphasizes the link between theory, research, and practice and is thus consistent with the principles of the scientist-practitioner model.

However, some researchers have criticized certain aspects of the RNR model. For instance, it has been argued that the RNR model places too much emphasis on rehabilitative needs and not enough emphasis on other aspects of treatment. For example, Wilson and Yates (2009) argue that the RNR model tends to overlook the importance of therapist qualities such as empathy and respect due to its focus on the needs of the offender. However, as outlined above, in a recent explication of the RNR model, Andrews and Bonta highlighted the significance of the therapeutic relationship in treatment success. Ward argues (e.g., Ward and Stewart 2003) that the RNR model is typically implemented in an inflexible manner which fails to adequately deal with individual needs. However, this may be an unfair criticism insofar as this may reflect as inadequate implementation of the model rather than a failing of the model per se. In their critique of the RNR model, Ward and Stewart (2003) also state that the model takes an overly negative approach to therapy by focusing on risk avoidance. They suggest that the model assists offenders in understanding what to avoid, but does not assist them in establishing new pro-social behaviors.

The RNR model continues to provide the framework upon which many contemporary treatment programs for offenders are designed and administered, and this is true also for sex offender programs. Furthermore, there is now mounting empirical support for the model. According to Andrews and Bonta (2010, p. 39), "...programs that adhere to the Risk Needs Responsivity (RNR) model have been shown to reduce offender recidivism by up to 35 %."

The Good Lives Model

The Good Lives Model (GLM) by Ward and colleagues (Ward and Stewart 2003) is another model that is influential in the area of offender rehabilitation. Furthermore, the GLM has been widely discussed in relation to sexual offenders. As illustrated above, Ward and various colleagues have criticized the RNR model, and they have developed the GLM, at least in part, to respond to some of the weaknesses of the RNR model. The GLM takes a very different approach to offender rehabilitation; rather than examining the risk level of an offender, it begins by asking what purpose the offending is serving. Specifically, the question is: What gap or need is the offending filling? Ward and colleagues (e.g., Serran et al. 2007) suggest that in order to bring about long-term change in offenders' behavior, therapy should identify and respond to the underlying motivation for the behavior.

The GLM is founded on the proposition that all human activity revolves around the desire to fulfill basic needs or "goods." For instance, eating nutritious food and engaging in regular physical exercise might fulfill the basic good of maintaining physical well-being. Painting a picture or acting in a play may fulfill the basic good of creativity. When these sorts of "goods" are maintained pro-socially in an individual's life that it can be said that he or she has a "good" life. Ward also argues that the drive to attain such "goods" is inherent by virtue of one's humanity. For example, he states that "…both sexual and non-sexual offenders are naturally disposed to seek a range of primary human goods that if secured will result in greater self-fulfilment and sense of purpose" (Ward et al. 2009, p. 304).

In explicating the GLM, Ward draws a distinction between primary and secondary goods. While primary goods are essentially ends in themselves, secondary goods relate to the means of attaining primary goods. For example, as shown below, knowledge is viewed as a primary good; thus, secondary goods that might bring this about would include activities such as reading a book and engaging in educational activities. Drawing on theoretical work from a range of research areas, including anthropology, evolutionary psychology, and ethics, Ward and Stewart (2003) propose that there are at least ten primary human goods, namely, "Life (including healthy living and functioning), knowledge, excellence in play and work (including mastery experiences), excellence in agency (i.e., autonomy and self-directedness), inner peace (i.e., freedom from emotional turmoil and stress), friendship (including intimate, romantic and family relationships), community, spirituality (in the broad sense of finding meaning and purpose in life), happiness, and creativity" (p. 356).

Ward proposes that offenders, like all human beings, value these primary goods and seek to manifest them in their daily lives. However, Ward stresses that for most offenders, and indeed most non-offenders, the drive to attain these goods is not necessarily part of one's conscious awareness. Thus, the drive to attain these goods is often natural and ingrained and not typically part of a carefully thought-out plan. Ward suggests that while offenders attempt to realize the same goods as those who do not commit crimes, they go about this in a problematic way and he describes four key types of problems. These are the use of *inappropriate means* (i.e., goods are sought in ways that are inappropriate and counterproductive), a *lack of scope* (i.e., only some goods are sought), *conflict or lack of coherence* (i.e., the ways some goods are sought directly reduces the chances of others being secured), and *a lack of capacity* (i.e., individuals lack the skills, opportunities, and resources to achieve a certain good in specific ways).

With regard to sexual offenders, the use of inappropriate means would be a common example. While a male sexual offender may seek a sexual partner as part of his intention to attain the "good" of "friendship," he may seek an inappropriate sexual partner. For instance, he may engage in sexual activity with a minor rather than an adult. Furthermore, his sexual offending may be related to a lack of capacity; he may lack the social skills required to establish and maintain an appropriate sexual relationship with an adult.

As outlined by Ward, a GLM approach to offender rehabilitation requires a comprehensive assessment of the relationship between the offending and goods that the offending is being used to attain. Then, a Good Lives Plan is developed which includes setting goals for the future which will ultimately bring about the manifestation of goods in a pro-social manner. Thus, treatment involves the acknowledgement that all human beings have basic needs and the encouragement of offenders to strive to meet these in their lives but to do so in the manner that is consistent with societal norms and laws. According to the GLM, when these basic needs are met, the risk for reoffending will be greatly reduced because the offender will no longer use offending as a means of achieving his goals.

The GLM approach to offender rehabilitation is consistent with the work of Maruna (e.g., 2001) which stresses the importance of taking a positive approach in therapy. The GLM is also compatible with the strengths-based approach which has become increasingly popular within the field of mental health treatment (Wong 2006). However, as yet, there is insufficient empirical evidence that applying the GLM to offender treatment is advantageous. Also, the suggestion put forward by proponents of the GLM that the more traditional RNR model has a negative focus and is not strengths-based has been challenged. For example, it has been noted that the RNR framework does have positive and forward-looking components (New Zealand Department of Corrections 2009). Furthermore, Andrews and Bonta (2003b) take issue with Ward's proposition that a focus on criminogenic needs and risk factors is incompatible with a focus on more positive factors.

At this time, in light of current research and theory, it would seem that a combination of the RNR model and a "good lives" approach is the best way forward in the treatment of sexual offenders. While the GLM still requires empirical support, given its alignment with positive and strengths-based approaches. which have already proven their worth, it is arguably a useful model which is likely to prove efficacious.

Process Issues

Over recent years researchers have predominantly focused on the content of sex offender treatment programs rather than the process. However, with regard to the process of treatment, there are a number of important issues which require attention.

Group Versus Individual Approaches

Treatment of sexual offenders is typically conducted in groups with between eight and ten participants with either one or two facilitators (Marshall 2001). As stated by Marshall, group treatment is more economical and has been found to be more effective. Marshall points out that in group settings, clinicians are less likely to collude with offenders. Collusion is more likely with this offender group as due to society's strong aversion to sexual offending; it is especially difficult for these sorts of offenders to admit to their crimes. Sexual offenders are more likely to deny their offending or to minimize their degree of culpability, and this can pose a challenge in terms of establishing rapport in individual treatment. In contrast, in a group setting, participants are able to challenge each other which assists in maintaining the rapport between the facilitator and the offender.

As explained by Harkins and Beech (2008), effective group treatment is dependent on the presence of several qualities within the group. One that has been found to be particularly important is cohesiveness (Harkins and Beech 2008) which is essentially the positive feelings that group members have for each other and the extent to which they are able to work together. As stated by Harkins and Beech, the role of the therapist is crucial in establishing cohesiveness within the group. In particular, the therapist needs to earn the respect of the participants by displaying a range of positive characteristics, such as flexibility, warmth, and empathy. However, it is equally important that the therapist is firm and directive and is able to challenge the participant when necessary, although this should be done in a gentle and compassionate manner (Serran et al. 2003).

Many contemporary sex offender treatment programs utilize mixed groups, that is, they treat rapists and child sexual offenders together, and some researchers have questioned whether this is appropriate. For example, Harkins and Beech (2008) compared the "therapeutic climate" in mixed groups and in homogenous groups. They measured therapeutic climate with the Group Environment Scale (GES) which targets a range of phenomena, including expressiveness, cohesion, and leader support. Harkins and Beech found that there was no difference in the quality of the therapeutic climate between the group types. Furthermore, they found that both types of group appeared to have very positive therapeutic climates. Also, recidivism data examined in the study showed that the type of group that child sexual offenders participated in had no impact on the likelihood of reoffending (however, similar data was not available for rapists).

Some researchers have argued that even when treatment is delivered within a group setting, it should still be tailored to the unique needs of the individual. For example, Marx et al. (1999) suggest that facilitators should adapt their approach to suit the various personality traits and learning styles of group members. Thus, it is proposed that even within a group setting, therapists can respond to individual needs. It is important to note though that such an approach would be dependent on a thorough and accurate assessment of the group participants which would allow for the identification of individual factors that would then facilitate appropriate tailoring of the therapist's interaction with group members.

Many group-based sex offender treatment programs provide individual therapy sessions as an adjunct to group treatment. For example, the Te Piriti Sex Offender Treatment Program in New Zealand includes individual therapy sessions alongside group-based treatment. These sessions allow the facilitator to provide additional support to the offender and to discuss any problematic issues that may arise during group sessions. They also provide an opportunity for the offender to raise issues that he may not feel comfortable raising within the group. For example, often offenders feel apprehensive about the idea of disclosing the details of their offending to their fellow group members, and thus individual sessions provide an opportunity to discuss such concerns prior to disclosure and to provide appropriate guidance and support.

Confrontation

There is an ongoing debate about the merit of using outright confrontation in the treatment of sexual offenders. This sort of approach is questioned because it is incompatible with the sorts of qualities which are considered to be fundamental to effective therapy. However, it is sometimes considered to be necessary because sexual offenders often deny or minimize their offending. Marques et al. (2005) state: "…too many sex offender treatment providers appear to believe that it is necessary to be extremely confrontative when working with these clients" (p. 1098). However, as Marque and colleagues explain, such an approach is inconsistent with the principles of motivational interviewing (MI), principles which the research shows are very helpful in guiding offender treatment. Although one of the key tasks of MI is to "develop discrepancy," this should be done carefully and in conjunction with the other components, which include the expression of empathy and avoiding arguments.

Marshall and others (Marshall et al. 2003) examined the effect of therapist qualities on the efficacy of sex offender treatment and concluded that there are several therapist characteristics which are associated with treatment success. For instance, they found that emotional warmth, empathy, directiveness, and positive reinforcement were all associated with positive treatment outcomes. Arguably, these types of therapist qualities are not compatible with a confrontational approach; thus, Marshall's research raises further doubts about the usefulness of such an approach in sex offender treatment. Overall, research suggests that therapists working with sexual offenders should probably be supportively challenging. That is, they should challenge in a way that allows them to remain positive and encouraging. Supportive challenges differ from confrontational challenges in that they are typically expressed in a warm and understanding manner which displays a genuine interest in the individual and concern for his or her well-being.

Coercion

Another process issue, which is pertinent to the rehabilitation of sexual offenders, is the impact of coercion on treatment effectiveness. Although many sexual offenders are recommended by judges, parole boards, and psychologists to engage in offense-related treatment, many choose not to. A comprehensive study by Langevin (2006) found that approximately 50 % reported that they wished to undertake treatment and about 13 % successfully completed treatment. Thus, a high number of sexual offenders decline treatment and only a small proportion complete treatment. Furthermore, with regard to those who do engage in treatment, there are a variety of reasons that may underlie their decision. For example, while some offenders may believe that they need treatment and will benefit from it, others simply undertake treatment in order to gain early release from prison. Thus, the provision of consent in a prison setting may not reflect a genuine motivation to engage in therapy but may simply reflect other motivations. Also, the offender may feel coerced by others; he may believe he has no choice but to abide by the wishes of the judicial system.

As explained by Burdon and Gallagher (2002), the coercion that forms the backdrop to offender treatment is part of broader societal efforts to coerce the offender, including imprisonment, registration, and community supervision. Thus, coercion reflects society's desire to control the offender in order to prevent reoffending. But of course, in terms of treatment some degree of motivation and cooperation is necessary in order for treatment to progress, and this is recognized by most therapists who are involved in selecting treatment participants. Also, often there are constraints on program delivery which limit the number that can be run at any one time, and this in turn limits the number of places that are available. Thus, it is often necessary to choose participants that are most likely to benefit from the program, and these are often those who express a desire to undertake treatment. However, it is interesting to note that involvement in sex offender treatment tends to increase an offender's openness to the idea of engaging in treatment and can lead to success in treatment, even in individuals who are initially unenthusiastic (Burdon and Gallagher 2002).

Treatment Components

There are many different components that may be used in the treatment of sexual offenders. The components that are covered herein are those that are commonly used in group treatment approaches and which have described in detail in the research literature.

Deviant Sexual Arousal

It is not surprising that deviant sexual arousal is often targeted in treatment as it has been found to be one of the most significant risk factors for sexual reoffending. However, it has been reported that deviant arousal is now not routinely targeted in treatment as it was previously, due to the acknowledgement that problematic sexual preferences do not always play a significant role in an individual's offending (e.g., Marshall 2006). Also, the factors that lead to sexual offending are many and varied and differ across offender and offense type. For example, in rape offenses, anger and aggression may play a more significant role than problematic sexual preferences. Further, research suggests that sexual arousal to stimuli associated with rape has been found in men who have not committed rape; thus, it is not necessarily associated with deviant behavior. Thus, it may be the case that offense-related sexual preference is more likely present in child sexual offenders. Nonetheless, many sexual offender treatment programs, for those with adult and juvenile victims, continue to include a component that focuses on deviant sexual arousal (Marshall 2006).

As explained by Marshall et al. (2009), there are two general types of behavioral approaches to treating deviant sexual preferences: aversion techniques (such as covert sensitization and satiation therapy) and techniques that utilize positive reinforcement (such as masturbatory reconditioning). Covert sensitization involves pairing the deviant sexual behavior with an aversive stimulus via imaginal exposure so that the offender eventually finds the sexual behavior to be aversive. In contrast, satiation therapy involves combining the deviant stimulus with prolonged masturbation so that over time the stimulus loses its appeal. Masturbatory reconditioning involves replacing the deviant sexual stimulus (e.g., child) with a pro-social stimulus (e.g., an adult) which is then reinforced through masturbation. While these sorts of techniques have been in use for many years, there is little research available that has examined their efficacy. Also, much of the research that has been conducted has used single-case designs which of course do not allow comparison with other treatment methods.

Marshall et al. (2009) conclude that based on the available evidence, the best approach to treating deviant sexual arousal would be to use a combination of masturbatory reconditioning and satiation therapy. In this way the individual's arousal to the pro-social stimulus would be strengthened, while the arousal to the deviant stimulus would be weakened.

Emotional Regulation

Research indicates that those who commit sexual offenses tend to have difficulties regulating their emotions and may commit sexual crimes as a means of avoiding experiencing negative emotion (Mandeville-Nordon and Beech 2004). Evidence suggests that, in particular, sexual offenders often struggle to cope adaptively with stressful life events. It seems that when faced with stressful situations, sexual offenders often use maladaptive and ineffective coping strategies which increase the likelihood of reoffending (Cortoni and Marshall 2001). For example, it has been observed that rapists may experience high levels of anger and resentment in response to stress which may contribute to their offending.

Other evidence indicates that sexual offenders often use masturbation with either appropriate or inappropriate sexual fantasies as a means of escaping the experience of negative emotion (Cortoni and Marshall 2001), and such responses could increase the likelihood of sexual offending, especially, if it reinforces the idea of inappropriate sexual interaction. Thus, researchers have suggested that treatment should include a component that teaches offenders how to respond constructively to the negative emotions that may arise from stressful life events (Beech and Fisher 2002). However, to date, there is little research available that shows whether the inclusion of such components in treatment leads to a reduction in sexual reoffending. A study by Serran and colleagues (2007) found that sex offenders who had completed treatment which included a coping skills component appeared to be better equipped (than the wait-listed controls) at dealing with high-risk situations. However, the study did not include a follow-up looking at recidivism; thus, it is unclear whether this would translate into a reduction in reoffending.

As mentioned above, in terms of rape, anger is a particularly prominent negative emotion. Howitt (2006) states: “Anger control problems have to be seen as an issue with rapists for whom issues of anger are common” (p. 369). However, some researchers have questioned the use of anger management components in treatment programs for rapists due to the fact that anger does not appear to be a problem for all rapists. For example, Loza and Loza-Fanous (1999) investigated anger levels across a range of offender groups and found no difference in levels between rapists and non-rapists (or between violent and nonviolent offenders). The authors then question the usefulness of anger management in the treatment of rapists. Arguably, this study would have been more worthwhile if it had also included a non-offender population as it may be the case that offender populations have high levels of anger problems. If so, then rapists' anger levels, though similar to other offenders, may still be problematic and potentially contribute to their risk of reoffending.

Cognition

It is widely acknowledged that sexual offenders may harbor a range of offense-related attitudes and beliefs. Cortoni (2009) states: “. . .an overall predisposition to be tolerant of sexual offending is related to sexual recidivism” (p. 44). Thus, the targeting of offense-related attitudes and beliefs is a mainstay of rehabilitation approaches. One common type of belief that is endorsed by sexual offenders is a belief of “entitlement” to sex. This can include specific beliefs such as “men need more sex than women do” and “everyone is entitled to sex” (Pemberton and Wakeling 2009). Also, child sex offenders may believe that children are sexual objects and that having sex with children is good because it educates them about sex. In contrast, research has shown that those who commit rape offenses tend to objectify and sexualize women and that they hold quite specific beliefs about specific situations. For instance, rapists often endorse beliefs along the lines of "if a woman flirts, then she wants to have sex" or "if a woman accepts a free drink, then she wants to have sex."

Within the sex offender field these problematic attitudes and beliefs are typically referred to a "cognitive distortions," and they are frequently used by offenders to justify their offending. In this way, they may be used by the offender to feel comfortable with continued offending. For example, a child sex offender might justify his ongoing abuse of a child with the belief that the sexual interaction with the child is appropriate because the child is choosing to engage in the sexual activity and shows no sign of being unwilling. In association with his belief, he may also believe that the child is not being harmed in any way. In this way the abuser attempts to minimize his level of culpability, and this contributes to his decision to continue with the behavior. While sexual offenders will usually report that they had an awareness of wrongdoing, they will often use their cognitive distortions to distract themselves from this awareness.

As mentioned above, sexual offenders often find it difficult to admit to their offending due to the social ramifications. For example, they may believe that if they admit to what they have done, they will lose the support of family and friends. Also, in some cases, the sense of shame and embarrassment make it very difficult for them to talk to others about it, including those involved in correctional and rehabilitative services. It has been reported that most sexual offenders either deny that they committed the crime or at least attempt to minimize their level of responsibility (Marshall 2006). Thus, it might be assumed that denial and minimization would be important targets for treatment. In fact, many treatment programs do not allow deniers to participate because some components of treatment require the offender to admit to their offending. For example, often offenders are expected to describe their offense in detail in order to identify points at which they could have behaved differently and avoided offending.

There may be a range of other reasons that treatment programs may preclude those who deny their offending. For instance, deniers may have a negative impact on other individuals in the group; if they are not willing to be honest, then others may be less inclined to be upfront and open. Also, those who are unwilling to admit to and discuss their offending may be less likely to benefit from treatment; thus, they may take the place of someone who may have had more to gain from taking part in treatment. This issue arises because most sex offender treatment programs have limited places available. As they require significant resources to run, organizations (typically prisons) are only able to run a limited number. However, Marshall (2001, 2006) argues that excluding those who deny their sexual offending has the effect of putting the public at greater risk because those offenders are then released untreated.

When denial is addressed in treatment, there are two general approaches. One approach is to include a specific module that targets denial during the initial stages of the treatment program, while the other approach is to place deniers in a specially designed treatment program. When the former approach is taken, the issue of denial is usually discussed in an individual setting, prior to the beginning of treatment proper, so that the offender can consider and perhaps reconsider the extent to which they will be willing to discuss the offense, prior to having to communicate with fellow group members.

Intimacy and Social Skills

Evidence suggests that sexual offenders find it difficult to establish and maintain consensual intimate relationships and that subsequently they are vulnerable to experiencing social isolation and loneliness (Mandeville-Nordon and Beech 2004). Mandeville-Norden and colleague also report that individuals who commit sexual crimes tend to lack confidence and assertiveness skills; thus, it may be hypothesized that the lack of confidence and problems being assertive contribute to the intimacy difficulties. Also, research has shown that sex offenders report significant feelings of loneliness even within the context of intimate relationships. Therefore, social skills training is a mainstay of sex offender treatment programs. As explained by Marshall (2006), social skills training is usually a broad-based aspect of treatment which may include a range of components, including problem solving skills, assertiveness training, self-esteem building, and sex education.

The Extended Sex Offender Treatment Programme (ESOTP) in the United Kingdom is an example of a program that addresses social functioning. This program for high-risk offenders, which involves 140 h of treatment over 68 sessions, includes a component titled “intimacy skills.” This component includes skill development in the areas of jealousy management, conflict resolution, and giving and receiving social support. A recent survey of sex offender treatment programs in Canada reported that three quarters of their programs included components that targeted intimacy, relationships, and social skills. Overall, research shows that both intimate relationships and more general social functioning are addressed in most sex offender treatment programs.

Some research has examined the relationship between sexual offending and adult attachment styles. For instance, Lyn and Burton (2004) examined attachment styles in a “Midwestern United States” sample of sex offenders and found that the majority (85 %) were assessed as having insecure patterns of attachment. Furthermore, when Lyn and colleague compared sex offenders with non-sex offenders, they found that the former were significantly more likely to display signs of insecure attachment. In a further study Lyn and Burton (2005) explored the particular types of problematic attachment that sexual offenders tended to display, and they found that anxiety and avoidance were seen most frequently.

William Marshall is well known for his work on the role of attachment in sexual offending. He has long argued that attachment problems contribute to the development of sexual offending. Furthermore, he has examined some of the childhood difficulties which may be associated with attachment problems. For example, he has reported that sexual offenders often have problematic childhoods, characterized by disruption, neglect, and abuse (both physical and sexual) (e.g., Marshall and Marshall 2000). Also, as explained by Marshall and Marshall, while such aversive early experiences may lead to attachment problems, they may also lead to a range of more general difficulties, such as low self-esteem and limited relationship skills. Thus, attachment theory offers a psychological mechanism that may explain the intimacy and relationship problems that are seen in sexual offenders.

Victim Empathy

Many, if not most, contemporary sex offender treatment programs include a component that focuses on the development of victim empathy. Research examining empathy in sexual offenders has found that while they often lack empathy for their victims, they do not typically have more generalized empathy deficits. Thus, treatment that aims to develop sexual offenders’ empathy is usually victim-focused. For instance, some treatment programs will require offenders to listen to a voice recording of a victim talking about the impact of his or her own sexual abuse experience. Alternatively, the offenders may be required to read stories of victims’ experiences or to read accounts written by their own victims.

Empathy is a complex concept and, historically, there have been a variety of approaches to defining it. While some theorists have conceptualized it as essentially involving cognitive processes, others have construed it as the ability to recognize emotion in others and to take on the perspective of another person. More recently, it seems that many theorists have viewed it as a multifaceted concept involving thoughts, emotions, and behaviors. With regard to sexual offenders, Marshall (2006) suggests that empathy deficits are frequently associated with the presence of victim-related cognitive distortions. For example, a child sex offender may believe that his sexual activity with his victim is educational and, therefore, not harmful. Or he may believe that if the child is quiet during the sexual interaction, then the child is enjoying it; thus, the offender may misinterpret the child’s emotional response.

Given the apparent connection between empathy deficits and cognitive distortions, Marshall proposes that it may be possible to address empathy deficits simply by challenging an offender's cognitive distortions, rather than directly targeting empathy problems.

Other researchers have suggested that empathy deficits in sexual offenders may be associated with difficulties with the identification and awareness of emotion (e.g., Gannon et al. 2008). Although, this seems to contrast with the suggestion that sexual offenders' empathy deficits are specific to their offending. Arguably, if they have difficulty with their own emotional awareness, then one might expect that they would have more general problems empathizing with others. One commonly used technique for the development of emotional awareness in group treatment is encouraging participants to identify and describe the emotion that they are experiencing at that moment in treatment. This is believed to facilitate the development of an ability to put a name to one's emotional experience and to describe that experience to others.

Some treatment programs utilize victim role plays as a way of enhancing offenders' empathy for their victims. A study by Webster et al. (2005) examined the effectiveness of offense reenactments and concluded that their inclusion in treatment appeared to enhance offenders' victim empathy. The approach used in the study, which was tailored to each participant, included the development of an offense map which was then used as a guide for walking the offender through the offense while he was role-playing the victim. Any sexual or violent acts were depicted symbolically, using light touch on a nonsexual area of the body. The study included a control group who carried out "empathy deficit role play scenarios" (p. 67) but did not engage in any victim role plays. While, as mentioned above, the researchers found this approach had clinical benefits, they also found that the method seemed to be more effective in treating rapists than child sex offenders and that the differences between the two approaches were small.

It is important to point out that although, as outlined above, victim empathy is a frequently utilized component of sex offender treatment programs, research has not been able to show that it leads to a decrease in reoffending. However, demonstrating this sort of causal connection will always be a challenging task because treatment is typically multifaceted; therefore, it is difficult to know for sure which elements of treatment are bringing about change. Furthermore, given that sexual offenders present with victim-specific empathy deficits, it makes clinical sense to address this in treatment.

Substance Abuse

There is now a significant body of research that demonstrates a link between alcohol use, other drug use, and various types of criminal behavior. Further, as stated by Fridell and colleagues (2008, p. 800), "Alcohol abuse precedes or accompanies a large proportion of violent crime." Also, research has shown that problematic alcohol use is associated with a tendency to reoffend. With regard to sexual offenders, evidence suggests that a significant proportion have drug and or alcohol-related problems. For example, a study by Marshall (1996) found that 50 % of sexual offenders were intoxicated with alcohol at the time that they committed their most recent sexual offense. Also, as with general offending, drug and alcohol abuse has also been found to be associated with sexual reoffending. For instance, research suggests that alcohol abuse at least doubles the likelihood that a sexual offender will reoffend. Some researchers have observed that drug and alcohol problems are often associated with problematic lifestyle choices which lend themselves to offending behavior. Thus, drug and alcohol issues and offending may have a common origin.

While this may indeed be the case, it is important to acknowledge that intoxication with any substance has a range of consequences that can directly impact on offending. For example, alcohol can significantly diminish an individual's ability to understand and respond appropriately to a social situation. Specifically, it impairs one's judgment, thus making it more likely that an individual will respond in an antisocial manner. Furthermore, research has shown that alcohol can increase one's tendency for impulsivity, meaning that an offender will be more likely to respond to a situation quickly and without a proper appraisal of the consequences of his behavior. Also, there are well-established links between excessive alcohol use and aggression in those who have already demonstrated aggressive tendencies.

A study by Abracen et al. (2006) compared sexual and violent (nonsexual) offenders in terms of the presence of alcohol abuse, using the Michigan Alcohol Screening Test (MAST). Results showed that sexual offenders had significantly higher scores thereby indicating that they were more likely to have problematic patterns of drinking. In their discussion of the results, they suggest that myopia theory may offer an explanation of why alcohol use may contribute to sexual offending. Myopia theory suggests that when an individual is considering engaging in a risky behavior, alcohol may have the effect of decreasing their inhibition via a reduction in their information processing capacity. This is similar to effect of alcohol use on judgment which is suggested above.

Evidence suggests that there are a variety of approaches to addressing drug and alcohol problems. While some programs include a substance abuse component, others do not address it directly but direct individuals to appropriate drug and alcohol programs. Often drug and alcohol problems are construed as responsivity barriers and are thus seen as being best addressed prior to offense-specific treatment. For example, even in many prison environments, drugs are available and, therefore, it is considered that in order for an offender to make the most of offense-specific treatment, he should first address his drug use. Obviously, in community settings drug and alcohol use is more prevalent; thus, the same approach is often taken.

Treatment Efficacy

There is now a growing body of research that has examined the efficacy of sex offender treatment programs. A study a decade ago (Hanson et al. 2002) examined the outcome evaluations of 43 sex offender treatment programs with a mean follow-up period of 76 months. Hanson et al. reported a sexual recidivism rate of 12.3 % for sex offenders who had completed treatment and a 16.8 % recidivism rate for untreated sex offenders. They also found that the treated sex offenders committed significantly fewer general offenses than their untreated counterparts (27.9 % and 39.2 %, respectively). Note that the majority of treatment programs that were included in this study had a cognitive-behavioral orientation; thus, this lends support to the efficacy of cognitive-behavioral programs.

Similarly, Lösel and Schmucker (2005) carried out a meta-analysis of 69 studies of sex offender treatment efficacy that contained 80 separate comparisons of treated and untreated offenders. The authors concluded that treatment led to a mean reduction in sexual recidivism of almost 37 % (when low base rates are taken into account). The actual difference in recidivism rates between treatment groups and control groups (who were untreated or had completed another type of treatment) was 11.1 % and 17.5 %, respectively. They also found that sex offender treatment led to a significant reduction in general reoffending. In summarizing their findings, Lösel and colleague state: “The most important message is an overall positive and significant effect of sex offender treatment” (p. 135).

Another study (Seager et al. 2004) looked at recidivism rates in 109 sex offenders who had completed offense-specific cognitive-behavioral treatment and 37 who had not completed any treatment for their sexual offending. Note that of the 109, only 81 were assessed as having successfully completed the program. The recidivism rates that were examined included sexual and violent offenses. Results showed that regardless of whether individuals were considered to have been successful in completing the program, those who completed were found to have a lower recidivism rate. Specifically, 4 % of successful completers and 7 % of unsuccessful completers were reconvicted within the 2-year follow-up period. This contrasted with 18 %, 42 %, and 100 % (respectively) of those who withdrew from treatment, declined it, or were terminated from the program. However, the authors concluded that there was no evidence of a connection between offenders' change in clinical phenomena (such as empathy) and their reoffending. For example, they found that the participants risk scores on the Static 99 (an actuarial risk measure) predicted their likelihood of reoffending regardless of whether they completed. Seager and colleagues concluded that "participation in the sex offender program did not reduce recidivism rates for those who complied with treatment but merely enabled motivated offenders to concretely demonstrate their commitment to not reoffend" (p. 609).

It is unclear whether the two aforementioned meta-analyses took into consideration the various ways in which treatment completers and those who did not complete treatment might have differed. The study by Seager et al. suggests that apparent treatment effects may simply be a result of preexisting differences between those who undertake such programs and those who do not. However, it is important to note that Seager's study was comparatively small and only included a small number of offenders. Nonetheless, it does raise questions about the way in which studies of treatment efficacy are conducted and how results are interpreted.

It seems reasonable to conclude that sex offender treatment is often effective and that at the very least it does no harm. Furthermore, there is growing evidence that cognitive-behavioral approaches may be especially useful. However, further studies are needed to determine if the effects that are being found are indeed due to treatment or to the fact that particular individuals tend to undertake and complete treatment.

Summary

This entry has discussed two of the key models that underlie sex offender treatment. It has also examined some of the relevant process issues, such as whether treatment should be delivered in group settings. Further, it looked at the components that are typically found in sex offender treatment programs. The entry concluded with a brief discussion of treatment efficacy. It is hoped that this overview will provide the reader with some understanding of how the treatment of sexual offenders is ordinarily delivered and of some of the issues surrounding such treatment. Obviously, there is a need for ongoing research in many areas as many findings remain preliminary.

Sex Offenders and Criminal Policy

Richard Tewksbury and David P. Connor
Justice Administration, University of Louisville,
Louisville, KY, USA

Overview

Over the past several years, individuals convicted of criminal acts have been subjected to increasingly severe sanctions. In particular, efforts have been made to increase the supervision of criminals and decrease offender opportunities to further perpetrate crimes. Without a doubt, many emerging laws and criminal justice policies have targeted sex offenders, especially those convicted of victimizing children. In addition to progressively long incarcerations, sex offenders potentially face civil commitment, registration and community notification, chemical castration, polygraph testing, and residency restrictions. The United States has held a leading position in passing these laws and enacting policies aimed at preventing future sex crimes.

Explanations for the renewed interest in punitive sex offender legislation may be found in the high-profile sexual attacks on children in the 1990s. Child sexual assault victims whose names saturated media headlines and generated castigating policies toward sex offenders included Jacob Wetterling, Megan Kanka, and Adam Walsh. Although not new concepts, the revival of criminal registration and civil commitment for sex offenders reflect growing public and political concerns. Technological innovations may also be responsible for intensified sex offender legislation. Chemical castration laws and polygraph testing, for example, are likely the result of expanding scientific know-how.

Background Description

Civil Commitment Statutes

In response to high-profile sex crimes, the first American sexual psychopath laws were passed in the 1930s. Community protection, as well as treatment and incapacitation of sex offenders, were the explicit goals of these laws. Often calling for the civil commitment of so-called mentally disordered sex offenders to public mental hospitals, these statutes rested on the assumption that mental health professionals were capable of identifying, confining, and treating sexual psychopaths.

Criticism surrounding sexual psychopath laws has always existed. Those offenders determined to be sexual psychopaths were often committed to mental institutions indefinitely with few procedural safeguards. These laws may have also been aimed at sex offenders other than violent recidivists and included exhibitionists, voyeurs, and homosexuals. Moreover, public disenchantment with rehabilitation generally, and lack of confidence in effective treatment methods for sexual psychopaths specifically, eventually dissuaded efforts to utilize these laws. By the late 1960s, many states started to repeal, intentionally disregard, and seldom employ these sexual psychopath laws.

Registration and Community Notification

Registration of individuals charged or convicted of various crimes has been used for decades. In 1994, the Jacob Wetterling Act put into practice the registration of sex offenders in statewide databases. Culpable for transforming sex offender registries into publicly available online domains, Megan’s Law, passed in 1996, requires state law enforcement agencies to make public information about sex offenders. Affording a sense of safety and control to the public, such laws have subsequently also been passed unanimously by many legislatures. Today, all states, as well as the federal government, have enacted and maintain publicly available, Internet-based sex offender registries.

Castration Laws

For many centuries, sex offenders were punished through physical castration. In the United States, castration was first popularly used for slaves suspected of having sex with white women. The eugenics movement (1905–1935) supported castration and sterilization of criminals and the mentally ill. Currently, voluntary chemical castration (combined with therapy) has largely replaced physical castration, as medical doctors believe that similarly effective results can be reached through treatment with medication.

Concerns over body mutilation, intrusiveness, and the lasting results of surgery have rendered physical castration of sex offenders in the United States as largely unacceptable. The widespread availability of medications as an alternative to physical castration may also explain this change in practice. Although some laws concerning sex offenders allow both physical and chemical castration as a substitute or adjunct to punishment, chemical castration seems to be the more socially acceptable solution.

Polygraph Testing

Over the last two decades, polygraph testing has been presented as yet another tool to manage, supervise, and treat sex offenders under community supervision. Numerous states require individuals convicted of two sex offenses to undergo periodic mandatory polygraph supervision. Until recently, *Frye v. United States* (1923) governed the admissibility of polygraph results in American courts. In this case, the Court of Appeals of District of Columbia ruled that when questions of fact require special knowledge, the opinions of witnesses skilled in the subject to which the questions relate are admissible in evidence.

In 1993, however, the US Supreme Court in *Daubert v. Merrell Dow Pharmaceuticals* ruled that the Federal Rules of Evidence should provide the standard for admitting expert scientific testimony. To determine the admissibility of polygraph evidence, trial courts must now consider factors such as whether lie detector testing has been scientifically tested, largely accepted within the scientific community, and exposed to review and publication. As a result, most states currently do not consider polygraph evidence as admissible; however, if both parties stipulate, a few courts may admit polygraph results.

Appellate courts in *Himes v. Thompson* (2000) and *Kansas v. Lumley* (1999) have ruled that polygraph evidence is admissible, as well as sufficiently reliable as evidence, at probation and parole revocation hearings. Courts in *State v. Flores-Moreno* (1994) and *State v. Riles* (1997) have also held that polygraph testing limited to topics related to crimes perpetrated by sex offenders is permissible as a condition of community supervision. Moreover, the Washington Court of Appeals in *State v. Eaton* (1996) expressed that polygraph testing as a requirement for probationers and parolees was a necessary and effective way in which to monitor compliance with terms of supervision.

Residency Restrictions

Residency restriction laws have been created as a result of increasing concern about registered sex offenders living in communities. After the murder of Jessica Lunsford in Florida by a previously convicted sex offender, housing restrictions for sex offenders in the United States became more widespread. Despite punishment, treatment, and supervision, many believe that sex offenders continue to pose a serious danger to society. These housing restrictions prevent sex offenders from living near schools, parks, daycare centers, and other designated "child congregation" locations. In this way, these laws seek to limit contact between registered sex offenders and children, and subsequently reduce sex offender recidivism.

State of the Art

Civil Commitment Statutes

The premise of civil commitment statutes is that many sex offenders cannot be rehabilitated; consequently, such criminals must be incapacitated to the greatest extent possible. Under civil law, sex offenders may be committed to institutions. Modern civil commitment statutes, commonly known as sexually violent predator laws, allow governments to confine particular sex offenders to secure mental health facilities upon their release from prison or a judicial finding of incompetency to stand trial. Upon the decision of a court, sex offenders considered to have mental abnormalities or other psychological disorders that may prompt harmful sexual conduct in the future may be subjected to civil commitment. As of 2009, 20 states and the federal government have civil commitment laws aimed at sex offenders.

Following the placement of committed sex offenders to secure institutions, mental health clinicians and other professionals are assigned the responsibility of evaluating offenders at regular intervals. During periods of civil commitment, medical and psychological assessments of sex offenders are performed to assess improvements in mental status. Examinations and subsequent reports prepared for the court concerning the mental conditions of committed sex offenders are typically completed on an annual basis. After these examinations by medical and mental health officials, sex offenders civilly committed to institutions may petition for release, appear before a judge, and ask the court to determine whether their commitments continue to be necessary to protect the public. In order to be released, psychologists and the court must agree that mental abnormalities or personality disorders once exhibited by sex offenders no longer pose a threat to society.

Whereas earlier sexual psychopath laws may have centered on rehabilitation, current civil commitment laws focus on the social control and incapacitation of sex offenders. Depicting the social control function of civil commitment laws, the US Supreme Court in *Kansas v. Hendricks* (1997) upheld a sexually violent predator statute, which sent sex offenders determined to be violent predators likely to recidivate to state mental hospitals. Although Hendricks challenged the civil commitment law as a violation of due process and prohibitions against double jeopardy and (*ex post facto*) laws, the Court found such to be constitutional as the civil commitment statute was not deemed to be punishment. In 2002, the Supreme Court ruled in *Kansas v. Crane* that mental abnormalities displayed by sex offenders must differentiate committed individuals from ordinary recidivists. Further, besides showing the likelihood that offenders will commit sex crimes upon release, it must be shown that offenders have a serious inability to control their behaviors.

Registration and Community Notification

Sex offenders have consistently faced stringent sentencing laws; moreover, society has consistently looked upon them with disdain. Spotlighting society's harsh treatment of sex offenders, one of the most recent developments has been the creation of sex offender registries. Sex offender registries are utilized in every jurisdiction in the United States, and these repositories of information provide online access to a wide array of facts about convicted sex offenders and their offenses. Individuals convicted of sex crimes are typically required to provide local law enforcement and corrections authorities with name, photograph, address, birth date, Social Security number, fingerprints, offense history, date of convictions, and other information. Sex offenders must verify the accuracy of this information on a routine basis for the duration of their registration, which may range from 10 years to life.

Most arguments supporting sex offender registries emphasize public safety, particularly the protection of children. Proponents also contend that registration will permit law enforcement officials to quickly and easily ascertain the locations of sex offenders in their communities, facilitating sex crime investigations. Because Internet databases reveal the identification of sex offenders to the community, it is further maintained that sex offender registries reduce opportunities for recidivism. Despite evidence suggesting little or no effect of registration and community notification on recidivism rates, there remains general public approval concerning sex offender registries and a belief that most sex offenders will reoffend.

Community notification typically occurs in neighborhood meetings, door-to-door visits by the police, newspaper advertisements, online notices, and flyers circulated throughout a jurisdiction. Many states that use community notification have a three-tiered system based on the purported dangerousness of sex offenders that determines the degree of notification that will take place. When sex offenders are categorized as the lowest risk to public safety, notification is typically reserved for law enforcement officials only. Schools, daycares, and other neighborhood organizations are notified of the presence of sex offenders posing a medium risk to public safety. Those sex offenders considered the most dangerous, designated at high risk, will generate the most widespread notification, as the general public is notified. Some states use formal assessment tools to classify sex offender risk levels. Other jurisdictions utilize committees of clinicians and other professionals to evaluate offenders and decide upon risk level.

Four major laws are associated with contemporary sex offender registration and notification policies. The Jacob Wetterling Crimes Against Children and Sexually Violent Offender Registration Act (1994) is the first federal law that mandated statewide registration of sex offenders. This statute requires all states to establish procedures for sex offender registration. If particular jurisdictions fail to comply with the Wetterling Act, they risk the loss of crime prevention funding from the federal government. As a result of the Wetterling Act, each state has a mandatory registration law that obligates sex offenders to provide their information to law enforcement officials.

Despite the fact that Washington enacted the first community notification law in 1990, it was Megan's Law (New Jersey Stat. Ann. §§ 2C: 7-1 to 2C: 7-11, 1996) in New Jersey that created registration and community notification legislation that was ultimately replicated nationwide. Megan Kanka was sexually assaulted and murdered by a twice-convicted sex offender on parole. Amending the Jacob Wetterling Act, Megan's Law calls for the registration of sex offenders with law enforcement at various time intervals. The frequency of registration is contingent upon assumed risk levels of sex offenders. In many states, Megan's Law also requires the local police to inform communities of the presence of sex offenders moving into neighborhoods. The jurisdiction in which sex offenders reside, as well as their risk status, will determine the degree of information that is made available to the public.

In 2000, the Campus Sex Crimes Prevention Act further amended the Wetterling Act, obligating registered sex offenders studying and working at colleges and universities to provide notice of their status as sex offenders to these institutions of higher learning. College and university officials are required to inform the campus community where information regarding registered sex offenders may be obtained. In fact, many colleges and universities maintain their own distinctive online sex offender registry. At the very least, these registries provide the full names of students and university employees convicted of sex offenses. More often, campus sex offender registries include demographic information, including physical descriptions and dates of birth. Some university registries also contain the offender's home address, conviction information, description of victims, and special conditions imposed at sentencing. Further, in addition to the academic institutions with campus-based registries, many institutions of higher learning provide online links to the state sex offender registry from the webpages of campus police or the public safety department. This information is also provided to law enforcement agencies in the jurisdiction of the college or university, and it is entered into state registry records.

The abduction of Polly Klaas generated the development of three-strikes laws. Polly's murder by a repeat sex offender who was not required to register infuriated the public and generated intense media coverage. This resulted in the overwhelming public support for Proposition 184 in California. Passed in 1994, this legislation allowed a third felony conviction to result in a sentence of 25 years to life. Although those championing three-strikes laws contend that such legislation serves as a general deterrent to potential three-time offenders, critics note that there is little evidence that shows reduction in serious crime has resulted from implementation of three-strikes laws.

Accessible to the public through the Internet, a nationwide databank of registered sex offenders was created in 2005. The Dru Sjodin National Sex Offender Public Registry, as it was named in 2006, was designed by the Department of Justice to provide more efficient access to individual state sex offender registries.

The Adam Walsh Child Protection and Safety Act was signed into law in 2006. This federal law includes the Sex Offender Registration and Notification Act (SORNA) and seeks to make the archiving and monitoring of sex offenders more efficient by creating a comprehensive and national system for sex offender registration. The legislation categorizes sex offenders into three tiers of risk. Tier three sex offenders are the most serious and must verify their location with law enforcement every 3 months for the rest of their lives. Individuals defined as tier two offenders must update their whereabouts every 6 months for 25 years, while sex offenders described as tier one lawbreakers must verify their location annually for 15 years.

The Adam Walsh Act includes additional provisions for those convicted of sex crimes. Failing to register and update information with authorities are increased to felony offenses. Failure to adhere to registration guidelines under SORNA is punishable by 10 years in prison and a $250,000 fine. The federal law also eliminates the statute of limitations concerning the prosecution of child abduction and felony child sexual offense cases. It allows victims of child abuse to utilize civil proceedings to seek monetary damages from perpetrators. Further, the Adam Walsh Act sets forth mandatory minimum sentencing for particular sex crimes. For instance, the law dictates a minimum sentence of 30 years for the rape of a child and calls for increasing the minimum prison terms for offenders traveling between states with minors.

All jurisdictions must comply with the Adam Walsh Act and the provisions of SORNA or face reduced federal grant funding. In September 2009, Ohio was the first state to comply with federal sex offender provisions under SORNA. However, as of 2011, 43 states have yet to achieve compliance with the mandates of the Adam Walsh Act.

The constitutionality of sex offender registration and community notification has been challenged in two US Supreme Court cases. *Smith v. Doe* (2003) considered the Fifth Amendment double-jeopardy clause and whether registration and notification laws amount to further punishment of sex offenders. The Supreme Court found that sex offender registration and notification is regulatory and consequently is not additional punishment. Moreover, the Court ruled that individuals convicted of sex crimes prior to the establishment of registration and notification for sex offenders can still be obligated to comply with these laws. The second Supreme Court case regarding sex offender registration and community notification examined the issue of cruel and unusual punishment. The Court in *Connecticut Department of Public Safety v. John Doe* (2003) ruled that the posting of sex offender photographs online is constitutional. Registration and notification laws, therefore, are not considered to be obstacles to personal freedom.

Castration Laws

In the last two decades, medication as a means of controlling the behavior of sex offenders has gained renewed interest. Chemical castration consists of injecting Depo-Provera, the synthetic hormone medroxyprogesterone acetate, to reduce the blood serum testosterone levels in males. Taken on a regular basis, Depo-Provera is supposed to reduce sexual impulses, erections, and ejaculations. The potential side effects of Depo-Provera include migraines, nausea, weight gain, insomnia, fatigue, and loss of body hair, although most of these are thought to be rare and reversible.

Presently, many chemical castration laws call for the forced dispensing of medication to control the behavior of recidivist sex offenders. In 1997, California was the first jurisdiction to require chemical castration for repeat sex offenders (with victims under the age of 13). Under California law, repeat sex offenders are obligated to receive chemical injections prior to their release on parole. These injections persist until offenders complete their criminal sentences. Although sex offenders may refuse chemical castration, parole will be immediately denied to those deciding not to participate. Following California's example, other states including Colorado, Florida, Georgia, Louisiana, Montana, Texas, and Wisconsin have similar sex offender castration laws. However, unlike California, many state statutes allow judicial discretion in regards to implementation of castration.

Chemical castration laws regarding sex offenders generally do not require complete medical or psychiatric assessments prior to the injections of medication. Further, there is no distinction between types of sex offenders most appropriate for chemical castration in the statutes.

Polygraph Testing

Polygraph (or “lie detector”) testing with sex offenders focus on disclosure polygraphs performed after sentencing, denial and specific issues examinations, and maintenance polygraphs administered during sex offender treatment for purposes of reducing offender denial and gauging compliance with conditions of supervision. Following sentencing, the disclosure polygraph involves questions asked of sex offenders about their history of sexual deviance. Polygraph examiners identify offender deception through responses of intensified physiological arousal to relevant questions. If there are discrepancies among crime descriptions, the denial polygraph examination will likely be administered. Also, when sex offenders refuse to accept responsibility for their crimes, probation and parole officials may perform the denial examination. Specific issues polygraph examinations usually center on a specific accusation or suspicion. The maintenance polygraph detects how sex offenders manage inappropriate thoughts and measures compliance with conditions of probation or parole. In total, these applications of polygraph technology serve to manage, supervise, and treat sex offenders living in the community.

Residency Restrictions

Well over one-half of all states and numerous municipalities have sex offender residency restriction laws. Residency restriction laws often feature nebulous language to restrict registered sex offenders from living near locations described as “child congregation” areas. Such places are typically defined to include schools, parks, school playgrounds, daycare centers, bus stops, and recreational facilities. Fluctuating between 500 ft and 2,500 ft, residency restriction laws assert that specific distances must be preserved between a sex offender’s residence and various landmarks in the community.

Restrictive zoning laws prohibiting sex offenders from residing near places frequented by children are often associated with registration statutes and typically involve all registered sex offenders without regard to victims’ ages. However, other residency restriction laws concern only sex offenders under community supervision or those with child victims. For instance, the first state law addressing sex offender residency restrictions, which was passed in 1995, applied only to Florida sex offenders on probation with child victims.

In 2005, after a registered sex offender confessed to sexually assaulting and killing 9-year-old Jessica Lunsford in Florida, sex offender housing restrictions became more intensified nationwide. For example, California voters overwhelmingly passed Proposition 83 in 2006. Among other initiatives, Proposition 83 prevents sex offenders from living 2,000 ft from child congregation locations. Further, municipal sex offender housing ordinances became more prevalent. Enacted in December 2005, a Dyersville, Iowa, ordinance is among the most extreme of residency restrictions for sex offenders. The law essentially prohibits any sex offender from living anywhere in the city.

Possible Controversies in the Literature

Civil Commitment Statutes

Research highlights many disputes surrounding the civil commitment of sex offenders. Critics assert that in reality sex offenders committed to mental facilities are almost never released. Washington and Minnesota, the two states with the longest contemporary commitment programs, never discharged committed sex offenders. Others oppose civil commitment for sex offenders because such laws apparently punish individuals who have already paid their debt to society. Despite the Supreme Court decision in *Kansas v. Hendricks* (1997), Friedland (1999) contends that the civil confinement seems to hinge on the desire to continue punishment and incapacitation.

Besides apprehensions relating to sex offenders themselves, civil commitment statutes have also raised issues concerning mental health professionals. Wettstein (1992) argues that civil commitment laws regarding sex offenders inappropriately utilize experts in the mental health field. Although many sex offenders are committed due to their mental deficiencies or personality disorders, he notes that this does not necessarily mean committed sex offenders are genuinely mentally ill.

In addition, the increasing number of sex offenders and the need to commit them may exhaust government money allotted for the entire mental health field (Friedland 1999; Wettstein 1992) and may not be the most effective use of mental health resources already in short supply. If mental health professionals are trusted to confine sex offenders, it is argued that funding for treatment and other mental health services for committed sex offenders and other patients will become even scarcer. When appropriate mental health treatment is absent, some scholars note that it is possible that many mental health patients likely to be responsive to treatment may gravitate toward criminal activities.

Registration and Community Notification

Controversies over sex offender registration and community notification also exist. Those supporting sex offender registration and community notification often contend that these laws are not punishment; instead, any punitive actions resulting from registration and notification are only related to the public protection function (Brooks 1995). Further, as a result of registration and community notification, there is evidence that probation and parole officials and the community are working together to actively monitor sex offenders (Zevitz and Farkas 2000b).

And yet, it has been found that notification laws associated with sex offender registration negatively impacted probation and parole officers (Zevitz and Farkas 2000a). In particular, officers assigned to sex offender caseloads described a loss of staff, time, and financial resources as a result of a new community notification program. In addition, research on sex offender registration has shown unintended outcomes for the general community. Scholars have noted that sex offender registration and notification "can have the effect of leaving neighborhood residents frightened but feeling powerless to do anything about it" (Zevitz and Farkas 2000b, p. 405). Although registration laws were meant to assist the community by providing information about sex criminals, these requirements have also increased a sense of alarm among residents attending community notification meetings.

Registration and community notification may prevent successful reintegration into the community. Mental health professionals have expressed concern that reactions from the community resulting from registration and notification may intensify the anxiety of sex offenders, ultimately generating recidivism through poor choices (Billings and Bulges 2000).

Available literature concerning sex offender registration and community notification shows that registered sex offenders often experience numerous deleterious consequences. Specific offender aftermath associated with registration and community notification includes loss of family contact, destruction of friendships, employment difficulties, hostile confrontations, and threats of violence and personal harm. Another consequence of sex offender registration and community notification is the stigma that is associated with labeling as a registered sex offender (Tewksbury and Lees 2006, 2007). Making reintegration more challenging for sex offenders, powerful and enduring stigmas that result from public disclosure are strong obstacles to employment, education, and community activity (Uggen et al. 2004). Registered sex offenders in numerous studies have reported these marks of disgrace as common experiences Tewksbury (2004, 2005; Tewksbury and Lees 2006). The most commonly reported collateral consequences for registered sex offenders are feelings of vulnerability, stigmatization, and housing difficulties (Tewksbury 2004, 2005; Tewksbury and Lees 2006). Tewksbury and Mustaine (2009) explain that these experiences are mutually influential, as feelings of vulnerability may intensify as registered sex offenders find themselves unable to locate housing.

Castration Laws

Debates continue over the effectiveness of sex offender castration laws. Research has suggested that sex offenders treated with both medication and counseling may have improved control of their sexual behaviors (Melella et al. 1989), and sex offenders under chemical castration and participating in therapy are less likely to recidivate than those individuals discontinuing medication (Meyer et al. 1992). Supporters of castration laws regarding also contend that chemical castration does not violate the fundamental right of individuals to procreate. The effects of Depo-Provera are temporary and completely revocable upon termination of the injections (Melella et al. 1989).

However, despite Depo-Provera's only temporary obstruction to sexual activity, Spalding (1998) suggests that the ability to procreate is still infringed upon during the period of treatment, which may last for years. Further, some chemical castration laws, such as Florida's statute, permit the courts to order injections of Depo-Provera for the lifetime of the offender. In this way, sex offenders sentenced to lifetime chemical castration may have their right to procreate removed permanently. According to Meyer and Cole (1997), the long-term effects of Depo-Provera on sexual functioning are still very much in question.

Some opponents argue that judges may not be the most appropriate individuals to impose sentences of chemical castration and doubt the capabilities of medical doctors working in corrections to make impartial decisions concerning the well-being of offenders. Interestingly, Fitzgerald (1990) suggests that injections of Depo-Provera will not have any meaningful influence on many sex offenders. These sex offenders include those that deny committing the offense or refuse to acknowledge the criminal nature of their actions, those blaming their actions on environmental factors, and violent individuals motivated by nonsexual elements. Moreover, the use of medications for castration purposes is widely considered effective only when employed in combination with psychotherapy specifically designed for sex offenders (Meyer and Cole 1997). Other research warns that the administrative procedures for involuntary medication outlined in *Washington v. Harper* (1990) may not protect inmates from uninformed and arbitrary decisions by prison psychiatrists. Ryan argues that the objectivity of a committee consisting of correctional employees and the cooperative nature of the hearing afford little protection from ill-advised psychiatric diagnosis.

Polygraph Testing

There are disputes in the literature surrounding sex offender polygraph examinations. Polygraph testing has been reported to improve the management of sex offenders in the community, as it purportedly reduces denial, extracts confessions of sexual offenses, and improves treatment results (Wilcox 2000). On the other hand, Iacono and Lykken (1997) raised questions concerning the possibility of false positives and negatives, in spite of the use of control questions present in polygraph testing. They also reported no evidence for the validity of polygraph results in their review of field studies. Further, the fear of being incorrectly accused causing innocent subjects to have physiological responses that indicate guilt has been considered as a flaw of the polygraph. Proponents of polygraph testing have described accuracy rates beyond 90 %; however, critics (Iacono and Lykken 1997) contend that these studies contain fatal methodological flaws.

Residency Restrictions

Research dedicated to sex offender residency restrictions has only emerged in the past decade. The available research points to controversies in the literature. Finding that nearly half of sex offenders with child victims lived in close proximity to child congregation zones, Walker et al. (2001) studied one Arkansas county and suggested that child sex offenders may be more likely to intentionally reside near schools, parks, and daycares. And yet, when compared with nonrecidivists, research has reported that recidivating child sex offenders under community supervision did not live closer to these congregation zones (Colorado Department of Public Safety 2004). Tewksbury and Mustaine (2006) also showed that only approximately one in five registered sex offenders live in close proximity to such locations. Further, a Minnesota study found that sex offenders were more likely to seek victims in neighborhoods other than their own to avoid detection (Minnesota Department of Corrections 2003).

Research has recognized the problematic nature of residency restrictions aimed at sex offenders. Lawmakers believe that residency in close proximity to potential (child) victims influences recidivism (Sample and Kadleck 2008). However, research generally shows such restrictions have little or no effect on sex offender recidivism. And yet, laws limiting housing opportunities for sex offenders potentially exacerbate the limited choices for home placement already facing many ex-convicts. Studies concerning the limitations of where registered sex offenders may live have been widely shown to impose negative consequences on both offenders (Tewksbury 2007; Tewksbury and Lees 2006; Zandbergen and Hart 2006, 2009) and their families (Farkas and Miller 2007; Tewksbury and Levenson 2009). For instance, research confirms that residency restrictions placed on registered sex offenders significantly decreases housing opportunities perhaps to as little as 2 % of all housing stock (Zandbergen and Hart 2006, 2009). As a result of residency restrictions, registered sex offenders are also likely to be concentrated in very dense, socially disorganized communities or in rural locations with limited employment, treatment, and transportation opportunities (Minnesota Department of Corrections 2003; Tewksbury and Mustaine 2006, 2008; Zandbergen and Hart 2006, 2009).

Conclusion

Clearly there are a number of criminal justice policies that are specific to sex offenders and which establish procedures and practices that are unique for offenders convicted of sexual offenses. What may be most interesting about the ways that policies have developed and been rapidly implemented across the country are both that they tend to be in response to particular, individual cases that have generated significant public (e.g., media) attention and that these policies and their outlined practices are largely untested.

As research has started to address sex offender criminal justice policies what is quickly becoming clear is that these policies are not being shown to be very effective, they are expensive and inefficient and in many cases seem to be overreaching and including many offenders who may not need to be responded to in such ways. The future holds many questions for how and why the types of policies discussed above can and should be continued to not. However, at the present time there is little to suggest that such policies will be scaled back. Rather, it seems that criminal justice policies regarding sex offenders are only continuing to be expanded and made more harsh, despite emerging evidence suggesting that they are not necessary effective and are very inefficient.

Sex Offending and Criminal Mobility

Eric Beauregard
School of Criminology, Simon Fraser University,
Burnaby, BC, Canada

Overview

For more than 60 years now, sex offenders have been the object of scrutinized attention by policy makers and the police (Barnes et al. 2009). However, it is only since 1994 that specific legislations regarding sex offenders have been passed throughout the United States to counter sex offender recidivism and alleviate community safety concerns. The Jacob Wetterling Act requires all states to track sex offenders through the use of registration systems. Such policy forces sex offenders to report to the authorities their home address. This was soon followed by Megan's Law, which requires law enforcement to notify communities when a sex offender is returned to the area (Zevitz 2006). Through the use of different means (e.g., flyers, posters, public meetings, automated phone messages), the public is informed of the identity and the residential address of the sex offender integrating into their community, allowing for an informal network of surveillance. Residence restriction laws constitute the most recent type of policy specifically targeting sex offenders. Such policies restrict sex offenders from living within close proximity (e.g., between 1,000 and 2,500 ft) of places where children are typically present (e.g., schools, parks, playgrounds, bus stops), in order to prevent them from getting access and making direct contact with potential victims (Duwe et al. 2008). What is particular to these policies is the fact that they all share a common focus – that is, *where* the offender lives. Thus, the rationale for such policies is based on the same underlying assumption – that sex offenders are geographically stable, meaning that they do not travel when committing their crimes. But is this really the case? The current paper aims to address three related questions: (1) What do we know about sex offenders' criminal mobility? (2) Is journey to crime an adequate measure of criminal mobility? (3) Are there any other ways to look at criminal mobility of sex offenders?

Criminal Mobility: The Case of the Sex Offender

Most studies interested in the criminal mobility of offenders use the journey to crime as their main measure. These studies generally show that offenders travel a longer distance to commit property offense compared to violent crimes (see for instance Brantingham and Brantingham 1981). When looking at violent crimes in particular, a total of 21 studies were identified that examined crime trips of sex offenders in North American and European cities (Beauregard et al. 2005). For all of these studies, it is interesting to note that the crime trip distance traveled by different types of sex offenders varies between no distance traveled (the offender committing the crime at home) and 40 km. On average, the distance traveled by different types of sex offenders between their home base and the crime location was a little more than 2 miles.

Interestingly, some authors have attempted to further our understanding of the criminal mobility of sex offenders by examining two types of factors influencing their journey to crime: the offender and the offense characteristics. The underlying principle of the relationship between offender characteristics and criminal mobility is that these characteristics influence the cognitive map of individuals. According to Brantingham and Brantingham (1993), cognitive maps are a representation of the awareness of space, which consists of subjective images of an individual's environment that are fundamental in determining the areas where the criminal's offense will be carried out. Furthermore, cognitive maps vary with the characteristics of individuals. For instance, age is one of the characteristics associated with criminal mobility. Most studies of sex offenders that investigate the relationship between age and distance come to the same conclusion as for other types of criminals: Younger men tend to offend nearer to home (Warren et al. 1998). According to these studies, this difference could be attributed to a greater impulsivity in the offense behavior of younger offenders, a greater access to vehicles by older offenders, or simply because of the age-related development of the cognitive map. However, recent studies have not confirmed this age-distance relationship (see Rossmo et al. 2004).

There appears to be a clear relationship between race and the criminal mobility of sex offenders. Findings show that white rapists traveled farther than nonwhite offenders (Canter and Gregory 1994; Warren et al. 1998). Even if this relationship was once again not confirmed by Rossmo et al. (2004), it is hypothesized that this finding may reflect class distinctions or cultural differences in the cognitive mapping of space. Moreover, Gabbor and Gottheil (1984) found that those with a criminal record were substantially more likely to be transient than those without one, suggesting a positive relationship between criminal career and mobility. Others have suggested that sexual fantasy is another factor related to longer sexual crime travel distance. These offenders spend long periods of time prowling for victims, and sometimes record a diary of their movements. In addition, they are willing to travel long distances to commit a crime that will reflect their fantasies (Dietz et al. 1990). Finally, a study showed that psychopaths displayed greater geographic mobility than did nonpsychopaths (Hunter 2004). The psychopath's impulsivity, short-term relationships, unstable employment, and need for stimulation/ proneness to boredom may predispose them to geographic mobility (Cooke 1998). Another explanation suggests that psychopaths frequently move locations, as their tendency to con and exploit others eventually becomes known and they are no longer able to take advantage of people in their surroundings.

As to the offense characteristics, Lebeau (1987a) focused on how the journey to rape varies as a function of the offender's approach method. Results revealed that offenders traveled the shortest mean distance to assault their victims when they illegally entered the victim's residence, suggesting that offenders travel shorter distances when using a method linked to crimes against property. In a different study, Canter and Gregory (1994) found that rapists who offend during the weekend travel farther than those who commit rape during a weekday and that rapists who attack outdoors traveled approximately 2.7 times farther to offend as those who raped indoor (e.g., in a house). Davies and Dale (1995) suggested also that rapists who target victims from a particular area (e.g., prostitutes from a red-light district), who commit sophisticated property offenses during a sexual assault, who spend large amounts of time roaming and using public transportation, and who are familiar with numerous neighborhoods (previous habitation, locations of significant people, current or past workplace locations), travel longer distances to commit their crimes. This was echoed by Warren et al. (1998) who found similar results in relation to the sophistication of the crime. Their results showed that rapists who had more extensive criminal antecedents, who used forced entry, and who burglarized the victim during the assault tended to travel farther. According to the authors, this could reflect a more generalized criminal motivation and a more experienced offender in terms of nonsexual crimes.

The research on the journey to crime of sex offenders has not only permitted to confirm that, as with other violent offenders, sex offenders do not travel long distances to commit their crime, but it has also allowed to examine the factors that could influence their criminal mobility. However, it appears that all the studies have taken for granted that journey to crime was the only and probably the most adequate measure of criminal mobility. Whether or not this is true, none of these studies have questioned the use of the journey to crime to measure their criminal mobility.

Journey to Crime: A Valid Measure of Criminal Mobility?

Previous studies on the criminal mobility of sex offenders show that their journey to crime is mostly constant, being not very far from their home base. This information is not only useful for environmental criminology but also for criminal investigations, more specifically geographic profiling techniques (Rossmo 2000). However, relying solely on the measure of journey to crime to characterize their criminal mobility can be problematic for three main reasons.

First, the studies examining the journey to crime have all used the home location of the offender as the starting point of this crime trip. Although this is congruent with theoretical models such as the routine activity theory (Cohen and Felson 1979), such a measure does not take into account a crime trip that might have originated from the offender's workplace for instance. A rapist could identify and target a victim while coming back from a friend's house. Moreover, as Bernasco (2010) found, offenders are more likely to target former residential areas to commit their crimes if they lived there for a long time. Moreover, as mentioned by Michaud and Morselli (2011), homeless offenders and many street criminals may not have a fixed home address, therefore choosing to base their criminal activities from other social activity locations such as bars or pool halls

(Rengert 1996). Again, as stated by Michaud and Morselli (2011), using the offender's home as the exclusive platform from which crimes are committed is even more surprising given the fact that most people spent around half of their days outside home (see for instance Wikström et al. 2010). Moreover, Pettiway (1995) is the only one to our knowledge who showed through interviews with crack users the true origin of the crack trip. Interestingly, he found that only 26 % of crack-purchasing trips originated from the user's place of residence. The lack of studies taking into consideration other points of origin in the journey to crime might be partly explained by the fact that most of these studies rely exclusively on police data and other anchor points of the offender might not be known.

Second, journey to crime research suggests that the whole criminal event takes place all at the same location. Although this may be the case for property crimes such as burglary, the reality is often different for crimes where the victim is mobile (Beauregard et al. 2010). In crimes such as sexual assaults, the offender may encounter a victim at a certain location, decide to attack her at another location, take her to a different location to commit the assault, and take her to another location to release her, the so-called EAMD classification used in geographic profiling (Rossmo 2000; see also Lebeau 1987b for rape). Michaud and Morselli (2011) explain that the non-consideration of multiple crime sites in journey to crime research is problematic, given that it may distort the estimation of the criminal mobility involved in the process. To illustrate their point, they provide the example of an offender who encounters a woman in a bar, takes her to a hotel, rapes and kills the woman there, to finally go back to his place with the dead body in order to dispose of her body parts in garbage bags. If the journey to crime was calculated with this case, police data would record the address where the body parts were found (offender's residence; distance-to-crime = 0 mi), thus greatly underestimating the criminal mobility that was involved in the process. Such example is not unusual in sex-related crimes. For instance, it has been shown that sexual murderers dispose of the victim's body on average 17.2 miles from the murder scene (Häkkänen et al. 2007).

Third, research on criminal mobility seems to suggest that the concept of mobility can and should only be measured in terms of distance traveled. However, the measure of distance traveled represents only one dimension of the mobility concept – that is, the movements or the mobility performances (Canzler et al. 2008). However, offenders also present other "movements" that may characterize their criminal mobility. Using the same example presented above, an offender may travel from one location to another during the same event. For instance, some sexual murderers decide to move the victim's body to a different location after the murder (Beauregard and Field 2008). Although such finding does not provide a measure of *distance* per se, it nonetheless provides some information on the mobility of the offender during the criminal event. This is not to suggest that the measure of journey to crime is not appropriate to examine criminal behavior and that this research is not important for our understanding of criminal mobility. However, this suggests that there is a need for criminology to look at complementary measures as well.

Alternative Measures of Criminal Mobility in Sex Offending

In addition to the journey to crime measure, a few alternative methods to conceptualize criminal mobility have been used in the research on sex offenders. One such approach has been to classify sex offenders according to their criminal mobility patterns. Although using different labels (see, for instance, Canter and Larkin 1993; Rossmo 1997), these typologies can be grouped under two main categories: the *geographically stable* and the *geographically mobile* offenders (Beauregard et al. 2005). This typological approach is interesting as it presents other characteristics (e.g., offender characteristics, modus operandi) associated with each mobility pattern. However, such approach presents also certain limitations. The majority of these typologies have been identified intuitively, without being tested empirically, which carries problems of validity and reliability. Moreover, the types are mainly descriptive and offer little information to explain the criminal mobility patterns of offenders (Michaud and Beauregard 2010). Also, using typologies to classify criminal mobility patterns presents the same problem as with any other typology: They assume that crime-commission processes are stable instead of being dynamic (Beauregard et al. 2007).

One way to overcome these specific limitations is to conceptualize geographic mobility as the use of multiple locations for the purpose of repetitive sexual contact with the same victim. In their study, Leclerc, Wortley, and Smallbone (2010) set out to examine whether offending differences existed between perpetrators who used multiple locations for sexual contact and those who used a single location for the entire crime-commission process. Overall, the results demonstrate that mobile offenders are more likely to isolate their victims, use violence, involve the victim in several sexual episodes, abuse the victim for over a 1-year period, and make the victim participate and perform sexual behaviors on them during sexual episodes. The authors concluded that by examining mobility of pedophiles from a location angle rather than measures of distance and direction provides a different perspective on the crime-commission process of these offenders (Leclerc et al. 2010).

Following Leclerc et al. (2010) study, Beauregard and Busina (2013) used a similar approach with serial sex offenders. They proposed that criminal mobility can be defined as the number of changes of location during the criminal event. As discussed previously, rape events present different stages – that is, encounter, attack, crime, and victim release – that may be associated with different locations. Although some sex offenders decide to commit all their action at the same location (i.e., stable offender with zero change of location), other mobile offenders may change location up to three times during the same event. As criminal mobility can be interpreted as a purposive action necessary to successfully commit a crime, the aim of their study was to predict the criminal mobility patterns exhibited in serial rape events from situational and modus operandi characteristics. The situational characteristics of the rape events and the modus operandi used in serial sex crimes might explain why some offenders need to be mobile and change location during the criminal event while others do not. Using negative binomial regression, the authors found that events which involve child or adolescent victims, committed during daytime, when the offender did not use pornography prior to crime, and where victim resistance is observed, should display more criminal mobility. Moreover, when the victim is selected, the victim is alone when approached by the offender, and the crime is characterized by sexual penetration and a lack of premeditation are exhibiting more criminal mobility. These results point toward the fact that criminal mobility is a goal-oriented action taken by serial sex offenders in order to complete successfully their crime and to avoid detection and apprehension (Beauregard and Busina 2013).

Rossmo, Lu, and Fang (2011) examined the spatial-temporal patterns of a group of reoffending parolees (many of which were sex offenders) on the Florida Department of Corrections electronic monitoring and global positioning system program. Their travel over a period of at least 8 days, including the offending day, was mapped and analyzed. This allowed analyzing the spatial activity patterns of criminals prior to, during, and after offending. At the aggregate level, results showed that the mean distance traveled 37.8 mi (min = 3.5 mi, max = 79.5 mi), covering an area of 27.2 mi^2. The average time spent traveling was 10.6 h (min = 1.0 h, max = 15.8 h), compared to an average of 12.4 h spent at home (min = 4.5 h, max = 20.9 h). On average, these offenders traveled 4.1 sites during their daily travel (min = 2.0, max = 6.5). When disaggregating these results, the findings are also very interesting, especially to further our knowledge on criminal mobility. Rossmo et al. (2011) described the spatial movements of a sex offender. This offender visited the offense location twice in the week before the crime. His movements started late in the day and went through to late in the night or early in the morning of the next day. The analysis revealed also that his routine began with a trip from his home to an activity site northwest of his residence and that he passed by the crime location for the first time during the study period, but did not stop. Moreover, their analysis showed that the actions of the offender were different when he next visited the site. On that day, the offender passed the crime location again on his way to his routine nighttime activity sites northwest of his home but he made extra turns and stops. The same travel pattern was repeated the day of the offense. As mentioned by Rossmo et al. (2011), "a better understanding on this level can assist practitioners and academics in several ways, such as providing early warning cues for offending, better knowledge of how criminals hunt for their targets, and an enhanced understanding of offender spatial behavior" (p. 39).

Finally, another alternative to the traditional journey to crime measure of criminal mobility has been suggested by Michaud and Beauregard (2010). They conceptualized the criminal mobility of offenders as having two distinct dimensions: the *criminal migration* – which is the effective distance traveled by a mobile offender between the activity spaces in which he commits crimes – and the *criminal nomadism* – which corresponds to the offender propensity to change the activity space in which he commits crimes, either by exploring new activity spaces or by traveling back to former ones. Instead of looking only at one criminal event, Michaud and Beauregard (2010) consider the entire criminal career of their sex offenders. As such, they have analyzed 3,003 criminal events (sex and non-sex crimes) committed by 461 sex offenders. Their findings showed that in terms of criminal migration, only a third of the sex offenders traveled a short distance (<150 km) during their criminal career and approximately one quarter traveled more than 1,000 km. As to the criminal nomadism, one third of the sample changed activity space in at least 70 % of their criminal career. In order to understand what could explain this criminal mobility, they examined different offender characteristics. Their findings showed that sex offenders who are psychopaths, Caucasian, educated, and specialized in sex offending present more nomadism than the sex offenders who are not.

Conclusion

Recent legislations specific to sex offenders – whether it is registration, community notification, or residence restriction – have all focused on one aspect of the crime-commission process: location. The rationale for such a focus is that by knowing where sex offenders live and by forbidding them to reside near certain location, we can prevent sexual recidivism. Although in theory, this all makes sense, all these approaches make the same mistake in assuming that criminals – more specifically sex offenders – are geographically stable and are not likely to travel when contemplating a criminal opportunity. Research shows the opposite. Sex offenders are rational individuals who may decide to travel to a different location either to avoid detection and apprehension, to complete successfully the sexual assault, or both. This suggests that even if a sex offender cannot live near a park because of a residence restriction law, nothing prevents him from leaving his residence, going to the park to encounter potential victims, and take them back to his place to sexually assault them. Studies have already shown that these legislations are ineffective to prevent sexual recidivism (e.g., Duwe et al. 2008). What has been presented here contribute further to this conclusion by showing how criminal mobility is an adaptive response to the criminal situation aiming to decrease the risks of detection and apprehension, while maximizing the chances of successfully completing the crime (e.g., obtaining sexual gratification, being able to perform sexual penetration actions).

Moreover, although journey to crime research has been helpful to the understanding of the geography of crime and to the development of investigative tools such as geographic profiling, this unique measure of criminal mobility is no longer adequate to capture the real spatial movement of offenders when committing crimes. New ways to investigate and conceptualize criminal mobility in sex offenders have been suggested which, it is hoped, will spark some interest in academics involved in the crime and place research for other types of crimes as well. The research on criminal mobility needs to be extended in order to investigate additional aspects that journey to crime has overlooked. In addition to what has been presented, two interesting concepts could further our understanding of criminal mobility. The first concept comes from Frank, Andresen, and Felson's (2012) study who found strong evidence for geodiversity (i.e., variations in the amount of area covered by various crimes depending on the variations of criminal opportunity) in cases of co-offending or co-victimization. The second concept of interest, which appears even more important to consider is directionality (Bernasco and Block 2009). Although it has been under-researched by environmental criminologists, some research has shown that directional knowledge is important for spatial decision making (Frank et al. 2012).
