As indicated above, without any training, it has been shown that the average person evaluates truthfulness at the level of chance (Bond and DePaulo 2006; Ekman and O'Sullivan 1991; Vrij 2008). A number of researchers/organizations have provided evidence-based training (i.e., based on the principles of reading verbal and nonverbal behavior discussed above) to various professional groups (e.g., law enforcement, corrections) in the general area of detecting deceit/evaluating truthfulness. However, there exist only a few studies examining the effectiveness of such training. In general, these studies show that 1- to 2-day workshops can improve participants from about chance level at pretest to an accuracy rate of 77 % or higher at posttest (e.g., Porter et al. 2000; Colwell et al. 2009). Training gains, although smaller in magnitude, have also been demonstrated after 3-hour workshops (e.g., Colwell et al. 2012: 58 % at pretest to 72 % at posttest; Porter et al. 2010: 51 % at pretest to 61 % at posttest). While these findings are encouraging, it remains to be seen whether the gains made in these workshop generalize to the real world. Clearly, future research on the effectiveness and generalizability of evidence-based training is required.

The gains that individuals make in training notwithstanding, it is important to acknowledge that the field will never advance to the point that training will provide the knowledge and skills to allow judgements to be 100 % accurate. Evaluating truthfulness is far too complex of an enterprise. It is more realistic to be able to improve most individuals' abilities to evaluate truthfulness from chance level to some reliable level above chance. The goal should not be to produce *wizards* – rare individuals who appear to be able to reliably evaluate truthfulness at an exceptionally high rate (O'Sullivan 2013). That said, the continued study of these types of individuals will hopefully lead to new insights into the personality characteristics of effective evaluators, the process of differentiating truths from lies, and key features to consider.

Summary and Future Directions

This entry provided an overview of the nature and complexity of evaluating truthfulness. Common pitfalls and approaches were described, and the interaction between effective interviewing, reading verbal and nonverbal behavior, and assessing credibility was reviewed. It was shown that individuals can learn to improve their ability to evaluate truthfulness through evidenced-based training. Despite the gains made in the field through decades of social science research, more research is clearly needed, particularly research that uses single-subject designs in real-world settings and takes into consideration the perspectives of practitioners who evaluate truthfulness as a core aspect of their professional duties. With a single-subject design, an individual's baseline could be assessed and changes from baseline could be examined within and across all of the observable behavioral channels (i.e., face, body language, voice, verbal style, and verbal content). In this regard, more attention should be devoted to individual differences (e.g., personality, personality pathology, mental illness, cognitive functioning, emotional intelligence, culture) as these differences can affect each aspect of the process of evaluating truthfulness reviewed above.

It is recommended that high-stakes lies be examined in a variety of contexts. For example, a promising area of research in evaluating truthfulness concerns the study of computer (and related)-mediated communication (CMC; Hancock and Woodworth 2013). Future research should also examine the ability of individuals to evaluate truthfulness in the context of interviewing. Variables such as the length of the interview, the focus of the interview (e.g., memory for past vs. future actions), and the nature of the interview (e.g., overt vs. covert) should be examined in the laboratory and in the field (e.g., low- vs. high-stakes lies). As well, research should identify the type of individuals best geared to evaluate truthfulness – no doubt the research on wizards holds promise in this regard. Not everyone is suited to be an investigative interviewer and/or able to effectively evaluate truthfulness. Key characteristics are likely to include an information-gathering mind-set, critical thinking skills, and the capacity to develop rapport, read people, and make decisions about truthfulness holistically.

Finally, research attention should be devoted to deciphering the most effective way to deliver evidence-based training to ensure that the training results generalize to on-the-job performance. Training should focus on investigative interviewing as a foundation (e.g., how to gather information – first level training), followed by modules on reading people (e.g., identifying and probing for hot spots – second level training), and evaluating truthfulness (e.g., making sense of hot spots via hypothesis testing and verbal content analysis – third level training). Actual cases/recorded interviews should be used for demonstration and practice as part of the training. Ideally, the training would include a refresher component – which has shown promise in the interviewing training literature (Price and Roberts 2011). This could include literature updates and practice cases to avoid drift in training gains. Finally, post-training on-the-job performance should be assessed in the context of supervision/mentoring and the review of actual recorded interviews in which ground truth has been determined.

Evidence-Based Policing

Cynthia Lum and Christopher S. Koper
Department of Criminology, Law and Society, George Mason University, Fairfax, VA, USA

Overview

Evidence-based policing is a law enforcement perspective and philosophy that implicates the use of research, evaluation, analysis, and scientific processes in law enforcement decision making. In this entry, we review the nuances of this definition, the research underpinning evidence-based policing, and what agencies employing evidence-based approaches might look like.

Fundamentals of Evidence-Based Policing

Evidence-based policing is a law-enforcement perspective and philosophy that implicates the use of research, evaluation, analysis, and scientific processes in law-enforcement decision making. This research could cover a wide array of subject matters, from evaluations on interventions and tactics to analysis of police behavior, activities, and internal management. In his 1998 "Ideas in American Policing" lecture for the Police Foundation, Lawrence Sherman gave one of the most well-known articulation of evidence-based policing. He posited that "police practices should be based on scientific evidence about what works best" (p. 2). In particular, Sherman focused on two dimensions of a research orientation in policing: (1) using the results of scientifically rigorous evaluations of law-enforcement tactics and strategies to guide decisions, and (2) generating and applying analytic knowledge derived from an agency's analysis of its own internal issues and crime problems. Although using research and analysis was not a new concept in governance and social interventions when Sherman gave this lecture, what was innovative was his assertion that police should use research and analysis more frequently, substantively, and directly, discontinuing the use of tactics that were shown not to be effective.

The idea of using objective scientific information and criteria to inform public policy and agency decision making reflects a common value in modern liberal democracies: there must be evaluative and objective accountability for governmental actions and spending (Chalmers 2003; National Research Council 2004; Sherman et al. 2002; Sherman 2003). Sherman has argued that this is especially important in policing, given the important mandate the police have ensure the rule of law. In a lecture at the Royal Society for the Encouragement of Arts, Manufactures, and Commerce (RSA) in November 2011, Sherman emphasized this point when he said:

> The competence that we achieve today stems largely from the 18th century Enlightenment. The debt we owe to that era is the great transition in so many professions from customs to science, from opinions to evidence. That enlightenment idea of objective knowledge is also crucial to the success of our liberal democracy in which the rule of the majority protects individual liberty under a rule of law. No institution is more important to that success than the police, whose competence at ensuring the rule of law is constantly challenged by thousands of opinions on how the police should do their job. It is therefore essential that our society improves the competence of its police not merely with our opinions but primarily with a fact that is derived from objective knowledge.

This notion that evidence-based approaches are implicated in the values and ethics of modern democratic governance – particularly of government accountability and reducing harm (Chalmers 2003) – is mirrored in many social arenas, but especially in public health and medical practices. There are many requirements (and laws) stipulating that medical treatments and remedies must be supported by believable and rigorous scientific testing and replication and that those treatments must provide the least amount of harm or negative side effects (or at least report those side effects). Our demand for evidence-based treatment is so strong that doctors spend a large proportion of their income insuring themselves against lawsuits if they commit malpractice. However, when the police carry out an intervention that does not work, or that increases crime or recidivism, or worsens police-community relations, it is much less likely that they will be held similarly responsible. The ideology behind evidence-based policing, however, suggests nurturing similar expectations. Former National Institute of Justice Director Jeremy Travis went so far as to assert in his keynote address at the Sentencing Project's 25th anniversary celebration that "[w]e need a professional ethic that views failure to adopt those proven policies and practices as a form of justice malpractice." While this type of legal accountability is not likely to be soon adopted in American criminal justice practice, the idea behind evidence-based policing emphasizes that law enforcement should at least be held accountable to the knowledge already known about policing interventions and also to crime analysis generated in their own jurisdictions. Police should be deploying patrol officers, specialized units, detectives, supervisors and commanders in ways that can be shown to achieve results, whatever results are sought (i.e., crime or fear reduction; legitimate, fair, and respectful treatment; or responsiveness).

Adopting an evidence-based approach to police decision making may bring numerous benefits to the police. Most obvious are the rewards reaped from employing strategies and tactics that have been shown to reduce crime, increase legitimacy, reduce internal problems, address community concerns, or reduce fear (Lum 2009; National Research Council 2004; Sherman and Eck 2002). Policies deemed harmful or ineffective could be discarded (or at least questioned), potentially saving law enforcement agencies time, money, frustration, and blame. Using more objective judgments regarding deploying tactics also seems more ethically justifiable than other nonscientific methods such as best guessing or strategies based on anecdotes or personal preferences. This approach to policing may lead to greater transparency, legitimacy, and accountability in practice, which could improve police-citizen relations and trust.

There may be additional benefits of such an approach. Evidence-based policing requires agencies to access their information and data capabilities regularly (to carry out outcome evaluations or analysis). This may lead to improvements in managerial accountability and efficiency, better data recording, collection and analysis, and a push to improve information technology systems to accommodate these needs. Other decision-making perspectives in policing, including community-oriented policing, problem-oriented policing, and professionalism, could be strengthened through the inclusion and use of scientific information and analysis. Problem-oriented policing, for example (see the Braga entry for this encyclopedia; Eck and Spelman 1987; Goldstein 1979, 1990), demands analyzing crime problems, using interventions that have been shown to be effective, evaluating interventions against sought outcomes, and potentially discarding interventions that are not shown to be effective through rigorous evaluation. Community policing might also be strengthened from an evidence-based approach, given that many different types of community-based strategies have been developed and also evaluated, some which have not been shown to either reduce crime or improve legitimacy (see Sherman and Eck 2002; Weisburd et al. in progress). Research has also played – and can continue to play – an important role in developing professional policing, especially for police concerns such as the use of force, racial profiling, or internal corruption.

An evidence-based approach may also increase satisfaction in police work by providing creative ways to carry out the profession and also challenge the status quo. Many strategies shown to be effective run counter to professional mainstays, such as rapidly responding to 911 calls, randomly patrolling one's beat, or making arrests. Weiss (1980) found that challenging the status quo is one reason bureaucrats may be receptive to research in the first place. Related to this, applying critical, analytic, and proactive thinking in police work is also more akin to transformational, as opposed to transactional, leadership and deployment styles. Transformational approaches implicate more satisfaction among both supervisors and subordinates because more creative and proactive thinking is involved (Bass 1985; Burns 1978; McCardle 2011). In this manner, evidence-based policing, as with problem-oriented policing, could influence organizational and cultural forces that can inhibit both growth and a dynamic learning environment in policing. If using certain strategies, tactics, and internal practices lead to more positive results, this may then lead to greater motivation and job satisfaction.

Yet, despite these potential benefits, laments continue about the proverbial "gap" between research and practice (Bayley 1998; Lum 2009; Lum et al. 2012; Mastrofski 1999; NRC 2004; Weisburd 2008; Weiss 1980). Even in the field of medicine, where we might expect that practices are guided by the best scientific research, these gaps persist (Chalmers 2003; Sherman 2003). In policing, Weisburd (2008) points out that the best example of the disconnect between the evidence and its use in practice is the general failure of police agencies to regularly adopt hot spots, or place-targeted patrol, despite the strong evidence of the efficacy of this approach for crime and disorder reduction (NRC 2004) and the clear criminological support for the spatial concentration of crime (Weisburd 2008). Further, Koper (2008) found that while many agencies claim to be doing hot spot policing, much of the strategies agencies discussed appear to be consistent with more traditional beat- and neighborhood-based strategies. Other examples are the continued use of the DARE program (Drug Abuse Resistance Education), reactive arrests, rapid response to 911 calls, and gun buybacks – all strategies that have evidence showing ineffectiveness.

Reasons for the lack of evidence-based approaches in policing are many. Transforming more abstract and general research findings and experiences into tangible and specific law-enforcement tactics, practices, and strategies is a difficult and hard-to-measure venture, just as is applying one's education or training to any workplace task. Research knowledge often is not written in ways that make it straightforward for officers to receive or use in practice. Police chiefs often cite the lack of resources, political will, and the potential for police unions to object as challenges to adopting an evidence-based approach. There are also false expectations and beliefs about the role of researchers and research in policing. Despite what some have argued (see Sparrow 2011), researchers have rarely claimed that research or scientific processes can run a police department's daily operations or resolve law-enforcement concerns, just as problem-oriented policing, community-oriented policing, or professionalism cannot. However, incorrect beliefs and prejudices about research and researchers may lead to a widening communication gap between researchers and practitioners.

Further, implementing evidence-based policing is a challenge because its principles of decision making compete with an organizational culture in which decisions are made using other philosophies and processes. These include hunches and best guesses; traditions and habits; anecdotes and stories; emotions, feelings, whims, and stereotypes; political pressures or moral panics; opinions about best practices; or just the fad of the day (Lum 2009). Granted, sometimes these processes and best practices can be influenced by knowledge, information, and analyses. However, they are also highly vulnerable to personal opinions, ideology, and stereotypes. The difficulty of evidence-based policing lies not only in the transformation of research into practice but also in adjusting the culture to be more receptive to research and scientific processes.

Some have also argued that evidence-based policing needs to acknowledge that crime control research sometimes focuses on outcomes that are not as practical as initially believed. For example, Mastrofski and Willis (2010) suggest that police visibility and responsiveness are how the public judges effectiveness of policing, not necessarily some abstract notion of crime reduction. In turn, this may explain why police have not fully adopted an approach that targets crime concentrations. Citizens may want to see police patrolling their own neighborhoods, irrespective of where crime is most prevalent. And they may focus on other performance measures when judging the police, such as quick response and fairness. Whether this is the reason why police have been reluctant to move from a reactive to a more proactive patrol strategy should itself be subjected to study. Nonetheless, these are important debates about the utility of evidence-based policing and its focus. As Professor Stephen Mastrofski emphasized in personal correspondence to the authors, "for evidence-based policing to be useful in a democratic setting, it needs to measure success with sufficient sensitivity to the diversity of values that come to play in making choices about policy and practice. An evidence-based policing strategy that focuses on only a narrow range of values is more appropriately termed 'blinder-based policing'."

Thus, while the notion of evidence-based policing may in theory seem reasonable, rational, and even democratic, using research in police daily practice is much more complex and nuanced in reality. Building on Sherman's discussion, therefore, Lum et al. (2012) add three nuances into the definition of evidence-based policing, which in turn highlight the difficulty in the fulfillment of its own definition:

1. Evidence-based policing is a decision-making *perspective*, not a panacea.
2. It is grounded in the idea that policies and practices should be *supported by* research evidence and analytics, not blindly determined by them.
3. It suggests that research is *not ignored* and that it at least becomes a *part of the conversation* on what to do about reducing crime, increasing legitimacy, or addressing internal problems.

The Research Supporting Evidence-Based Policing

Given that evidence-based policing requires the use of research in practice, what then is the research evidence that supports it? There have been decades of policing and criminal justice research that can benefit police decision making across multiple areas of police practices and activities, as most recently reviewed by a special committee of the National Research Council (NRC 2004). Below, we focus on the research evidence regarding crime control and prevention of police interventions as only *one example*. We italicize "one example" because some critics view evidence-based policing as a "what works" movement, focused only on experimental evaluations of crime prevention interventions. However, we remind and caution the reader that there is much evidence in policing that is not about tactical interventions, which is also part of the research base in evidence-based policing, as Moore (2006) and Willis (2012) point out. Evidence-based policing is a *general* reform concept about the use of research in policing, not about the specific areas of research or the type of researcher that should be its focus.

But even though research can span the gamut of areas and types, it should also be mentioned that no matter what area of research is used to underpin law-enforcement decisions, a fundamental tenet of an evidence-based approach is that not *all* research in that area should be used. Research in policing uses a wide gamut of methods, including experiments, quasi-experiments, before-and-after designs with (and without) control groups, correlational research, case studies, ethnographies, and other qualitative studies. An evidence-based approach posits that agencies should make use of what Sherman (1998) calls the "best available" evidence – research that is of high quality, scientifically sound, believable, and therefore of high internal and external validity (Boruch et al. 2000; Campbell and Boruch 1975; Farrington 2003; MacKenzie 2008; Weisburd 2000). However, like the "what works" critique mentioned above, what constitutes high-quality research is also debated (Moore 2006). For example, with crime-control evaluation research, not all research evidence is created equal (Sherman et al. 2002). What is the threshold of methodological rigor by which an evaluation study should matter? Further, there are ranges of quality and fidelity in the implementation of research designs. Various sampling and measurement issues may also influence the validity of findings.

At the same time, we know there are many examples of criminal justice interventions that were deemed effective using scientifically weak assessments (or no assessment at all) and that were later discovered to be ineffective or even harmful (DARE, boot camps, reactive arrests, some community policing strategies, intensive supervised probation). As Weisburd et al. (2001) discovered, evaluation studies of lower quality in criminal justice, which may be less valid and reliable, are also more likely to report positive findings. While there are specific debates regarding the utility and ability of experimentation to evaluate crime prevention interventions (see Berk 2005), there is general agreement that an evidence-based approach posits that the rigor of the science behind an evaluation is an important consideration in the believability (and utility) of any particular study.

Thus, many reviews of research attempting to synthesize crime prevention and control research for practical use have been sensitive to the methodological rigor of studies. One of the more influential and recent reviews was conducted by Sherman as part of the University of Maryland Report to Congress on "What Works, What Doesn't, and What's Promising" in crime prevention, later updated by Sherman and Eck in Sherman and colleagues' (2002) study. Each policing evaluation was scored with regard to rigor of method used for evaluation, and then, based on evidence and the methodological rigor underpinning that evidence, a judgment was made about the effectiveness of policing interventions. Relying on the studies exhibiting strong internal validity, Sherman and Eck (2002) concluded in their update that directed patrols to hot spots, proactive arrests of serious repeat offenders and drunk drivers, arrest for employed suspects for domestic violence, and problem-oriented policing seemed to be evidence-based policing approaches. On the other hand, minor juvenile arrests, arrest for unemployed suspects of domestic violence, drug market arrests, some community policing approaches, or increasing police numbers did not seem evidence based.

In addition to – and prompted by – the Maryland Report were a number of subsequent reviews of the evidence of policing interventions promoted by the Campbell Collaboration, specifically its Crime and Justice Coordinating Group (see Farrington and Petrosino 2001). Similar to the Maryland Report, Campbell reviews emphasize that more weight should be given to research evidence with high levels of internal validity. In many reviews, only experiments and multi-subject quasi-experiments are considered in making final determinations about interventions in which multiple studies have been undertaken. Unlike the Maryland Report, Campbell reviews hone in on specific areas of policing and law enforcement. In policing and security, the most highly cited is likely the systematic reviews of the research evidence on hot spot policing (Braga 2007), which have shown place-based targeted patrol to be effective in reducing crime at places. The problem-oriented policing review (see Weisburd et al. 2010) indicates that specific and tailored approaches, in particular focusing on small places, can be effective. Bennett et al. (2008) neighborhood watch review found positive effects of neighborhood watch, although studies with lower internal validity were included in this review, and the conclusions of which counter Sherman and colleagues' (2002) more pessimistic findings. In their review of gun-carrying suppression, Koper and Mayo-Wilson (2006) found that police crackdowns on gun carrying are effective on reducing gun crime in crime hot spots.

Further, contrary to the Braga hot spots review, Mazerolle et al. (2007) systematic review of evaluations regarding street-level drug enforcement interventions found that problem- and community-oriented approaches were more effective in reducing drug calls and incidents than only focusing law enforcement at drug hot spots using standard tactics. In a review of second-responder programs for family abuse, Davis et al. (2008) found that such programs do not reduce the likelihood of future violence. Upcoming reviews include studies on pulling levers (Braga and Weisburd 2012) and community policing (Weisburd et al. in progress). These systematic reviews examine multiple studies on the same subject to draw conclusions and generalizations about the evidence, so that law-enforcement entities can better digest large amounts of research in an organized way.

Recently, a committee of policing scholars conducted a broader review of law-enforcement research for the National Research Council (NRC). Writing about the *Fairness and Effectiveness in Policing* (NRC 2004), the committee found that with regard to research on the "effectiveness of police activities in reducing crime, disorder and fear," the committee noted four key points about the state of research evidence in policing (summarized from NRC 2004: pp. 246–247):

1. The standard model of policing that emphasizes random patrol, rapid response to calls for service, follow-up investigations by detectives, and unfocused enforcement efforts has not been effective in reducing crime (see also Sherman 1997; Sherman and Eck 2002).
2. Some of the strategies falling under the umbrella of community policing have been effective in reducing crime, disorder, or fear of crime, while others have not (also see Bennett et al. 2008; Sherman 1997; Sherman and Eck 2002).

3. Police strategies that are more focused and tailored to specific types of crimes, criminals, and places are more effective (also see Braga 2007; Koper and Mayo-Wilson 2006; Mazerolle et al. 2007; Weisburd et al. 2010).
4. Problem-oriented policing – a strategy involving systematic analysis of crime and disorder problems and the development of tailored solutions (Goldstein 1979) – is effective (also see Weisburd et al. 2010).

Supporting many of the findings from the Campbell reviews and Sherman (1997) and Sherman colleagues' (2002) reviews, place-focused, hot spot policing strategies – that is, patrol, problem-solving, and/or other interventions focused on small areas or specific places of crime concentration – have proven particularly effective in several rigorous outcome interventions (Braga 2007). In the judgment of NRC, the research on hot spot policing constitutes the "strongest collective evidence of police effectiveness that is now available" (NRC 2004, p. 250).

Finally, and most recently, Lum (2009) and Lum et al. (2011) have developed the *Evidence-Based Policing Matrix* (http://cebcp.org/evidence-based-policing/the-matrix/) an interactive web-based tool which houses all police crime-control intervention research of moderate to high methodological quality. As with other reviews, the Matrix's intentions are to provide easy ways for the evidence base to be accessed and used by decision makers (i.e., practitioners, policy makers, and researchers). However, the goal of the Matrix is not just to show but also to refine knowledge and to facilitate its translation and implementation through the application of the online tool (Lum 2009; Lum et al. forthcoming). The idea of evidence-based policing translation tools suggest that such tools can draw out generalizations of tactics that are effective by examining a range of studies and then transform and apply that knowledge to specific problems an agency faces.

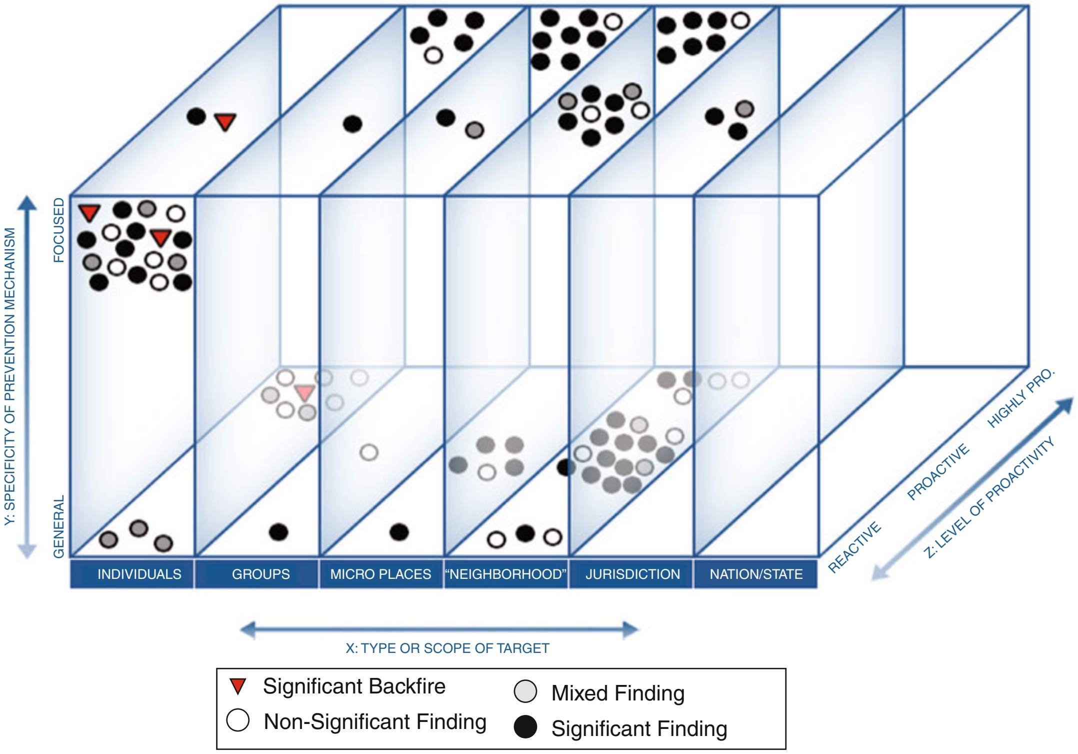
The Matrix uses a classification system for police interventions based on three very common dimensions of crime prevention strategies: the nature and type of target, the degree to which the strategy is reactive or proactive, and the strategy's level of focus (the specificity of the prevention mechanism it used). Using this three-dimensional "matrix," Lum (2009) and Lum and colleagues (2011) mapped all moderately rigorous to highly rigorous research evidence on police crime-control interventions according to how they might be characterized on these three dimensions (see Fig. 1, from Lum et al. 2011). By doing this, clusters of studies (and their findings) illustrate the distribution and concentration of evaluations and effective practices along intersections of dimensions. In other words, police might be able to better glean generalizations from a large body of research about what intersecting dimensions tend to characterize effective interventions.

In general, the Matrix indicates the following general principles of the evidence base of police crime-control interventions:

- A large majority (79 % at the time of writing) of successful interventions studied occur at "micro-places" or "neighborhoods."
- 64 % of successful interventions are "focused" or tailored strategies.
- 80 % of successful interventions are either "proactive" or "highly proactive."
- 53 % of interventions that show "no effect" or a "backfire effect" focus on targeting individual(s).

The evidence from the Matrix suggests that when police build strategies and tactics that are more proactive (or are based on using information-led and problem-solving approaches to reduce crime and related problems), when they target problems with greater specificity as to place and prevention mechanism, and when they shift from only a reactive/individual approach to incorporating more proactive place-based approaches, they will likely be more effective in reducing crime and disorder (see Lum et al. 2011). These findings are even more marked when only considering studies within the Matrix that are high-quality quasi-experimental and experimental research.

Although reviews of evaluation research by Campbell reviews, the Matrix, or the Maryland Report help to organize studies by rigor or type,



Evidence-Based Policing, Fig. 1 The evidence-based policing matrix (Lum 2009; Lum et al. 2011); www.policingmatrix.org

there are other sources that could also be used to support an evidence-based approach in policing. For example, Crimesolutions.gov, an Office of Justice Programs web site, reviews a number of studies across multiple criminal justice arenas. The Center for Problem-Oriented Policing (http://www.popcenter.org/) houses a number of guides, which emphasize not only the application of research knowledge but also systematic problem-solving approaches using crime analysis. Numerous centers and universities also house information and research regarding faculty areas of expertise.

What Would an Evidence-Based Policing Agency "Look Like"?

Additional insights into defining "evidence-based policing" can be gleaned from a discussion of what an evidence-based law-enforcement agency might look like given this specific research base. Again, the examples used here focus on the crime-control research base reflected in the Matrix, but other research categories could also be similarly applied (e.g., research on what strengthens police legitimacy). Given the evidence, at the most basic level, an evidence-based policing agency requires an effort to at least balance traditional and reactive deployment approaches with other types of patrol and investigative techniques that are *generally* supported by research evidence. But what are these more evidence-based patrol and investigative techniques? From the knowledge gained from the last three decades of research, an agency would be more "evidence-based" if it shifted its deployment strategy from one primarily spent on rapid response and random patrol to more proactive, directed, and problem-oriented targeting of crime hot spots. The research also indicates in its totality that a shift from vague community-oriented approaches to more targeted, problem-solving approaches at specific places involving multiple agencies may be more effective (Weisburd and Eck 2004; Weisburd et al. 2010). If agencies want to focus on individuals, focusing on repeat violent offenders and strengthening postarrest case enhancement and the use of DNA analysis may be important. Further, as Mastrofski commented above (see footnote 4), research on other values and priorities, such as due process, respectfulness, and fairness, would also have to be considered in developing these different patrol approaches.

Another basic requirement for an agency to be more research-oriented is that it has to have some way of assessing tactics and strategies and gathering knowledge about crime, the community, and internal issues. This involves having personnel assigned and committed to data collection, analysis, and evaluation, as well as having regular systems and procedures for using research and analytic evidence for various organizational functions (e.g., in managerial meetings, promotions, and assessments). This can include strengthening crime analysis or research and planning units, as wells as establishing standard operating procedures that ensure that units apply this information.

Finally, at the most basic level, knowledge from research, whether it comes from evaluations of policing interventions, research on racial profiling or traffic stops, or research regarding different ways to interact with the community, must be incorporated into academy and in-service training. This is a basic requirement that seems the easiest (and most obvious) to implement yet is likely furthest from reality. As indicated by Bureau of Justice Statistics data on academies (see Reeves 2009), it would not be surprising to find that many police academies and in-service systems do not seriously incorporate the latest information on what are the most effective ways police can use to reduce crime, increase legitimacy in the community, or reduce problem behaviors within the agency. Academies traditionally teach reactive skills such as applying police procedures and the law, writing reports and submitting evidence, or using firearms and motor vehicles. All of these focus on police reactive response to crime. Yet, a large portion of an officer's time is not committed to reactive procedural response but is uncommitted, leaving room for high levels of officer discretion (see Famega et al. 2005). Given this, the proactive skills and knowledge base that are needed to carry out effective and legitimate crime prevention during this discretionary time are often not taught. Yet a large portion of an officer's time is not committed to reactive procedural response but is open to use at the officer's discretion (see Famega et al. 2005). Further, knowledge disseminated about respectful and fair policing may build a more respective and legitimate police force.

Such efforts only reflect what an evidence-based approach would be *at the minimum*. Agencies that want to be more advanced in using analytic and research knowledge may pursue these with greater intensity and innovation. For example, mid-level achievement in evidence-based policing might be reflected in an agency having an active crime analysis culture (and specifically allocated resources) that constantly generates information for proactive enforcement and assessment of activities. In even more intense versions of evidence-based policing, these analysts become the criminologists, seeking to find underlying reasons for crime problems and patterns and also assisting the agency in evaluating both its strategies and tactics to reduce crime and its approaches to addressing internal concerns.

More intensive evidence-based approaches might include not only incorporating research and analytic knowledge into academy and in-service training but also using it to rewrite standard operating procedures (SOPs) to conform more to research knowledge. An example might be the SOPs related to preventive patrol and noncommitted time. Currently, SOPs may not include guidance or directives on what officers should be doing when they are not answering calls or writing reports. By building research knowledge into SOPs, such knowledge also becomes part of the information base used for decisions about issues such as promotions and transfers. Further, when police receive research information through familiar agency sources, it increases their receptivity to the information – (Lum et al. 2012). In these agencies, commanders, first line supervisors, and officers ideally would develop a more sophisticated understanding of these issues which become part of their technical expertise (and a requirement for promotion).

Agencies well entrenched in an evidence-based approach work regularly with researchers inside and outside of their agencies and use that knowledge and those relationships to mold both officer *and* citizen expectations of the law-enforcement role and function in society. The sheriff or chief might even take an active role in reminding his or her political counterparts in the city council or state governments about outputs from research as justifications for activities and resource allocation. Agencies committed to evidence-based approaches would have a portion of their budget specifically devoted to research and analysis of the agency's activities and behaviors.

These are only just a few examples of how research might be incorporated into police practices. Institutionalizing the use of research in practice involves many adjustments to organizational, personnel, incentive, and policy structures in policing. (For more in-depth discussion and examples of these ideas, see the *Matrix Demonstration Project* (http://cebcp.org/evidence-based-policing/the-matrix/matrix-demonstration-project/) as well as Lum et al. 2012 and Weisburd and Neyroud 2011.) Further, achieving evidence-based policing cannot rely only on the will of police leaders or the merits and volume of the research base. Police must be receptive to such an approach; the research must be useful, and there needs to be a demand for such knowledge in policing. The logic and rationality of evidence-based policy more generally in medicine, governance, or social interventions can be overshadowed by stronger human tendencies of habit, tradition, and culture that can block receptivity toward research use in policing. The example of the continued use of DARE (Drug Awareness Resistance Education) comes to mind (Birkeland et al. 2005). Despite research evidence showing DARE's ineffectiveness, police, schools, and parents support the program for reasons other than meeting its intended outcome. Overcoming a culture of reactivity, low use of analysis, weak supervision and accountability, and a suspicion of researchers, research, and scientific processes will be keys to successfully implement such an approach. This not only requires a sea change in law enforcement culture but also real changes in organizational infrastructure that allows for research to be better received and digested by members of the agency.

Overview

Evidence-based policy in crime and justice is defined here as a conscientious approach to intentionally use research to make decisions about programs, practices, and larger scale policies. Evidence-based policies, by and large, are those found to be effective in prior rigorous studies to reduce crime or improve justice. This article first summarizes the rationale for an evidence-based approach and the different types of evidence needed to respond to different policy questions. Exactly how much influence evidence should have on policy is then considered, and key mechanisms in the approach are illuminated. After providing a brisk history of evidence-based policy, the article concludes with some important by-products and limitations to the approach.

Introduction

In recent years, the term "evidence-based" has become the catch phrase to describe the intentional use of research evidence to make policy and practice decisions. The cornerstone of evidence-based policy would be a conscientious attempt by government and other decision-makers to adopt policies, practices, and programs (hereafter, policies) that have been shown to be effective in prior evaluation studies, usually rigorous randomized controlled trials or high-quality quasi-experiments. There are a few who would argue that policies are "evidence-based" if they have sound theoretical and conceptual footing based on prior research, even if the actual policy has not been previously tested. A commitment to evidence-based policy would be demonstrated, among other things, by decision-makers determining what prior research indicates about their current policies and whether they should be continued or revised and what prior evidence is on any new policies they are considering adopting.

Why Evidence-Based Policy in Crime and Justice?

Why has evidence-based policy become "all the rage" (Tilley and Laycock 2000), in the USA and elsewhere? The pursuit of evidence-based policy has several drivers. First, policies may have a range of effects, from strong positive impact (helping the situation) to no effect (basically a zero impact in the setting) to a large negative effect (hurting the situation). Policy makers who wish to maximize the possibility of having positive impacts with the future policies they implement may do so by adopting policies shown to be effective in prior research.

Second, governments are under pressure to make choices and commitments while simultaneously dealing with shrinking resources. Dollars spent and resources expended toward ineffective strategies are costly and hard to recoup. Allocating those resources to policies that, at least, have been demonstrably effective somewhere else is seen as a "safer bet."

Third, evidence is viewed as a more rational input for making decisions about policies than factors such as the special case or anecdote, ideology, politics, pressures from special interests, and tradition. Policies implemented on the basis of such input are sometimes criticized for not being based on rational consideration of the problem and potential solutions.

Finally, it is important to recognize that some policy makers and decision-makers do indeed want to make improvements in their venue and collaborate with others to help generate the evidence on what works and what does not. Indeed, some of these individuals are recognized annually through awards, made by George Mason University's Center for Evidence-Based Crime Policy, for instance, to police chiefs and others who have contributed notably to improvement through the generation and use of evidence.

What Evidence Should Answer What Question?

Evidence-based policy in crime and justice invites attention to the kinds of dependable evidence that exists, or can be generated, so as to inform decisions at the policy level. Five major evaluation questions invite efforts to generate dependable evidence.

The first is "What is the nature and severity of the problem? And what is the evidence?" No consideration of crime and justice policy can proceed without good understanding of where the problems are. Sherman (1998), in his seminal paper for the Police Foundation, argued that evidence-based policing would come to depend on large-scale monitoring databases which would help to empirically identify problems requiring law enforcement intervention. In recent years, such dependable evidence has been embodied in such information sources as COMSTAT, police administrative data (which is often used to identify trouble spots in the jurisdiction known as hot spots), and other sources in local jurisdictions. At the national level, answers have depended on sources such as the National Crime Victimization Surveys (NCVS) and Federal Bureau of Crime (FBI) police-captured crime reports. There are many standards for these kinds of data. The most critical and best articulated concern the statistical quality of the sample, the data's reliability currently and over time, and the data's validity in capturing what the researchers and policy or practice partners intend to measure.

The second set of questions fall under the general umbrella of etiology or causation, such as "Where did the problem come from?" and "what is the evidence?" There are many approaches to identifying potential causes of crime or other problems related to justice. However, longitudinal cohort studies are often recommended as a powerful form of evidence to answer questions about etiology of criminal behavior. This is because such studies usually include repeated measurements on individuals over substantial time periods. For example, longitudinal studies that included measurements on individuals from a very young age to adulthood can better identify factors that preceded the start or onset of delinquency or crime than cross-sectional studies that include only one measurement at the same point in time.

The third set of questions regarding evidence-based crime and justice policy is "What programs are deployed to address the problem, and how well are they deployed, and what is the evidence?" Before implementing new policies and programs to address a problem, it is useful to inventory what is currently being done about it. These data can be elusive, but funding agencies, organizations providing services, and schools or communities receiving services may be sources of learning what is going on. Evidence standards for such data are not as well thought out, but would likely include how comprehensive and reliable the data are, including how was current practice sampled. Some organizations will conduct "policy scans" to identify what is going on; this strategy may be simple, as in documenting state laws for sentencing sex offenders, or it may be more complex, as in documenting violence prevention strategies employed by schools, police, and community groups in a city. In any case, the quality of the policy or program's implementation is usually a crucial consideration whether the activity is ongoing or new and whether the program is tested in a controlled trial or not.

A fourth set of questions has to do with "What works and could work better?" Further, what is the evidence? This is often the crux of research contributions to evidence-based policy. As mentioned earlier, the initial policy idea may seem to be a good one, but it may go belly up after implementation. There may be unforeseen negative or backfire effects. Evaluations provide the evidence on answering questions about whether a policy has worked or not. But such impact evaluations are not all "created equal," and some types of studies have higher internal validity, i.e., they do a better job of convincing the skeptic that reasons for the outcome other than the program have been satisfactorily controlled.

In the context of this fourth set of questions, the randomized controlled trial is viewed by most researchers as providing the least equivocal evidence on what works. The aim of the randomized trial is to generate fair and unbiased evidence about whether one or another approach works better. The key theme is fair comparison. Randomized controlled trials, including place-based ones, on hot spot policing, mandatory arrest for domestic violence, Scared Straight programs, and others mounted since the 1960s which are described elsewhere in this Encyclopedia.

Because policies in crime and justice are often administered at federal or state level, they may be difficult to evaluate through randomized experimental design. Another class of statistical designs for impact evaluations that are viewed by some researchers as convincing (and having high internal validity) are quasi-experiments. These study designs do not use randomization to assign entities in the study to conditions. Instead, they use matching or other techniques to assess the impact of policies so as to approximate the results of a randomized controlled trial.

The final set of questions is "What is the cost effectiveness of alternatives? And what is the evidence?" Once there is some demonstrable evidence on effectiveness of a policy, it is also important to capture data on the costs of the policy and potential alternatives. This can be a very important consideration for policymakers, particularly if two alternatives are likely to achieve similar effects; the cheaper alternative may be the best option. To date, explicit standards for cost data are not well articulated or agreed upon. Cost-benefit analyses are demanding and often require researchers to make assumptions that are difficult to sustain and to estimate costs for phenomenon such as "psychic harm." Cost-effectiveness analyses are generally easier to generate as they estimate costs per unit of improvement for a program, i.e., every $1.00 spent under the policy results in a return on investment of $1.50. Data such as these permit researchers to compare economic data across interventions, thereby increasing the policy relevance of the research.

How Strong a Connection Between Evidence and Policy?

In some sense, evidence-based policy is simply a new label for a goal to which applied researchers have long aspired: a greater role for science in decision-making. Substantial research has been done, for instance, whether and why or why not dependable scientific evidence gets used in policy decision-making. The themes in this "knowledge utilization" literature are complex but indicate that the uses of research to make definitive decisions about policy, often referred to as "instrumental use," are not common. Carol Weiss, a leading scholar on the uses of research, discussed a different role for evidence, which she calls "conceptual use." Evidence may not be used to make clear-cut decisions about policies, for instance. But over time, in a context which she calls "the circuitry of enlightenment," the research results to provide new generalizations, ideas, or concepts that are useful for making better sense of the policy scene (Weiss et al. 2005).

The term, evidence-based policy, however, indicates a stronger role for research and evaluation than conceptual use. Many writers in the evidence-based arena argue for an evidence-informed approach that research and evaluation would, at the very least, "have a seat at the table," with other input criteria before a decision is made. Some writers have argued that decision-making should go beyond mere consideration of research (or being informed by studies) to actively using it in making choices about policies. In recent years, some have articulated a different role, in which policy makers implement a decision about a program and then seek evidence to post hoc "support" their decision. This has been referred to, with appropriate sarcasm, as *policy-based evidence*.

The Mechanisms for Evidence-Based Policy

Regardless of the exact nature of the connection, the current emphasis on evidence-based policy has created concern about the causal chain between research and evaluation evidence and the decisions and choices that are made about policy and practice in crime and justice. Enhancing the likelihood that the evidence will be used presents the challenges considered next.

First, the potential user of evidence must *know* of the existence of evidence. Evidence producers often assure that this happens by identifying potential users and developing a system that gets the information to them. Many organizations have been using passive mechanisms, such as having potential users self-subscribe to email newsletters and making specialized websites available. Active dissemination campaigns take time and money to develop properly even if one can identify the relevant target populations and the most appropriate vehicle for transmission of information to them. For example, the University of Maryland Report to the Congress on Crime Prevention (Sherman et al. 1997) was subsequently sent with summary and cover letter by the Jerry Lee Foundation to 500 leading US justice policymakers.

Another link in the evidence-based policy chain concerns the fact that the mere receipt of evidence does not assure understanding. How researchers can communicate the evidence is one aspect of this. Another aspect is the ability of the intended users to understand the evidence they receive. For example, legislators and legislative staff vary in their ability to understand what a randomized controlled trial is and why it is important. Lum et al. (2011) have generated an evidence policing matrix that portrays in brief prose, simple numbers, and graphs on the evidence for what works with what target populations and to what extent. New publications such as *Translational Criminology* have the aim of assuring that potential users can understand easily the evidence from dependable research. The US Department of Justice Office of Justice Programs has initiated a web-based effort with similar aims at http://crimesolutions.gov.

A major consideration is the organizational or political constraints on the use of evidence. The potential user may well be aware of the evidence and have an understanding of it (including limitations), but there may be serious internal and external constraints to its use. For example, on rotating shifts among the New York City Police Department officers was the subject of an evaluation conducted by the Vera Institute in the 1980s (Cosgrove and McElroy 1986). One set of precincts retained the rotating shift (where officers were continuously rotated every few weeks to different shift hours, such as 8–4, 4–12, 12–8), and the treatment precincts were provided with steady shifts. Although the experiment found that rotating shifts harmed officer health, increased sick days, and had other negative effects, the NYPD kept rotating shifts because of its traditional concerns with potential for officer corruption (i.e., shifting rotations makes it harder to know the "wrong people"). Although some actors in the NYPD asked for the study and welcomed the news, the more powerful in the bureaucracy were reluctant to make any changes.

Finally, there must be incentives to use dependable scientific evidence. Not everyone will want to come to the party or have incentives to do so. Weiss and colleagues (2008) have identified one major incentive, however, that has surfaced since the late 1990s in the United States, the "mandated use" of evidence. Mandated use means that grant funding is tied to the use of programs or policies from an accepted list or registry of evidence that identifies evidence-based programs. Jurisdictions sometimes will receive money to implement programs selected from the list. Weiss et al. (2008) raised concerns about this approach, particularly as the criteria for making the lists can also be questioned and can be politicized.

Often, there are disincentives to evidence-based policy, as decision-makers may worry about the consequences of adopting evidence-based programs if it means admitting that the ones they had implemented earlier were the wrong choices. For instance, high-quality evaluations may be eschewed by risk-averse executives who do not want to have to answer questions about their having earlier adopted "bad policy." Donald Campbell (Campbell 1969), one of the seminal writers on the evidence-based approach to policy decision-making, argued that policy makers should not be punished for using evidence when it showed their decision was wrong. Instead, they should be applauded – even rewarded – for following an approach of implementing, rigorously testing, and then modifying policy in light of this evidence.

A Brisk History of Evidence-Based Policy

Researchers have long focused on and written about the relationship between scientific research evidence and policy, although they did not specifically use the phrase "evidence-based." Indeed, in the seventeenth century, John Graunt, who produced the first serious statistical compendium of policy-related data for England, declared that one of his motives for doing so was "good, certain, and easy government." More recently, Donald T. Campbell (1969), for whom the international Campbell Collaboration is named, called for the US and other modern governments to adopt an experimental approach to developing and testing public policy:

> The United States and other modern nations should be ready for an experimental approach to social reform, an approach in which we try out new programs designed to cure specific social problems, in which we learn whether or not these programs are effective, and in which we retain, imitate, modify, or discard them on the basis of apparent effectiveness on the multiple imperfect criteria available. (p. 409)

Oakley (1998) called the period of the 1960s–1970s in the United States the "golden age of evaluation" because many government programs, rigorous experiments and quasi-experiments were influential in considerations about policy choices. As Oakley (1998) lamented, however, rigorous studies produced a number of null results, and the general critics' response was that there was something inherent in experimentation that could not detect those positive impacts that such interventions were undoubtedly having.

Although randomized experiments and quantitative systematic reviews of such evidence, called meta-analyses, have become common approaches to evidence generation since the 1960s, the more modern view of "evidence-based" policy was formulated in medicine and in the United Kingdom. A government researcher named Archie Cochrane argued that many health-care practices had already been shown to be ineffective in clinical trials but were still being used to the detriment of patients. Conversely, some medical procedures had been demonstrably effective in such rigorous studies but were being ignored in light of tradition, authority, education, clinical experience, and anecdote. Later, a group of researchers led by Iain Chalmers summarized the results of controlled trials in the area of childbirth and pregnancy, so as to identify what worked or did not based on rigorous studies. The success of that effort led Chalmers to begin working with other researchers to develop an international organization that would summarize trials in all other areas of health care. This was named the Cochrane Collaboration in honor of the man who inspired it (www.cochrane.org). Thus, an apparatus for summarizing research and getting that evidence into the hands of medical practitioners was born.

The early work summarizing the results of childbirth and pregnancy trials in Oxford and the success of the nascent Cochrane Collaboration led some to more closely connect prior evidence and current decision-making. A Canadian medical researcher, David Sackett, and his colleagues are often credited with articulating the first modern use of the term "evidence-based." Sackett and others (1996) called evidence-based medicine:

> . . .the conscientious, explicit and judicious use of current best evidence in making decisions about the care of the individual patient. It means integrating individual clinical expertise with the best available external clinical evidence from systematic research. (p. 71)

Since the early 1990s, the use of the term evidence-based has grown appreciably. In crime and justice research, Sherman's (1998) evidence-based policing report invoked the phrase probably for the first time. Sherman argued that large-scale police databases would serve as information to identify problems in need of innovation (new policies), and randomized experiments would be conducted to test the impact of the innovation on the problem. Police departments would be learning organizations that would refine their policies based on evidence from these RCTs.

The close coupling of evidence-based policy and systematic reviews began in the late 1990s. During that time, Chalmers approached the authors and others about establishing an analog to the Cochrane Collaboration that would prepare, update, and disseminate high-quality reviews of research in other areas outside of health care, such as crime and justice, education, and social welfare. These early discussions led to the official inauguration of the international Campbell Collaboration (www.campbellcollaboration.org) in January 2000. The Campbell Crime and Justice Group has overseen the development of systematic reviews relevant to crime policy and has organized annual conferences funded by the Jerry Lee Foundation to disseminate the results of these reviews to federal decision-makers and others on Capitol Hill. Collections of these reviews have also been published by notable journals including the *Annals of the American Academy of Political and Social Science* and the *Journal of Experimental Criminology*.

The advent of the C2 coincided with other major, cross-field evidence-based policy efforts, including the funding by the UK Economic and Social Research Council (ESRC) for several centers (called nodes) on various aspects of the interplay between research and decision-making, including the creation of a new journal called *Evidence & Policy*, published by the Policy Press. A US-based group called the Coalition for Evidence-Based Policy (http://coalition4evidence.org/wordpress/) that would advocate for federal government decisions to be closely tied to results of rigorous evaluations was created and has had considerable influence in getting legislation to mandate randomized controlled trials as the design of choice to evaluate these new policy initiatives (Wallace 2011). This has been mirrored in the UK by the creation of the Alliance for Evidence.

Evidence-based policy has now become a popular term throughout criminal justice, demonstrated by the creation of the Center for Evidence-Based Crime Policy at George Mason University in Virginia, USA (http://gemini.gmu.edu/cebcp/), directed by David Weisburd, and two new book series, on *Evidence-based Crime Prevention* and *Translational Criminology*, respectively, started by Springer Press.

Some By-Products of the Evidence-Based Policy Movement

Regardless of the long-standing interest in criminal justice and other fields on generating and using research in government decision-making, the more recent emphasis on evidence-based policy has led to a number of important by-products. For one, it has led to even more discussion and debate over the nature and quality of evidence that should influence policy decisions. This is seen most convincingly in the area of determining what evidence should be relied upon to determine whether an intervention works. There seems to be a consensus among scientists and policy makers that randomized controlled trials provide the least equivocal evidence on the effects of a policy intervention. But this is, by no means, unanimous, and challenges have been periodically raised to whether experiments are the best design for generating evidence on what works (e.g., see Derzon (in this Encyclopedia); Boruch 1975; Pawson and Tilley 1994). Despite these "common contentions," the emphasis on evidence-based policy has led to the recognition of the role of randomized experiments to evaluate justice policy when it is appropriate and possible to do so. For example, the Academy of Experimental Criminology was initiated in 2005 to recognize researchers who have conducted experiments as "Fellows" and to promote the use of experimental methods generally in the field of criminal justice (Weisburd et al. 2007). The *Journal of Experimental Criminology* was also initiated to provide a forum for rigorous evaluations and systematic reviews relevant to crime policy.

As aforementioned, because some policies cannot be evaluated using random assignment, such as when all of a population is receiving the intervention at the same time, the emphasis on evidence-based policy has led to proposals for using more sophisticated quasi-experimental approaches to evaluate crime policy (e.g., Henry 2009). Statistical impact evaluation designs such as regression discontinuity approaches and propensity score matching have been advocated and tried out in the social sciences (e.g., Campbell and Stanley 1966) and criminal justice (Berk and Rauma 1983; Minor et al. 1990) for several decades are now more commonly utilized. In fact, workshops for researchers to become better acquainted with the latest techniques have been offered since 2010 by professional associations such as the American Society of Criminology.

Besides putting the light on evidence, and highlighting the generation and use of results from randomized controlled trials and certain classes of quasi-experiments, the evidence-based policy focus has also led to increased attention to how the results of prior studies that bear on a policy are synthesized. Techniques for analyzing separate but related studies have been around for many decades (e.g., Mosteller and Bush 1954). Further, quantitative approaches popularized by the term "meta-analysis" have been extensively used in the social sciences since the late 1970s (see Smith and Glass 1977). "Systematic reviews," as they are now commonly referred to, have become the fulcrum of the evidence-based policy approach. This has also led to even more attention to how researchers locate relevant studies, how they can be pulled together and appraised for quality, and how they can be analyzed (Boruch and Petrosino 2010). For example, some studies are not published in peer reviewed journals, but if they meet quality standards, the evidence needs to be considered. The focus on evidence-based policy has brought with it attention on the rigorous and explicit methods needed to make sure that such evidence is located and included in syntheses designed for the decision-maker.

Another important by-product of the focus on evidence-based policy has been on developing systems that get the evidence on policies into hands of busy decision-makers. Many public agencies do not have staff that can spend the time necessary to do a systematic review, and they generally rely on external and trusted sources for evidence. The advent of electronic technology has meant that summaries of evidence from systematic reviews can be provided quickly so long as the intended user has access to the Internet and can download documents. Groups such as the Campbell Collaboration's Crime and Justice Group not only prepare and update

Evidence-Based Policy in Crime and Justice, Table 1 Evidence ratings for crime solutions

Evidence ratings			
	Icon		
Evidence rating	One study	More than one study	Description
Effective	✓+	✓+	Programs have strong evidence indicating they achieve their intended outcomes when implemented with fidelity.
Promising	✓	✓	Programs have some evidence indicating they achieve their intended outcomes. Additional research is recommended.
No Effects			Programs have strong evidence indicating that they did not achieve their intended outcomes when implemented with fidelity.

[a] A single study icon is used to identify programs that have been evaluated with only one study. A multiple study icon is used to represent a greater extent of evidence supporting the evidence rating. The icon depicts programs that have more than one study in the evidence base demonstrating effects in a consistent direction

reviews of evidence but make them freely available to any intended user around the world.

Campbell Collaboration reviews tend to be broad summaries of “what works” for a particular problem (e.g., gun violence) and classes of interventions (cognitive-behavioral programs). They are not usually focused on brand name programs or very specific, fine-grained definitions of an intervention.

Because decision-makers often need evidence on *particular* interventions, other approaches to providing evidence that is more fine grained have been developed. Some of these approaches fall under the rubrics of “best practice lists” or “evidence-based registries.” For instance, such a registry might summarize the evaluation evidence for a particular brand name of a program (e.g., D.A.R.E., Drug Abuse Resistance Education). Although the number of such registries and lists relevant to justice have grown since the late 1990s (Petrosino 2005), the largest effort in the field, Crime Solutions (crimesolutions.gov), was initiated in 2010. This project compiles the available evidence on more or less branded programs like “Functional Family Therapy” and “Aggression Therapy,” rates how rigorous the evidence is according to a schema (which prioritizes results from randomized controlled trials), and then provides a summary based on rigor and amount of evidence. Table 1 provides the schema on how evidence for these programs and policies are rated (Crime Solutions.gov 2012) (Table 1).

Limitations of Evidence-Based Policy

Despite the gains in the development and synthesis of rigorous evidence and the methods for rapid transmission into hands of policy makers (e.g., electronic distribution), there are some century-old barriers that limit and challenge those who wish to see evidence inform crime policy. As Lipton (1992) has written, the justice decision-maker at the policy level has many inputs into the choices made about funding, programs, allocations, and deployment. Research evidence is but one of the many “desiderata” of factors, and although evidence-based policy places a premium on scientific research to guide decision-making, choices are also influenced by ethics, fairness, resources, politics, ideology, special interests, tradition, experience, training, and many other factors. Researchers in criminal justice want a seat at the table, but they might find that the table is very crowded and that their voice may not be heard in the din.

There are many areas in US policy in which emotions are so charged that it is difficult for evidence to make an impact. For example, gun control has zealous advocates both for and against it, and impassioned discussions about evidence and their role in policy are often difficult if not impossible to have (Webster et al. 1997). A high profile murder, particularly if it is sexual in nature and involves a child victim, can cause knee jerk policy reactions and overreactions that have no basis or even run counter to research evidence (Petrosino 2000). In such charged situations, it is difficult for evidence to get a fair hearing, if any hearing at all.

As Boruch and Lum (2012:4) have written, "sturdy indifference to new and dependable evidence are a fact of life." Reluctance to trust evidence, even the most compelling, is true in the policy sector and other parts of society. As aforementioned, Campbell (1969) wrote about the reluctance of policy makers to embrace evaluation for fear that it will highlight failure of their decisions. Overcoming this to promote learning organizations that are not in fear of "upsets" has long been a challenge. Finckenauer and Gavin (1999) write that after the evaluation questioning the effect of California's Scared Straight program (known as SQUIRES) came out in 1983, the reaction by policy makers was to get rid of evaluation and keep the program. Instead of studying the program further, they evaluated it with "testimonials" from letters written to and by participating prisoners.

"Evidence destruction techniques" are easy to mount and often difficult to contend with. For example, in the case of Drug Abuse Resistance Education, or D.A.R.E., a long litany of evaluations questioned whether a police-led drug prevention program in elementary school reduced self-reported drug use by D.A.R.E. youth. D.A.R.E.'s leadership group, (D.A.R.E America) responded to each new evaluation with the same criticism: "D.A.R.E. has already revised its curriculum, the evaluation was of the old curriculum, therefore, the evaluation has no merit" (Petrosino 2005). Even minor tweaks of the curriculum were touted as major revisions and attempted to nullify evaluation evidence by making it appear obsolete and irrelevant. Vested interests often lead to the use of such techniques. A supporter of the "Campaign for Dark Skies" (Marchant 2004) criticized the methods in Farrington and Welsh (2002) systematic review of research on the effects of street lighting, motivated by fear of how their positive findings would affect the ability of professional and amateur astronomers to see the stars and planets in the UK.

Mears (2007) has highlighted some other challenges to evidence-based crime policy, including little questioning about whether the policies are needed in the first place, the pursuit of silver bullets or panaceas instead of a rational and holistic crime policy, the difficulties of implementing ideal evidence-based policy in the real world, the lack and misinterpretation of rigorous studies, and the challenge of getting good data on costs so that decision-makers can make rational choices.

Weiss and colleagues (2008) also make the point that in a democratic society, multiple inputs are expected and may be necessary. A strict adoption of evidence-based crime policy could translate into one small group (influential members of the scientific community) exerting too much influence on a process that, in a democratic society, should be representative of the majority of citizens.

Evolutionary Perspectives on Crime Prevention

Jason Roach[1] and Ken Pease[2]
[1]Crime and Policing Group, University of Huddersfield, Huddersfield, West Yorkshire, UK
[2]Jill Dando Institute, University College London, London, UK

Overview

The Darwinian worldview, whereby organisms evolve by a process of natural and sexual selection, has come to permeate biological science and to varying degrees the social sciences, with anthropology, psychology, and economics the disciplines most influenced. Criminology has remained slightly touched by Darwinian thinking. This entry describes and refutes common criticisms of the application of evolutionary theory in the social sciences and sets out some possible points of contact between evolutionary theory and crime prevention. The policy recommendations which may be tentatively made by drawing on the meager volume of relevant research conducted to date are diverse and unlikely to offend liberal sensibilities.

Key Issues and Controversies

Evolution is the process whereby attributes of plants or animals, including people, change over generations as a result of selection pressures operating on random genetic mutations. Organisms best adapted to their environment (i.e., most equipped to survive and bring their offspring to reproductive maturity), thereby, come to feature in increasing numbers within the population. While the evidence base for evolution is seen as overwhelming by the great majority of scholars in the life sciences (see Coyne 2009), the theory remains controversial for three reasons. First, it may be rejected because its account of the origins of life is at odds with that of major religious texts. Second, the notion of "survival of the fittest" (not a quotation from Darwin) is seen as the theoretical undergirding for eugenics, the Holocaust and subsequent horrors in the name of "ethnic cleansing." The third reason is the erroneous ascription of biological determinism to Darwinian thought.

The first reason for rejection is not liable to challenge by evidence and will not be discussed, save to affirm the right of people to their own theology. The second reason stems from Herbert Spencer's perversion of Darwinian thought and should not preclude an open-minded consideration of the implications of evolutionary thinking for crime and criminality. Darwin's own view (Darwin 1871) was that the intentional neglect of the weak and helpless was a "certain and great present evil" (p. 169). The third reason is simply wrong, with large human brains offering diversity and flexibility of behavior consistent with Darwinian purposes (see Pagel 2012).

If evolution were to be accepted as a true account of the shaping of organisms' attributes, the implications for criminology are no less profound than they are for the other social sciences. Readers wishing to consider evolutionary implications for social policy generally are referred to the website of the Evolution Institute, brainchild of the biologist David Sloan Wilson http://evolution-institute.org/. The Institute's foci include risky adolescent behavior and other crime-relevant topics.

The key presumption of the theory of human evolution is that modern Homo sapiens represents the product of selection pressures operating on our forebears in the late Pleistocene era, known as the Era of Evolutionary Adaptedness (EEA). Since (excepting for a few remaining hunter-gatherer communities) our environment is now very different from that of the EEA, there is a mismatch between the setting for which evolution shaped us and the setting in which we are required to function. The plausibility of this view is best illustrated by current obesity and diabetes epidemics, the consequences of dietary preferences established at a time when food availability favored those ingesting protein and sugar-laden diets coming to prove disastrous in times of plenty (Gluckman and Hanson 2006).

Criminologists are used to confronting the most predatory and socially disruptive of human actions (plus those perhaps foolishly deemed by authorities of a particular culture and epoch as socially disruptive, hence, for example, legislation on sexual mores). But if one thinks of human behavior as lying on a continuum from cruel predation to heroic altruism, things (at least to the writers) look somewhat different. The bulk of the relevant evolutionary literature characterizes people as ultra-social, and "super-cooperators" (Nowak 2011). The term eusociality (deriving from the Greek prefix eu meaning good or real) represents a state of affairs in which some individuals reduce their own lifetime reproductive potential to raise the offspring of others. Eusociality underlies the most advanced forms of social organization and the ecologically dominant role of social insects and humans (see E.O. Wilson 2012). Wilson's view (in common with other scholars) is that communities require a majority of cooperators, with deviant "free riders" threatening community cohesion when constituting more than a small minority. Areas vary massively in rates of crime. Crime levels remain an important determinant of the decision to move home, especially for those with children and the affluent (see, e.g., Katzman 1980). The Wilson view would imply a highly skewed small area distribution of crime rates and a "tipping point" as those able to move away from an area do so.

To return to the central notion of Homo sapiens as a super-cooperator, it will come as a surprise to many criminologists, together with believers in Original Sin, that the default setting for human nature in maturity seems to be cooperation with, and weak altruism towards, other people. With that changed perception comes the suspicion that criminology ought not to form a distinct discipline. If the overarching aim of applied social science is to foster cooperative social relationships, then there is a case for ceasing to see the task as one of reducing the number of outlier behaviors labeled as crime and instead to see it as directing people towards the cooperative end of the continuum, *wherever on that continuum they started*, that is, to nudge altruists as well as the selfish further towards the heroic altruism pole. This would possibly be achieved by a rapprochement with the emergent discipline known as positive psychology. This perspective (bear in mind its origins in clinical practice) seeks to make normal life more fulfilling rather than exclusively to treat mental illness. It emphasizes the importance of using the scientific method to determine how things go right (Seligman and Csikszentmihaly 2000). In the same way, reconfiguring research so that the prosocial-antisocial continuum is treated as such, rather than antisocial outliers being hived off for study by a separate discipline called criminology, makes sense against the background of the raft of research on human eusociality. It should be stressed that evolutionary thinking is not the only route towards the incorporation of criminology within positive psychology. Indeed, religious and other obstacles mean that it may always be "the road less travelled." While the implications of what amounts to a paradigm shift in criminology are immense, that theme will not be pursued here. Rather, the bulk of what follows is restricted to the implications of evolutionary thought for criminology as currently conceived.

The Dunbar Number

Put crudely, if one accepts the Darwinian account, we evolved to act locally. How local is local? The Dunbar number refers to the maximum number of other people with whom a person can maintain stable social relationships (Dunbar 1992). Robin Dunbar found a relatively narrow band of group sizes with an average of 150. This number (plus or minus some) characterized group size among numerous contemporary hunter-gatherer groups and also the average estimated size of Neolithic farming villages. Modern comparisons were made with the size of military units. Whatever its evolutionary origins, the Dunbar number has major *unexplored* implications for designing conflict-minimal contemporary human settlements. We know that real differences in rates of crime are immense and that crime is a major reason for moving home among those who can afford to do so. We know that certain street types are associated with low levels of crime (Johnson and Bowers 2009), and the recent work of David Weisburd and colleagues at George Mason University have emphasized the need for small-scale, *street segment* analyses of crime levels (see Weisburd et al. 2012). What we have yet to do is to consider attributes of late Pleistocene settlements *alongside* contemporary variations in residential crime risk. For example, do sinuous cul-de-sacs of the kind identified by Johnson and Bowers as low in crime share line-of-sight or other attributes with hunter-gatherer settlements? The reader will think it unsatisfactory in an encyclopedia entry to say what should be done rather than what has been done, and indeed it is. However, it is inevitable given the lack of penetration of evolutionary thinking into contemporary criminology.

Child Abuse and Parenthood

Margo Wilson and Martin Daly have looked at violence (among other things) from a Darwinian standpoint for some 30 years. Their work provides an illustration of what was implicit in the foregoing text, namely, that an evolutionary mindset leads one to ask different kinds of question from those typically encountered in criminology.

For most, the killing of a child is the most heinous and distressing of all crimes (Adler and Polk 2001). It is mercifully rarer for children to be victims of homicide than adults. In England and Wales, there will be approximately 110 child homicides per year from an average total number of approximately 700 recorded homicides, roughly equating to 14 % of all homicide victims (Brookman 2005).

The notion that your own family represents the greatest danger to your well-being was conventional wisdom in the 1960s, and that undifferentiated view is still held in some quarters to this day. It was obvious to Daly and Wilson that biological and stepparents should be separated in any analysis of abuse (including lethal abuse) of children. When this was done, it was found that rates of child homicide by stepparents were *one hundred times or more* greater than rates of child homicide by biological parents. In a nod to the eponymous fairy story, they called this the Cinderella effect (Daly and Wilson 1998).

Daly and Wilson do not argue that killing the offspring of others is adaptive for humans, though it is for some other species, such as lions (see Packer and Pusey 1983) as a means whereby incoming males prevent females from investing in the care of the offspring of other males and eliminating the partial contraceptive effect of lactation, thus maximizing the period in which females may conceive their cubs. Rather, they argue that nurturance tends to be given preferentially to one's own offspring. Abuse and homicide are outliers. Most people don't keep their stepdaughters from going to balls or feed them poisoned apples. The Cinderella research has been much criticized, with Daly and Wilson defending their position persuasively (Daly and Wilson 2007). They assert that:

> "Abundant confirmatory research has followed, such that the disproportionate victimization of stepchildren is now the most extensively documented generalization in the family violence literature. This... raises further questions, such as what explains variability in the magnitude of Cinderella effects between maltreatment types and locales, and whether the individual level predictors of abuse are the same for fathers, mothers, stepfathers and step-mothers. Unfortunately, progress on these important issues has been hindered by a relentless distraction: the manufacture of "controversy" about whether Cinderella effects exist at all. We suspect that the reason for this nay-saying resides largely, though not entirely, in antipathy to the Darwinian world-view and its application to Homo sapiens." (pp. 383–384)

Daly and Wilson write thus of their critics:

> "From the perspective of two researchers on the receiving end of these attacks, a disturbing and sometimes perplexing element has been their incivility.... [our critics] are not just sceptical, they are angry, and we are still not entirely sure what they are angry about." (p. 396)

Future Discounting and Crime

Comparisons with ants and termites (the only other eusocial organisms) will be treated in some quarters with derision, but one is included here because it provides an arresting image to act as a mnemonic for the serious point subsequently made:

> "Old-aged termites go out with a bang, it appears. While aging, the insects brew a backpack of deadly chemicals, which they use to self-destruct when under attack, taking out any enemies with them… When the spotted termites were physically unable to defend themselves with their jaws, they would commit the ultimate sacrifice and burst a pouch on their backs, releasing a toxic liquid that quickly paralysed and killed any other termites it touched."(p. 14)

The moral is as follows: if you haven't got long to go, make the most of what you have. It has long been asserted that offenders are liable to high levels of future discounting, characterized by the preference for short-term rewards over larger long-term rewards (Daly and Wilson 2005). They apply an evolutionary lens to the issue. They interpret future discounting in terms of realistic anticipation of future life. They found homicide to be most frequent among those with least to lose, unemployed, and unmarried men, with divorced and widowed men reverting to higher rates of homicide. They interpret this in terms of the deployment of reproductive effort as a gamble. If one anticipates the nontrivial probability of an early death, or other form of removal from the ranks of the reproductively active, one chooses a strategy of attempting risky and frequent and if necessary coerced impregnation and the pursuit of short-term reputation and the acquisition of status symbols by acquisitive crime. Wilson and Daly argue that life expectancy itself may be a psychologically salient determinant of risk-taking.

Clearly linked to anticipations of future life is the decision known as "Dads or cads," referring to the choice of reproductive strategy among males (Cashdan 1993). Cads seek to impregnate as widely as possible, making no contribution to child rearing. Dads stay with the woman or women with whom they have conceived children. Cads will be the more effective survival vehicles if more of their children survive and reproduce. Otherwise, the genes of Dads win out in the next generation. If Wilson and Daly are correct in placing life expectancy at the center of strategy choice, the implications are clear in engendering hope of life and possible success in adolescents, especially adolescent males. This clearly has implications beyond the narrowly criminological.

Domestic Violence Against Women

According to the 2009/2010 British Crime Survey (BCS), 7 % of women aged between 16 and 59 years in England and Wales were victims of domestic abuse over the course of 1 year, the majority of the violence being "nonsexual" abuse by a partner. Although only 14 % of the total 2,087,000 violent incidents estimated by the BCS for that year were described as domestic violence, equivalent figures have been found to be up to five times higher wherein participant "self-completion" was used. Domestic violence is ubiquitous and as such if we are working to prevent violent crime than we can best make inroads by focusing on intimate partner violence. For example, a study in England and Wales (1995–2000) showed that 30 % of all the homicides were "femicides." Moreover, 57 % of these female victims were killed by an intimate (or ex-intimate) male sexual partner (Brookman 2005).

How can an evolutionary-informed violence prevention strategy help reduce domestic violence? The first step, as always, should be to try and understand what is going on.

Male "sexual jealousy" is the most frequently given explanation for intimate partner violence (Daly and Wilson 1988; Buss 2005) and so will only be briefly mentioned here. For example, research consistently points to male on female violence as being primarily motivated by "jealousy/control" on the part of the male. Put simply, men appear to use violence against women as a tactic to restrict their sexual behavior, primarily as means of enforcing sexual (i.e., reproductive) "exclusivity" (Daly and Wilson 1988). Fiona Brookman found that more than 80 % of femicides occurred where the female was either planning to leave her partner or where he perceived her at least to have been "unfaithful" with another sexual intimate, thereby compromising sexual exclusivity (Brookman 2005).

The foremost writer on this topic from an evolutionary perspective is Anne Campbell. Campbell makes the observation that in trying to explain the gender difference in crime, the male-centered approach has dominated evolutionary psychology, where there appears to be a broad consensus that the motivation to achieve status and "surplus resources" is more critical to male than female reproductive success (Campbell 2009). However, where a female-centered approach is taken, a different perspective on male on female violence is achieved, where her most important proximal goal is to stay alive for her present (and future) offspring (Campbell 2009).

Reproduction (and therefore sexual intercourse) poses more of a risk to female safety and survival than for males (Campbell 2009), a kind of male–female genetic arm race in which females must evolve defenses against the lethal potential of the sex drive of males. Intimate partner violence being one such defense, as when women kill, it is more often than not an intimate (or previously intimate) partner who is the victim (Daly and Wilson 1988).

One practical lesson which the writers take from the Campbell perspective is the significance of women's refusal to press charges or report violence committed against them by intimates. If their "wired-in" aim is survival with support (however flawed), this becomes more comprehensible. Perhaps the most common of police officer reactions to the victims of domestic violence who refuse to proceed down a criminal justice route is deep frustration, with a "why bother" bottom line. Understanding the survival perspective, alongside legal changes to maximize chances of conviction even when the victim has become unwilling to proceed, seem justified.

Epigenetics

Evolutionary history is written in our genome but does not determine our behavior. Surely all competent scholars now accept that both genetic (nature) and environmental (nurture) factors play crucial interacting roles in human development. With regard to crime and antisocial behavior, Moffitt and Caspi (2006) assert that familial inheritance is always both the result of genetic endowment and environment, but environments are made and are often correlated with the dispositions of those who inhabit them. Of particular current interest is the gene variant MOAO which lowers the expression of the enzyme monoamine oxidase A and which seems implicated in violence. This relationship is stronger among maltreated children (see Caspi et al. 2002). In brief, the effects of abuse are more pernicious in those with a particular genetic makeup. Rescue of all children from abuse is the only defensible child protection objective, but this is made more acute by the recognition that some of those children are genetically "primed" towards violence. Failure to rescue such children from abuse has a consequence in their and their victims' later misfortunes. Despite a sense of urgency for the work of the Moffitt-Caspi team to be incorporated into the child protection literature, as far as the writers have been able to determine after questioning relevant domain experts and practitioners, the implications of the Moffitt-Caspi work has not yet been translated into practice. So what are the implications for child protection? We may discard the notion of being indifferent to the parental practices imposed on those children whose genotypes afford them some protection against the acquisition of violent personalities! Rather it places an extra premium on ensuring as far as possible the quality of child care generally. Not to do so is effectively to collude in allowing preventable harm, which compounds the effects of the genetic lottery itself. A parallel may perhaps be drawn with phenylketonuria (PKU), where screening on neonates allows management and avoidance of the progressive mental impairment which otherwise ensues.

It has been speculated that the mechanism underlying the MAOA-abuse interaction may be epigenetic in nature. Epigenetics is concerned with the role that environments, including intrauterine environments, play in gene expression (see Francis 2011; Wortley 2011). This, both in the sense of responsivity to the cues which make primary crime reduction effective and in the particular sense of empathy (or its lack), will be a crucial point of departure for research which seeks to link applied criminology and evolution.

What has epigenetics got to do with evolution? The background to this question lies in very recent advances in genetics and related disciplines whereby much of what was hitherto regarded as “junk” DNA (i.e., DNA which does not code for proteins) in fact consists of a huge array of switches regulating gene expression. These switches can be thrown in pregnancy to yield enduring characteristics of the fetus, as was vividly revealed by the research following the Dutch “hungry winter” famine of 1944, in which the phase of pregnancy during which women went without food had long-term effects on the resulting child’s personality (Francis 2011).

Evolution requires many generations to yield change. It would aid a fetus’ prospects to get some idea of what awaits outside the womb. Epigenetic changes allow the possibility of switching genes on or off depending upon the clues which the environment gives. This makes evolutionary sense for both in utero and childhood clues. In the Caspi-Moffitt research, parental aggression is an early indicator of how aggressive one needs to be to prosper in the adult world. This form of gene regulation seems to be primarily under matrilineal control and has likely evolved partly to coordinate in utero development with maternal resource availability. The defensible next step will be to reanalyze longitudinal studies of criminality (the Cambridge study now incorporates data from three generations) to test epigenetic hypotheses. The literature on this topic continues to expand rapidly.

Evolution Without Tears: Natural Selection as Analogy

Assuming the reader is wholly unpersuaded by everything written here so far, the writer’s remaining hope is that evolution as analogy may be seen as an unthreatening heuristic device. The approach of selecting among varying designs on the basis of performance is an engineering technique known as genetic programming, the title brilliantly obscuring from those who would otherwise reject the approach on religious grounds the fact that it is in essence a simulation of biological evolution used in product design. In any event, evolution as analogy requires a user only to consider that it represents a way that improvement could occur, not necessarily the way it did occur. In this way, the theological teeth are drawn!

Perhaps the earliest proponent of this way of using Darwinian theory in relation to crime was Paul Ekblom, psychologist and polymath. He wrote in 1999:

> “But natural evolution is not simply a matter of ‘medieval warfare’ with increasingly better-armoured prey slogging it out against equally-improving armour-piercing capability of carnivores. The less dramatic struggle between plants and grazers is equally important (and may be a better model for property crime). The even longer struggle between *pathogens and immune system* has resulted in dynamic and adaptive strategies on each side. This has culminated in such sophisticated attackers as the HIV or smallpox viruses. Smallpox has about a hundred genes that interact with human defence mechanisms. In fact it has evolved *counter-countermeasures* to cope for example with a ‘virus alert’ chemical produced by infected cells, whose function is to warn nearby *uninfected* cells to activate their defences against virus attack.” (p. 29)

Ekblom details the links between other evolutionary struggles and specific crime types (see Table 1 below). The coevolutionary analogy has more recently been taken up by Raphael Sagarin and Terence Taylor in their book *Natural Security: A Darwinian Approach to a Dangerous World* (Sagarin and Taylor 2008) and applied to risk assessment in general and the threat of terrorism in particular.

Conclusions

Reluctance to apply an evolutionary perspective to problems of crime and criminality may be attributed to fundamentalist religious beliefs, the ascription of eugenic horrors of the past to Darwinian theory, and the notion of biological determinism erroneously laid at Darwin’s door. E. O. Wilson (1978) infamously wrote “genes hold culture on a leash” (p. 172). While containing a grain of truth, it turns out that there are multiple leads, very long and very twisted (see Pagel 2012).

Evolutionary Perspectives on Crime Prevention, Table 1 Some other evolutionary struggles

Realm	Struggle	Description and possible crime equivalent
The natural world	*Prey versus predators*	(Confronters, trappers, dupers), mainly resembling crimes against the person – assault, robbery, homicide
	Plant versus herbivore	Grazing- taking stored energy and materials from plants, resembling theft
	Host versus parasite	Parasitism by insects, tapeworms etc – resembling theft
	Host immune system versus pathogen	Infection by bacteria etc resembling robbery (overcoming host's defences)
	Host immune system versus viral pathogen	Infection by viruses, resembling fraud or embezzlement in misappropriation of resources for and control of production; computer hacking (breaking access and control codes), and computer viruses themselves
	Natural "*theft or robbery*"	Within or between species – eg birds taking each others' nest sticks, or robbing others' food in mid-air attacks
	Natural "*fraud*"	Birds taking nectar by pecking a hole in the side of the flower to avoid the effort required to pass on pollen, orchids pretending to be female wasps and cheating males of reproductive effort and opportunity
	Natural "*threat, assault*" *or killing*	Conflict over territory, mates, food
Humanity versus nature	*Disease control*	Hygiene, public health, inoculation, vaccination, antibiotics – resembling prevention of theft/robbery
	Pest control	Rats etc spoiling/stealing crops or livestock, spreading human diseases, acting offensively – resembling prevention of theft/damage. Disorder/ nuisance
The human world	*Military arms races and* (*counter*) *terrorism*	Arms versus armour, missiles versus electronic countermeasures, manoeuvrability – resembling assault and prevention of assault, homicide, disorder, theft of property, coercion, control of production
	War-games	Military training; evolution of new strategies in chess; computer-games of tactics and strategy
	Economic warfare	Outgrowing the enemy or disrupting their economy (shading into real crimes like forgery or extortion)
	Hacking	Shading into serious computer crime
	Espionage	Military/industrial, to steal information on resources, products, tactics and strategy, shading into theft of information/obtaining it in preparation for crime

There are enough results of interest produced by researchers operating within a Darwinian framework to offer recommendations for crime reduction policy, alongside social policy of other kinds. It turns out that these recommendations are by and large recognizably liberal. They include the need to nourish pregnant women well, to seek to ensure that adolescents have a realistically long life expectancy and some anticipation of later success in order to minimize early pregnancies and profligate and coercive sex. It emphasizes the absolute need to eliminate child abuse, given the genetic priming for violence of some so abused. It argues for recognition of the disincentive to report domestic abuse, given the preeminent family survival agenda of abused women. In the only clear enforcement item on the agenda, it argues for the particular monitoring of stepparents given their markedly greater prevalence of abuse against children within the home, always mindful of the fact that most stepparents behave well towards the children for whom they care. These recommendations represent the low-hanging fruit of the evolutionary perspective applied to crime, but given the marginality of such research within the discipline to date, it is surprising there is so much already. The wider question of whether the evolutionary perspective requires the abandonment of the discipline of criminology in favor of a perspective which encompasses the whole of the prosocial-antisocial continuum has been dodged here, but is probably crucial.

Evolutionary Theories of Criminal Behaviors

Danielle Boisvert
College of Criminal Justice, Sam Houston State University, Huntsville, TX, USA

Overview

Rooted in Darwin's theory of natural selection, evolutionary explanations of antisocial and criminal behaviors have been studied extensively across various disciplines. This entry will focus specifically on the evolution of rape, spousal abuse, child abuse, and neglect, as well as homicide. In addition, a review of the most prominent evolutionary theories of antisocial and criminal behaviors, more broadly, is provided. These include cheater theory, r/K theory, conditional adaptation theory, alternative adaptation theory, staying alive hypothesis, and evolutionary neuroandrogenic theory. A review of this literature suggests that antisocial and criminal behaviors evolved as a way for our ancestors to overcome obstacles related to survival and/or reproduction. Incorporating evolutionary theories of antisocial behavior into mainstream criminological research has the potential to greatly enhance our current understanding of criminal behaviors.

Introduction

When studying criminal behavior from an evolutionary perspective, it is assumed that the behaviors considered "antisocial" today must have evolved because they had, at one point in time, served to increase our ancestors' likelihood of survival and chances of reproducing. Based on Darwin's (1859) theory of natural selection, certain selection pressures can lead to adaptations (physical, psychological, and behavioral) as a way to address a specific problem associated with survival and reproduction. Individuals who engaged in these adaptive behaviors were more likely to pass on their genes to future generations. Evolutionary theories of criminal behavior assume that the adaptive benefits to engaging in what we call "antisocial behavior" must have at some point outweighed the costs, at least in certain contexts and for certain people. While adaptations may have served to increase our ancestors' chances of survival and reproduction, not all adaptive behaviors from the past remain beneficial in today's environment. For example, the evolution of a "sweet tooth" may have been adaptive in ancestral environments as a way to recognize food that had valuable nutrients; today, however, this adaptation is associated with obesity, which is a leading cause of death (Wright 1994). Furthermore, adaptive behaviors from the past, such as aggressive/victimizing behaviors, may have increased an individual's chances of survival and procreation but are considered criminal and immoral by today's standards.

Several evolutionary theories have been developed to explain specific types of criminal behaviors, such as rape, spousal abuse, child abuse/neglect, and homicide. Other evolutionary theories have been proposed to explain criminal and antisocial behaviors more generally. These theories include cheater theory, r/K theory, conditional adaptation theory, alternative adaptation theory, staying alive hypothesis, and evolutionary neuroandrogenic theory. A review of these evolutionary theories and perspectives is provided next.

Rape

Perhaps one of the most controversial topics in evolutionary explanations of criminal behavior is rape. Research has clearly shown that males are more likely to be the perpetrator in rape cases compared to females. Similarly, rape (i.e., forced copulation) is not a human-specific behavior; it occurs in many other species, especially in those who are genetically similar to humans, such as orangutans (Ellis 1986). In 2000, Thornhill and Palmer presented an evolutionary explanation of rape in their book *A Natural History of Rape: Biological Bases of Sexual Coercion*. This book has received both positive and negative attention in the academic community. In discussing the ways rape could have evolved, Thornhill and Palmer present two distinct hypotheses: a rape-specific hypothesis and a by-product hypothesis.

First, the authors propose a rape-specific hypothesis, which states that males have evolved, through the process of natural selection, rape-specific behaviors. From this perspective, rape evolved in humans due to the tension between men and women in terms of their reproductive strategies. Specifically, males are able to reproduce with minimal to no parental investment and there is little restriction in the number of offspring they can produce. As a result, the male reproductive strategy is ultimately based on the number of fertile women he can mate with. Females, on the other hand, can only produce a limited number of offspring in their lifetime. Thus, their reproductive strategy is to choose mates carefully and to avoid mating with males who would provide little to no parental investment. Therefore, females are more selective in their mate choices (Thornhill and Palmer 2000).

Due to these sex differences in reproductive strategies, in some contexts, rape may have evolved as a conditional mating strategy for some men. For example, in the past, disadvantaged men who were unable to secure a voluntary mate, men who perceived a low cost of consequences (e.g., a woman who is alone and unprotected), and/or men who suspected that their partner was unfaithful may have resorted to forceful copulation (McKibbin et al. 2008). Overall, it is suggested that some males rape to increase their likelihood of reproductive success. As a result, their genes will be more represented in future generations compared to males who do not use force. If genes that promote rape have evolved to increase reproductive success, severe punishments would be needed to prevent their proliferation in future generations (Ellis 1998).

Next, Thornhill and Palmer (2000) propose a by-product hypothesis, which states that rape is a consequence of some other male sexual adaptations that served some other purpose. Specifically, a male's strong sex drive and desire to mate with several females may have accidentally led to rape. In other words, rape did not evolve as a specific reproductive strategy, but rather as a side effect of some other sexual adaptation (e.g., promiscuity, strong sex drive) that served to increase the chances of reproducing.

Although both hypotheses differ with regard to how/why rape evolved in humans, they both suggest that rapists are motivated by innate sexual desires. This perspective contrasts the feminist's view on rape as being motivated by a man's urge to control and dominate a woman and not by his need for sexual gratification (e.g., Brownmiller 1975). There are many critiques of Thornhill and Palmers's (2000) hypotheses, interpretations, and suggestions concerning the evolution of rape (see Coyne and Berry 2000; Lloyd 2001).

Spousal Abuse

Spousal abuse/assault can be viewed from an evolutionary perspective as an evolved form of aggressive behavior. While the research has predominantly focused on male abusers, females also commit a nontrivial amount of abuse toward their significant others (Dutton 2007). It has been suggested that spousal abuse/assault by women may have evolved as a way to discourage abandonment from a mate in an effort to retain his involvement in raising their offspring (Ellis 1998).

For men, one of the main motivators underlying spousal abuse and assault is sexual jealousy either as a result of infidelity or suspicions of infidelity (Daly et al. 1982). It has been suggested that there are at least two conditions under which it may have been adaptive, in ancestral environments, for men to abuse/kill their wives. These include cuckoldry as well as the possibility of losing a fertile partner to another man (Buss 2004). Cuckoldry refers to the parental investment in another person's offspring (Wilson and Daly 1993). Males are more likely than females to be cuckolded because they are not the ones who carry the child to term. Put differently, men are more likely to be cuckolded because, while a woman is always certain she is the parent, a man cannot be as sure. There are many consequences associated with being cuckolded including the following: (1) wasted time, effort, and resources in rearing another man's child; (2) the loss of time, effort, and resources invested in originally securing his sexual partner; (3) the loss of his partner's investment in any future children they could have produced together; as well as (4) reputational damage if others find out that he was cuckolded (Buss 2004).

It is clearly disadvantageous for a male to be parentally invested in an unrelated offspring as their own genes will not be passed on to future generations as a result of that investment. Due to uncertainty in paternity, males have evolved feelings of sexual jealousy and may take extreme measures to ensure that their mate is not sexually involved with other males (Wilson and Daly 1993). These extreme measures include physical abuse and violence as a way to either control a woman's sexual behavior, to intimidate a woman from sexually straying from the relationship or as a way to induce stress. Research has shown that stress can impact a woman's reproductive ability by lowering her chances of becoming pregnant as well as increasing her chances of miscarrying if pregnant. Thus, from an evolutionary perspective, it has been suggested that younger women with higher reproductive value are at greatest risk of domestic violence by males who are sexually jealous (Wilson and Daly 1993).

Child Abuse/Neglect

It would seem counterproductive, from an evolutionary perspective, to harm one's own child. There are, however, at least four conditions under which parental abuse, parental neglect, and/or even murdering one's own child could have evolved. First, if parents already have children who require care and resources, the addition of any new child will increase the likelihood of abuse and neglect as there is not enough time and/or resources to successfully care for multiple children. Therefore, if child abuse/neglect is an evolved adaptation, it would occur most often in larger families, with multiple births, and with few resources (Daly and Wilson 1988a; Ellis and Walsh 1997). These factors have in fact been found to be associated with child abuse/neglect. A second condition that could lead to child abuse/neglect is when one parent is not investing any time/resources into the care of their child. The absence of one parent can increase the likelihood that the remaining parent would also provide less resources and care toward their child (Daly and Wilson 1988a; Ellis and Walsh 1997). Research has shown that abuse is more likely to occur in single-parent households. Third, parents may be more likely to abuse/neglect their nonbiologically related children (e.g., stepchildren) compared to their biological children. This is because harming one's own biological child has greater repercussions by decreasing the likelihood of passing on familial genes to future generations (Daly and Wilson 1988a; Ellis and Walsh 1997). It is argued, however, that parents may also abuse/neglect their biological offspring if that child is perceived to be less likely to reproduce in the future, such as children who are ill or deformed (Daly and Wilson 1988a; Ellis and Walsh 1997). Overall, these four conditions are closely tied to circumstances where investing any time/effort into raising the offspring interferes with one's own potential of passing on genes to future generations.

Homicide

There are differing perspectives with regard to the evolution of homicide. Two in particular, set forth by Daly and Wilson (1988b) and Buss and Duntley (2002), have received quite a bit of attention in the evolutionary literature. First, Daly and Wilson (1988b) argue that homicide itself is not an adaptation, rather it is an unintended consequence, often referred to as an "overactive mistake," a "slipup," or a "dysfunctional by-product" of mechanisms evolved for some other nonlethal purpose (e.g., violence). For example, if a man kills his wife because of sexual jealousy, it is not because of an evolved psychological mechanism for murder, but rather it is a by-product of an evolved mechanism for violence. In this scenario, the man is intending to control his wife's sexual behavior through violence but it simply goes too far and results in death. This viewpoint, however, does not explain premeditated homicides. This led Buss and Duntley (2002) to propose that males have in fact evolved psychological mechanisms specifically designed to kill under certain circumstances.

Unlike Daly and Wilson (1988b) who suggest that homicide is a by-product of some other evolved response, Buss and Duntley (2002) state that homicide itself is an evolved response to solving adaptive problems and that the mechanisms underlying homicide are context specific. Their homicide adaptation/design theory acknowledges that, for the most part, the costs associated with killing another human far outweigh the benefits (Buss and Duntley 2002). However, they also recognize that in certain contexts, it may have been beneficial to kill another human. These circumstances are closely tied to situations where the killer may be (1) directly eliminating a competitor, which would result in greater reproductive advantages for the killer; (2) gaining access to the rival's material resources and fertile mates; (3) protecting not only himself but also his mates, offspring, relatives, and allies from being exploited, injured, raped, or killed by a rival; (4) gaining social status and the respect of others, thereby decreasing the chances of being exploited, injured, raped, or killed by others in the future; (5) protecting his territory, resources, shelter, and food from rivals; (6) eliminating the possibility of expending resources on individuals who are not genetically related, such as stepchildren; and/or (7) eliminating the possibility of expending resources on genetically related individuals who are incapable of themselves reproducing in the future, such as children who are ill or deformed. As such, under some circumstances, psychological adaptations for homicide may have evolved as the best strategy to solve adaptive problems (Buss and Duntley 2002).

Criminal Behavior in General

r/K Theory

MacArthur's (1962) r/K selection theory views reproductive strategies of organisms on a continuum with r- (growth rate) and K- (caring capacity) selection located at each end of the spectrum. First, those who reproduce in large quantities and provide little to no resources to raise their offspring are said to be r-strategists. These types of organisms can succeed in environments in which resources are plentiful and competition is low. On the other hand, organisms that follow a K-strategy will reproduce only a few times and will devote a great deal of time, effort, and resources into raising their offspring. This strategy is most often adopted in environments in which obtaining resources is competitive, and it serves to increase the likelihood that the few offspring will live on to reproduce (MacArthur 1962). In general, humans follow a K-reproductive strategy. However, there is a great deal of variation with regard to reproductive strategies within humans, with males being more r-selected than females due to their greater capacity to reproduce. There is also variation in reproductive strategies within individuals (Jolly 1985). Specifically, individuals tend to follow more of an r-strategy when younger but will eventually adopt a K-strategy as they age, especially if they have already produced children. This is because it is more beneficial to the parent, at a later point in their life, to devote their energy and resources to already existing children as opposed to putting effort toward gaining new mates in which to create new offspring with (Ellis 1987).

The r/K theory as it applies to criminal behavior suggests that criminals are more r-strategists compared to noncriminals who tend to follow a K-strategy. Ellis (1987) proposed that an r-selection approach to reproduction is highly intertwined with factors that are related to criminal behavior. Specifically, characteristics used to identify r-strategists are often the same ones associated with individuals who commit crimes against others. These factors include (1) large numbers of siblings within the home, (2) single-parent homes, (3) demographics (e.g., gender, age, and race), (4) prematurity and low birth weight, (5) short-life expectancy, (6) lower parental investment in child (i.e., child abuse and neglect), (7) early onset of sexual experiences, and (8) greater promiscuity. It is evident that these correlates of criminal behavior overlap with the description of an r-strategy approach to reproduction (Ellis 1987). r/K theory can be applied to explain criminal behavior in general as well as specific types of crimes, such as rape. For example, in the case of rape, an r-strategist may go to the extreme to achieve his goal of reproducing in large quantities with no or little investment in rearing offspring.

Cheater Theory

Cheater theory views criminal behavior as an evolved male strategy that is due to the distinct reproductive strategies employed by males and females (Machalek and Cohen 1991). For example, the mating strategy for males is based on the number of fertile females available to reproduce with. The more females they can have sex with, the greater their reproductive success. On the other hand, the number of times that females can produce offspring is limited by pregnancy, lactation, and menopause. This limitation makes females more selective when deciding on a sexual partner compared to males (Buss 1994; Wright 1994).

It is more beneficial for females to procreate with males who will provide resources and assistance in raising their offspring. However, males vary in terms of the amount of parental investment they will provide in raising their offspring, and their reproductive strategies have been termed "cads" and "dads" (Cashdan 1993). Cads are males who trick/force females to have sex with them and then leave to pursue additional women. This strategy is often used by adolescent males when pursuing a sexual partner and involves various techniques, such as (1) proclaiming love and commitment to a woman yet leaving once impregnated, (2) threatening and/or injuring rival males, (3) overstating their ability to provide resources by stealing and cheating others, and/or (4) resorting to the use of coercion/force to have sex. Cads tend to be self-gratifying and pleasure-seeking – characteristics that tend to overlap with antisocial individuals. The reproductive strategy used by cads will continue for males who are lacking in emotions (e.g., psychopaths) but for the most part will be replaced by strategies used by dads (Lykken 1995). Dads are the alternative male reproductive strategy to cads; these men help to raise their young by providing a great deal of parental involvement. This strategy is eventually adopted by most males in adulthood and is facilitated by social emotions, such as love (Walsh 1995). Overall, traits used to describe individuals who follow a cad strategy are similar to the traits used to describe antisocial individuals.

Conditional Adaptation Theory

While cheater theory focuses primarily on the reproductive strategies of males (i.e., cads and dads), conditional adaptation theory discusses female reproductive strategies as well (Walsh 2006). Specifically, conditional adaptation theory states that reproductive strategies vary based on environmental factors, such as the degree of paternal bonding that occurs early in the life course. The absence of a father in a child's life can have a profound effect on the reproductive strategy later employed by his offspring, particularly female offspring (Draper and Harpending 1982). For example, in unstable, resource-scarce environments where the quality of relationships is low and/or unpredictable, individuals are more likely to adopt an active and unrestricted reproductive strategy (Walsh 2006). For females, in particular, when early experiences with men are unstable (e.g., lack of attachment with father), she will be more likely to adopt a promiscuous sexual strategy. This is because her experiences with men tell her that there is a low probability that a man will invest much time in helping to raise their children (Hrdy 1999). Thus, in order to obtain short-term benefits from several men, a female is better off adhering to an unrestricted sexual strategy. On the other hand, individuals who have secure and stable relationships are more likely to adopt a restricted mating strategy and mate selectively. For young females, a strong relationship with their father shapes their perceptions of males as devoted caregivers. As a result, it is in the female's best interest to portray fidelity and to secure a sexual partner who is devoted to long-term care of her offspring (Walsh 2006). As it relates to criminal behavior, conditional adaptation theory proposes that when resources/attachments are unstable and low, there will be an increased likelihood that individuals will adopt a risky lifestyle.

Alternative Adaptation Theory

Alternative adaptation theory differs from conditional adaptation theory in that it incorporates individual genetic differences as a way to explain why some people choose one mating strategy over another (Rowe 1996; Walsh 2006). Similar to r/K theory, alternative adaptation theory views reproductive strategies on a continuum with one extreme representing mating efforts and the other extreme reflecting parenting effort. Mating effort is defined as the energy, time, and resources invested in the acquisition of a sexual partner (e.g., searching, courting, and procreating). Parenting effort, on the other hand, is defined as the time, energy, and resources invested in one's mate and offspring (e.g., caring, providing, protecting). Genetics, rather than the environment, will dictate where an individual falls along this continuum (Rowe 1996; Walsh 2006). Specifically, genetic differences that lead to increased mating efforts result in deception and criminality in the pursuit of mating opportunities. In other words, characteristics such as dishonesty, risk-taking, and self-gratification may help to secure sexual partners by putting effort into mating, and they are also useful in conducting criminal acts (Walsh 2006). On the other hand, traits such as compassion, selflessness, and caring are often found in individuals who devote much of their efforts toward parenting and who lead a prosocial lifestyle.

Alternative adaptation theory also incorporates the element of intelligence as an important factor in determining a person's reproductive strategy (Walsh 2006). Individuals who are more intelligent will be more likely to invest their time and effort into raising their children. These individuals are also better equipped at delaying gratification and living a prosocial life. Conversely, individuals who are less intelligent are more likely to devote their time and energy toward obtaining sexual partners. These individuals seek immediate gratification and give little to no thought to the consequences of their actions (Walsh 2006). Overall, from an evolutionary perspective, the genetically influenced traits used to characterize an individual who tends toward the mating end of the continuum are the same traits used to explain antisocial individuals.

Campbell's Staying Alive Theory

Campbell's (1999) staying alive theory focuses primarily on female criminal behaviors, or more accurately attempts to explain why women do not engage in as much criminal behavior as men do. Campbell (1999) proposed that females have evolved to avoid engaging in risky types of activities because their survival is critical to the survival of their offspring. In other words, greater female investment in their offspring leads them to avoid risky situations and therefore less likely to engage in criminal activities. By ensuring their own survival, women are increasing the likelihood that their children will survive and that their genes will be passed on to future generations. As such, a woman's reproductive success is dependent on her ability to "stay alive" by avoiding dangerous situations. The mechanism by which females have evolved to avoid risky situations is said to be through fearfulness (Campbell 1999). Specifically, even though women need resources to support their reproductive efforts (i.e., ovulation, pregnancy, lactation) and to provide for their developing child, fear counteracts the pressure on women to physically compete for resources themselves as the risks of injury/death are too high and costly. As an alternative, women tend to compete with other women to secure a partner who can provide for them and their children. Their success in securing a partner hinges primarily on the male's perception of her fidelity, which will impact his certainty in paternity and subsequently the degree to which he will invest in his offspring (Campbell et al. 2001). Overall, Campbell's staying alive theory hypothesizes that sex differences in criminal involvement are due to sex differences in fear threshold, which may have evolved due to the selected pressures on women to avoid risky situations in order to increase their chances of survival and the likelihood that their offspring will survive as well.

Evolutionary Neuroandrogenic Theory

Ellis (2000, 2005) developed his evolutionary neuroandrogenic theory (ENA) in order to explain the higher prevalence of competitive/victimizing behaviors displayed by men compared to women. While the evolutionary component of his theory seeks to explain why males tend to commit crimes at higher rates than females, the androgenic component focuses on how male sex hormones affect the male's brain to promote criminal behaviors, especially during the teenage years.

The first component of ENA theory involves the evolutionary process. Based on Darwin's theory of natural selection, biological and physical characteristics that increase the likelihood of survival also tend to increase the likelihood of reproducing (Darwin 1859). These characteristics are in turn passed on to future generations. For example, the strongest and most competitive organisms of a given species are more likely to survive and thus produce offspring, while the weaker and more timid organisms are more likely to die before they have the chance to procreate. Similar to natural selection, sexual selection also promotes the transmission of certain characteristics. For example, competitiveness in males can be considered a desired and sought after characteristic for females who are looking to reproduce. Therefore, males who can demonstrate this desired trait would be more attractive mating partners. This process is often referred to as "female choice."

Female mating preferences can explain, in part, why males typically engage in higher rates of aggressive behaviors. Specifically, women are more likely to mate with males who are reliable providers of necessary resources. In other words, a female is more likely to choose a sexual partner based on his ability to compete for resources and provide for both her and her children. In turn, this allows the woman to focus on caring for and raising children as opposed to spending her energy on obtaining resources. Therefore, the female choice phenomenon has the effect of encouraging competitive and victimizing behaviors in males. For example, males will aggressively compete with other males, even to the extent of victimization, in order to procure resources and increase their chances of being chosen by a female as a sexual partner (Ellis 2000, 2005). Since the majority of females prefer competitive males, genes which promote competitive/victimizing behaviors are more likely to be passed on from generation to generation. This theoretical perspective helps to explain why males are, in general, more prone to committing aggressive crimes compared to females.

The second component of ENA theory involves male sex hormones (i.e., androgens), particularly testosterone. Sex differences in testosterone levels may help to explain why males are more likely to engage in aggressive and victimizing behaviors compared to females (Ellis 2000, 2005). This component of ENA theory explains how increased levels of testosterone affect brain functioning in three ways: (1) suboptimal arousal, (2) susceptibility to seizures, and (3) rightward shift (Ellis 2000, 2005). First, exposing the brain to testosterone, both at the perinatal and pubertal stages, results in decreased brain sensitivity to incoming environmental stimuli. This reduction in sensitivity, often referred to as suboptimal arousal, increases the likelihood that an individual will exhibit criminal forms of competitive/victimizing behavior. Second, high levels of testosterone in the brain increase the susceptibility of the limbic system to experience seizures. Minor forms of seizures, known as episodic dyscontrol and limbic psychotic trigger action, occur in areas of the brain that regulate emotions, which can result in impulsive bursts of rage, especially when an individual is exposed to stressful events (Ellis 2000, 2005). Thus, increased levels of testosterone in the brain increases the brain's susceptibility to seizures, thereby resulting in aggressive outbursts. Finally, increased levels of testosterone shifts the brain's functioning away from the left hemisphere of the brain toward the right hemisphere (Ellis 2000). This results in individuals having better spatial reasoning abilities while simultaneously lacking in language-based reasoning, thereby increasing the probability of engaging in antisocial forms of competitive/victimizing behaviors.

While these three biological factors operate to promote competitive/victimizing behaviors, two neurological factors function to inhibit criminal forms of competitive/victimizing behaviors. These two factors include an individual's ability to learn (i.e., intelligence) as well as their ability to plan and foresee consequences (i.e., executive functioning). Specifically, greater mental capabilities and effective executive functioning capabilities can result in an increased likelihood of exhibiting more sophisticated and socially acceptable forms of competitive behaviors (e.g., becoming a competitive businessman)

(Ellis 2000, 2005). Conversely, males are more likely to engage in criminal activities when they fail, as the result of insensitivity to punishment and low IQ, to learn competitive strategies that avoid retaliation. Overall, ENA theory states that biological factors have evolved to promote competitive behaviors in males and, in turn, competitive behaviors have become pronounced within the human species because women prefer mating with men who are secure providers. The theory further assumes that most forms of criminality are "crude" expressions of male competitiveness.

Conclusion

Evolutionary theories have been used to explain a wide range of behaviors deemed antisocial by today's standards. A review of these theories and perspectives suggests that antisocial/criminal behaviors evolved as a way for our ancestors to overcome obstacles related to survival and/or reproduction. Whether the criminal behavior itself (e.g., rape, murder) is the adaptation or whether it is a by-product of another adaptation remains debatable. In a way, antisocial/criminal behaviors are said to be maintained over time through the process of natural and/or sexual selection. Future research should continue to investigate the evolved psychological mechanisms that motivate antisocial/criminal behavior. It is only through rigorous empirical studies that incorporate both ultimate and proximate explanations of antisocial/criminal behavior will we gain a greater understanding of these types of behaviors. In turn, a deeper understanding of the causes of antisocial/criminal behaviors can serve to better inform intervention and prevention efforts.

Impartiality and fairness in judging; Job of a judge; Judicial temperament; Key skills involved in judging

Overview

The role of courts has evolved over time and the role of judges has adapted to match the changing role of courts. This entry discusses the role of the judge as originally conceived in the context of the adversary system and how that role has adapted to meet the needs of high-volume and problem-solving courts. The entry ends with a discussion of the importance of procedural fairness and how it comports with the three roles of a judge discussed here: the umpire, the adjudicator, and the problem solver.

Fundamental Issues

> . . .the way in which a judge conceives his judicial role is the most significant single factor in the whole decisional process. Kenneth Dolbeare

The role of courts has evolved over time and the role of judges has adapted to match the changing role of courts. Courts in the Common Law countries began using the adversary process, which shaped many of our expectations of what courts should be and therefore what judges should do. The adversary process with its emphasis on public trial is too slow and costly to be used to resolve the vast volume of ordinary cases, but it is still used for the “important” large-stakes cases as well as the “notorious” cases – mostly criminal cases with a large enough public interest to be covered in the news and perhaps televised. As case volume increased, a more streamlined and disposition-oriented process supplanted the adversary process for the ordinary cases. The role of the judge for these cases then becomes more of a decision-maker than umpire. The third stage of the evolution began relatively recently with the advent of the more treatment-oriented problem-solving court process and the consequent more active involvement of the judge as treatment team leader.

Henderson et al. (1984) identified three separate adjudication processes – procedural, decisional, and diagnostic – and noted that *all* three adjudicatory processes coexist and are used by contemporary courts in varying combinations. Flango and Clarke (2011) go a step further and suggest that court structures be modified to be more congruent with adjudication processes in use. It may be that the creation of different types of courts was an early attempt to separate the three functions – courts of general jurisdiction using the adversary process to resolve more serious cases, such as felonies; courts of limited jurisdiction using a more bureaucratic process to resolve the large volume of less serious cases, such as misdemeanors; and courts of special jurisdiction, such as juvenile courts, using a problem-solving adjudicatory process. In any event, different adjudication processes require different judicial attributes and skills – a confusion that becomes manifest when litigants come to court expecting an adversary process with an aloof judge and find themselves in a problem-solving court with an actively engaged judge.

This entry begins with the "classic" conception of a court – the neutral, aloof "umpire" judge using an adversary process to resolve cases – and then proceeds to elaborate on the temperament and skills required of judges using the more disposition-oriented and problem-solving court processes. This entry concludes by asking whether the new emphasis on procedural fairness can bridge the gap among the three roles.

The Umpire

The classic image of judge as neutral arbiter has its roots in the adversary system. The very conception of courts, and therefore the expectations we have of them, is derived from the adversary process, more particularly the criminal trial. Is the following image not what comes to mind when the word "court" is mentioned?

> There is a definite image about every aspect of the trial even what the courtroom is supposed to be like; the jury sits in its box, the judge sits on his or her high bench in a robe with an American flag in the background, the witnesses come in and sit on the witness chair; they raise their right hands and swear; the lawyers and the defendant sit at tables facing the judge. The trial begins with elaborate voir dire – the meticulous process of selecting a jury. The lawyers battle and squabble, trying to stack the jury with people they feel will vote the way they want. The trial itself gets going with opening arguments and statements from the lawyers. The trial itself is long, tense, and full of excitement. The lawyers joust with each other. There is clever and dramatic cross-examination. Lawyers jump up and cry, "I object";. . . . . .They end the trial with impassioned arguments. Then the judge instructs the jury, the jury retires to a locked room, and a spine-tingling period of waiting begins. Finally, the door opens, a hush comes over the crowd in the courtroom, and the jury comes in and announces its verdict. (Friedman 2004, p. 690)

This expectation of what a court is like, and what the role of the judge is, is derived much more from motion pictures and television programs than from court observations. These types of full-blown trials with all the trimmings do exist today, but for a very small percentage of cases. Yet this image provides the standard against which all courts are judged.

The adversary process assumes that there are two sides to the case – perhaps rooted in the medieval process of trial by combat (Strick 1977, p. 21). The core of the adversary system is the *form* of participation accorded to the parties. Lon Fuller (1960, p. 2) defines these as the "institutionally protected opportunity to present proofs and arguments for a decision in his favor." The government in a criminal case asserts a claim which the defendant denies. Each side has the opportunity to present arguments in his or her favor. Logically, the requirement for the participant to be able to provide proofs and arguments requires a neutral arbiter before whom to present the arguments and a set of standards or laws so that the litigants know the basis upon which the decision will be made.

Accordingly, the role of the judge in the adversary process is to preside over the proceedings and maintain order. During a trial, the judge rules on whether any of the evidence the parties want to use is illegal or improper. If the trial is before a jury, the judge gives instructions about the law that applies to the case; if the trial is before the court, the judge determines the facts and decides the case. After the trial, bench, or jury, the judge metes out the sentence to the convicted. Note also the role of the judge in this idealized conception – a very passive umpire enforcing the procedural rules of the game. In the language of modern confirmation hearing, the judge role is a passive referee who just “calls balls and strikes” (Roberts 2005).

Adversary proceedings are especially important when contending parties are unequal in power, e.g., the government versus an individual. The need for an impartial forum to equalize the contending parties is paramount. Lieberman (1981, p. 169) notes that “for certain types of problems, an adversary system is inescapable” and for a society with a commitment to political freedom,

> . . . putting the state to an extreme burden of proof and by guaranteeing defendants access to fiercely independent lawyers, we can in general prevent the state from imprisoning those whom it distrusts or fears.

For courts to be impartial, judges must be free to decide cases based upon the laws and facts of the case uninfluenced by *either external pressures or internal preferences*. Impartiality is impossible unless judges are independent – free from the external pressures of threats, intimidation, or fears of sanctions based upon the content of their decisions. In some places in the world, threats to impartiality can range from direct and drastic, such as threats on a judge’s life, to more subtle pressures, such as denial of salary increases, promotions, and staff or equipment needed to do the job.

Impartiality is also threatened to the extent that judges permit their personal conceptions of justice to enter into the decision-making equation rather than setting aside personal predispositions in deference to law as written. One object of law school is to socialize potential judges to defer to law rather than relying on their own conceptions of justice. This “precedent orientation” taught in law school makes judges feel bound by previous decisions made by other judges (Becker 1964). The role of the judge is to apply the law to different sets of facts raised in various cases and to rule accordingly. This “law applier” role is important to litigants because following precedent leads to consistency in decision-making, and therefore makes outcomes more predictable. About half of the judges responding to various questionnaires by different researchers consider themselves law appliers, implying that most cases can be decided by analogy to cases decided earlier (Flango et al. 1975, p. 285).

One way to safeguard judicial impartiality is the practice of rotating judges among judicial assignments – even among civil, criminal, and family law cases.

The Adjudicator

Role orientations are beliefs about “the kind of behavior proper for a judge” (Gibson 1978, p. 918). The role of the judge as umpire, primarily presiding over trials, gives way to reality for observers more familiar with the actual court processes. The criminal justice system would simply break down if most cases went to trial. According to the National Center for State Courts’ Court Statistics Project, there were over 21 (21.3) million criminal cases filed in state courts in 2008, and that is an undercount because of underreporting from some states. One look at these numbers confirms that a full-blown trial is not now, nor ever has been, a practical way to resolve most criminal cases – even most felonies. In 1976, only 7.6 % of criminal cases were resolved by trial, and that proportion has been declining steadily so that by 2008 that percentage dropped to 2 %. Trials are the last resort – the ultimate proceeding used when all other efforts at reaching an agreement have failed.

In most criminal cases, the prosecutor is the key de facto decision-maker because of the important role in screening cases in effect determines the resolution of most criminal cases. Prosecutors decide *whether* charges will be brought or dismissed, *which* charges will be brought, *how many* counts of each charge will be brought, and what will be offered in return for a guilty plea (Eisenstein 1973, p. 103; Blumberg 1967, p. 58). Plea agreements are how most cases are resolved now and have been since they replaced jury trials in the middle of the nineteenth century (Moley 1929, Chap. 7; Friedman 1993, p. 253; Fisher 2003). Before plea bargaining, most criminal cases were handled in summary fashion. Trials then did not resemble the full adversary process we expect today but were more “quick, slapdash” proceedings, where 12 people, impaneled without voir dire, sat for a series of "trials" (Friedman 2004, p. 692). Most defendants were not represented by counsel, there was little or no cross-examination and few objections, and the jury did not spend much time in deliberation.

The role of the judge in most criminal cases then is one of ratifying agreements reached between prosecutor and defense counsel. This is not a trivial function because it does provide a safeguard that the plea agreement was reached using a fair process, i.e., without coercion of the defendant.

If these aspects of a bureaucracy are true for state courts of general jurisdiction, they are even more applicable to courts of limited jurisdiction which resolve less serious, but more numerous, criminal offenses. Misdemeanor cases are now and have always been handled quickly and summarily without much technicality (Friedman 2004, p. 693). Approximately 80 % of criminal cases are misdemeanors, and most of them (more than 70 %) are handled by municipal judges, justices of the peace, or magistrates in courts of limited jurisdiction. (Even that 70 % is an underestimate because ten states plus the District of Columbia and Puerto Rico are unified and thus do not distinguish courts of general jurisdiction from courts of limited jurisdiction. Unified courts do, however, have a separate category of judge, e.g., associate judges, to handle misdemeanors and traffic cases.) In the sense that these lower criminal courts hear the bulk of criminal cases, including disorderly conduct, drunkenness, prostitution, petty theft, and simple assault cases, they *are* the courts with the most contact with offenders, and it is in these courts that the stereotype of "assembly line" justice was created (Feeley 1979). One Albany lawyer (Redlich 2007) describes in his blog the situation in the lower courts of New York:

> The biggest problem with our court system is the volume of cases. The volume is so large that the courts have to rely on assembly line justice. It really is an assembly line. The police officer prepares the initial papers and files them with the clerk. The clerk gives the papers to the prosecutor who reviews them and discusses the case with the lawyer or the pro-se defendant. The papers then go back to the clerk, who then hands them to the judge. The judge calls the case. There's a brief discussion at the bench. Then the papers go back to the clerk, who then processes the result (fine notice, schedule next date, etc.).
>
> Think about this: If a court has 100 cases on for a particular session (a typical number for courts like Colonie, Guilderland, Albany, etc), and each case takes 15 minutes, that would take 25 hours. That's not going to work. If each case takes only 5 minutes, it still takes 8 hours, so that's still not going to work. Most courts end up at about 1-2 minutes per case. That's assembly line justice.

These types of cases require facts to be established so that the law can be quickly applied. Sentences and financial penalties are limited so that dispositions can be expeditious (Henderson et al. 1984, p. 11). Glick (1971, pp. 30–34) divided this judicial role into two parts, which could be viewed as complementary sides of the same coin – the "adjudicator" who emphasized deciding cases and the "task performer" who emphasized processing litigation and maintaining smooth court operations. The "disposition-oriented" or "administrator" role of this judge is to skillfully apply judicial procedures to achieve the swift and consistent disposition of cases (Vines 1969; Ungs and Baas 1972). Clearing the docket then becomes very important, and the task becomes to process large number of individual cases, a more bureaucratic process not unfamiliar to the administrative agencies in the executive branch of government. Judges must decide large numbers of lower-stakes cases every day, rather than spending days or weeks making a decision in one case at trial, and so the procedures must be streamlined. Consequently, judges may take a more active role in all phases of case processing to move the case along while ensuring that the attorneys, many of whom may be court appointed, are devoting the proper attention to their clients. Judges simply cannot rely on parties to frame disputes. Overcrowded dockets and "overzealous litigants" lead judges to take a more "active, largely discretionary approach to pretrial case management" (Molot 2003, p. 29). Federal judges have described their involvement in pretrial management as "moderate" or "intensive," including "holding pretrial conferences, setting pretrial schedules and trial dates, setting limits on discovery and ruling on motions" (Lande 2005). Boyum (1979) found that judges who emphasized the "administrator" role did indeed take a shorter amount of time, on average, to resolve their cases. Timely resolution is a positive outcome if it does not inhibit litigants from seeking information, including clarification and follow-up questions, or make them feel that their concerns are not taken seriously.

The Problem Solver

In 1984, then Chief Justice Warren Burger said:

> The entire legal profession. . .has become so mesmerized with the stimulation of the courtroom contest that we tend to forget that we ought to be healers of conflicts. For many claims, trials by adversarial contest must in time go the way of the ancient trial by battle and blood. (Toohey 2010, p. 7)

Spurred by the perceived inadequacies of the adversary process, some legal leaders have promoted a more cooperative approach to dispute resolution. Particularly in family law, once a fertile source of trials, there have been calls to abandon adversarial proceedings "in favor of more informal approaches with the goal of encouraging parts to develop positive postdivorce co-parenting relationships" (Murphy 2010, p. 895).

Some types of cases, such as those involving juveniles, have never fit comfortably within the traditional law-court framework. Separate courts for juveniles were created first in Chicago in 1899 (Stevenson et al. 1996, pp. 5–6) and served as a model for the later development of specialized family courts, which have jurisdiction not only over juvenile cases but also of other cases affecting the family from divorce to domestic violence. More recent "problem-solving" courts originated from the efforts of "practical, creative, and intuitive judges and court personnel, grappling to find an alternative to revolving door justice, especially as dispensed to drug-addicted defendants" (Winick and Wexler 2003, p. 6). From the opening of the first drug court in Dade County, Florida in 1989, drug courts spread rapidly based upon anecdotal reports of success in reducing recidivism, as well as the infusion of federal dollars (Berman and Feinblatt 2001, p. 23). By the end of 2009, there were 2,459 drug courts and an additional 1,189 problem-solving courts in the United States, including courts for DWI, mental health, domestic violence, truancy, child support, homeless, prostitution, reentry, and gambling (Huddleston and Marlowe 2011, p. 1). The conventional term "problem-solving courts" has passed into the language even though most are not separate courts but separate dockets or calendars of larger courts or divisions. In most instances, they involve a single judge handling a single type of case on a periodic schedule.

Problem-solving courts require judges to be more active, less formal, and personally engaged with each offender, and this personal involvement creates a tension with the traditional role of the judge as a detached, neutral arbiter. Indeed, Hanson (2002, p. 10) sees the problem-solving judge going beyond Becker's "situation-oriented" judge by not only taking into account the impact of their decisions on the litigants and perhaps the public at large but by becoming a partner in the "therapeutic-oriented response" to ameliorate the underlying problems of litigants. This tension the "polar-opposite roles" provides the base for the charge that problem-solving judges need to become "social workers" or "therapists." One *New York Times* article (Eaton and Kaufman 2005) summarized:

> The judges often have an unusual amount of information about the people who appear before them. These people, who are often called clients, rather than defendants, can talk directly to the judges, rather than communicating through lawyers. And the judges monitor these defendants for months, even years, using a system of rewards and punishments, which can include jail time. Judges also receive training in their court's specialty and may have a psychologist on the staff.

The collaborative nature of the problem-solving-court approach sometimes raises questions about the impartiality of the judge. For example, problem-solving judges need to praise and sanction defendants, rather than remain aloof, but this active engagement could create the perception that they are not impartial. Some may also consider collaboration in "staffings," where the judge and treatment team meet in advance of hearings to discuss the offender's progress in treatment and to reach consensus about rewards and sanctions to be in conflict with the judicial role.

The counter position, as presented in the commentary to the ABA Model Code of Judicial Conduct, states that judges in problem-solving courts may be authorized by court rules to act in nontraditional ways. The new ABA Model Code states that a judge may "initiate, permit, or consider" ex parte communications expressly authorized by law, such as when serving on therapeutic or problem-solving courts. The collaborative decision-making process "does not violate the judge's duty of independent judgment so long as the final decision rests with the judge" (Freeman-Wilson et al. 2001, p. 3). Judicial ethics do not require disengagement but impartiality, and so a judge may show concern about recovery, even celebrate the successes, but must be equally concerned about the progress of each offender.

Problem-solving courts have raised related issues about the proper judge's role outside the courtroom and outside the context of dealing with an individual case. Judges presiding in drug courts and monitoring the progress of participants in those courts' programs may be authorized and even encouraged to communicate directly with social workers, probation officers, and others outside the context of their usual judicial role as independent decision-makers on issues of fact and law. Furthermore, judges are in a good position to advocate for court reform in general because of their respected position in the community. Section 4(B) of the Canons of Judicial Ethics permits judges to act as educators (Freeman-Wilson et al. 2001, p. 13). This is especially important for judges in problem-solving courts who want to build public support for treatment-oriented programs. Often education involves Illustrations using success stories, which is ethical as long as confidentiality is not breached or specific individuals identified.

Procedural Fairness

Are there any attributes of judges that transcend the three roles mentioned above? In an essay on "What Makes a Good Judge?" Sir Gary Higginbottom (2011) notes that the attributes of a good judge include professional, personal, and administrative components. Professional attributes include knowledge of the law, legal analytic skills, "good judgment," and intellectual concentration, whereas personal attributes include such qualities as integrity, objectivity, and temperament. Many other judges have provided summaries of the qualities of a good judge, and these usually include professional competence (legal abilities and intellect), integrity, and judicial temperament (neutral, decisive, respectful, and composed). Note that these qualities are ambiguous, amorphous, and hard to define.

Judges Burke and Leben (2007, p. 4) present a powerful case for the principles of "procedural fairness" as a construct to define the desirable qualities of a judge and to make them measurable.

> Judges must be aware of the dissonance that exists between how they view the legal process and how the public before them views it. While judges should definitely continue to pay attention to creating fair outcomes, they should also tailor their actions, language, and responses to the public's expectations of procedural fairness. By doing so, these judges will establish themselves as legitimate authorities; substantial research suggests that increased compliance with court orders and decreased recidivism by criminal offenders will result. Procedural fairness also will lessen the difference in how minority populations perceive and react to the courts.

Although the lists of characteristics are worded differently at times, the four key expectations of procedural fairness are:

1. *Voice*: The ability to participate in the case by expressing their viewpoint.
2. *Neutrality*: Consistently applied legal principles, unbiased decision-makers, and a "transparency" about how decisions are made.
3. *Respectful treatment*: Individuals are treated with dignity and their rights are obviously protected.

4. *Trustworthy authorities*: Authorities are benevolent, caring, and sincerely trying to help the litigants – this trust is garnered by listening to individuals and by explaining or justifying decisions that address the litigants' needs (Burke and Leben).

These principles are laudable. The principle of neutrality, however, suggests that they were developed with the image of a traditional trial court in mind and are therefore most applicable to courts using the traditional process of procedural adjudication. Procedural fairness meshes very well with the umpire role of judges.

Procedural fairness would appear to be tailor-made for the problem-solving courts as well, especially the principles of voice, respectful treatment, and trustworthiness. Clients often communicate with the judge directly rather than through an attorney, for example. Neutrality is more of a stumbling block in these courts, however. Problem-solving courts require judges to be more active, less formal, and personally engaged with each offender, and this personal involvement creates a tension with the traditional role of the judge as a detached, neutral arbiter. This collaborative venture means that problem-solving judges are not neutral – they are rooting that treatment succeeds. They need to praise and sanction defendants, rather than remain aloof, but this active engagement could create the perception that they are not impartial. Some may also consider collaboration in "staffings," where the judge and treatment team meet in advance of hearings to discuss the offender's progress in treatment and to reach consensus about rewards and sanctions, to be in conflict with the role of judge as umpire.

There is a way out of this dilemma; however, problem-solving methods could be used post-adjudication only. Especially in criminal cases with a substance abuse component, such as DWI cases, the full adversary process with all of its due process protections could be employed until guilt has been established. After guilt is established, problem-solving principles designed to prevent repeat offenses could be used to select the best sentencing options, whether they be therapeutic or punitive. If problem-solving processes were used primarily post-adjudication, procedural fairness is an amenable tool for problem-solving judges as well.

Procedural fairness principles are not compatible with the adjudicator role, however. When clearing the docket is the goal, processing large numbers of cases expeditiously is the key requirement. Consequently, judges must consider not only how to offer each client due process rights but how to do so and still resolve the cases quickly. Consequently, they must take a more proactive role in all phases of case processing. The point here is with that many cases to resolve in such a short time, can lower court judges really be expected to provide litigants with meaningful *voice* – the ability to participate in a case by expressing their viewpoint – and still keep ahead of their dockets? Is there time to express their caring to explain and justify their decisions? In sum, is procedural fairness possible in high-volume lower courts? Because judges have such short interactions with litigants in these high-volume courts, the way litigants are treated by court staff becomes more important. There is no reason why procedural fairness principles could not be employed by court staff as well as by judges. Court staff includes not only clerks but also security personnel, bailiffs, administrative staff, and any other staff members that interact with the public (Porter 2011).

This entry has suggested that the various processes by which courts resolve cases today be acknowledged explicitly and matched with the judicial role most appropriate for each process. All judges need not have the "umpire" role as the dominant model, but it is the role most appropriate for the adversary process. Similarly, "adjudicators" with case processing abilities and talents are most appropriate for courts handling the large bulk of the cases, and "problem-solving judges" are most appropriate for treatment-oriented courts. The principles of procedural fairness can improve the sensitivity of all judges, especially trial judges, but are least applicable to judges sitting in high-volume courts. In those courts, it is particularly important that court staff adopt a procedural fairness approach to litigants by answering questions, even those that are poorly phrased; by providing information about court rules, procedures, and resources even though they cannot provide legal advice; and generally by treating litigants with respect.

Cognitive transformation; Correctional interventions; Correctional treatment; Evidence-based corrections; What works in corrections

Overview

"Evidence-based corrections" has become a popular phase to explain how an ideal correctional system should function. From this perspective, research, evaluation, and scientific processes should be used to make correctional decisions. To accomplish this objective, scientific research and evaluation needs to be completed to determine which correctional strategies, policies, programs, and interventions effectively result in the desired outcome or outcomes. A body of research conducted over the past 40 years provides guidance to policymakers who are interested in the effectiveness of specific correctional interventions. While there are many potential outcomes desired by the public, policymakers, and correctional experts, perhaps the most consistent interest is in interventions and decisions that are successful in reducing future criminal activities or, in other words, reducing recidivism. Using an evidence-based perspective, this entry reviews the literature on "what works in corrections" and proposes a theoretical explanation, a theory of cognitive transformation, for why some interventions are effective in reducing the recidivism of delinquents and offenders while others are not. Despite the fact that we have some evidence of what works, overall the research on corrections and sentencing interventions fails to match the scientific rigor in methodology and research design that is evident in other fields. The entry ends with a caution about the complexity of transferring interventions from the original controlled setting to environments that may be completely different.

Introduction

Past behavior is the best predictor of future behavior, and, therefore, it is reasonable to attempt to prevent crime by preventing known offenders and delinquents from continuing their criminal and delinquent activities. Once these individuals are convicted or adjudicated, they come under the supervision of correctional systems and this provides an ideal period of time to attempt to change them so that they will cease their criminal activities. Reducing the future criminal activities of delinquents and offenders is of concern because many of these individuals are rearrested or convicted of new crimes a relatively short time after they are released from correctional supervision. Thus, while not the only reason for developing particular correctional strategies, reducing recidivism has remained a major goal of many correctional systems.

Decision makers, the public, and correctional personnel differ greatly in their perspectives on what to do with people who break the law, and their perspectives change dramatically over time. Some of the differences in viewpoints depend on political ideologies on what should be done to those who disobey criminal statutes. Equally as important are more utilitarian considerations related to what is believed to be effective in reducing recidivism and making communities safer. The new "evidence-based" paradigm is central to the utilitarian perspective of reducing recidivism.

The focus on evidence-based practices in criminal justice organizations began with a provocative entry by Sherman (1998). He argued that justice systems, like medicine, should adopt an evidence-based perspective to guide practice. In this way, approaches to crime prevention would be based on evaluation research demonstrating what is effective and this would be used to construct guidelines for effective practice. The approach emphasizes the need for accountability and continual improvement through the use of the most current research results. Thus, continual feedback from research would improve the effectiveness of the justice system in achieving the desired goals. In his opinion, the basic premise of evidence-based practice "is that we are entitled to our own opinions but not to our own facts" (Sherman 1998, p. 4).

For corrections, the idea of an evidence-based perspective is that correctional systems will be more successful in achieving their goals to the degree that science is used to assist in decision making (MacKenzie 2000, 2001). Policymakers, judges, and correctional administrators must make decisions about how to intervene in the lives of convicted offenders and adjudicated delinquents. Most often they do so with some specific goals or objectives in mind. Two major objectives are to increase public safety and to change offenders so that they do not continue committing crimes. From the perspective of evidence-based corrections, interventions intended to accomplish these objectives should be studied with rigorous research and evaluations to determine whether they are successful in achieving the desired outcome or outcomes, in this discussion a reduction in recidivism. Frequently, however, decisions are made with little knowledge of whether the intervention is effective in reaching the desired results. Or as Sherman argued, too frequently, practitioners come up with their own "facts" with little evidence to support their views.

In corrections, too often decisions are made based on "gut-feelings" about what will be effective. For example, despite the fact that a growing body of research demonstrated that correctional boot camps were not successful in achieving the desired reduction in future criminal activities, for many years, people continued to assert that the discipline and challenge in the camps was "just what young offenders needed." Policymakers referred to their experiences in the military and how this made them grow up. The correctional camps quickly proliferated in the USA; however, few jurisdictions conducted the meticulous research needed to determine if they were really accomplishing the reduction in recidivism that was the stated objective of the camps. Fortunately, some jurisdictions did provide support for research to examine whether the camps had an impact on criminal activity. For example, during the time when boot camps were proliferating across the USA, the California Youth Authority (CYA) investigated whether boot camps were something they wanted to initiate on a widespread basis in their facilities (Bottcher 1997). To answer the question of whether the programs would be successful in the desired objective of reducing recidivism, they conducted an experiment of a small pilot program. Researchers randomly assigned youth to the camp or the control group and compared the recidivism rates after youth were released from facilities. Their question about whether to start a large number of boot camps in their facilities was answered when they found releasees from the camps had no lower recidivism than those released from the traditional facilities. Decision makers decided not to start the boot camps in Youth Authority facilities. This is a good example of both how research can be used in decision making and the limitations of "gut-feelings."

In my experience, another reason science is not used more often in correctional decision making is due to differences between law and science in how they conceptualize "research." Many policymakers and court personnel are trained as lawyers and not as social scientists. The law profession looks to past precedence and authorities for guidance to answer questions, not empirical research. Legal research entails a search for past precedence and authorities in order to support one perspective. In law, one takes a position and then tries to find support for this position. Social scientists proceed from a very different perspective. The scientist goes into a research project to ask a question not to support a position and looks to the empirical world to provide the answer. The researcher in this case tries to stay as objective as possible so as not to influence the outcome of the research. Past experience, opinions of authorities, and past research helps the scientist formulate the question, but empirical data is what is used to answer the question.

A further reason given for not doing research to investigate whether an intervention is effective is that funding for research takes away from support for programs and interventions. This argument is frequently used by people who deliver services and treatment. So again, it is a difference in perspective with service providers believing that it is most important to use any funding available to actually deliver programs and services. In contrast, the scientist questions the wisdom of delivering programs before it is clear that the program really does achieve the desired goals or outcomes. For example, there has been little evidence that the programs designed for batterers are effective in changing their behavior. Yet much of the funding goes to providing programs while the quantity and quality of the research is very limited. A better use of funds, from the perspective of evidence-based scientists, is to conduct rigorous studies of the programs to identify what is effective in reducing future battering.

Overall, the expression "evidence-based corrections" has been widely accepted and the phrase has almost become a mantra; however, the number and quality of research in corrections is still relatively limited when compared with other fields. Despite the fact that there are factors that have contributed to limiting the research examining the impact of interventions on recidivism, a sufficient body of research currently exists on some interventions to draw conclusions about what works.

Examining the Effectiveness of Correctional Interventions

This entry focuses on what reduces criminal recidivism using an evidence-based perspective. Policymakers must consider many factors in sentencing and correctional decision making. Many and varied outcomes are important in these decisions including such things as public perceptions of safety, public acceptance of punishments, victim satisfaction, costs, and impacts on the offender like increased educational achievement and reduced substance abuse. These are all germane for policymakers to consider; however, the one factor that almost always is considered a central focus is the impact of decisions on preventing future criminal activity. That is, does the sentencing or correctional option have an impact on recidivism. Therefore, it is important to examine what strategies, programs, or interventions have been demonstrated in the research to be effective in reducing recidivism (MacKenzie 2006). The question becomes: What works in corrections to reduce recidivism?

Meta-analysis is a relatively new statistical technique for conducting systematic reviews of research literature to answer question such as whether an intervention has an impact on recidivism. These analyses are quantitative statistical methods for assessing the impact of a group of studies to determine if they are effective in achieving an identified outcome or outcomes (Lipsey and Wilson 2001 encyclopedia entry on meta-analysis). The studies are the units of analysis. Effect sizes are calculated to determine difference between treated groups who receive the target intervention and control or comparison groups who do not. Meta-analyses with recidivism as the outcome variable examine the impact of the intervention on recidivism and compare the recidivism rate of the treated group to the comparison. This quantitative data is used in the analysis to draw conclusions about effectiveness and to examine whether differences among studies vary as a function of participant characteristics, program components, or research design.

An examination of the literature using meta-analysis to examine the impact of various correctional options clearly demonstrates that certain types of programs are effective in reducing recidivism (MacKenzie 2006; see also the Campbell Collaboration 2012; Lösel 2012: 988 ff.). The following types of programs have been found to be effective in reducing future delinquent and criminal activities: academic and vocational education; cognitive skills programs (Moral Reconation Therapy; Reasoning and Rehabilitation; cognitive restructuring); cognitive behavior and behavioral treatment for sex offenders; Multi-Systemic Therapy (MST) for juveniles; drug courts; and, drug treatment for those in the community and in correctional facilities (MacKenzie 2006). All of these interventions have human service components that address individual deficits and programs that target the individual-level characteristics directly associated with criminal behavior, called "criminogenic needs" by correctional psychologists (Andrews and Bonta 2006). Furthermore, the deficits or problems targeted are dynamic, or changeable, and not static. From this perspective, effective programs address changeable deficits or problems directly related to criminal behavior; in other words, the programs address "dynamic criminogenic needs (Andrews and Bonta 2006)." In addition, the effective interventions address cognitive processes and appear to bring about cognitive transformations in many participants.

Ineffective Policies, Practices, and Philosophies

Correctional interventions that provide increased control or are based on the philosophies of deterrence and incapacitation have not been found to be effective in reducing recidivism. In the past 40 years, policymakers and many correctional system decision makers moved away from a philosophy of rehabilitation toward increased use of interventions focusing on incapacitation, deterrence, and control. Many of these interventions have been submitted to rigorous research to determine whether they are effective in reducing recidivism. The conclusion from the research is that neither increasing the onerousness of punishment to deter nor increasing control to limit individuals' ability to offend is effective in reducing recidivism. Deterrence, incapacitation, increased control, and other punitive approaches to corrections are not effective in reducing future criminal activities (MacKenzie 2006; Lösel 2012: 989 f.). The interventions do not address the criminogenic needs of those who offend. Investigations of popular correctional interventions reflecting this paradigm, such as correctional boot camps, intensive probation and parole supervision, electronic monitoring, and drug testing, have not been demonstrated to be effective in reducing recidivism. None of these interventions address the criminogenic needs of the offenders nor do they create cognitive change.

Lipsey and Cullen's (2007) review of meta-analyses of aversive sanctions and supervision provides further support to the findings of the failure of control, deterrence, and incapacitation interventions to reduce recidivism. They conclude that such sanctions do not inhibit subsequent criminal behavior, and they found evidence that many actually increase future criminal activities. One such program, Scared Straight, has consistently been found to increase recidivism. In addition, existing policies increasing the length of prison sentences do little to deter criminal behavior and such sentences may actually be criminogenic (Nagin et al. 2009). Unintended consequences of incapacitation and deterrence philosophies had other unplanned, negative impacts. The large number of young people being sent to prison in the USA decimated some urban communities and many of those suffering from these policies are young minorities from inner cities (Clear 2007).

Another philosophy about how to decrease recidivism comes from the traditional sociological perspective attributing crime to social conditions. Interventions developed from this perspective have not been found to be effective in reducing recidivism. From this point of view, the focus of interventions should be on changing peoples' social environments by giving them employment and housing, and not on individual differences such as thought processes and rehabilitation. Social bonds or ties to social institutions are assumed to be the keys to successful desistance from crime and, therefore, giving people opportunities to form these bonds was expected to reduce their criminal activity. Life course criminologists who promote this control theory position argue that the attachments or bonds to marriage and employment are critical events leading to desistance and, consequently, interventions should focus on giving offenders and delinquents environment opportunities to develop these times and bonds.

Interventions providing increased social opportunities have not been found to effectively reduce recidivism, a disappointing finding to many social bonds theorists and life course sociologists (see later section on the need for cognitive transformations prior to opportunities). Programs are designed to help offenders obtain employment or housing in order to help them adjust to community life. Reentry programs provide assistance in these areas for those leaving facilities. In-prison work programs and correctional industry are expected to reduce recidivism by giving offenders future employment opportunities. Life-skills program provide assistance in job searches, resume writing, check writing, and other general skills needed for successful adjustment to the community. Yet, these interventions have not been found to be effective. Work programs, multicomponent work programs, prison industries, and life skills have not been found to be successful in reducing recidivism. It is likely the reason these interventions have not been effective is because they are designed to give opportunities to people who may not be cognitively prepared to take advantage of the opportunities.

Another disappointing research finding is that programs designed for batterers or domestic violence perpetrators do not have an impact on recidivism. It is unclear why these programs are not effective (MacKenzie 2006). It may be that the attitudes and corresponding behavior of perpetrators are so deep-rooted that they are very difficult to change. Another possibility is that the relationship between the perpetrator and victim is more complex than realized and treatment does not address this in a manner that is effective. What is clear is that both the quantity and quality of scientific studies is inadequate, considering the large number of programs operating and the magnitude of the problem. One of the problems in this area of research is the hesitancy of those developing programs to test the effectiveness with rigorous research. They frequently take the position that any money used for research will limit the number and size of the programs. Of course, the response is that it is a waste of time and money to operate ineffective programs when research would help give us evidence of what is truly effective and provide evidence of this effectiveness.

Other ineffective programs are those that have little theoretical basis for expecting an impact on recidivism. For example, psychosocial sex offender treatment is based on a psychodynamic theoretical perspective that demands insight, self-reflection, and verbal abilities that are often beyond the skill level of the offenders. The therapy is not responsive to the particular learning styles of the offenders. Other ineffective programs are based on threats of punishment or additional control that do not have a theoretical basis. In general, residential placement for juveniles or adults does not reduce recidivism. Unless the residents receive some type of effective programming while they are in the facility.

Cognitive Transformations

As noted earlier, correctional interventions such as drug treatment, education, and cognitive skills programs are effective in reducing future recidivism. One consistency among the effective programs is a focus on human service. Furthermore, an important aspect of this programming, and the reason they may be successful, is that the interventions address cognitive processes. From this perspective, an individual-level change in cognition must occur before the person is prepared to form ties or bonds to social institutions (MacKenzie 2006). In order to form positive relationships with family, keep a job, support children, or form strong commitments to other social institutions, a person must be cognitively ready to move toward these ties and bonds, and, in many cases, for offenders or delinquents, this requires a change in cognitive reasoning and attitudes. Such a focus on individual change in thinking and information processing is critical to understanding what works in corrections and developing interventions that will successfully impact future criminal activity.

Before a person is prepared to move away from criminal and delinquent activity toward a noncriminal life style, a cognitive transformation is required. It is not the social conditions that have driven these people to become involved in crime. The way individuals think and process information influences whether they violate the law. Deficiencies in social cognition, problem-solving abilities, and sense of self-efficacy are all cognitive deficits or "criminogenic needs" found to be associated with criminal activity. According to the cognitive transformation theory, programs are effective to the degree they are capable of creating a cognitive change in thinking whether this is through changes in criminal thinking or criminogenic attitudes, improved executive functioning and problem solving, or increased maturity and moral development.

Various theories have been proposed to explain the cause of crimes and desistance from crime or the lack thereof. Many of these theories reflect the sociological tradition of criminology and focus on social bonds or ties as the causes for criminal activity. Recently, these theories have been called into question particularly when the literature on "what works" in corrections is examined. Programs based on providing opportunities have not been found to reduce recidivism. While marriage, employment, and school may be correlated with reduced criminal activity, they are not the explanation for why someone chooses to become involved in criminal activity nor do they provide a blueprint for the development of effective correctional programs. Effective correctional programs address cognitions and prepare people for a transition into a noncriminal lifestyle. A cognitive transformation must occur prior to the move away from criminal activities (MacKenzie 2006). Until this transition occurs, people will not be prepared to take advantage of environmental opportunities. Consistent with this perspective, desistance theorists, most notably Giordano and her colleagues (Giordano et al. 2002), Paternoster and Bushway (2009), and Maruna (2001), have proposed theories to explain how cognitive or self-identify changes occur and how these lead to a shift away from criminal activities.

In summary, the research demonstrates that correctional interventions can effectively reduce future criminal behavior. Effective programs address cognitions and prepare people for a transition to a noncriminal lifestyle. A cognitive transformation must occur prior to the move away from criminal activities. Until such a transformation transpires, people will not be prepared to take advantage of environmental opportunities for employment or housing. Consistent with this perspective are the new theories, proposed by several desistance theorists, to explain how changes in cognitions or self-identity can lead to a shift away from criminal activities. Empirical research has demonstrated the type of correctional programs that are effective in changing offenders and, given this information, theorists have developed hypotheses about how and why these programs are effective. The evidence-based correctional paradigm will need to incorporate these viewpoints into policy decisions if one of the goals of programming is to reduce recidivism.

Research Quality and Program Implementation

Approximately 40 years ago, Martinson and his colleagues reviewed the research literature on correctional interventions and concluded that few if any programs could be said to be effective (Martinson 1974; Lipton et al. 1975). Many people interpreted this to mean that nothing works in correctional management and treatment. However, the conclusion from the report was not that nothing could work but instead the researchers attributed the failure to find effective programs to two factors: (1) poor research design and methodology and (2) inadequate implementation of the programs that were studied. These two issues remain important in any assessment of the effectiveness of programs today. The first issue has to do with the quality of the research and the ability of the study design to rule out alternative explanations for the results. The second deals with the integrity of the program or how the program is designed and operated, the amount of time the participant spends in the program, and the training and oversight of the staff.

Since the time of the Martinson study, improvements have been made in research design and statistical techniques. Improved statistical techniques along with systematic reviews and meta-analyses provide evidence of what is effective in preventing and reducing criminal behavior. An increased number of studies have used experimental designs randomly assigning subjects to the intervention or control groups. For example, in a recent review, Farrington and Welsh (2005) found 83 experiments examining offending outcomes had been conducted since an earlier review in 1983. Meta-analytical techniques have increased researchers' ability to combine studies and statistically investigate the effectiveness of a group of studies.

The good news is that there is evidence that some correctional interventions do work and these interventions have specific characteristics consistent with certain principles that can be replicated in future program development. Scientific evidence exists that some correctional interventions are effective in reducing future criminal activity of delinquents and offenders.

Yet problems still exist. "Corrections" is far from other fields, such as medicine, in the use of randomized trials to examine effectiveness. In one study of correctional interventions, MacKenzie (2006) found only 14.8 % of the evaluations were successful randomized trials. In contrast, 23.2 % of the studies were evaluated as so low in the quality of the research methodology that they could not be used to determine effectiveness. The latter were considered to have very dissimilar comparison groups and, therefore, it was impossible to tell if the results were due to differences between the groups being compared or the intervention. That is, it was impossible to draw conclusions about the effectiveness of the program. MacKenzie's (2006) work only included studies that compared a group who received the intervention to a group that did not. The great majority of the published and unpublished manuscripts were excluded from the review because they were qualitative or descriptive studies without any comparison group, so it would be impossible to draw conclusions about the impact on participants. In the future, it will be critical to increase the rigor of the research designs if we are going to successfully employ evidence-based knowledge to correctional decision making.

The second issue Martinson and his colleagues believed limited their ability to draw conclusions about what was effective in reducing recidivism was the quality of the programs studied. We have made progress since that time and now have a body of research literature demonstrating what programs are effective in reducing recidivism. While research has successfully identified therapeutic programs that are effective, much less is known about how to insure these programs are delivered with fidelity and/or therapeutic integrity, or the extent to which interventions conform to the manner of service intended by the developers of the intervention. Insuring the quality of programs remains an issue today. Criminology has been criticized for its lack of focus on what goes on inside correctional programs (Petersilia 2004). Despite the increased knowledge and statistical precision, correctional research continues to fail to investigate what is in the "black box" of the program. If the program is going to be transferred to another jurisdiction with a different population of offenders, detailed information about the characteristics of the intervention is necessary. Martinson and his colleagues found that the programs studied were so poorly implemented that it was impossible to tell whether a well-implemented program would have had an impact. This remains an important element in the research today. Certainly, a program with well-trained staff, designed and operated according to plans in accordance with principles of effective programming, targeting cognitions, providing sufficient dosage appropriate for the risk level of participants, and having enough administrative oversight to afford quality control would be expected to be more effective than a program without such essentials. Consequently, an ideal component of any correctional program evaluation is a relatively thorough, yet unobtrusive assessment of program delivery, especially when a program is adopted from another jurisdiction or population. The portability of a promising program does not always go smoothly (Armstrong 2003). Some researchers have begun to study the implementation of programs by measuring the characteristics of programs, participants, and administration (Latessa and Holsinger 1998; Taxman and Friedmann 2009).

Conclusion

"Corrections" appears to be on the cusp of a new age with a focus on evidence-based programming and smart sentencing. The old paradigm emphasizing punitive punishments has failed and changes are on the way. A large number of delinquents and offenders who come under the supervision of correctional personnel continue to be involved in criminal activity while they are in the community or return to crime when they are released from a facility. How to change this behavior in order to prevent crimes is a critical question for correctional interventions. The research provides guidelines for the components of interventions that will be effective in reducing recidivism. The research clearly points in the direction of the need to develop programs that will address dynamic criminogenic characteristics that will bring about cognitive transformations. Interventions that were popular during the law-and-order state of US correctional philosophy have not effectively reduced recidivism nor have interventions that provide offenders with opportunities for housing or employment if these are not combined with programs addressing cognitive processes.

The emphasis on evidence-based corrections and smart sentencing appears to be heralding a new age. To be successful in these endeavors, we will need more research using rigorous research designs. Also important will be future efforts to understand the specific components of effective programs and how these can be successfully transferred to new populations and jurisdictions.

Expert Evidence and Criminal Trial Procedure

Paul Roberts
School of Law, University of Nottingham,
Nottingham, UK

Overview

This entry examines the main procedural rules and principles applied to scientific and other expert evidence in criminal trials, taking criminal adjudication in England and Wales as its primary illustration. English criminal trials are "adversarial" and, in serious cases, tried before lay juries, but these distinctive institutional design features do not determine the shape and content of criminal procedure rules to the extent commonly assumed. By considering a fuller taxonomy of criminal procedure law we can see that many types of procedural rules – such as those regulating the flow of information to the fact-finder and helping to structure inferential reasoning, as well as rules promoting normative conceptions of procedural integrity and due process – are common, in some form, to all modern legal systems. Turning to more detailed analysis of trial procedure in one particular legal jurisdiction, the admissibility and uses of expert evidence in England and Wales are governed, firstly, by general evidentiary principles applicable to all types of evidence, and secondly, by criminal procedure doctrines specifically tailored to receiving and evaluating expert witness testimony. Both strands of evidentiary doctrine are summarized in this entry, before concluding with some brief observations on possible reform options.

Institutional Contexts of Criminal Trial Procedure

Criminal trials are formal, public, carefully orchestrated, and closely regulated institutional events, quite unlike ordinary everyday forms of social interaction and distinct, even, from just about every other public occasion of major social, cultural, and political significance. If modern states can be said to "govern through crime" (Simon 2007), criminal adjudication might be viewed as a nodal point in the constitution and reaffirmation of political authority, when the administration of criminal justice is at its most visibly "spectacular" (cf. Levenson 2008). Yet criminal trials also perforce involve human participants, some of whom have specialist training as judges and lawyers and cumulative experience as "repeat players" in criminal litigation; others, including most complainants and witnesses and many accused, have neither. Seasoned practitioners and uninitiated laypeople alike, however, share broadly similar biologically endowed cognitive capacities and limitations. One pervasive challenge in the design and operation of criminal trial proceedings, then, is to accommodate these extraordinary public events to the prosaic realities of human cognition, reason, and motivation.

Every system of criminal adjudication confronts this challenge more or less self-consciously and answers it – to the extent that it does – in its own distinctive way. There is no such thing as "free" forensic proof in any literal sense. The question is always how, and to what extent, a particular legal system seeks to manage and regulate the ways in which relevant information ("evidence") is gathered, organized, presented, tested, and finally evaluated by the fact-finder. Various institutional tools, procedures, and mechanisms have been devised and adapted to this end. This entry focuses specifically on the law of criminal trial procedure as one prominent regulatory technique. Legal cultures differ markedly even in their basic concepts and terminology. Common lawyers might be slightly puzzled by the notion of the "law of criminal trial procedure," because they would generally refer to these trial rules as the law of criminal evidence and procedure, or simply as "the law of evidence." But the Law of Evidence, as an identifiable legal specialism, is alien to civilian jurisprudence, which normally treats criminal procedure and civil procedure as separate branches of procedural law. My improvised terminology is intended to cover all of the rules of procedure and evidence which regulate criminal trials, both in Anglophone common law and in continental civilian legal jurisdictions.

It is sometimes thought that trial rules of evidence emerged in response to the adoption in England and, later, in the USA, of trial by jury, but this is misconceived (Schauer 2006). The functional separation between the common law judge, as master of the law, and lay juries as triers of fact makes it easier, in practice, to withhold information deemed unsuitable from the fact-finder than it would be in trial systems where the tribunal (whether a single judge, panel of judges, or mixed panel of judges and jurors) determines both law and fact. In criminal trials in England and Wales or the USA inadmissible evidence can be excluded from the trial without the jury's ever knowing anything about it. But this functional convenience is not *the reason* for evidentiary exclusion. As John Jackson shows in his entry "▶ Scientific Evidence in Criminal Adjudication," evidence may be regarded as problematic quite irrespective of its validity or reliability – for example, because the way in which it was obtained or presented is regarded as being inconsistent with the normative requirements of a fair trial. Likewise, evidence obtained by torture is categorically inadmissible under Article 6 of the ECHR (*Gäfgen* v *Germany* (2011) 52 EHRR 1), irrespective of whether the fact-finder is a professional judge or a lay jury (or an institutional hybrid). So while it is right to say that *certain kinds* of exclusionary rule – chiefly, those predicated on assumptions about lay jurors' cognitive shortcomings – are characteristic of the common law world, rules of evidence and procedure, considered generically as tools for regulating criminal trials, are a universal feature of modern legal systems. There are important differences of degree and kind, but these distinctions can be drawn just as sharply within (cf. Roberts and Hunter 2012), as much as between, the idealized "adversarial" and "inquisitorial" procedural families.

Trials must always be viewed in procedural and temporal context. They are shaped to some extent by what comes after, and more particularly by what went before. Where juries give unreasoned general verdicts simply stating "guilty" or "not guilty," as they generally do in serious criminal cases in common law jurisdictions, opportunities for post-verdict review may be severely curtailed. Criminal appeals against conviction in England and Wales can succeed only if the accused identifies some serious procedural defect in the course of his trial. In the absence of genuinely new evidence or arguments, claims of "actual innocence" will be met with the stony-faced response that the jury has already considered, and rejected, the accused's protestations of innocence. The Court of Appeal is not empowered to substitute its own *ex post* evaluation of the evidence for the jury's verdict. In this procedural environment, where opportunities for reviewing the quality of the jury's output are limited, "input control" regulating the flow of information to the jury during the trial is at a premium. This plausibly accounts, in part, for the breadth, detail, and fastidiousness of evidentiary regulation that has evolved in common law jurisdictions (see Roberts and Zuckerman 2010), compared with the more freewheeling approach to receiving and evaluating evidence in Continental jurisdictions, where pretrial evidence gathering is routinely subject to much closer judicial supervision than it is in party-dominated adversarial systems and appeals against trial verdicts on points of law or fact are more freely available.

It is tempting to equate the law of evidence with exclusionary rules, and doing so tends to reinforce the widespread perception that detailed evidentiary regulation is a peculiarly common law preoccupation, while continental courts and jurists embrace "freedom of proof." But this is fatuous, as Murphy (2010) rightly insists, because legal proof is never a no-holds-barred forensic scrum in which just anything goes. Irrespective of local technical exclusions, if any, there must be legally regulated and epistemically defensible standards, first, for assessing the relevance of potential evidence, and subsequently for determining its probative value, in the context of the case as a whole and in the light of the applicable burden and standard of proof. Forensic science and other expert evidence provides an excellent illustration of these general features of criminal adjudication. The fact-finder always needs to determine, among other things: what does expert evidence go to prove? Has it been adequately tested? Can it safely be relied on? Does it alone, or in combination with other evidence, satisfy the requisite standard of proof for finding the accused guilty of the offense or offenses charged?

Taxonomy of Procedural Regulation of Expert Evidence

Procedural rules, principles, and related normative standards can be classified in different ways. One might distinguish, for example, (i) rules constituting the court and delimiting its jurisdiction; (ii) rules for the conduct of trial proceedings; (iii) evidentiary rules of admissibility; (iv) forensic reasoning rules; and (v) rules for rendering judgment (see Roberts 2011: 395 ff.). Every modern criminal trial system has rules falling under each of these five subheadings, though of course their number and detailed specification vary enormously across individual legal systems. If we further subdivide part (iii) of the suggested taxonomy we might well discover that certain kinds of admissibility rule, for example, those directed towards preempting lay fact-finders from drawing impermissible inferences or falling prey to prejudicial reasoning, are particularly associated with common law jurisdictions and are found less frequently, or not at all, in the civilian legal world.

Regarding part (ii) of the taxonomy, common law trial systems generally adopt adversarial criminal trial procedures. Adversarial trials proceed as a kind of contest or debate between two partisan factions, each urging a different conclusion on the fact-finder, who must somehow reconstruct an accurate portrayal of disputed events from the evidential debris of full-blooded forensic conflict. Adversarialism pervades the broader institutional structures and cultural milieu of criminal adjudication in England and Wales. In a procedural system in which expert witnesses are instructed by adversarial parties, it is likely that experts will experience diffuse, and perhaps occasionally more concentrated, pressures to tailor their evidence to lawyers' expectations (cf. Harris 2000). However, as independent advisors to the administration of justice whose advice is valued precisely because it is assumed to be scientifically valid and nonpartisan, there is only one type of advocacy that expert witnesses can afford to be drawn into, and that is advocacy promoting the integrity of their own, technical evidence. The potential for role-conflict and possible ethical dilemmas involved in being a party-instructed expert in an adversarial criminal trial are explored by Tony Ward in his *Encyclopedia* entry "▶ Expert Witnesses: Role, Ethics, and Accountability."

Another significant trait of common law systems' commitment to adversarial trial procedure is a reflex distrust of court-appointed experts. Although English judges notionally have a general common law power to instruct their own witnesses (*R v Roberts* (1985) 80 Cr App R 89, CA; *R v Cleghorn* [1967] 2 QB 584, CA), including experts (*R v Holden* (1838) 8 Car & P 606, 173 ER 638), this power is hardly ever exercised in criminal trials, and never to the exclusion of party-instructed expert witnesses. Depriving the accused of opportunities to develop the defense case by instructing scientific experts of his own choosing is presumptively unfair. Appearing to sanctify an expert's testimony with the imprimatur of the court might also be regarded as detracting from judicial impartiality and trenching on the jury's constitutional prerogatives. Yet without exclusivity, many of the vaunted advantages of court-appointed experts evaporate. For example, the fact-finder's task is hardly made any easier by being confronted with a three-cornered scientific dispute involving court-appointed as well as party-instructed experts.

Mirjan Damaška (1986) has argued that countries with inquisitorial criminal procedures tend to be characterized by relatively high levels of social trust in state bureaucracies and professional expertise, whereas adversarial cultures are generally more suspicious of state officials and tend to place greater store by lay involvement in public decision-making, even if this sometimes entails contradicting expert opinion. Though admittedly drawn in sweeping and somewhat indistinct brush-strokes, Damaška's suggestive parallels between a society's political culture and its design preferences for legal procedure provide a more-than-plausible explanation of the markedly contrasting fortunes of court-appointed experts on different sides of the English Channel. Court experts flourish where officials dominate legal process and authoritative expert pronouncements are seldom challenged (a theoretical hypothesis confirmed in practice by the deference typically extended to expert evidence by Continental fact-finders: van Kampen and Nijboer 1997). Where, by contrast, the parties develop their own cases and dictate the course of legal proceedings, while professionals, experts, and officials of all kinds incite popular ambivalence and even a measure of suspicion, the court expert will not be held in comparably high esteem and is unlikely to be an acceptable surrogate for party-instructed expert witnesses.

The remainder of this entry concentrates on parts (iii) and (iv) of my suggested taxonomy of criminal trial procedure rules. The next section on "General Principles of Admissibility" outlines general evidentiary doctrines applicable to all evidence, including scientific and other expert evidence. The following section then considers "Rules Specifically Regulating Expert Witness Testimony." Descriptions of the logic of inferential fact-finding apply, more or less, to all modern systems of criminal adjudication because they relate to the cognitive capacities and limitations of human fact-finders. Other features of the analysis are indicative of broad trends within the common law world or apply to any jurisdiction in which criminal trial procedure is broadly speaking adversarial (a classification incorporating an expanding number of legal systems, partly owing to the influence of the ECHR). Ultimately, however, each legal jurisdiction has its own unique set of procedural rules, institutions, and processes, suffused with a distinctive legal culture. Precision can therefore be achieved only at the cost of parochialism. The relevant legal jurisdiction for my purposes is England and Wales, and I will cite English law examples by way of illustration. Scotland, Northern Ireland, and a host of other, smaller legal jurisdictions within the United Kingdom and the British Isles have their own independent criminal justice systems. Even *within* the UK's legal jurisdictions there are major differences in criminal procedure, to say nothing of attempted comparisons with other common law systems of criminal adjudication in North America, Australasia, the Indian subcontinent, South East Asia, or the English-speaking parts of Africa. Generalizations about criminal adjudication in "common law" or "adversarial" systems may be useful signposts indicating likely assumptions and promising avenues for further inquiry, but they are always somewhat tendentious at the level of doctrinal detail or customary institutional practice.

General Principles of Admissibility

General principles of admissibility apply to scientific evidence and expert witness testimony *in addition to* bespoke procedural rules. Scientifically impeccable expert evidence might therefore still be inadmissible at trial, if it infringes one or more of the general legal principles of admissibility discussed in this section pertaining to: (i) relevance, (ii) fair trial, (iii) hearsay, and (iv) character.

Relevance

Only *relevant* evidence is admissible in criminal trials. Evidence is worthless to the legal process unless it might help to resolve the (legally defined) issues in dispute. Relevant evidence might still be excluded on other grounds, but irrelevant information falls at the first hurdle: it is categorically inadmissible. "[T]o be relevant," Lord Steyn observed in *R v A (No 2)* [2002] 1 AC 45, [31], "the evidence need merely have some tendency in logic and common sense to advance the proposition in issue." While the weight or "probative value" of any piece of evidence may vary, depending on how persuasively or conclusively it proves (or disproves) a fact in issue, evidence is relevant if it has *any* probative value whatsoever, and irrelevant if it has none.

The low threshold of relevance mandated by English law is normally easily satisfied by forensic science or other expert evidence. A fingerprint or blood sample placing the accused at the scene of the crime is patently relevant; as are the results of drug tests, toxicological screens, questioned document analysis, pathology reports, and so on, whenever such information tends to confirm (or disprove) that a crime has been committed or to identify particular perpetrators. Indeed, such evidence is not merely relevant, but often of immense and sometimes decisive probative value. There are, however, two types of situations in which scientific evidence might fail to surmount the relevance hurdle to admissibility. The first is where scientific evidence relates to matters no longer in dispute in the litigation, as where the accused in a rape case admits the fact of intercourse, but claims that the complainant consented. In these circumstances, DNA evidence establishing that the accused was the donor of semen recovered from the complainant is no longer strictly relevant to any contested fact (though in practice the DNA report would still be adduced unopposed or submitted to the court as agreed evidence). A striking example is provided by Barry George's successful appeal against his conviction of murdering the TV personality Jill Dando, partly on the basis of a single particle of firearms discharge residue (FDR) which was adduced at his trial to show that George had recently fired a gun. On appeal, it was conceded by forensic scientists that "the possibility that the FDR had come from the gun that killed Miss Dando was equally as remote as all other possibilities [including innocent contamination] and thus, on its own, entirely inconclusive": *R v George* [2007] EWCA Crim 2722, [51]. In fact, evidence which is incapable of distinguishing between the prosecution's case and the defense case, because it is equally likely under either hypothesis, would normally be regarded as irrelevant and should be excluded from the trial.

A second type of scenario conceivably raising relevancy objections concerns recent scientific discoveries or novel or idiosyncratic techniques. Since crack-pot theories, untested hypotheses, and unvalidated scientific techniques fail to satisfy even the threshold expectations of commonsense rationality, they are irrelevant in law, and consequently inadmissible in criminal trials. This is one basis on which, for example, the results of lie detector tests remain inadmissible in English (*R v Chapman* [2006] EWCA Crim 2545, [33]) and Scottish (*HM Advocate* v *Sheridan* [2011] HCJ 1) courts.

Fair Trial

Criminal justice cannot be achieved unless criminal proceedings, including trials, are conducted fairly. Dispensing justice demands due process of law, and justice must be seen to be done in order to sustain the moral legitimacy of criminal verdicts and foster their popular acceptability. Ensuring a fair trial has always been regarded as one of the judge's most fundamental common law duties (*R v Christie* [1914] AC 545, HL), but this traditional precept has been reinforced and greatly expanded in recent decades by judicial innovation against a backdrop of the growing influence of human rights law (Roberts and Hunter 2012; Emmerson et al. 2007). Article 6 of the ECHR guarantees the right to a fair trial and elaborates a number of specific procedural rights for criminal suspects and the accused (Trechsel and Summers 2005). Crucially, the "right to a fair trial" is not limited to what takes place *at trial*. It also regulates criminal investigations (e.g., *Teixeira de Castro* v *Portugal* (1998) 28 EHRR 101), evidence gathering (e.g., *Edwards and Lewis* v *UK* (2005) 40 EHRR 24), and pretrial criminal procedure (e.g., *Rowe and Davis* v *UK* (2000) 30 EHRR 1).

Fair trial standards bear on the way in which evidentiary material is first obtained, its handling and storage, and defense access to scientific testing, results, and data in the pretrial process. Thus, irrespective of the scientific validity of a particular testing procedure, scientific results establishing – say – a suspected substance's chemical composition or the identity of a perpetrator may still be ruled inadmissible at trial if the trace material on which the tests were conducted was obtained or retained illegally, if a proper chain of custody cannot be demonstrated to rule out the risk of accidental contamination (Pattenden 2008), or if test results were not disclosed to the defense when they should have been (ACPO/CPS 2010; *R v Ward* (1993) 96 Cr App R 1, CA). Proactive investigative methods can easily result in evidentiary exclusion if they are not carefully planned and monitored in order to keep criminal investigations within the bounds of propriety and preserve the integrity of their evidential product. Police "entrapment" is not a stand-alone defense in English criminal law (*R v Sang* [1980] AC 402, HL), but collusion by undercover officers or police informants which might be regarded as crossing the line into active incitement of criminality runs a serious risk that evidence of subsequent offending by a targeted suspect will be excluded (*R v Looseley; Attorney General's Reference (No.3 of 2000)* [2001] UKHL 53, [2001] 1 WLR 2060). In particularly egregious circumstances, the trial judge may effectively throw the case out of court by staying proceedings indefinitely as an abuse of process (Choo 2008: Chap. 5).

The unifying normative thread linking police illegality, unfair investigative tactics, and failures of prosecution disclosure is *procedural impropriety*. Justice demands due process and fair trial. Irrespective of internal standards of scientific validity and methodological rigor, scientific or other expert evidence tainted by procedural impropriety is flawed, from a legal perspective, and it is consequently vulnerable to be being sacrificed – ruled inadmissible at trial – in order to preserve the procedural integrity of criminal adjudication.

Hearsay

In the adversarial common law tradition, the oral testimony of witnesses speaking live, on oath and in the presence of the jury in the courtroom is regarded as the paradigm of judicial evidence. The rule against hearsay is the alter ego of this principle of orality (Roberts and Zuckerman 2010: Chaps. 7 and 9). Witnesses must testify only to what they themselves have personally observed, heard, or otherwise perceived through their senses, and be available for cross-examination on the veracity and accuracy of their reported sensory perceptions. Mere hearsay – information told to the witness by somebody else, other people's conversations overheard by the witness, and even the witness's own out-of-court statements – does not qualify as original evidence in English criminal trials.

The hearsay prohibition could, in theory, be a major irritant for forensic science evidence. A great deal of the informational content of expert witness testimony is technically hearsay. Scientific literature and experimental data are compiled over many decades, or even centuries, by countless scientific researchers scattered across the globe. Any individual scientist can, at best, claim first-hand, personal knowledge of only a tiny fraction of the theoretical underpinnings and empirical substance of their courtroom testimony. Likewise, the generation of scientific evidence in individual cases is typically a collaborative enterprise. Trace evidence is routinely collected by scenes of crime officers (SOCOs) or Crime Scene Investigators (CSIs) and submitted to the forensic laboratory where one scientist might undertake preliminary screening, subsequently distributing evidential material to a lab technician who prepares samples, for a third colleague to undertake scientific testing, ultimately reporting to a fourth, more senior forensic scientist who interprets the test results in a final written report and will later testify to its contents in court if called upon to do so. Strictly speaking, however, most of this report is hearsay, because the testifying expert did not personally collect the samples, conduct the scientific testing, or record the data produced in court. With the exception of direct observations or interpretations for which the scientist can personally vouch, courtroom testimony repeats only what the scientist has been told by his or her colleagues, and this is classically hearsay. The same objection theoretically applies to forensic databases of fingerprints, shoeprints, toolmarks, firearms, glass composition, DNA profiles, and so forth, which are likewise compiled over extended periods of time, possibly in multiple locations, by scores or hundreds of individuals who may not even be identifiable at a later date, but at any rate will not be in court to testify to the continuity and reliability of the processes for collecting, testing, and retaining relevant samples on the basis of their own first-hand, personal knowledge.

In practice, courts in England and Wales have on pragmatic grounds largely exempted expert evidence from the operation of the hearsay prohibition. Information derived from general scientific literature, reference works, experimental data, and the common store of scientific knowledge is admissible in court provided that it is incorporated into, or subsumed within, the "opinion" of an appropriately qualified expert witness (*R v Harris* [2006] 1 Cr App R 5; CJA 2003, s.118(1) rules 1 and 8). Evidence of "matches" between crime scene trace evidence and samples or data contained on large-scale criminal justice databases are also admissible (*R v Abadom* [1983] 1 WLR 126, CA; *R v Kempster (No.2)* [2008] 2 Cr App R 19, CA). It might be thought that any other conclusion would be idiotic, in view of the tried-and-tested probative value of statistical and experimental data. However, the hearsay rule is a doctrine of conceptual logic rather than common sense, and it sometimes leads to counter-intuitive results, including, in the past, the exclusion of apparently reliable database evidence which cannot be "laundered" through expert testimony (*Myers* v *DPP* [1965] AC 1001, HL). The position is notably far less flexible in the USA, where suspects enjoy a constitutional right of confrontation *in addition to* being able to object to prosecution evidence on traditional hearsay grounds. In *Melendez-Diaz* v *Massachusetts*, 129 S Ct 2527 (2009), the US Supreme Court ruled, by a 5–4 majority, that drug analysts must be available to testify in person and undergo cross-examination, even though drug testing is mostly routine and uncontroversial and its results could easily be summarized in a short written report. Considerations of cost and convenience had to give way to the Sixth Amendment right to confrontation, as the Justices comprising the majority interpreted it.

Notwithstanding English courts' evidentiary concessions, expert witnesses must still be cautious about their use of second-hand information relating to the current proceedings when writing their reports and testifying in court. For example, case details divulged to a forensic scientist by an investigating police officer, or factual information provided to the doctor who examines an injured complainant, or to a psychiatrist while interviewing the accused (e.g., *R v Miah* [2011] EWCA Crim 945, [60]; *R v Hurst* [1995] 1 Cr App R 82, CA) are all hearsay, and their legal status should be clearly flagged if experts make any reference to such alleged facts in their reports or testimony. Where an expert's conclusions are built upon particular factual assumptions, the expert's evidence is not even admissible, let alone persuasive, until the party calling the expert has laid an appropriate evidential foundation by proving the assumed facts through admissible, nonhearsay, evidence (Roberts 1996). If after the expert has already testified it turns out that the underlying facts cannot be established after all, the jury will be instructed to disregard the expert's evidence in its entirety. Scientific evidence which, although internally valid, has no demonstrable factual connection to the matters disputed in the trial is legally irrelevant, and therefore inadmissible.

Character Evidence

A criminal trial in the common law world is an investigation into particularized allegations of wrongdoing, not a wide-ranging evaluation of the accused's whole life and moral character. To the extent that character may be probative of conduct, however, there is room for admitting general character evidence at trial as material proof of the instant charge(s). This inferential logic applies to witnesses and complainants, whose character might be thought to shed light both on the events currently in dispute and on individuals' testimonial credibility as witnesses in court. It also applies to the accused, who might, for example, have committed similar offenses in the past or revealed distinctive criminal tendencies or patterns or techniques of offending (a signature "m.o.," *modus operandi*) through his previous – charged or uncharged – conduct.

Routine reliance by the prosecution on evidence of the accused's previous convictions or other extraneous misconduct has generally been regarded as unfairly prejudicial in common law jurisdictions. Such evidence is not normally admissible unless its probative value is compelling (*DPP* v *Boardman* [1975] AC 421, HL; *Makin* v *A.G. for New South Wales* [1894] AC 57, PC). The Criminal Justice Act 2003 relaxed English law's traditional aversion to character-based proofs, but evidence of the accused's extraneous misconduct still remains subject to a special evidentiary regime requiring more than bare relevance to secure its admissibility at trial. The general common law prohibition on evidence of the accused's bad character, and in particular on reasoning directly from propensity, still retains its traditional vitality in many parts of the English-speaking legal world.

It is conceivable that scientific evidence might be employed to link the accused to uncharged – or even previously acquitted (*R v Z (Prior Acquittal)* [2000] 2 AC 483, HL) – crimes in order to demonstrate the accused's propensity for committing the type of offense currently before the court, in which case the evidence must satisfy the additional admissibility criteria specified by ss.101–106 of the Criminal Justice Act 2003. If the evidence is excluded, this will not reflect any inherent scientific defect, but rather the court's judgment that revelations of extraneous misconduct would be unfairly prejudicial and disproportionate to the probative value of the evidence.

Fingerprint evidence and DNA matches potentially engage the law of bad character in more subtle ways. If it emerges during the course of a trial that the accused was first identified from a fingerprint left at another crime scene, or by a DNA profile derived from the National DNA Database (NDNAD), a savvy juror could easily infer that the accused must already have been "known to the police." The NDNAD currently contains profiles not only from offenders, but also from suspects who were ultimately acquitted or not even charged in the first place. Jurors might therefore wrongly infer from a matching profile that the accused has a criminal record when, in fact, he has none. In (somewhat tardy) response to the judgment of the European Court of Human Rights in *S and Marper* v *UK* (2009) 48 EHRR 50, English law is currently being amended so that only the DNA profiles and fingerprints of convicted offenders will be retained on the NDNAD (Protection of Freedoms Act 2012). Even if this will in future preclude criminal juries from *mistakenly* inferring that the accused has a criminal record because his profile was on the NDNAD, trial judges should still strive to avoid, or failing that seek to neutralise, any unfair prejudice that could arise from gratuitous disclosures of the accused's extraneous misconduct.

Character can be good as well as bad. Just as the prosecution may attempt to show that the accused has a propensity for engaging in distinctive types of criminality, the defense might try to invoke the accused's character and previous conduct in order to persuade the fact-finder that the accused is "*not* the sort of person" who would do what he is alleged to have done. Although the accused enjoys an antique dispensation to adduce evidence of good reputation (*R v Rowton* (1865) 34 LJMC 57; 10 Cox CC 25, CCR), however, the law has traditionally frowned on self-serving evidence of disposition (*R v Redgrave* (1982) 74 Cr App R 10, CA), which is normally regarded as easily manufactured and probatively trifling. Accordingly, the general rule is that a party is prohibited from leading self-serving character evidence to "bolster the credit" of the party's own witness. This prohibition operates, for example, to prevent a psychiatrist or psychologist who has examined the accused from advising the court that the accused is not a person disposed to violence, or that the accused is a truthful witness (*R v Robinson* (1994) 98 Cr App R 370, CA). Whether or not the accused was violent on the occasion in question, and whether his courtroom testimony should now be believed, are matters on which the jury is supposed to arrive at its own, common sense, judgments. It would be different if the accused or another witness was suffering from a clinical condition making him a pathological liar: the jury can always be informed of such expert medical or psychological diagnoses (*Toohey* v *Metropolitan Police Commissioner* [1965] AC 595, HL). In more recent pronouncements, the Court of Appeal has indicated somewhat "greater willingness to accept medical expert evidence on the issue of the credibility of a witness," in accordance with its professed general inclination to be "more generous towards the admission of expert evidence than was once the case" (*R v Pinfold and MacKenney* [2004] 2 Cr App R 32, [14]–[15]; see Roberts (2004) for discussion).

Rules Specifically Regulating Expert Witness Testimony

We have established that admissible expert evidence must be relevant to the matters in dispute, consistent with procedural due process and the right to a fair trial, and compatible with complex legal doctrines governing hearsay and character evidence. In addition, to secure its admissibility expert evidence must also be (i) helpful to the jury; and (ii) presented by a competent, properly qualified expert. Finally, if it succeeds in being admitted, scientific and other expert evidence is subject to (iii) a clutch of evidentiary doctrines seeking to guide or constrain its uses in fact-finding. These doctrines can be described, collectively, as "forensic reasoning rules" (Roberts and Zuckerman 2010: Chap. 15). They operate as instructions to the trial judge on how to direct the jury before jurors retire to deliberate on the evidence and produce a verdict. English criminal trial judges sum-up on the facts, as well as directing the jury on the applicable law; a practice not generally followed in US criminal trials. This gives the English trial judge a certain measure of practical influence over the jury's evaluation of the evidence, though the judge must always stress that the jury has the final word on questions of fact. In any event, the jury deliberates in secret and will presumably only follow those judicial directions and suggestions which jurors both understand and, broadly speaking, endorse as sensible and appropriate.

Helpfulness: The Primary Criterion

There is no comprehensive statutory framework to regulate the admissibility of expert testimony in England and Wales. The applicable rules are almost entirely derived from judge-made case-law precedents. In the leading case of *R v Turner* [1975] 1 QB 834, 841–2, 843, CA, Lawton LJ explained that the trial judge had correctly excluded psychiatric evidence tendered by the defense, on the grounds that it would not have assisted the jury's deliberations in this particular trial:

> An expert's opinion is admissible to furnish the court with scientific information which is likely to be outside the experience and knowledge of a judge or jury. If on the proven facts a judge or jury can form their own conclusions without help, then the opinion of an expert is unnecessary .... Jurors do not need psychiatrists to tell them how ordinary folk who are not suffering from any mental illness are likely to react to the stresses and strains of life .... [W]e are firmly of the opinion that psychiatry has not yet become a satisfactory substitute for the common sense of juries or magistrates on matters within their experience of life.

This passage has been taken as authority for the existence of a "common knowledge" rule, according to which expert evidence cannot be admitted if it concerns matters within the knowledge and experience of "ordinary folk" (Mackay and Colman 1991; Freckelton 1987: Chap. 3). Alternatively, or in addition, *Turner* is said to imply that expert evidence must be confined to mental abnormality as opposed to normal mental or psychological processes – an "abnormality rule" of admissibility (Sheldon and MacLeod 1991; Thornton 1995). More generally, Lawton LJ's observations are held up as a typical example of legal ignorance and hostility towards science in general, and mental health professionals in particular. As later decisions have tended to confirm, however, Lawton LJ probably meant to insist on nothing more provocative than this banal proposition: expert evidence should be admitted in criminal trials only when, and just insofar as, it is likely to be genuinely helpful to the jury.

Turner's critics rightly insist that expert testimony might still be helpful even if it concerns matters within jurors' broad general knowledge or questions of normal human psychology. Jurors are unlikely to share an expert's detailed, systematic knowledge of specific aspects of normal psychological processes, for example. Where "common sense" beliefs are a witches' brew of genuine knowledge, mangled half-truths, urban myth, and popular invention, an expert might be able to help jurors disentangle fact from fiction so that they can evaluate the disputed evidence more objectively. It is for these sound reasons that English courts do *not* routinely insist on any "common knowledge" or "abnormality" criterion: such tests are rarely more than rough-and-ready rules of thumb to guide the application of the helpfulness standard in particular cases.

If English law really did propound a "common knowledge" rule, for example, expert evidence of identification from a photograph could not have been received in *R v Stockwell* (1993) 97 Cr App R 260, CA. Looking at photographs is hardly an arcane, specialist activity, yet the Court of Appeal endorsed the reception of expert evidence where it was felt that jurors would benefit from further assistance in a matter well within their everyday experience. Likewise, courts in England and Wales have received expert evidence of child psychology (e.g., *DPP* v *A and BC Chewing Gum Ltd* [1968] 1 QB 159, DC), without any suggestion that children, as a class, are "abnormal" or beyond the experience of ordinary people. Helpfulness, however, is a composite standard encompassing costs as well as benefits, and this is something *Turner's* critics tend to overlook. Expert evidence may be misinterpreted or misunderstood, divert jurors' attention into collateral issues, or waste time with cumulative proof of points already well-established by other evidence. Some forms of expert evidence may be especially prone to misinterpretation. It is widely held, for example, that lay jurors have a poor grasp of probability and statistical evidence, though there is disagreement about whether fact-finders are overawed by statistics or more commonly underestimate their true probative value (Koehler 2001; Lempert 1991; Tribe 1971). Irrespective of its theoretical relevance or weight, expert evidence is likely to be excluded if the trial judge is persuaded that it is probably going to be more trouble than it could be worth to hear it.

Helpfulness is the only master-key necessary to unlock the logic of admissibility decisions in England and Wales. Whether expert evidence will actually be admitted on any particular occasion turns on a detailed evaluation of all the available evidence in the case viewed in light of the parties' respective litigation strategies, a factual matrix which will necessarily vary enormously from one trial to the next. Judicial assessments of the admissibility of expert evidence in the current proceedings may consequently be of limited value as legal precedents in subsequent cases.

Expert Qualification

English courts have demonstrated similar flexibility in their assessments of experts' scientific credentials. The legal test of competence for expert witnesses adds little to the threshold relevancy standard, and operates in practice to promote the reception of expert testimony.

There is no requirement of formal training or paper qualifications, professional practice, or even membership of a relevant organization or learned society. The well-known case of *R v Silverlock* [1894] 2 QB 766, CCR, decided that a witness's amateur interest and study were sufficient to qualify him as an expert in handwriting analysis. As Lord Russell of Killowen CJ explained, the question is simply whether or not the witness possesses expert knowledge relevant to an issue before the tribunal, irrespective of how he or she might have acquired it: "The question is, is he *peritus*? Is he skilled? Has he an adequate knowledge? .... There is no decision which requires that the evidence of a man who is skilled in comparing handwriting, and who has formed a reliable opinion from past experience, should be excluded because his experience had not been gained in the way of his business" (ibid. 771).

Case-law illustrations of English courts' catholic conception of forensic "expertise" abound. A drug user with no scientific training or knowledge was permitted to identify a substance in his possession as cannabis (*R v Chatwood* [1980] 1 WLR 874, CA), while a police officer with experience in drug offenses could testify as an expert on the street price of heroin (*R v Hodges* [2003] 2 Cr App R 247, CA). It is perfectly proper for an artist to give "facial mapping" evidence, even though he has "no scientific qualifications, no specific training, no professional body and no database" (*R v Stockwell* (1993) 97 Cr App R 260, 264, CA; confirmed in *R v Atkins* [2010] 1 Cr App R 8, [2009] EWCA Crim 1876). In another memorable case, membership of the Inner Circle of Magic qualified a witness as "a highly expert magician" (*Moore* v *Medley*, *The Times*, 3 February 1955, cited by Smith (1995: 113)). Just about anybody who can provide the jury with specialist information relevant to the proceedings qualifies as an "expert" in English law.

Bespoke Forensic Reasoning Rules for Expert Evidence

Once questions of admissibility have been determined, the focus shifts to how evidence may be used in the trial. English criminal procedure law's "forensic reasoning rules" come in various shapes and sizes. Some forensic reasoning rules are mandatory, notably including the trial judge's obligation to direct the jury on the burden and standard of proof. Other doctrines prescribe flexible directions drawing the jury's attention to the inherent infirmities of particular sorts of evidence, such as eye-witness identifications (*R* v *Turnbull* [1977] QB 224, CA) or the incriminating testimony of an erstwhile accomplice (*R v Beck* [1982] 1 WLR 461, CA) or warn the jury to resist slipping into enticing reasoning fallacies, such as misinterpreting the probative significance of a lie (*R v Lucas* [1981] QB 720, CA) and other forms of evidential "double-counting."

A number of forensic reasoning rules pertaining specifically to expert evidence have been crafted by common law judges over the years. The most fundamental precept is that the jury is the ultimate arbiter of disputed facts, and must be clearly instructed to form its own view, even in relation to uncontradicted scientific, technical, or other expert evidence (e.g., *R v Allen* [2005] EWCA Crim 1344). As Lord President Cooper famously put it in *Davie* v *Edinburgh Magistrates* [1953] SC 34, 40, the role of the expert witness is "to furnish the judge or jury with the necessary scientific criteria for testing the accuracy of their conclusions, so as to enable the judge or jury to form their own independent judgment by the application of these criteria to the facts proved in evidence." Legal commentators differ on the extent to which "juror education" is a practically feasible aspiration for legal adjudication (Allen 1994; Imwinkelreid 1997; Edmond 1998). It is implausible to imagine that a short, intensive course of juror education within the context of criminal trial proceedings could truly substitute for an expert's long years of education, training, and practical experience. But jurors can at least be expected to exercise their critical faculties in deciding to rely on expert evidence bearing on contested factual issues. Measured, reflective, rational deference to expertise should not be equated with slavish acceptance or abdication of deliberative responsibility. And the jury must emphatically retain its sovereignty in determining "factual" questions with a normative dimension, such as whether the accused was "grossly negligent" (e.g., *R v Misra and Srivastava* [2005] 1 Cr App R 21, [2004] EWCA Crim 2375) or acted with diminished "mental responsibility" (e.g., *R v Dietschmann* [2003] 1 AC 1209, HL).

Rational deference to expertise might be an attractive option when the jury is presented with uncontradicted expert evidence, but how should the jury proceed in cases where experts called by the adversarial parties disagree? The answer is that the jury should do its common sense best to interpret the experts' disagreement in the light of all the evidence in the case and its relevance to the charges and the facts in issue. Ultimately, in cases of enduring uncertainty or doubt, the criminal burden and standard of proof weigh in favor of an acquittal (e.g., *R v Cannings* [2004] 1 WLR 2607, CA). It is sometimes argued that cases involving disagreements between experts should attract a special judicial direction, but the Court of Appeal has resisted the notion that there is some ubiquitous form of words that must be used to cover this situation (*R v Hookway and Noakes* [2011] EWCA Crim 1989). The judge is merely required to do what trial judges must do in every case: to summarize fairly and fully any factual disagreement between the (expert) witnesses, indicate the potential salience of that disagreement for the questions that need to be determined, and leave the rest to the jury's good sense.

It should already be apparent from the preceding discussion that a firm presupposition of lay jurors' expertise in common sense reasoning is cemented into the institutional architecture of English criminal adjudication. Attempts to encourage the jury to depart from its ordinary reasoning processes are consequently frowned upon. Thus, in a case in which a defense expert encouraged jurors to apply Bayes' Theorem to contested evidence, the Court of Appeal thundered:

> [T]he attempt to determine guilt or innocence on the basis of a mathematical formula, applied to each separate piece of evidence, is simply inappropriate to the jury's task. Jurors evaluate evidence and reach a conclusion not by means of a formula, mathematical or otherwise, but by the joint application of their individual common sense and knowledge of the world to the evidence before them. (*R v Adams* [1996] 2 Cr App R 467, 481)

Moreover, the "ultimate issue" of determining the accused's guilt or innocence is always reserved to the fact-finder. The courts are assiduous in ensuring that "trial by expert," or even "trial by science," is never allowed to usurp the constitutional functions of trial by judge and jury. As Lawton LJ intoned in *Turner*, "We do not find that prospect attractive and the law does not at present provide for it" ([1975] 1 QB 834, 842).

The way in which juries are expected to reason about forensic science and other expert evidence has further implications for the way in which expert witnesses are expected to present their evidence in the courtroom. Expert testimony must be reasonably intelligible to lay people and communicated in a manner that successfully conveys its true probative significance. Thus, English courts have striven to ensure that DNA profiling evidence does not inadvertently encourage jurors (or trial judges directing them) to commit the well-known "prosecutor's fallacy," as reproduced by the Court of Appeal in *R v Doheny and Adams* [1997] 1 Cr App R 369, 372–373:

1. Only one person in a million will have a DNA profile which matches that of the crime stain.
2. The defendant has a DNA profile which matches the crime stain.
3. Ergo there is a million to one probability that the defendant left the crime stain and is guilty of the crime.

Deduction (3) is clearly fallacious, because "one in a million" is the frequency of the DNA profile in the suspect population, not the probability that the accused is the source of the profiled crime stain. If there were, say, four million people in the relevant suspect population, one would expect to find four individuals, plus the actual donor of the crime stain (who may or may not be the accused), with that matching DNA profile. Taking the profiling evidence in isolation, the probability that the accused is the source of the crime stain is actually 1-in-5 or 0.2. Glaring and pronounced though the fallacy seems when illustrated through simple hypotheticals, anecdotal evidence suggests that it may occur in practice with alarming regularity. English courts have attempted to insulate the jury from its distorting impact by insisting that a forensic scientist "should not be asked his opinion on the likelihood that it was the defendant who left the crime stain, nor when giving evidence should he use terminology which may lead the jury to believe that he is expressing such an opinion" (ibid. 374: generally, see Puch-Solis et al. 2012; Redmayne 2001).

More recently, in *R v T* [2011] 1 Cr App R 9, [2010] EWCA Crim 2439, the Court of Appeal went so far as to say that experts should not even employ likelihood ratios in their own case-work in the absence of a robust statistical basis to support further quantitative analysis. This was something of an overreaction (Redmayne et al. 2011), but the Court's chief concern was entirely legitimate. It feared that the expert, who testified regarding footwear marks, was building factual assumptions into his evidence which were being concealed from the jury at trial. Experts' own inferential reasoning needs to be transparent so that the jury can perform its designated role as fact-finder, rather than simply being presented with an expert witness's inferential conclusions as a forensic *fait accompli*. These procedural rules are perhaps best categorized as supplementary admissibility standards, regulating not so much *what* information can be adduced at trial but *how* it may be presented. But their rationale is evidently rooted in traditional conceptions of the methodology and status of jury fact-finding in English criminal adjudication, and particularly when expressly incorporated into the trial judge's summing-up to the jury, these procedural requirements are also aptly characterized as forensic reasoning rules.

Future Prospects: Reliability Through Reform?

Functional competence and "*Turner* helpfulness" constitute a flexible and relatively undemanding framework of bespoke admissibility standards, which in practice (and with the possible exception of certain kinds of behavioral science evidence) tends to militate in favor of receiving relevant expert witness testimony even when its probative value is sometimes questionable. Indeed, it might be said that English law has been rather *too* liberal in receiving scientific evidence in criminal trials, with too little scrutiny of its scientific credentials (Roberts 2008; Ormerod 2002). Some purported science is only "junk science" (Bernstein 1996; Huber 1991); not all forensic experts are properly qualified, and a few may be irresponsible charlatans. Even genuine experts might unwittingly propound false theories, make operational errors in their testing or calculations, or overstep the boundaries of their legitimate expertise. The question then arises as to whether criminal trial procedure is sufficiently well-insulated from fake science and bogus experts, and capable of distinguishing between valid and invalid scientific claims. Given that the whole system of criminal adjudication is predicated on lay fact-finders utilizing ordinary common sense techniques – principally listening to the testimony and observing the demeanor of witnesses who appear before them in the courtroom – ensuring scientific validity obviously poses a major design challenge for English criminal proceedings.

Promoting the validity and reliability of scientific and other expert evidence might be achieved in various ways. One might attempt to regulate forensic science providers directly, to subject crime labs to schemes of accreditation and performance management, or to compile registers of appropriately qualified experts certified court-safe. One might rely on internal professional regulation and codes of professional ethics to maintain standards. There is a sense in which criminal litigation itself exerts a kind of market pressure on expert witnesses, since experts judged poor by the adversarial party hiring them are unlikely to be instructed again in future cases. (However, this is a very imperfect market by any standards, and may be warped by perverse incentives: the most effective courtroom performers, who delight their instructing lawyers time after time, might be poor scientists or willing to indulge in unethical behavior in order to help "their" side win the case.) It is likely that an effective legal framework for promoting and monitoring the quality of forensic science evidence and expert witness testimony would incorporate several, and perhaps all, of these complementary strategies. A final question to consider is whether reform of existing trial procedure law should form part of a comprehensive regulatory package in England and Wales (or anywhere else).

Drawing on the experiences of other common law jurisdictions, and in particular the "*Daubert* trilogy" in the USA (Berger 2011), the Law Commission (2011) has recently recommended the introduction in England and Wales of an enhanced judicial gatekeeping function in relation to expert evidence. The basic idea, modeled on *Daubert* v *Merrell Dow* 113 S Ct 2786 (1993), is that, whenever the reliability of expert evidence proffered by the prosecutor or defense lawyers is challenged, the trial judge ruling on admissibility should be obliged to undertake a preliminary assessment of its validity and reliability, by reference to an open-ended list of statutory criteria. The proposed statutory criteria include "generic factors" like data quality and completeness, appropriateness of methodology, soundness of inferential conclusions, and extent of peer review, and make provision for supplementary “factors for specific fields” to be added by the Lord Chancellor through delegated legislation.

It remains to be seen whether these recommendations will find their way onto the statute-book. US courts’ mixed experiences with *Daubert* over the last two decades (Risinger 2007) clearly demonstrate that investing trial judges with a gatekeeping duty to scrutinize the validity and reliability of scientific and other expert evidence does not, at a stroke, solve all the practical problems associated with expert witness testimony in the courtroom. It could, indeed, create new difficulties. In its preliminary consultation paper the Law Commission (2009: 1.13) wisely cautioned that “reforming the law governing the admissibility of expert evidence would not provide a panacea.” Re-engineering formal admissibility rules does not necessarily alter judicial culture or practice, or to the extent that it does, adaptive behavior may defeat reformers’ expectations. There is potentially greater scope for effective intervention in pretrial proceedings, for example, through comprehensive pretrial disclosure and judicial encouragement to agree scientific evidence and narrow down the issues for trial. These are now prime objectives of proactive judicial trial management in England and Wales, within the framework of the Criminal Procedure Rules first promulgated in 2005 (see, e.g., *R v Reed and Reed* [2010] 1 Cr App R 23; [2009] EWCA Crim 2698). None of this amounts to an argument against reforming rules of admissibility, if reform is desirable and well-executed. It simply reaffirms the truism that the law of criminal trial procedure is only one among many influences on the conduct and outcomes of criminal adjudication, not least in trials involving scientific evidence or expert witness testimony.

Expert Witnesses: Role, Ethics, and Accountability

Tony Ward
School of Psychology, Victoria University of Wellington, Wellington, New Zealand

Overview

Expert witnesses make observations or draw inferences that lay or judicial fact finders would not be able to make for themselves. It is, nevertheless, the jury or judge and not the expert that is the ultimate fact finder. It is therefore central to the role of expert witnesses, and to their ethical obligations, that they give a clear account of their conclusions and reasoning that enables the fact finder to reach an informed and independent judgment as to how far expert evidence can be relied upon. In adversarial systems of trial, great reliance is placed upon cross-examination and the ability to call opposing experts to ensure that experts are held accountable for their methods and that fact finders are not misled. In practice, however, these methods have serious shortcomings and need to be combined with other forms of accountability such as oversight by professional bodies.

The Role of the Expert Witness

The role of expert witnesses differs from that of ordinary witnesses of fact in the scope they have to draw inferences from their own observations and those of other witnesses. In this respect, the expert is an exception to the general preference, at least in the common-world, for witnesses to stick as closely as practicable to an unvarnished account of what they saw and heard, leaving the fact finder – often the lay jury – to draw its own inferences from those facts (see ▶ Scientific Evidence in Criminal Prosecutions).

"Expert evidence" is a much wider category than "scientific evidence," although arguments about exactly which experts qualify as "scientists" are not particularly helpful. Gross and Mnookin (2003) offer a taxonomy which usefully captures the range of roles expert witnesses may play. Much expert evidence, they point out, is primarily descriptive. Experts may observe phenomena that lay people would miss, or know the meaning of terms (e.g., in a drug-using subculture) that a jury might not, or be able summarize information by means of a calculation ("the deceased's blood alcohol level was three times the drink-driving limit"). A second role for experts is that of instructing fact finders as to general propositions relevant to the case, such as the nature of mitochondrial DNA, the characteristic symptoms of autism, or the norms of acceptable medical practice. The role that gives rise to the greatest difficulty, however, is that of assessment of evidence. Experts draw upon their general knowledge and experience to offer opinions on diagnosis, causation, prognosis, identity – "this fingerprint matches that of the defendant" – or value (e.g., of drugs or stolen goods). In this role, experts go beyond merely providing information to the court, to interpret the factual or normative significance of the phenomena that they or others have observed. In doing so, they are undertaking a task that is normally reserved for the judge or jury.

Expert witnesses have to accept that their cognitive authority is, in principle, subordinate to that of the court: "forensic experts. . .agree to surrender ultimate control over the way scientific evidence becomes built into constructions of factual reality" (Smith 1989, p. 71). If challenged to justify lay fact finders' control over the "construction of reality," lawyers might point to the fact that legal disputes are rarely resolved by scientific evidence *alone* (Dwyer 2008), and that the "reality" that emerges is one that the community as a whole is asked to accept as a legitimate basis for social action – in particular, punishment. The question for the court is not what the experts think is true but what the community at large can accept as true, given such trust as it can justifiably place in the experts. The court might be able to assess the substantive merits of the expert's argument, but even if it cannot, judges or juries may have good reason to believe that the expert's conclusions are soundly based, albeit for reasons the court does not fully understand (Hardwig 1994). Even if they understand a good deal of an expert's reasoning, lay fact finders generally have to take some of what an expert says on trust. So an important part of the expert's role is to communicate information in a way that the fact finder will both understand and trust.

The dynamics of trust differ according to whether the system of trial approximates to an inquisitorial or an adversarial model (see ► Scientific Evidence in Criminal Adjudication). In inquisitorial, civil-law systems, where experts are normally appointed by the court, judges (or coroners in some common-law systems) are likely to trust "their" experts as a matter of routine, although that trust may be challenged in exceptional cases (Bal 2005). The adversarial model has been described, with some exaggeration, as one of "institutionalized pure mistrust" (Wynne 1989, p. 33). The expert is called, almost invariably, to support one side in a contest, so their evidence cannot be accepted as something like objective truth until the other side has had an opportunity to challenge it. Conversely, the absence or failure of a challenge is taken to indicate that the expert evidence is reliable. In a circular process, what is unchallenged appears unchallengeable, and therefore remains unchallenged, as was until recently the case with fingerprint evidence (Cole 2001; Fingerprint Inquiry Scotland 2011). Where the evidence is more contentious, the adversarial system puts a premium on the ability to persuade juries (or judges), and can be accused of distorting the expert's role by making presentational skills more important than scientific acumen (House of Commons 2005).

The potential for conflict between an expert's roles as servant of the court and as a member of the prosecution or defense team is exacerbated by the fact that experts are involved in the investigation as well as the prosecution of crime. The emphasis in forensic work appears, indeed, to be shifting away from the courtroom and towards what Barclay (2009, p. 339) calls "a completely integrated approach" to major criminal investigations, "with detectives, crime analysts, forensic scientists, pathologists and behavioural experts all part of the same team." This "paradigm shift," as Barclay describes it, requires that scientists be given much more information than would previously have been thought desirable about lines of enquiry being pursued by the police, and offer more "personal interpretations, soft facts, and opinions expressed in shades of grey" (Barclay 2009) than they would when giving evidence in court.

There is a tension between the usefulness for investigative purposes of interpreting evidence in context and the need for objectivity, which may be undermined by knowledge of contextual information. Such information may simply lead experts to see what they expect to see (Dror and Rosenthal 2008). Risinger et al. (2002, p. 28) argue that for a forensic scientist to rely on any information outside her own domain is to "abuse her warrant," since it is for the jury, not the scientist, to assess the nonscientific evidence of the "case circumstances." On the other hand, it appears legitimate for scientists to take contextual circumstances into account in deciding which hypotheses to test and how to test them.

Tensions between investigative and courtroom roles can also arise in civil law, inquisitorial systems. The leading case on expert evidence in the European Court of Human Rights, *Bönisch v. Austria* (1987) 9 EHRR 191, concerned a prosecution for food hygiene offenses in which the President of the institute who initiated the prosecution also served as court expert at the trial. The defendant was able to call another expert, but as a mere "witness" this person had a lower status than the ostensibly impartial "expert" appointed by the Court. This was held to be a breach of the principle of "equality of arms." Jakobs and Sprangers (2000, p. 383) report that in "almost all European countries" there is some provision for the state to bear the costs of appointing defense experts, "but this situation creates some kind of control by the state" since prosecutors, judges, or legal aid authorities have discretion whether to provide for a publicly funded expert.

Adversarial proceedings – and the "equality of arms" principle makes all European criminal proceedings adversarial to some extent – depend upon experts being available to testify for the defense as well as for the prosecution. Defense lawyers also need experts to advise them on possible weaknesses in prosecution evidence. In practice, access to such resources on the part of the defense may not be forthcoming – particularly in the USA, where judges routinely deny expert assistance to indigent defendants (Giannelli 2003; Garrett and Neufeld 2009). Both the "battle of the experts" that sometimes develops, and the situation where a prosecution expert faces little effective challenge, raise important ethical issues about the limits of appropriate persuasion.

The Ethics of Expert Witnessing

It is uncontroversial that the first duty of a witness is to tell the truth. However, because the roles of the expert include "instruction" and "assessment" as well as "description" (Gross and Mnookin 2003), telling "the whole truth" is not such a simple matter for an expert as it might appear to be for an ordinary witness of fact. Experts implicitly warrant not only that the factual content of their evidence is true, but that the opinions they express are based on good reasons. Given the reliance that others will place on their testimony, it "is unethical for expert witnesses to hold or express unjustified beliefs" (Sanders 2007, p. 1542).

In England and Wales, the Criminal Procedure Rules (CrimPR) and accompanying practice directions have recently codified the ethical duties of experts to ensure that their opinions are justified, and to provide the court with the information it needs in order to assess whether they are justified. According to the CrimPR, the duty of the expert is to "help the court to achieve the overriding objective" of dealing with cases justly "by giving objective, unbiased opinion on matters within his expertise" (r. 33.2).

One form of "objectivity" in expert evidence is that the expert states what she takes to be what any competent expert would observe or conclude given the same information (Smith 1989) – or if not, she explains why divergent views are possible. The duty to be objective and unbiased also entails that the evidence that experts give should not be colored by any interest they may have in the proceedings. Yet it is arguably unrealistic to expect experts involved in criminal cases to be entirely disinterested, for at least four reasons. First, as we have seen, expectations may create unconscious biases: Experts are only human, and human beings tend to see what they expect to see. Secondly, in an adversarial system there are inevitably pressures to identify with the party and lawyers by whom one is called. Thirdly, many experts are subject to the pressures of the market, either as individual professionals or as employees of commercial service providers. In such an environment, the probative value that experts can claim for their evidence, its power to discriminate between conflicting hypotheses, may be directly correlated with its market value (Lawless 2011). Fourthly, serious crimes arouse strong emotions to which experts are not immune, particularly if their work involves examining or treating the victim. It is questionable whether complete objectivity is possible in this situation (Candilis et al. 2007); at all events, it is hard to judge objectively whether one is objective or not! What is fairly uncontroversial is that experts should "strive for objectivity" (AAPL 2005, Section IV). This involves not only telling the court what one honestly believes, but explaining the reasons for *and against* those beliefs: what Candilis et al. (2007, p. 21) call the "duty of transparency."

Transparency involves stating the basis of one's opinions in a way that enables the court to make its own assessment of the reliance it can place on them. The ethical duty of transparency has at least four aspects.

Transparency as to the Basis of the Expert's Evidence

When an expert is testifying about matters beyond the knowledge of the court, the court may not be in a position to evaluate independently the reasoning on which the experts' conclusions are based. The court may then have little choice but to defer to the expert, assuming that – given their training and experience in the application of an established body of knowledge – experts probably have good reasons for what they assert (Hardwig 1994). Where the expert is relying not on specialized observations but on matters that the court is equally, or more, competent to assess, this kind of deference to expert authority has no place. The court needs to know when this is the case, both so that unwarranted deference can be avoided and to guard against "double-counting" the evidence.

This points to the particular importance of transparency on the part of experts who engage in the kind of contextual interpretation that Barclay's (2009) "new paradigm" of forensic science, and many kinds of medical or psychological diagnosis, require. For example, it is important for pediatricians reporting alleged signs of sexual abuse to make clear when they are relying on hearsay information or behavioral signs in interpreting ambiguous physical signs (*Lillie and Reid v Newcastle City Council* [2002] EWHC 600 (QB), [395]–[396]). Hence, the requirements in the CrimPR state that an expert's report must include the following:

(a) Give details of the expert's qualifications, relevant experience and accreditation
(b) Give details of any literature or other information which the expert has relied on in making the report
(c) Contain a statement setting out the substance of all facts given to the expert which are material to the opinions expressed in the report, or upon which those opinions are based
(d) Make clear which of the facts stated in the report are within the expert's own knowledge (r. 33.3)

Transparency as to Disagreement Within the Expert Community

One of the reasons that may induce a court to accept an inference drawn by an expert is that it derives from premises that the whole community of qualified experts accepts. The court, however, will usually be dependent on the expert witnesses themselves to tell it whether a consensus exists. Experts should "not give the impression that [they] speak for the community of experts when [they] do not. When the community of expert opinion is divided, there is an obligation to say that it is" (Hardwig 1994, p. 92). Or as the CrimPR put it, "where there is a range of opinion on the matters dealt with in the report," the report must include the following:

1. Summarize the range of opinion
2. Give reasons for his own opinion (r. 33.3(1)(f))

Transparency as to Areas of Uncertainty and Conflicting Evidence

The Criminal Procedure Rules require that "if the expert is not able to give his opinion without qualification, [his report must] state the qualification" (r. 33.3(1)(g)). This is particularly important where the limitations of research may afford grounds for reasonable doubt – even if the experts personally have no doubt about their conclusions. For example, one should not declare confidently that certain features of a young girl's vagina and hymen are abnormal and indicative of penetration, while failing to mention that very little is known about the incidence of similar characteristics in non-abused girls (*R v T* [2008] EWCA Crim 3229).

Transparency and Clarity in Explaining Degrees of Probability

Terms like "match" or "similar in all microscopic characteristics" may be highly misleading to juries (McQuiston-Surrett and Saks 2009). The phrase "consistent with" can make neutral evidence – evidence equally consistent with the prosecution or defense hypotheses – sound as if it is highly probative (e.g., *Barry George v R* [2007] EWCA Crim 2722). On the other hand, evidence couched in statistical terms but based on very rough estimates may confuse the jury and create an unwarranted "verisimilitude of mathematical probability" (*R v T (footwear mark evidence)* [2010] EWCA Crim 2439, [86]). The most candid way of expressing such testimony would appear to be to give a "subjective probability estimate" which makes clear that it is "a product of the examiner's subjective judgment – a guesstimate" (McQuiston-Surrett and Saks 2009, p. 438). Such estimates can be expressed in the form of a "likelihood ratio" – the relative likelihood of a particular finding given either the prosecution hypothesis (e.g., that the defendant's shoe made a certain mark) or the defense hypothesis (i.e., it was a different shoe). The Court of Appeal in *R v T* controversially ruled that likelihood ratios should not be used at all in the absence of satisfactory data. It is difficult to see how a bar on *thinking* in terms of likelihood ratios can be enforced, and to insist that any statistical "guesstimates" must not appear in the expert's report appears to defeat the Court's emphasis on transparency about the methods an expert has used. The use of Bayesian methods (in which likelihood ratios are a central element) may also have an ethical advantage in that it compels the expert to consider the likelihood of hypotheses favoring the defense as well as the prosecution; this appears to have been one reason behind the introduction of the Bayesian CAI (Case Assessment and Interpretation) model used in British forensic science (Lawless 2011, pp. 677–679).

Another controversial form of probabilistic evidence is the prediction of future violence. While some psychiatrists consider it inherently unethical to offer such evidence given the high rate of false-positives in such predictions, Grisso and Appelbaum (1992) argue that it is ethically permissible to give estimates of risk based on sound scientific research. The difficulty with this position, as pointed out by Litwack (1993), is that in many cases where psychiatrists would consider there was clearly a high risk if an offender were released (e.g., the patient has committed serious violence before when actively psychotic and is unwilling to take antipsychotic medication), actuarial data about the risk of reoffending may not be available because of the rarity of people in such supposedly high-risk categories being released.

An expert witness's duties of objectivity and transparency may be difficult to follow to the letter if the expert is also acting as a therapist to the victim (e.g., in a sexual assault case) or to the defendant. It may be difficult to combine the objectivity of a witness with the empathy of a therapist. A therapist's first duty is to the interests of the patient, a witness's is to the court, and these duties may conflict, especially if the witness gives evidence that is harmful or traumatic to the client

(Strasburger et al. 1997). Giving evidence may also conflict with the duty of confidentiality to a patient (e.g., Bal 2005). Such conflicts do not arise in every case, but a potential witness must always consider whether giving the most honest and objective possible evidence is compatible with therapeutic goals and with respect to patient confidentiality.

Accountability

The report of the searching *Inquiry into Paediatric Forensic Pathology in Ontario* defines accountability as "the obligation to answer for a responsibility conferred" by explaining and justifying one's decisions and actions (Goudge 2008, pp. 332–333). In this sense, the courtroom itself is one of the most important fora in which expert witnesses are called to account. In some respects, this can be effective. Timmermans (2006) found that it was the prospect of being called to account in court for every inference they drew that led to the cautious approach adopted by the medical examiners he observed. The care that is usually taken to document the "chain of custody" of DNA samples might also be attributed to the accountability exercised through courtroom cross-examination (Lynch et al. 2008). "History has shown" Aronson (2007, p. 211) concludes in his study of DNA profiling, "that a competent defense review of forensic evidence can reveal problems that are either consciously ignored or overlooked by forensic scientists and prosecutors." However, lack of knowledge, motivation, or ability among defense lawyers and lack of resources to pay for alternative experts allow many errors in forensic evidence to go undetected. Garrett and Neufeld (2009) studied 137 transcripts from US trials where defendants were convicted, partly on the basis of forensic evidence, and later exonerated by DNA evidence. In this admittedly unrepresentative sample of trials, they found that 60 % included scientific evidence that was "invalid" in some respect, usually either the misstatement of empirical data or the drawing of conclusions unsupported by the data. Invalid testimony was rarely subject to cross-examination, and the defense was rarely able to call its own experts, as courts declined to fund them. As Gross and Mnookin (2003, p. 158) observe, "If we are going to rely on the adversary system to guarantee competence and honesty in expert evidence we must actually have an adversary process. When one side is absent, the result may be disastrous."

In addition to competent and adequately funded defense lawyers, adequate disclosure of the basis of expert evidence is essential if the trial is to be an effective form of accountability. Lack of such disclosure has been central to several notorious miscarriages of justice in England. This issue is closely linked to the ethical duty of transparency discussed above. Giannelli (2007) cites several US cases where fraudulent or incompetent forensic scientists have disclosed only very terse and cryptic reports, thus increasing the difficulties the defense face in cross-examining them. The Federal Rules of Criminal Procedure do require that the summary of expert evidence disclosed to the defense must "describe the witness's opinions, the bases and reasons for those opinions, and the witness's qualifications" (r. 16(1)(G)), but this falls far short of the duties of transparency set out in the English Criminal Procedure Rules. The Fingerprint Inquiry Scotland (2011) called for fingerprint examiners to be "more transparent and ultimately more descriptive of their methodology, work practices and the specific factors involved in any particular conclusion" (para. 37.51) so as to facilitate more effective scrutiny of their work in court.

As Giannelli (2007) points out, even when criminal courts do expose shortcomings or misrepresentations in an expert's work, this does not necessarily prevent the same expert from testifying again in other cases. In this respect, civil-law systems with their panels of court-appointed experts have an advantage, since there is usually some form of disciplinary procedure by which experts can be removed from the panel (Jakobs and Sprangers 2000).

Given the uneven nature of the trial process as a form of accountability, it is often thought desirable that expert evidence given at trial should be scrutinized by other experts. The Ontario inquiry discussed a number of mechanisms operating in various parts of Canada for holding pathologists and forensic scientists accountable for evidence they give in court, including observation of a forensic scientist's testimony, or examination of the transcript, by a manager; asking prosecution and defense counsel to complete questionnaires on the expert's evidence; and having each forensic pathologist accompanied to court at least annually by another pathologist who observes and evaluates their testimony (Goudge 2008, p. 358). The report recommended an annual process of peer review for forensic pathology testimony, which "should be documented and encompass a process of discussion and feedback" (Goudge 2008, p. 359).

In England and Wales, the Forensic Science Regulator (2011) has issued a Code of Practice which includes provisions that providers whose staff give evidence in court should be able to demonstrate, inter alia, "that the principles, techniques and assumptions they have relied upon are valid," that the inferences they draw are sound and alternative hypotheses have been considered, that their methodology has been considered by other scientists and any objections have been addressed, and that they can cite specific instances of their methods resulting in demonstrably valid or misleading conclusions and explain how these support or undermine their claims (paras. 25.2.1–25.2.2). These are all matters that could appropriately be raised in cross-examination but often are not; they are also similar to the criteria for admissibility recently recommended by the Law Commission. At the time of writing, the Regulator has no statutory powers (although the Government has indicated that it may reconsider the position). The Code of Practice builds upon an ISO (International Standards Organization) standard, no. 17,025. EU Framework Decision 2009/905/JHA requires all member states to accredit DNA laboratories to this standard by November 2013 and fingerprint examiners by November 2015. With the publicly owned Forensic Science Service (FSS) having been closed down in 2012, private contractors bidding for forensic work are expected to be accredited by the UK Accreditation Service under ISO 17025 (House of Commons 2011, para. 97). As yet, there is no such requirement for police in-house forensic services which have taken over some of the work formerly done by the FSS (House of Commons 2011, paras. 101–109).

Other forms of accountability involve disciplinary or legal proceedings against experts who have failed in their duties. These have recently been the subject of two major cases in England. *Meadow v General Medical Council* concerned an eminent pediatrician who was struck off the medical register following his statistically illiterate evidence in the case of a mother convicted of murdering her two young children. At first instance ([2006] EWHC 146 (Admin)), Mr Justice Collins held that the common law immunity of witnesses from suit in respect of their evidence protected them not only from civil actions for damages but also from disciplinary proceedings by professional bodies. This ruling, based largely on policy considerations about the deterrent effect of possible complaints on the willingness of medical experts to undertake forensic work, was overturned on appeal. The Court of Appeal's view was consistent with the US authorities on this issue (Sanders 2007, pp. 1564–1565). Again the main ground was one of policy: the need to protect the public against unreliable experts. The majority of the Court, however, considered that Professor Meadow's misconduct in testifying erroneously on statistical matters outside his expertise had to be set in its "forensic context" ([2006] EWCA Civ 1390, [89], [205]). Defense counsel had failed to challenge the admissibility of this evidence or to expose Professor Meadow's fallacious reasoning in cross-examination, and the evidence they later called to refute his claims may have been insufficient to counter the "major effect" which the Court of Appeal suspected his vividly worded evidence to have had on the jury (*R v. Clark* [2003] EWCA Crim 1020, [178]). Since the lawyers carried some of the blame for what had gone wrong, the judges considered that Professor Meadow had not committed *serious* professional misconduct by straying beyond his expertise. He was therefore reinstated on the medical register.

In *Jones v. Kaney* [2011] UKSC 13, the Supreme Court decided that expert witnesses should not enjoy immunity from suit for breach of their duty to the party instructing them. The defendant had signed a joint statement by the experts in civil proceedings for personal injuries, which she later admitted did not reflect her true opinion and which undermined her client's claim for damages. Lords Phillips and Dyson both indicated, however, that civil liability would also extend to testimony by a defense expert in a criminal case (ibid. [60], [125]) – although a civil action by a convicted defendant would be stayed as an abuse of process if the conviction had not been quashed on appeal. As Lord Hope pointed out in his dissenting judgment, this produces the seemingly anomalous result that a prosecution expert continues to enjoy immunity but a defense expert does not. Lord Collins, who concurred with the majority, pointed to a number of US authorities holding that "friendly" experts are not immune to civil actions by their clients. These cases, however, all concern expert evidence in civil litigation. Witnesses in US criminal trials enjoy immunity from suit even if they perjure themselves (*Briscoe v LaHue* 460 US 325 (1982)).

Conclusion

Jones v Kaney brings us back to the ambiguity of the expert witness's role in an adversarial system. The defense expert's duty to the client is, in principle, identical to her duty to the court – a duty to give honest and impartial evidence in accordance with acceptable professional standards. Similarly the prosecution expert, particularly in the case of a private provider in the neoliberal economy of forensic science (Lawless 2011), is under a contractual duty to comply with standards of impartiality and scientific rigor. The idea that duties of impartiality are best enforced through legal accountability to the partisan purchasers of expert services may appear somewhat paradoxical.

On a more optimistic note, it may be that a model of accountability is gradually emerging under which courtroom processes and regulatory systems reinforce one another. If admissibility requirements (see ▶ Scientific Evidence in Criminal Prosecutions), the cross-examination of witnesses and the requirements of regulators are all informed by similar criteria of impartiality and reliability; if regulators can keep track of experts' performance in court; and if lawyers are aware of experts' compliance or noncompliance with regulatory requirements, we may develop an appropriate set of ethical standards for expert witnesses underpinned by an effective system of accountability for their breach.

Extent of Imprisonment: Global View

Roy Walmsley
World Prison Brief, The International Centre for Prison Studies, London, UK

Overview

The extent of imprisonment worldwide cannot be determined precisely, but a broad estimate can be achieved. The opportunity to compare the figures for individual countries provides the basis for assessing the need for policy changes. The first attempt at compiling a complete list of world prison populations was published in 1999; since then, information has been traced on the extent of imprisonment in almost all countries.

The estimated world prison population is now in excess of 10 million. The rate per 100,000 of the world's population (the prison population rate) is around 150. The country with the highest prison population rate is the USA with a rate of 730 per 100,000 of the national population. Fifteen other countries have rates over 400. By contrast, 15 countries have rates below 40; ten of these are in Africa. Prison population rates vary considerably between different regions of the world, and between different parts of the same continent.

Female imprisonment constitutes between 2 and 9 % of the total prison population in most countries. Six of the seven highest levels (between 15 and 22 %) are in Asian prison systems. Overall, more than 625,000 women and girls are held in penal institutions throughout the world.

Pretrial/remand prisoners constitute the vast majority of the prison population in some countries and only a small minority in others. Nine of the 12 highest levels (over 70 %) are in Africa. In 16 countries, the level is below 10 %. It is likely that there are now more than three million in pretrial/remand imprisonment.

Foreign prisoners generally constitute less than 30 % of the prison population, but in six countries more than 70 % of prisoners are foreign nationals.

Overcrowding in the world's prison systems is evidenced by the fact that the official capacity of the systems is exceeded in three fifths of the 196 countries on which information is available. In 23 countries, the occupancy level is more than twice the intended capacity.

Introduction

Imprisonment may be defined as custodial confinement as a result of being suspected or convicted of one or more criminal offenses.

It is not possible to know precisely the extent of imprisonment worldwide, but a broad estimate can be achieved.

There are several reasons why the precise level cannot be known, including the following:

(a) Some countries never reveal the number of people detained in prisons or other penal institutions as a result of being suspected or convicted of criminal offenses – e.g., the Democratic People's Republic of Korea (North Korea), Eritrea, and Somalia.

(b) Some countries only publish incomplete figures – e.g., the People's Republic of China only reveals the number of sentenced prisoners in Ministry of Justice facilities, while Maldives and Vietnam only reveal the number of sentenced prisoners; the number of pretrial/remand prisoners in these countries is not published.

(c) Some countries do not include in their prison population totals young people suspected or convicted of a criminal offense but held in a form of custody that is not known as a prison. Likewise, some do not include persons suspected or convicted of a criminal offense but held in custody in a police-run institution or a psychiatric facility.

(d) Some countries include in their prison population totals persons detained as illegal immigrants, even though they are not suspected or convicted of a criminal offense.

(e) People held in a form of custody that is not under the authority of the national prison administration are not usually included in national prison population totals.

(f) The information available as to the number of prisoners in each country does not relate to the same date.

Many of the above considerations do not generally have a large effect on the calculation of the extent of imprisonment worldwide. For example, in those countries where juveniles are held in custody in respect of a criminal offense but excluded from the published prison population total the number of such juveniles is generally not large, and the same is true of the number of persons held in psychiatric facilities as a result of criminal offenses.

It is (a) and (b) above that are the main obstacles to knowing the full extent of imprisonment worldwide. But by assuming that the prison population levels in the countries for which information is missing or incomplete are similar to the median figures for the subcontinental region in which they are situated, a broad estimate can be achieved.

The availability of information about the extent of imprisonment in the individual countries enables governments and prison administrations, and all those who have an interest in improving criminal justice, to compare the level of imprisonment in one country with that in another and to consider the reasons and justifications for the differences that are revealed. This provides the opportunity for the development of evidence-based policy changes.

Background of the Data Collection

Many countries have for a long time been recording the number of prisoners in their own prisons and detention centers, although others have only started doing so quite recently, and it is believed that there are still a small number of countries that do not keep such records on a regular basis even now.

But efforts to assemble prison population totals in a large number of countries have been very few. The Howard League for Penal Reform assembled figures (in respect of a date between December 1932 and June 1936) for 54 countries in "The Prisoner Population of the World," a document submitted to the League of Nations in August 1936.

The International Penal and Penitentiary Commission (now the International Penal and Penitentiary Federation) assembled figures (mostly in respect of 31 December 1936) for 55 countries, in response to a request by the League of Nations, in "Enquiry into the number of prisoners and measures taken to reduce it" a report submitted to the League of Nations in 1938.

In the 1970s, the United Nations commenced its series of surveys of "Crime Trends and the Operations of Criminal Justice Systems" which include a section that includes prison population data. These surveys (the most recent, the 12th, obtained data for 2009) generally receive prison data from 60 to 65 countries, about half of them in Europe.

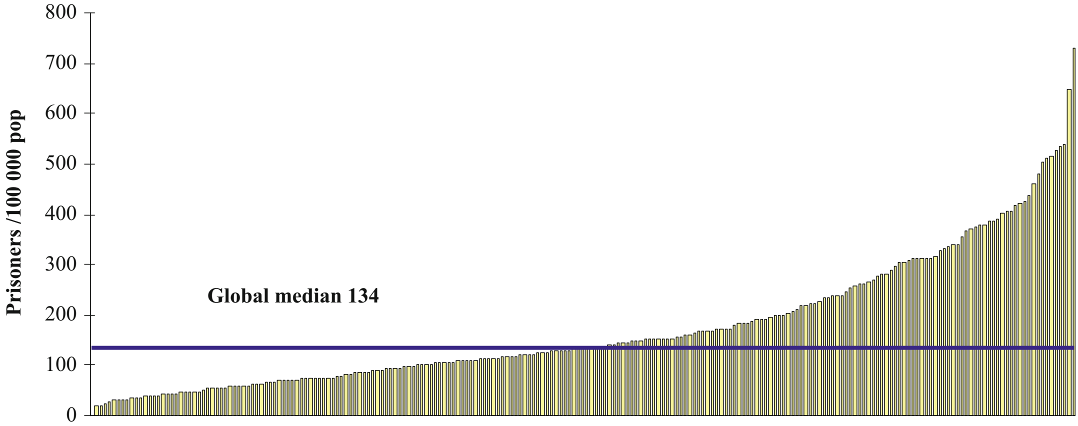
In 1983, the Council of Europe commenced its annual series of prison statistics in its member states "Council of Europe Annual Penal Statistics" or, using its French language acronym, "SPACE" (Tournier 1983). Reflecting the increasing membership of the Council, the number of countries for which prison population data was received has grown from 19 in 1983 to 31 in 2000 and 47 (52 prison systems) in the most recent (2010) edition (Aebi and Delgrande 2012).

The first attempt at producing a complete list showing the number of prisoners in each of the world's countries was compiled in 1998 and published by the British Home Office (Walmsley 1999, 2001). Containing data for 180 countries, it acknowledged the limitations described in the above introduction and drew attention to the desirability of improving the reliability and comprehensiveness of the data and of including information on the proportion of females and of pretrial detainees in penal institutions and on occupancy levels.

The World Prison Population List has now reached its ninth edition (Walmsley 2011), which contains figures for 218 countries. From 2000, it has been complemented by the online World Prison Brief, which has substantially developed the information available on the extent of each country's imprisonment level along the lines indicated above, including the proportion of foreign prisoners, information on trends and lists ranking countries from the highest to the lowest on prison population data variables.

Overall Imprisonment Levels

Global overview. The world prison population rate, calculated on the basis of 10.1 million prisoners and a world population of 6.9 billion, is 146 per 100,000, or 156 per 100,000 on the basis of a world prison population of 10.75 million (including 650,000 in Chinese "detention centers") (Walmsley 2011). The median rate is 134 (World Prison Brief, accessed 10.8.12).



Extent of Imprisonment: Global View, Fig. 1 Prison population rates in 221 countries (Source: World Prison Brief (ICPS), Lappi-Seppälä 2013)

The country with the highest prison population rate is the USA with a rate of 730 per 100,000 of the national population. Fifteen other countries have rates over 400 per 100,000, seven of which are small Caribbean islands – Saint Kitts and Nevis (649), US Virgin Islands (539), Anguilla (480), British Virgin Islands (c. 460), Curacao (422), Bermuda (417), and Grenada (402); the other eight are Seychelles (535), Rwanda (527), Georgia (514), Cuba (510), Russian Federation (505), Belarus (438), and Azerbaijan and Belize (both 407) (World Prison Brief, accessed 10.8.12).

The countries with the lowest prison population rates are predominantly in Africa. This applies to ten of the fifteen countries that have rates under 40 per 100,000, namely, Liberia and Guinea (both 39), Mali (36), Chad (34), Republic of Congo and Democratic Republic of Congo (both 33), Nigeria (31), Burkina Faso (28), and Central African Republic and Comoros (both 19); the other five are Liechtenstein (39), Monaco (34), India (30), Faeroe Islands (21), and Timor-Leste (20) (ibidem).

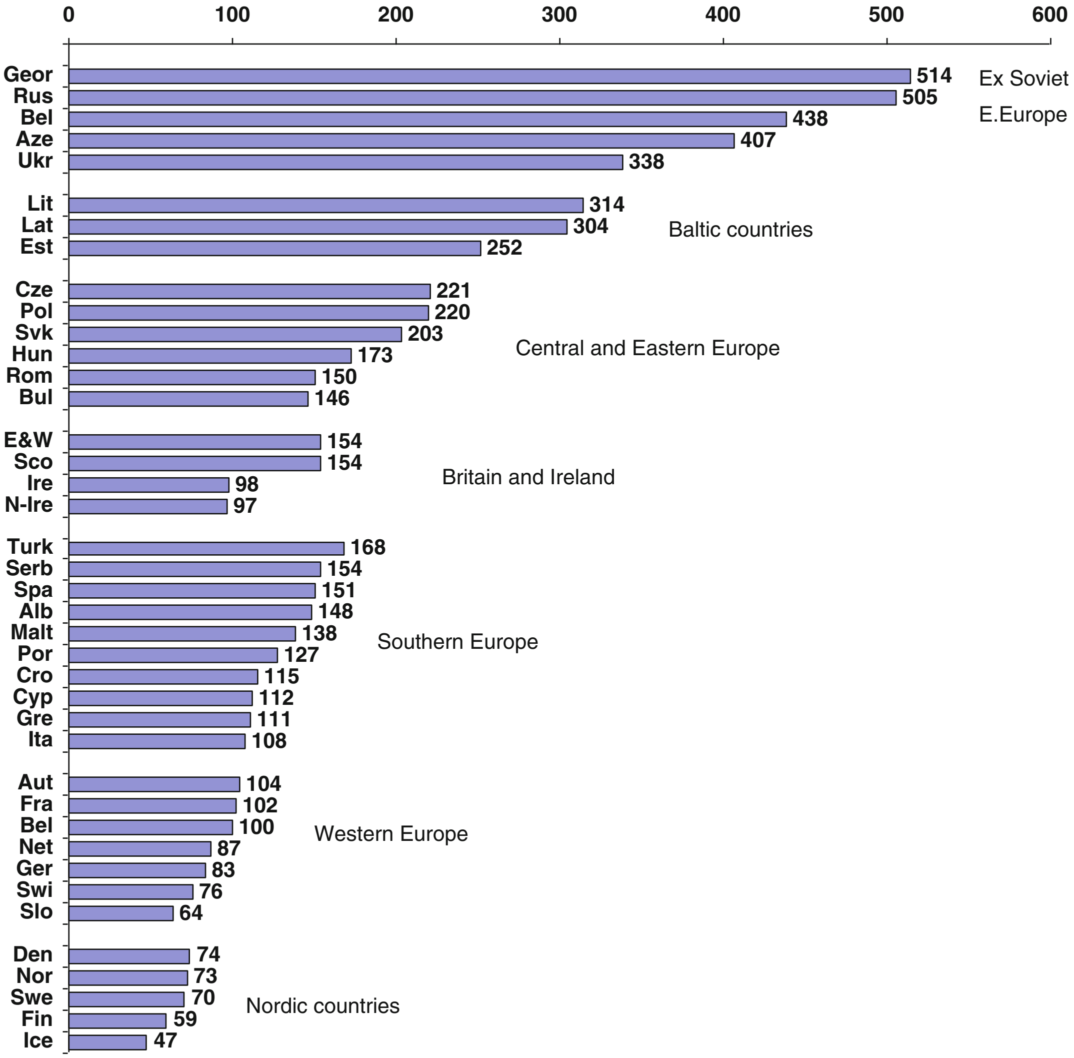
Figure 1 displays the number of prisoners relative to 100,000 population (the prison population rate) in 221 countries. The figures range from below 20 to 730.

Prison population rates vary considerably between different regions of the world, and between different parts of the same continent. For example:

- In Africa, the median rate for western African countries is 47.5, whereas for southern African countries it is 219.
- In the Americas, the median rate for south American countries is 175, whereas for Caribbean countries it is 357.5.
- In Asia, the median rate for south central Asian countries (mainly the Indian subcontinent) is 42, whereas for eastern Asian countries it is 155.5.
- In Europe, the median rate for western European countries is 96, whereas for the countries spanning Europe and Asia (e.g., Russia and Turkey) it is 228.
- In Oceania (including Australia and New Zealand) the median rate is 135 (Walmsley 2011).

Figure 2 demonstrates the variation between different regions in Europe.

Nordic countries as a region have the lowest level of prisoners in Europe (with Slovenia and Switzerland on the same level). The Nordic figures vary from 47 to 74. The corresponding figures for Western European countries are 64–104, Southern Europe 108–168, Britain and Ireland 97–154, Central and Eastern Europe 146–221, Baltic countries 252–314, and countries of former Soviet Eastern Europe 338–514 (for explanations of differences, Lappi-Seppälä 2008, 2013).



Extent of Imprisonment: Global View, Fig. 2 Prison population rates in 40 European countries (Source: World Prison Brief (ICPS))

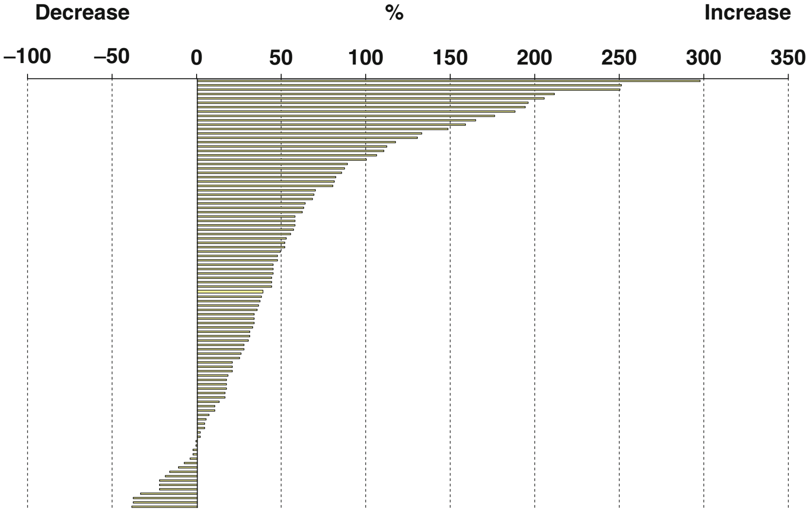
Trends and changes. The estimated world prison population has risen from 8 million (based on the latest data available at November 1998) to more than 10.1 million (based on the latest data available at May 2011) – or 10.75 million if persons in Chinese "detention centers" are included (Walmsley 1999, 2011, for global trends 1997–2007 see Walmsley 2010 and Lappi-Seppälä 2013).

Figure 3 displays percentage changes in prison population rates from 1992 to 2012 in around 100 nations for which data is available.

More than four out of five countries have experienced increasing prison population rates since the early 1990s. Some have more than tripled their rates and the majority of countries have at least doubled their rates.

Imprisonment and Specific Groups

Female imprisonment constitutes between 2 and 9 % of the total prison population in most countries. The highest levels are in six Asian prison



Extent of Imprisonment: Global View, Fig. 3 Percentage changes in prison population rates from 1992 to 2012 (Source: World Prison Brief (ICPS), Lappi-Seppälä 2013)

systems – Maldives (22 %); Hong Kong-China (20 %); Bahrain (18.5 %); Macau-China, Qatar, and Thailand (all 15 %); and also in Andorra (16 %) (Walmsley 2012).

There are continental variations in the prevalence of women and girls within the total prison population. The median level is 4.45 %, but in African countries, female prisoners constitute a much smaller percentage of the total (the median is 3.1 %) than in Asia where the median is almost twice as high (5.95 %). The median levels in the Americas, Europe, and Oceania are 5.15 %, 4.9 %, and 3.9 %, respectively (ibidem).

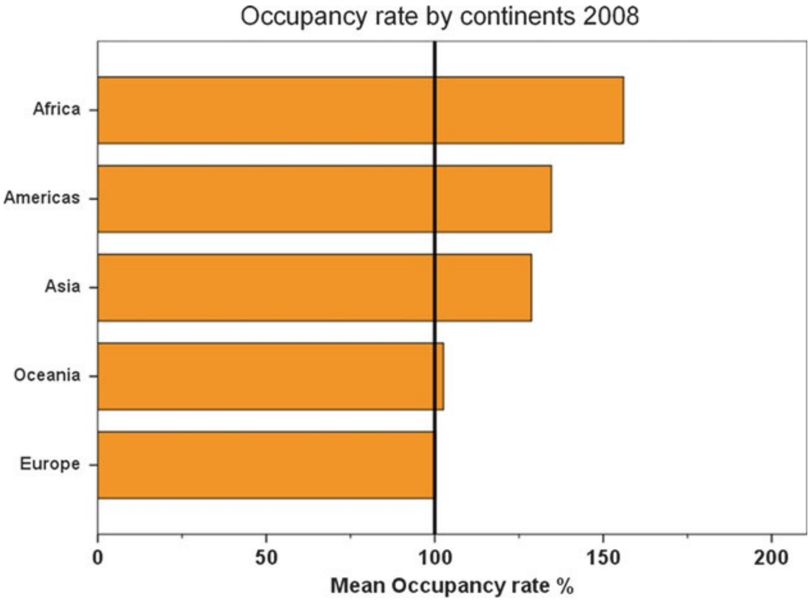
Overall, more than 625,000 women and girls are held in penal institutions throughout the world (ibidem). Nearly a third of these are in the USA (201,200). The next three countries in terms of numbers are China (with 84,600 plus women and girls in pretrial detention or "administrative detention"), the Russian Federation (59,200), Brazil (35,596), and Thailand (29,175). The other countries with more than 7,000 female prisoners are India (15,406), Vietnam (12,591 plus women and girls in pretrial detention), Mexico (10,072), Ukraine (9,697), and the Philippines (7,726).

There is evidence that the female prison population has increased by more than 16 % between 2006 and 2012. Further, the prevalence of women and girls within the total prison population has increased in recent years, especially in Asia and Europe (ibidem).

Pretrial/remand prisoners constitute the vast majority of the prison population in some countries and only a small minority in others. In 12 countries, nine of them in Africa, more than 70 % of prisoners are in this category. By contrast, in 16 countries pretrial/remand prisoners constitute less than 10 % of the prison population. The median level is 30 % (World Prison Brief, accessed 10.8.12).

In 2007, two and a quarter million persons were known to be held in pretrial and other forms of remand imprisonment, and it was estimated that a further quarter of a million were so held in countries on which such information was not available (Walmsley 2008). The subsequent increase in the total prison population would suggest that there are now at least three million in pretrial/remand imprisonment.

Foreign prisoners constitute less than 30 % of the prison population in most countries, but more than half the prison population are foreign nationals in 15 countries and in six of these foreign nationals make up more than 70 % of prisoners – United Arab Emirates and Monaco (both 92 %), Qatar (73 %), Saudi Arabia (72 %), and Liechtenstein and Switzerland (both 71 %) (World Prison Brief, accessed 10.8.12).



Extent of Imprisonment: Global View, Fig. 4 Occupancy rate by continents 2008

Overcrowding

High levels of imprisonment are invariably accompanied by overcrowding. If a country has a prison population that exceeds its official capacity (i.e., has an occupancy rate in excess of 100 %) it can safely be assumed that there is overcrowding and the higher the rate the more likely that the overcrowding is of a serious nature.

Three fifths of the 196 countries on which information is available (ibidem) have occupancy rates in excess of 100 %; 49 of these have rates over 150 %; and 23 of the 49 have rates over 200 %, which means that two prisoners are accommodated in the space intended for one. In the worst cases, the number of prisoners exceeds the number of prison places by three to one.

Eleven of the 23 nations with rates over 200 % are in Africa, a continent in which there are only a small number of countries where the prison system is not known to be over capacity. In the Americas, the system is over capacity in over three quarters of countries. Many prison systems are overcrowded also in Asia, where most countries in South Central Asia have rates over 150 %. The situation is less bad in Europe and Oceania; however, even in these continents about half the prison systems are over capacity.

Figure 4 shows the continental variations in occupancy levels in 2008.

Overcrowding is even worse than these figures suggest. This is because the official capacity of institutions is set in many countries at a level that provides prisoners with less space than international human rights bodies consider adequate. Furthermore, even in a prison system that is not overcrowded when taken as a whole, there are often individual prisons that are overcrowded – and sometimes severely overcrowded.

Eyewitness Evidence: Historical Background

James M. Doyle
Independent Researcher, Carney & Bassil,
Boston, MA, USA

Overview

The growing general recognition that eyewitness memory does not operate as a stable DVR or videotape record of experience but rather requires a complex multistage process of encoding, storage, and reconstruction that is vulnerable at every step to influence and contamination has intersected with a growing list of exonerations of wrongfully convicted individuals in eyewitness cases revealed by DNA comparisons. There is now a widespread perception that honest but mistaken eyewitnesses are the leading cause of wrongful convictions.

Law enforcement and legal practitioners have long recognized that their dangerous dependency on unreliable identifications of perpetrators by eyewitnesses in criminal cases is an important weakness in criminal justice systems (Borchard 1932). Since at least the end of the nineteenth century, social scientists have investigated the sources of eyewitness error and have attempted to persuade criminal justice practitioners to apply their findings in modernizing investigative and adjudicatory practices. The result has been a long and complicated relationship between researchers and criminal justice practitioners: a dynamic of reciprocal challenge and response that has influenced both the research agenda of the scientists and the daily routines of the practitioners. The history of the psychology/criminal justice interface in the eyewitness context parallels and may in fact have formed a template for interactions in other contexts such as the evaluation of interrogations leading to false confessions.

Concern with eyewitness unreliability is an international phenomenon that has attracted the attention of a polyglot array of researchers (Sporer and Cutler 2003; Roberts 2009), but the structure of the dialogue concerning eyewitnesses can be seen most clearly in common-law countries where investigative fact development is later subjected to adversarial end-stage adjudicative inspections. The collision between social science research and criminal justice system practice is starkly illuminated by experience in the United States, where the relationship of the science of eyewitness memory and the criminal justice system can be described as a chronicle of running battles that have stretched over more than 100 years.

This historical background exercises a significant influence over current discussions and contributes to the fact that while there is now a very substantial body of research and commentary addressing the eyewitness issue, “A significant shortcoming in much of the writing on the subject is the adoption of a parochial and procedurally atomistic approach” (Roberts 2009).

Early Encounters: Munsterberg and His Peers

The basic battle lines or the interaction of the psychology researchers and the criminal justice community was laid down in early controversies initiated by Hugo Munsterberg, a student in Wundt’s earliest psychology courses, who was brought to Harvard by William James to run Harvard’s experimental psychology laboratory. Munsterberg, an energetic promoter of his new discipline, had outlined in his best selling 1908 book, *On the Witness Stand*, a remarkably prescient series of insights concerning the operation of witness memory. He provided, for example, demonstrations that eyewitness mistakes were frequent, that memory was not permanent but malleable, and that witness confidence was not sure evidence of witness accuracy (Munsterberg 1908). These findings had obvious forensic applications, but Munsterberg, in his self-appointed role as publicist and controversialist, complained that although other disciplines and professions were eager to learn the lessons about eyewitness memory that his new field of experimental psychology was beginning to teach: “the lawyer alone is obdurate.” Munsterberg charged that the lawyers chose traditional primitive ignorance over scientific enlightenment.

This charge drew the attention of John Henry Wigmore, the Dean of Northwestern University School of Law and the preeminent evidence scholar of his era. Wigmore was an early proponent of the integration of scientific psychology into legal practice, and in his article responding to Munsterberg’s charges, he provided an appendix that compiled a full list of the extant psychological material and that indicated that Wigmore had actually reviewed that material more thoroughly than had Munsterberg himself (Doyle 2005).

The real purpose of Wigmore’s article was to illuminate the potential in a law and psychology relationship and to throw his prestige behind its inception. Wigmore agreed that the legal system had neglected psychologists’ research. Wigmore’s goal was to herald the day when the lawyers and psychologists could move forward in “a friendly and energetic alliance in the noble cause of justice” (Wigmore 1909). Even so, according to Wigmore, Munsterberg was premature in announcing the immediate utility of such an alliance; Wigmore thought that was still on the distant horizon. Wigmore pointed out that while Munsterberg’s findings on the reliability of witnesses were highly significant, the legal system’s concern was not with the reliability of *witnesses* in general but with the reliability of *verdicts* in individual cases. Munsterberg’s mistake, according to Wigmore, was his assumption that contemporary psychology could immediately help the criminal justice system to sort the correct eyewitnesses from the incorrect ones. Wigmore argued that day had not arrived. Still, Wigmore looked forward to its arrival, and he was confident that day would come. “When the psychologists are ready for the courts,” he announced in a subsequent piece, “the courts will be ready for the psychologists” (Wigmore 1937).

But it was not the substance of Wigmore’s response to Munsterberg that was best remembered by psychologists; it was the caustic satirical tone of his article. Wigmore’s criticism is still recalled as a paradigm of the kind of welcome social scientists should expect from the legal system and its practitioners (Doyle 2005).

In fact, Wigmore did want to issue a mild call to order: to correct Munsterberg’s overstatements and to address Munsterberg’s misapprehensions about the realities of legal practice. But Wigmore structured his article as a mock trial of a Munsterberg proxy for libeling the legal system and then proceeded to humiliate this fictional psychologist and, by extension, to humiliate psychology. Deployed in this starkly adversarial format, Wigmore’s Olympian status in the legal world and Wigmore’s corrosive sarcasm combined were devastating and drove Munsterberg from the field. After Wigmore’s article, although research continued in the laboratories, the question of the proper role of psychology in assessing eyewitness memory lay dormant as a public issue for close to 70 years.

The Expert Witness Era: Robert Buckhout and Elizabeth Loftus

Psychologist Robert Buckhout picked up Munsterberg's fallen banner in the politically charged atmosphere of the United States in the 1970s, and he relied on a modernized version of Munsterberg's demonstration approach (Doyle 2005). For example, Buckhout induced a New York television station to broadcast a staged crime and invite viewers to make choices from a staged lineup. The number of correct identifications this process yielded was lower than would have been achieved by random guessing (Doyle 2005). But while his method may have been similar to Munsterberg's, Buckhout's temperament was very different from his predecessor's. Munsterberg was an academic who retreated when faced with Wigmore's onslaught. Buckhout knew his science, but he was a cheerful agitator who carried the battle into the courts and into the popular media.

Buckhout published an accessible survey article on eyewitness error in the general audience magazine *Scientific American* (Buckhout 1974). He testified on the unreliability of eyewitness testimony in the trial of California radical Angela Davis and was instrumental in winning her acquittal. He seized every opportunity to comment in the media (e.g., opining on the case of a butcher identifying his own pork chops from a pork-chop lineup) where the lessons of eyewitness psychology could be taught. His science was aligned with his politics. Buckhout believed that criminal defendants, particularly poor and minority indigent defendants, were being abused by the legal system's complacent reliance on an antique view of how memory worked. He almost immediately rallied two groups of partners.

The first group was a cohort of idealistic younger psychologists, like Elizabeth Loftus, who were anxious to see that their science have an impact in the world. Loftus attacked the eyewitness issue in a radically different way: She "did science" in the form of rigorously controlled experiments, changing one variable while holding all others constant. The results she began to produce were striking. She showed, for example, that when questions about a white barn were introduced into interrogations of witnesses who had viewed a film of an auto accident, over 20 % of those viewers later reported seeing a white barn although in fact there had been no white barn in the film (Loftus and Palmer 1974).

This was a crucial finding for criminal eyewitness cases: It showed that eyewitness memory not only decayed but also *changed*. It showed that a witness could not only forget the right man but also – after being unknowingly influenced by viewing mug shots or showups (which operate as "post-event information" like the white barn in an interview question) – could remember the *wrong* man.

Loftus's findings and those of her colleagues mounted quickly, and they went to the heart of the eyewitness experience as it is encountered in the criminal justice system. Taken together they indicated that in an eyewitness case, the memory of the witness is for all practical purposes the scene of the crime. They showed that memory evidence was, in effect, "trace evidence": difficult to collect, easy to contaminate, but impossible to test for contamination after any contamination has occurred.

At the same time, Loftus's scrupulous scientific methods were winning her work admission to the blue-ribbon, peer-reviewed academic journals and encouraging younger academic psychologists to extend and challenge her research. Experimental findings such as Loftus's (unlike the demonstrations of Munsterberg and Buckhout) could be replicated or falsified. The number of published studies multiplied (Cutler and Penrod 1995). Forensically relevant findings on the effects of stress, own-race bias, and post-event information burgeoned.

By the late 1970s, the history of the eyewitness issue in the United States had become completely entangled with the peculiar features of common-law adversarial tradition. The United States

Supreme Court had ruled in a series of cases that identifications that had been so infected by police misconduct as to be irreparably unreliable would be excluded from trials on constitutional grounds (Manson v. Braithwaite 1977). But those rulings left open the question of how to assess the credibility of identifications that were not unconstitutional but may have been less reliable than jurors' "commonsense" understanding of memory as a stable DVR or videotape capacity suggested.

Tantalized by psychological research's potential for undermining confidence in that range of identifications, Buckhout's second group of recruits, the desperate criminal defense lawyers, joined in. Buckhout's testimony in the Angela Davis case had drawn their attention, and his *Scientific American* article quickly circulated through the defense bar. Elizabeth Loftus published a popular general audience account of eyewitness science, *Eyewitness Testimony*, at about this time, and that contribution was buttressed by an influential Stanford Law Review comment written by Frederick Woocher (a trained psychologist then in law school), which provided a blueprint for arguments for conveying psychological science through expert witnesses. Defense lawyers began to demand the admission of expert testimony before juries by Loftus, Buckhout, and their colleagues aimed at debunking faith in eyewitness evidence.

This point of entry was bad luck for anyone who hoped for Wigmore's "friendly and energetic alliance." Persistent litigation over admissibility of psychological testimony did help to keep the issue of eyewitness science alive in the courts, and feedback from skeptical courts did help to provoke new, better-targeted research. But these benefits came at a steep price.

The initial environment has affected discussions of eyewitness science in criminal justice ever since. Admissibility questions arise at the most acutely adversarial moments of the criminal process, and their resolution (at least in the eyes of the contending advocates) may determine who wins and who loses a trial. The US prosecutors – goaded by inflammatory rhetoric from Buckhout – quickly denounced eyewitness findings as enemy pseudoscience: a trick designed to let criminals go free by unnerving credulous lay jurors and sliming all eyewitnesses, most of whom were right and many of whom were crime victims. For some American prosecutors – then and now – eyewitness science is simply a shield for the guilty. For many judges, the cumulative price of the skirmishing over marginally interesting science the experts offered seemed enormous in terms of hours, dollars, and distended docket backlog.

The critics of expert psychological testimony garnered important support from within the research community. Well-respected psychologists took the position that the field's existing body of knowledge was crippled by problems of ecological validity and theoretical inadequacy and was insufficient to aid the accurate resolution of disputed identification questions. It was the position of this group – which was quickly found and utilized by prosecutors – that efforts to use experts' psychological testimony promised more harm than good: more juror confusion than enlightenment, more guilty people freed than innocent people protected. In this view, the testimony of Buckhout and his successors misappropriated the prestige of science to produce only unjustified and destructive general skepticism about eyewitnesses (McCloskey and Egeth 1983). Since the prevailing test for the admission of novel expert testimony in the United States at that time focused on the "general acceptance" of the science offered by the proposed experts within the relevant scientific community, adversarial battles over the admissibility of evidence focused tightly (for purely forensic reasons) on this fault line within the research community.

This dispute had the unexpected effect of acting as a goad to further research, as researcher-experts attempted to address the criticisms of skeptical adversaries and colleagues. A substantial body of knowledge began to accumulate, one peer-reviewed publication at a time. By 1989, Kassin and his colleagues, in a survey of psychologists, were able to generate a list of propositions – for example, the focus on a weapon degrades eyewitness reliability – with which 80 % of psychologist-experts agreed

(Kassin et al. 1989). In the view of some, the desire for pragmatic usefulness outran the substance of the research findings. For example, legal actors understandably sought to make use of psychologists' findings that post-event information had an impact on witness performance before scientists had determined whether that impact was to replace original memories, to alter memory traces, to lead to attribution of a memory to the wrong source, or to instigate a "memory blend" of old and new information.

New Focus on the Prevention of Error: "System-Variable" Research and Application

While the battles over admissibility of expert testimony ground on in American courts, another of Buckhout's recruits, Gary Wells, was engineering a shift in perspective (Wells 1978; Doyle 2005). Wells admired Loftus and accepted her findings as good science, but he also pointed out limits on their utility.

Because Loftus and her peers were scrupulous scientists, they had isolated and studied a single factor (e.g., the wording of a question, the stress of the event, the presence of post-event information) at a time. Wells noted that these studies yielded statistical results that could tell you what happened eight times out of ten, but could not tell you whether *this* case was one of the eight or one of the two. That second question, clinical and diagnostic (not probabilistic in nature as were the research results), was the challenge the legal system actually faced. Wells also noted that every criminal event incorporates many factors, not just one, and there was no science-based mechanism for combining these factors and assessing their interactions. From Wells' point of view, offering post hoc diagnosis of eyewitness error from the witness stand was the wrong way to mobilize the solid (but inherently probability-based) science that Loftus and a generation of their colleagues were producing.

Wells successfully called for the new orientation that has dominated criminal justice policy discussions about eyewitnesses for the past decade. He noted that some factors Loftus had studied (e.g., lighting, age of witness, stress of event) are not under the criminal justice system's control. He called these "estimator variables." But he also noted that there were other factors (e.g., lineup construction, lineup administration, witness interview technique) that the system's actors *do* have power over. If you understood how these "system variables" could be modernized, you could reduce the rate of error. Wells argued that preventing mistakes by identifying new "best practices" in investigation would be better than trying to catch mistakes from the witness stand after they happened. The task of psychological science in this conception was the prevention of eyewitness errors as evidence was being produced, not the retrospective inspection of eyewitness testimony to see if an error had occurred.

A torrent of research followed, exploring and refining new elements of "system-variable" design (Malpass 1981). In part, this was because the ethical barriers that bedevil research into the witness's time-of-event "estimator" experiences do not generally arise in "system-variable" investigations. Research-based designs for new techniques for interviewing witnesses without contaminating memories (Fisher and Geiselman 1989), for choosing the members for lineups and photographic arrays, and for performing identification procedures began to be developed and to gain momentum. That research coalesced around a photo-array and lineup protocol described by a number of leading researchers in an influential consensus "white paper" of the American Psychology-Law Society.

This document urged the adoption of four reforms to prevailing procedural routine. First, the authors recommended that a "blind" official who did not know the identity of the suspect administer the test. Second, the authors, adopting a line of defense pioneered by Malpass, aimed at reducing the likelihood that a witness might make a "relative judgment" that an innocent suspect "looks most like" the perpetrator and choose the suspect on that basis by urging that the eyewitness be told at every procedure that the real perpetrator "may or may not" be present in the lineup or photographic array (Malpass 1981). Third, the authors agreed that research indicated that the "fillers" in the procedure should be chosen to match the witness's verbal description of the perpetrator rather than the suspect. Finally, the "white paper" urged that the police take a statement of confidence from the witness immediately after any choice in order to minimize the influence of "feedback" which might later boost the witness's confidence artificially.

An alternative attack on the "relative judgment" problem, the "sequential" display of suspect and fillers one at a time was discussed but not included in the four core recommendations of the white paper, although it has since become an important (and controversial) focus of reform efforts.

Controversies over Developing "Systems" Applications

Criminal justice system efforts to harvest the lessons of social science findings in the eyewitness area received powerful new impetus from the release of the first lists of DNA exonerations of wrongfully convicted defendants: lists on which convictions driven by mistaken eyewitnesses predominated (Garrett 2011). Many systems have begun to institute "system-variable" procedural changes based on scientific findings.

These changes have been quite varied, and they have been arrived at by different routes in different systems. In the United Kingdom, for example, where the administration of criminal justice is highly centralized, the Devlin Commission and its successors assessed the problem and suggested changes that were made broadly applicable and supported by legislation (Roberts 2009). Innovations such as a preference for video lineups over traditional live identification parades have been adopted relatively seamlessly.

In the United States, where thousands of individual jurisdictions make independent decisions about eyewitness procedures, advances have not followed a straight line.

The origin of many changes in routine practice can be traced to an influential document produced by the United States Department of Justice's research arm, the National Institute of Justice, in 1999, in the immediate aftermath of the first DNA exonerations. The NIJ convened a mixed "Technical Working Group" composed of leading researchers, experienced police and prosecutors, and defense bar representatives (Technical Working Group 1999). That group debated the existing research in light of law enforcement operational concerns and then published and disseminated *Eyewitness Evidence: A Guide for Law Enforcement*, with the explicit goals of increasing the amount of eyewitness evidence collected (e.g., by employing research-generated "cognitive interview" techniques), enhancing the quality of eyewitness evidence (e.g., by avoiding memory contamination in interviews and decreasing "looks-most-like" pressures by providing pre-lineup instructions), and improving the justice system's ability to evaluate eyewitness evidence (e.g., by requiring recording of an immediate witness confidence statement at the time of any identification).

The *Guide* was not an expression of scientific consensus; it emerged from a long and contentious process during which operational realities, political compromises, and an awareness that US jurisdictions are diverse in their resources and attitudes all played a role. No scientist would have considered the *Guide* to be "cutting edge." For example, the *Guide* did not embrace a requirement that lineups be administered "double blind," and while it did include instructions for conducting the new "sequential" lineups in which the suspect and fillers are displayed individually, it did not announce a preference for that procedure. Nor did the *Guide* have any binding effect on anyone; it was purely advisory.

Nevertheless, the N.I.J. *Guide* seems to have inspired the creation in state and local jurisdictions of similar "all-stakeholders" working groups, task forces, and commissions which have wrestled over and then ultimately adopted versions of the "double-blind sequential" approach to lineup administration. This approach, often associated with Iowa State

University researcher Gary Wells, has at its core double-blind administration, fillers matched to descriptions, pre-lineup ("perpetrator may or not be there") instructions to witnesses, "sequential" presentation of lineup members, and an immediate confidence measurement.

The spreading application of the double-blind sequential approach has not been uncontested.

Even psychologists broadly supportive of system-variable reforms have expressed doubts about the empirical basis for particular elements of the new approach, especially the "sequential" approach to the display of suspects and fillers in a lineup or photographic array (McQuiston-Surrett et al. 2006).

Some feel that the double-blind sequential protocol imposes unacceptable burdens on frontline police investigators, although police in jurisdictions employing the method generally express satisfaction with its operability.

Others, both within and outside the academy, have objected on utilitarian policy grounds. They argue that the double-blind sequential format's successes in protecting the innocent are outweighed by the fact that it also seems to reduce the rate of correct identifications of the guilty (Clark 2012). While results vary on this point somewhat from study to study, it generally appears that the double-blind sequential technique reduces the number of false identifications when the actual perpetrator is not present in the lineup or array but at the price of reducing the number of accurate identifications when the actual perpetrator *is* in the group (Steblay 2011). Although the increase in the rate of "false misses" in the "target present" identifications is considerably smaller than the reduction in the rate of "false hits" when the actual perpetrator is not present, the debate over whether the costs of the traditional system (in which falsely identified suspects result in the guilty going free *and* innocents going to prison) are outweighed by the costs an aggravated rate of "false misses" in the double-blind sequential format is a point of contention in many discussions of reform (Clark 2012).

There have also been perennial challenges focused on the ecological validity of the entire body of eyewitness findings. Most study has occurred in laboratory settings, utilizing student subjects. Within that setting, certain conditions (e.g., the terror experienced by an actual sexual assault victim during a crime) simply cannot be duplicated for ethical reasons. Although, in general, such scant "real-world," archival data as has been compiled and studied (Berman and Davey 2001) conforms in general outline to the laboratory findings, there are exceptions, and the generalizability of eyewitness studies to real-world conditions can be expected to remain an ongoing issue.

Skepticism about the usefulness of laboratory studies in gauging the effectiveness of reformed "system-variable" practices has led to calls for "field tests" of the double-blind sequential technique in actual cases. An initial effort in this direction, designed and conducted by the Chicago Police, led to a substantial detour when it was offered as proof that the in the field the "double-blind sequential" protocol when it was claimed that it produced a higher rate of inaccurate identifications than did traditional "non-blind, simultaneous" methods. Examination of that study, however, showed that it suffered from fatal design flaws that rendered its results largely to interpret and useless (Schacter et al. 2007). A subsequent, more carefully designed field study appears to have vindicated the laboratory findings of the superiority of the double-blind sequential approach (Wells et al. 2011). Even so, it is important to remember that "superiority" here is used to mean "producing fewer mistakes" (Steblay 2011). Some commentators would put a higher value on freeing the innocent, others on identifying the guilty. It is still contested as a utilitarian matter what ratio of imprisoned innocents/freed perpetrators one finds "superior." Although most law enforcement agencies that have confronted the trade-offs required have been satisfied that the double-blind sequential technique strikes the best balance, the issue cannot be regarded as settled. Different agencies and jurisdictions may come to different conclusions. In the United Kingdom, for example, although video identification procedures display one suspect or filler at a time, individually, the witness controls whether the viewings terminate after one round or repeat, converting a procedure into the functional equivalent of a "simultaneous," multiple choice test (Roberts 2009).

All field studies are hampered by the fact that they can assess only the rate of *suspect* identifications, using the identifications or failures to identify suspects (who may or may not be factually guilty) as a proxy measure for perpetrator identifications. Although the most recent field study, conducted by an alliance led by the American Judicature Society, made strenuous efforts to develop an approximation of the "ground truth" of the identity of the real perpetrator who was (or was not) identified in the real-world cases under examination, there is no way to be certain in a field study whether the suspect identified (or missed) was, in fact, the person seen during the commission of the crime.

Future Directions

There is one sense in which the future direction of the psychology and criminal justice relationship will remain unchanged: The participants will continue to attempt to educate their interlocutors in the methods, findings, and practical requirements of their mutually unfamiliar fields.

But there will be change as well as continuity. The future development of eyewitness issues in criminal justice will advance along distinct but not unrelated paths.

Continuing "system-variable" experimentation in the laboratories and in the field will have direct impact on the fact-generating, investigations, stage of the criminal process. It can be expected that the prevention of eyewitness error through the design of better techniques will remain a primary focus and that inquiries into emerging "best practices" sparked by field experience will result in modifications. It can also be expected that adjustments in police operations – for example, the migration of identification tasks such as lineup and photo-array administration to digital media and mobile devices – will require additional scientific inquiry to guarantee that new utilities take an evidence-based approach to the gathering of memory evidence.

At the same time, weaknesses in the adjudicative, inspection, stage of the process when seen in light of the modern scientific findings must also be addressed. The DNA exonerations lists have provoked extensive commentary (Simon 2012) concerning the limited diagnostic capabilities of the traditional criminal adjudicative vehicles. Lawyers and courts will have to supplement their existing toolbox with others devices. In the aftermath of the extensive system-variable reforms to investigative interview, lineup, and photo-array routines, courts are being forced to confront the issue of how to manage the adjudication of cases where there are imperfections in the eyewitness evidence gathering that fall short of best practices but where identifications are still admissible because they do not reach the level of crude suggestion that would require their elimination from evidence altogether. This issue has reinvigorated the debate over the efficacy of expert testimony. It has led to calls to enhanced "expert-substitute" jury instructions. The question of the handling of imperfectly derived but not constitutionally excludable identification evidence has also focused renewed attention on the impact of "estimator variables," since no set of "system-variable procedures" can completely eliminate the dangers created by a confluence of damaging "estimator variables" like lighting, race, or acute stress. Besides, a suboptimal investigative practice (e.g., a failure to give appropriate pre-lineup instructions) matters less when a calm witness viewed a criminal for a long time in an extended nonviolent crime event than it does when the event was traumatic and brief. A more sensitive ability to evaluate these complex situations can be hoped for as the education of courts and lawyers advances.

Finally, there is broad agreement among psychologists – some of whom disagree with each other on many specific issues – that the field needs to develop a more robust interest in basic theory (Clark 2012; Charman and Wells 2007). Psychologists have gained the place that Munsterberg claimed for them: They are now intimately involved in the development and evaluation of evidence. But there is a consensus that to continue to contribute in that hard-won role, psychologists will have to diligently pursue not simply discrete individual applications responding to challenges from practitioners but a broad, theory-driven program of research (Brewer et al. 2007).

Eyewitness Identification Evidence

Karen A. Newirth and Barry C. Scheck
The Innocence Project, New York, NY, USA

Overview

The admissibility and treatment of eyewitness identification evidence in criminal trials is governed in almost every US jurisdiction by the legal framework set forth by the United States Supreme Court in a series of cases decided between 1967 and 1977, when little was known about eyewitness memory and perception. This legal framework has remained firmly in place, despite the fact that in the intervening period there has been an explosion of research in the field of eyewitness identification, which now contains the largest and most rigorous body of scientific research of all the law-related social science fields (*State v. Henderson*, 27 A. 3d 872, 916 (NJ 2011)). The scientific research makes it abundantly clear that the current legal framework for evaluating eyewitness identification evidence is broken, a conclusion supported by the fact that eyewitness identification is the most common cause of wrongful convictions, playing a role in nearly 75 % of the 297 convictions overturned by post-conviction DNA testing. *See Eyewitness Misidentification*, Innocence Project, http://www.innocenceproject.org/understand/Eyewitness-Misidentification.php (last visited Jan. 12, 2012); *see also* Brandon L. Garrett, *Convicting The Innocent: Where Criminal Prosecutions Go Wrong* 48 (2011) (finding that 190 of the first 250 DNA-based exonerations in the United States involved eyewitness misidentification). This entry describes the current legal framework for evaluating eyewitness identification evidence and modifications to that framework imposed by lower courts, as well as suggestions for improvement based on scientific research.

Introduction

The Supreme Court has long recognized the significant and unique dangers that the admission of unreliable eyewitness testimony can pose for the criminal justice system. Forty-five years ago, long before the era of exculpatory DNA evidence, the Supreme Court held that the "vagaries of eyewitness identification are well-known; the annals of criminal law are rife with instances of mistaken identification" (*United States v. Wade*, 388 U.S. 218, 228 (1967)). The Court recognized that "a major factor contributing to the high incidence of miscarriage of justice from mistaken identification has been the degree of suggestion inherent in the manner in which the prosecution presents the suspect to witnesses for pretrial identification" (*Id.*). The work of the Innocence Project and affiliated entities that use post-conviction DNA evidence to exonerate the wrongly convicted have confirmed the Supreme Court's worst fears: mistaken eyewitness identifications have played a role in nearly 75 % of the 306 wrongful convictions identified by post-conviction DNA evidence, making eyewitness misidentification the most common contributing cause of wrongful convictions. The experiences of these exonerees, together with robust scientific research concerning eyewitness memory and perception, have identified fundamental flaws not only in traditional forms of pretrial identification procedures but also in the legal framework created by the Supreme Court and applied by courts to evaluate the admissibility of eyewitness identification evidence. Both the exonerations and the scientific research provide a useful roadmap toward an improved legal framework, which some state supreme courts have adopted in part in renovating aspects of the existing legal framework. *See*, e.g*., State v. Henderson*, 27 A.3d 872 (N.J. 2011); *State v. Lawson*, 291 P.3d 673 (Or. 2012).

The Current Legal Framework

A defendant's constitutional rights may be implicated by eyewitness identification procedures in one of two ways. First, and most commonly, due process is implicated when state-orchestrated identification procedures are impermissibly suggestive, resulting in a "very substantial likelihood of an irreparable misidentification" (*Simmons v. United States*, 390 U.S. 377, 384 (1968)). Second, a defendant's Sixth Amendment right to counsel is implicated if he is denied counsel at an identification procedure at which counsel has the right to be present. The Supreme Court has taken two distinct approaches to these different potential constitutional violations.

The Due Process Approach

Prior to 1967, when the Supreme Court heard *Stovall v. Denno*, 388 U.S. 293 (1967), the Court had never considered whether a pretrial identification procedure could implicate a defendant's right to due process. In *Stovall*, the Supreme Court recognized that the "totality of the circumstances" of an identification procedure may be "so unnecessarily suggestive and conducive to irreparable mistaken identification" as to deny a defendant due process of law (*Id.* at 302). *Stovall* involved a showup procedure where the defendant was brought to the victim's hospital room for a confrontation. The defendant was handcuffed to one of the seven police officers who escorted him and was the only black person in the room. The victim was asked by one of the police officers if the defendant "was the man," after which the victim identified the defendant as the person who stabbed him.

The Court set forth a two-part due process test, which directed that courts first ask whether the initial identification procedure was "unnecessarily" or "impermissibly suggestive" and, if so, to consider whether that suggestive procedure was "conducive to irreparable mistaken identification" (*Id.* at 302). While the Supreme Court noted that a showup identification, like the one at issue in *Stovall*, was "inherently suggestive" and "widely condemned," the Court acknowledged that exigent circumstances may make showups necessary. In *Stovall*, the "totality of the circumstances," including the victim's life-threatening injury and her inability to leave the hospital, led the Court to conclude that the showup was not impermissibly or unnecessarily suggestive as "an immediate hospital confrontation was imperative" (*Id.*).

One year later, in 1968, the Court applied the holding of *Stovall* to a case involving pretrial photographic identification procedures. In *Simmons v. United States*, 390 U.S. 377 (1968), the Court considered whether multiple, suggestive pretrial photographic identification procedures was so unduly prejudicial as to make the in-court identification at trial unreliable, thereby fatally tainting the conviction. The Court considered the "totality of the circumstances" and found that the in-court identification was not irreparably tainted by the suggestive pretrial identification procedure. The Court found that the suggestive procedures were necessarily given that a "serious felony had been committed;" the "perpetrators were still at large;" and the "inconclusive clues which law enforcement possessed led to [the defendants]" (*Id.* at 384–85).

The next year, the Court again considered whether a defendant's due process rights had been violated by pretrial identification procedures in *Foster v. California*, 394 U.S. 440 (1969). In that case, following the robbery of a Western Union, the police showed the witness a lineup that consisted of Foster and two others. Foster was at least six inches taller than the other two and was the only lineup member to wear a leather jacket, similar to the one the witness described the robber as having worn. The witness was unable to make a positive identification (stating that he "thought" that Foster was the robber) and asked for an opportunity to speak with him. The police allowed the witness to meet with and speak to Foster, after which the witness was still unsure whether Foster was the robber. A week later, the witness was shown a second lineup which consisted of Foster and four others; Foster was the only person to appear in both lineups. The witness reported that he was certain that Foster was the robber and testified to his out-of-court identification at trial, also making an in-court identification of Foster at trial. The Court reversed the conviction and held that Foster's right to due process had been violated because "the pretrial confrontations clearly were so arranged as to make the resulting identifications virtually inevitable" (*Id.* at 443). This was the first – and remains the only – time that the Supreme Court reversed a conviction on the grounds that a defendant's due process rights were violated as a result of a flawed identification procedure.

The next year, 1970, the Court heard *Coleman v. Alabama*, 399 U.S. 1 (1970), where petitioners appealed their convictions for assault with intent to murder. With respect to the identification procedures, Petitioners argued that the lineup they were subjected to was suggestive in several ways: first, the victim believed that the police had caught the assailants; second, Petitioners and their codefendant were the only lineup members required to utter specific words requested by the victim; and third, one of the Petitioners was the only lineup member wearing a hat like that worn by one of the assailants. The Court, considering the "totality of the circumstances," found that the identifications were "entirely based upon observations at the time of the assault, and not at all induced by the conduct of the lineup" (*Id.* at 5–6).

In *Neil v. Biggers*, 409 U.S. 188 (1972), the Court considered whether a showup identification procedure in a police station was so suggestive that the admission of the identifications violated the defendant's right to due process. The Court reviewed its earlier decisions from *Stovall* to *Coleman* and set forth the test for admissibility of eyewitness identification evidence that was then adopted by the Court in 1977 in *Manson v. Brathwaite*. 432 U.S. 98 (1977). It is this test that remains in place today. The two-part test first asks whether the procedure used was "unnecessarily suggestive," and, if so, whether the identification is nevertheless "reliable." The "reliability factors" set forth by the Court in *Biggers* and adopted in *Manson* are the following: (1) the opportunity of the witness to view the perpetrator, (2) the degree of attention paid by the witness, (3) the accuracy of the witness' prior description of the perpetrator, (4) the witness's level of certainty at the time of the confrontation, and (5) the length of time between the crime and the confrontation (*Id.* at 114). As the Court explained in *Manson*, "[r]eliability is the linchpin in determining the admissibility of identification testimony" (*Id.*).

In May 2011, for the first time since 1977, the United States Supreme Court agreed to consider a case involving a challenge to the admission of eyewitness identification evidence. *Perry v. New Hampshire*, 565 U. S. ____ (2012), involved the accidental (i.e., not police-orchestrated) viewing by a witness of a suspect who was the only civilian and only African American standing at the scene of a crime in the presence of uniformed law enforcement. In *Perry*, the Supreme Court considered a narrow question: does the Due Process Clause require an inquiry into the reliability of an eyewitness identification when the unnecessarily suggestive circumstances that produced the identification were not orchestrated by law enforcement. The Court held that "[w]hen no improper law enforcement activity is involved . . . it suffices to test reliability through the rights and opportunities generally designed for that purpose, notably, the presence of counsel at post-indictment lineups, vigorous cross-examination, protective rules of evidence, and jury instructions on both the fallibility of eyewitness identification and the requirement that guilt be proved beyond a reasonable doubt" (*Id.* at 1). Thus, while the Court once again recognized the "fallibility of eyewitness identifications" (*Id.* at 15) and the role of eyewitness identifications in miscarriages of justice, it concluded that the protections inherent in the trial process are sufficient to protect defendants when there has been no law enforcement involvement in the identification procedure, and a hearing that could result in suppression of eyewitness evidence was not constitutionally required. The Court explained its unwillingness to require a Due Process analysis where suggestion did not emanate from law enforcement as rooted in the Court's recognition that "[t]he Constitution . . . protects a defendant against a conviction based on evidence of questionable reliability, not by prohibiting introduction of the evidence, but by affording the defendant means to persuade the jury that the evidence should be discounted as unworthy of credit" (*Id.* at 6). The Court elaborated, "the jury, not the judge, traditionally determines the reliability of evidence" (*Id.* at 15).

The dissent, authored by Justice Sotomayor, disagreed that the traditional rights and opportunities available to defendants in the course of a trial are sufficient to protect against the possibility of "miscarriage[s] of justice from mistaken identification" (*Id.* at 1) (Sotomayor, J., dissenting) (*quoting Wade*, 388 U.S. at 228). Justice Sotomayor – relying on scientific research and the cases of the wrongfully convicted – found that the serious risk presented by suggestive circumstances exists no matter the source of the suggestion, and therefore, the protections of the Due Process Clause should apply whenever an identification is the product of suggestive circumstances:

> This Court has long recognized that eyewitness identifications' unique confluence of features – their unreliability, susceptibility to suggestion, powerful impact on the jury, and resistance to the ordinary tests of the adversarial process – can undermine the fairness of a trial

(*Id.* at 2) (Sotomayor, J., dissenting).

The dissent argued that the majority opinion represents a significant departure from the Court's jurisprudence, which had until *Perry* set forth "a clear rule: The admission at trial of out-of-court eyewitness identifications derived from impermissibly suggestive circumstances that pose a very substantial likelihood of misidentification violates due process" (*Id.* at 1) (Sotomayor, J., dissenting). In contrast, the majority opinion described the Court's jurisprudence as having a narrower procedural focus that permitted pretrial screening of identification evidence only in situations involving identification procedures arranged by law enforcement (*Id.* at 2). ("We have not extended pretrial screening for reliability to cases in which the suggestive circumstances were not arranged by law enforcement officers.") *See also Id.* at 2, n.1. ("Neither Perry nor the dissent, however, points to a single case in which we have required pretrial screening absent a police arranged identification procedure. Understandably so, for there are no such cases.").

The dissent further identified *Perry* as presenting a break from the Court's jurisprudence in that it "recasts the driving force of our decisions as an interest in police deterrence, rather than reliability" (*Id.* at 2) (Sotomayor, J., dissenting). Indeed, for the first time in any decision concerning the admissibility of eyewitness identification evidence, the Court identified police deterrence as "a primary aim" (*Id.* at 11). *Manson* cast deterrence as one of "several interests to be considered," together with reliability and the administration of justice (*Manson*, 432 U.S. at 112. *Accord Perry* at 10–11) (Sotomayor, J. dissenting).

Scientific and legal attacks on the validity of the *Manson* "balancing" test as a method for assessing the reliability of eyewitness evidence were not before the Court in *Perry*, the "all-or-nothing" aspect of the Manson legal architecture that provides no guidance to juries when suggestive procedures ("system variables") are used that increase the risk of error or "estimator variables" are involved that can also undermine the reliability of identifications. Arguments along these lines (arguments that were recently adopted in influential decisions of the New Jersey Supreme Court and the Oregon Supreme Court in *State v. Henderson* and *State v. Lawson*, respectively) were presented by certain *amici* including the Innocence Network and the American Psychological Association, but the Court did not choose to reach out to address them, not even in *dicta*. Since these arguments, based on decades of scientific findings, go more toward a "renovation" or improvement of *Manson* with respect to the way trial courts evaluate the reliability of eyewitness evidence and instruct juries when suggestive procedures by state actors occur, and not a new, lower standard for the exclusion of evidence, it should not be assumed that the *Perry* decision signals a hostility to the approach adopted by the New Jersey Supreme Court in *Henderson*. The *Perry* decision probably reflects, more than anything else, a predisposition against any expansion of the exclusionary rule and confidence in the ability of trial courts to use traditional procedures (jury instructions, motions in limine, or expert testimony) to assist juries in the evaluation of questionable eyewitness evidence. Indeed, the scientifically based framework adopted in *Henderson* is directed toward strengthening the traditional trial-based protections identified in *Perry* to ensure they are sufficiently flexible and robust to prevent a due process violation.

The Sixth Amendment Approach

On the same day in 1967 that the Court issued *Stovall*, the Court issued two other cases involving eyewitness identification procedures: *United States v. Wade*, 388 U.S. 218 (1967), and *Gilbert v. California*, 388 U.S. 263 (1967), which addressed whether violations of the Sixth Amendment right to counsel occurred during post-indictment identification procedures.

In *Wade*, the Court considered whether the failure to alert counsel that the client would be placed in a lineup post-indictment violated the client's right to counsel. Concluding that it did, the Court held that the Sixth Amendment guarantees an accused the right to counsel not only at his trial but at any "critical confrontation by the prosecution at pretrial proceedings where the results might well determine his fate and where the absence of counsel might derogate from his right to a fair trial" (388 U.S. at 223). The Court went on to find that a post-indictment lineup was just such a critical stage (*Id.* at 227). The remedy for this violation was to exclude the out-of-court identification from being admitted in evidence at trial, although the state would have "the opportunity to establish by clear and convincing evidence that the in-court identifications were based upon observations of the suspect other than the lineup identification" (*Id.* at 240). The Court identified factors to determine whether there exists an independent source for the in-court identification: the prior opportunity to observe the alleged criminal act, any discrepancy between any pre-lineup description and the defendant's actual appearance, any prior identifications or failures to identify the defendant, and the time between the crime and the confrontation (*Id.* at 241).

In *Gilbert v. California*, 388 U.S. 263 (1967), the Court applied the *Wade* test to determine whether Gilbert's rights were violated by a series of suggestive, post-indictment identification procedures conducted outside of the presence of counsel. The Court, concluding that Gilbert's right to counsel had been violated, announced a per se exclusionary rule for out-of-court identifications that are the product of procedures where the defendant had a right to counsel but that right was violated (*Id.* at 271). ("The admission of the in-court identifications without first determining that they were not tainted by the illegal lineup but were of independent origin was constitutional error.").

The Manson Balancing Test Is Flawed

Manson arose in an era when the exclusionary rule was being used by the Supreme Court as a remedy to deter police from violating citizens' constitutional rights. But, as the *Manson* court recognized, unnecessarily suggestive identification procedures themselves do not violate a suspect's constitutional rights because "[u]nlike a warrantless search, a suggestive pre-indictment identification procedure does not in itself intrude upon a constitutionally protected interest" (*Id.* at 113 n.13). The constitutionally protected interest at stake in eyewitness identification cases is the due process right to a fair trial.

Therefore, the *Manson* Court focused on the trustworthiness of the identification evidence and declared reliability to be the linchpin for its admissibility (*Id.* at 144). It feared that a per se rule suppressing unnecessarily suggestive out-of-court identification procedures "goes too far since its application automatically and peremptorily, and without consideration of alleviating factors, keeps evidence from the jury that is reliable and relevant" (*Id.* at 112). While conceding that a per se suppression rule has a "significant deterrent effect" in preventing the use of unnecessarily suggestive procedures, the Court still worried that the "rigidity" and "inflexibility" of a per se rule "may result, on occasion, in the guilty going free" and would make error by trial courts "more likely" (*Id.*).

The *Manson* Court was by no means refusing to acknowledge the "awful risks of misidentification" (*Id.* at 110), or the dangers posed by unnecessarily suggestive identification procedures, but believed that juries would understand that "[s]uggestive procedures often will vitiate the weight of evidence" and juries could be counted on to appropriately "discount" it (*Id.* at 112 n. 12). By developing what it believed was a flexible "totality of the circumstances" approach that stressed "reliability" and forced trial courts to make detailed, pretrial assessments of evidence, the *Manson* Court envisioned that its two-part balancing test would improve the "administration of justice" and produce more accurate verdicts (*Id.* at 112–113).

It is now clear that the *Manson* test, as currently configured, does not meet the objectives the Court set for it. Ironically, *Manson* was written the very year, 1977, that eyewitness identification research started to advance toward its current status as the "gold standard" for the reliable application of social science to the law (*State v. Henderson*, 27 A. 3d 872, 916 (NJ 2011)). Three decades of empirical findings demonstrate that the *Manson* framework suffers from five serious flaws that increase the chance of wrongful convictions based on eyewitness misidentifications: its balancing test is skewed by a scientific confound; it focuses solely on police misconduct; it limits trial courts to an inflexible, all-or-nothing suppression remedy; it does virtually nothing to deter unnecessarily suggestive identification procedures; and it fails to provide much needed "context" and guidance for jurors on how to evaluate eyewitness identification evidence.

The "Balancing" Test Is Confounded

Under *Manson*, courts are first supposed to balance the corrupting effects of unduly suggestive identification procedures against "reliability factors" and then decide whether to suppress in-court and out-of-court identification evidence if they find a "very substantial likelihood of an irreparable misidentification" (*Manson*, 432 U.S. at 122). The problem, of course, with such "balancing" is the undisputed scientific finding that both post-identification feedback and the use of unduly suggestive identification procedures tend to artificially inflate post-identification self-reports from witnesses about key reliability factors – opportunity to observe, the degree of attention paid, certainty, and description (Wells and Quinlivan 2009). The consequences of this confound are profound. It artificially inflates the apparent reliability of the eyewitness identification both for judges deciding admissibility and for jurors trying to evaluate the real weight of the evidence. This, in turn, brings about an unintended but deeply disturbing result: the improper use of a suggestive procedure tends to make it *more* likely that courts and juries will find the identification reliable. The *Manson* Court, of course, assumed exactly the opposite was true, that juries would realize that suggestive procedures "vitiate the weight of the [identification] evidence" and would, accordingly, "discount" it (432 U.S. at 112 n.12).

The confound also provides a perverse incentive to law enforcement who believe a suspect is guilty and hope an eyewitness can provide evidence to support their case – the more suggestive an identification procedure, the more likely an identification will be made, the more confirming feedback the witness will receive, and the more likely the witness will be certain about the identification itself, the opportunity to view, and the degree of attention paid. While the *Manson* Court recognized its approach would not "significantly" deter the use of suggestive police procedures, it still envisioned, misguided as its expectations were, that its two-part test would curtail police suggestion to some extent, and it certainly did not intend to create an impetus for law enforcement to conduct biased lineups (*Manson*, 432 U.S. at 112). ("Although the per se approach has the more significant deterrent effect, the totality approach also has an influence on police behavior. The police will guard against unnecessarily suggestive procedures under the totality rule, as well as the per se one, for fear that their actions will lead to the exclusion of identifications as unreliable.") Since the *Perry* Court labeled deterrence of police misconduct the "primary aim" of the Due Process analysis, it follows, whenever it reaches the issue, it should seriously consider "renovating" the Manson "balancing" test to prevent the confound from actually rewarding police misconduct.

Focus Is Exclusively on Police Misconduct

The seminal identification cases of the late 1960s and 1970s arose in the context of a contentious Supreme Court jurisprudence focused on the utility of the exclusionary rule as a remedy against misconduct by state actors. However, given our contemporary scientific knowledge that eyewitness memory is best understood as trace evidence susceptible to contamination from a wide spectrum of sources, it would be an error to scrutinize identification evidence only through the prism of police misconduct. Unlike the law, science does not differentiate between intentional and unintentional suggestion, since the good faith of a police officer is unrelated to the contaminating effects of police conduct on memory. Moreover, the linchpin of admissibility should be reliability, not whether the identification testimony was elicited by state or non-state actors.

To be sure, suggestive police procedures can taint the memory of an eyewitness and render any subsequent identification unreliable, but equally pernicious contamination of eyewitness memory is often brought about by sources unconnected to law enforcement – family members, friends, other witnesses to the same event, media reports, or simply the passage of time. Therefore, focusing solely on state action will surely miss non-state factors that contaminate eyewitness memory and fatally undermine the reliability of the identification evidence. State court decisions holding that non-state suggestion can contaminate eyewitness memory, as either a state constitutional matter or pursuant to their supervisory powers, are better suited to build on the growing, robust body of scientific research from experimental psychologists and neuroscientists about the malleability of memory than the more restrictive approach adopted by the Supreme Court in *Perry*. Indeed, in some cases, estimator variables alone could demonstrate that identification evidence was so weak it should be suppressed, or at least the jury should be instructed to treat it with great caution and distrust. Under the *Manson* framework, a defendant cannot claim that estimator variables so undermine the reliability of the eyewitness identification evidence as to render the admission of that evidence a violation of due process. Instead, the defendant's recourse will likely be limited to remedies available under the rules of evidence and procedure.

The All-or-Nothing Test Forgoes Helpful Intermediate Remedies, Such as *In Limine* Rulings and "Contextual" Jury Instructions, Based on Findings Made at Pretrial Judicial Assessments of Reliability

When courts apply *Manson*, their purpose is usually limited to answering one question: to suppress or not to suppress the identification evidence. Once courts decide that issue, they conceive of their mission as complete. The problem is that since courts rarely suppress identification evidence, they rarely see any purpose in identifying suggestive procedures that increase the risk of error or making findings about other factors relating to the event or the witness which tend to decrease the reliability of the identification.

Intermediate remedies short of suppression, including *in limine* rulings (such as limiting testimony based on artificially inflated self-reports about certainty and description) and "contextual" instructions (such as telling the jury that failure to comply with certain best practices can increase the risk of misidentification), would result in comprehensive assessments of reliability, which would require identifying and understanding key estimator and system variables. In this way, intermediate remedies would generate a more substantive judicial screening process, more reliable evidence, and more accurate verdicts.

Failure to Provide Jurors with "Context" and Guidance to Correct Misconceptions About Eyewitness Memory

After refocusing the analysis of eyewitness identification evidence on reliability and ensuring that juries would not be deprived of critical, if "flawed," evidence ("evidence with some element of untrustworthiness is customary grist for the jury mill"), the *Manson* Court was "content to rely upon the good sense and judgment of American juries" (432 U.S. at 116). The Court felt that "[j]uries are not so susceptible that they cannot measure intelligently the weight of identification testimony that has some questionable feature" (*Id.*).

Unfortunately, long-standing research studies show that jurors have great difficulty distinguishing between accurate and inaccurate eyewitnesses. *See* Tanja Rapus Benton et al., *Has Eyewitness Testimony Research Penetrated the American Legal System? A Synthesis of Case History, Juror Knowledge, and Expert Testimony*, in The Handbook of Eyewitness Psychology: Memory for People 453 (R.C.L. Lindsay et al. eds. 2007). Mistaken eyewitnesses are telling the truth as they believe it, and thus the cognitive faculties jurors usually deploy in making credibility judgments about lying witnesses do not work in this context. This also explains why cross-examination – the supposed great engine for uncovering truth – often sputters in the face of an honest but mistaken eyewitness, is insufficient, on its own, to guard against wrongful convictions based on mistaken identifications (as both the DNA exonerations and empirical study show), and serves as an inadequate substitute for expert testimony or jury instructions. *See* Jules Epstein, *The Great Engine That Couldn't: Science, Mistaken Identifications and the Limits of Cross-Examination*, 36 STETSON L. REV. 727 (2007); Wells (1995), *Eyewitness Identification Procedures: Recommendations for Lineups and Photospreads*, 22 LAW & HUM. BEHAV. 603, 609. ("Cross-examination, a marvelous tool for helping jurors discriminate between witnesses who are intentionally deceptive and those who are truthful, is largely useless for detecting witnesses who are trying to be truthful but are genuinely mistaken.") Research shows that jurors have fundamental misconceptions about eyewitness memory. *See*, e.g., Melissa Boyce et al., *Belief of Eyewitness Identification Evidence*, in THE HANDBOOK OF EYEWITNESS PSYCHOLOGY: MEMORY FOR PEOPLE 501 (R.C.L. Lindsay et al. eds. 2007); Elizabeth F. Loftus et al., EYEWITNESS TESTIMONY: CIVIL AND CRIMINAL (4th ed. 2007); Brian L. Cutler et al., *Juror Sensitivity to Eyewitness Identification Evidence*, 14 LAW & HUM. BEHAV. 185–191(1990); Richard S. Schmechel et al., BEYOND THE KEN? TESTING JURORS' UNDERSTANDING OF EYEWITNESS RELIABILITY EVIDENCE (2006); Tanja Rapus Benton et al., *Eyewitness Memory is Still Not Common Sense: Comparing Jurors, Judges and Law Enforcement to Eyewitness Experts*, 20 APPLIED COGNITIVE PSYCHOL. 115 (2006). Jurors tend to believe that memory works like a videotape; generally misunderstand the effect of confirming feedback on the self-reported factors in *Manson*; do not understand the effects of biased witness warnings; are not inherently sensitive to estimator variables such as disguises, weapon focus, violence during the event, retention intervals between the event and the identification procedure, foil bias, and cross-race identifications; tend to rely heavily on eyewitness factors that are not good indicators of accuracy (particularly the witness's confidence in her identification); overestimate eyewitness identification accuracy rates; and are not familiar with the trace evidence analogy. It is, therefore, critically important to correct these scientifically incorrect notions and provide jurors with "context" or guidance about eyewitness testimony that is firmly grounded in sound science.

Failure to Provide Significant Deterrence of Suggestive Identification Procedures

The *Manson* Court lamented the "inflexibility" and "rigidity" of the exclusionary rule and acknowledged that deterrence of improper police practices would be significantly diminished by not suppressing out-of-court identification procedures (432 U.S. at 114). The Supreme Court has now taken a different view of the importance of police deterrence, a view that supports the adoption of intermediate remedies that enforce best practices while informing juries accurately about the risks created by violations of best practices. In this way, courts can achieve a greater measure of deterrence while also providing much needed guidance to the jury.

State Law Challenges to the *Manson* Balancing Test

While the United States Supreme Court has not yet demonstrated an interest in reevaluating the existing legal framework for evaluating eyewitness identification evidence, state courts – which have firsthand experience with both the range of eyewitness identification evidence offered at trials and the human cost of "miscarriages of justice" resulting from eyewitness misidentifications – have indicated a willingness to reevaluate the existing legal framework.

The most comprehensive example of this is the New Jersey Supreme Court's decision in *State v. Henderson*, discussed below. While a full survey of the changing national landscape is beyond the scope of this entry, it is worth mentioning a few examples.

In September 2011, recognizing the role of eyewitness misidentification in wrongful convictions, the Massachusetts Supreme Judicial Court directed that a study group be convened to address all aspects of the handling of eyewitness identification evidence, from law enforcement practices to admissibility standards and the treatment of the evidence by courts (*Commonwealth v. Walker*, 460 Mass. 590, – n.16 (2011)). The court explained, "Our convening of a study committee on eyewitness identification reflects our willingness to revisit our jurisprudence regarding such evidence . . . and to consider, among other alternatives, the approach established in New Jersey . . ." Indeed, the study group ultimately created is comprised of attorneys, judges, and members of law enforcement and has been divided into subcommittees focusing on hearings, jury instructions, and police procedures.

The Oregon Supreme Court is considering a case, *State v. Lawson*, involving eyewitness identification. The court will consider several questions including whether any error in admitting eyewitness testimony in suggestive identification cases can be cured at trial by cross-examination, expert testimony, closing arguments, and jury instructions.

Other state courts (both trial and appellate) have stopped short of reconsidering the entire legal framework but have instead eliminated those parts of the *Manson* test not supported by science (such as the use of certainty as a reliability factor) and strengthened protections available to defendants against whom eyewitness identification evidence is offered. Typically, these protections have been in the form of expert testimony and jury instructions. The Texas Court of Criminal Appeals recently found that the trial court abused its discretion in excluding an eyewitness identification expert, which was "reliable, relevant evidence that would 'assist the trier of fact' by increasing the jurors' awareness of biasing factors in eyewitness identification." *Tillman v. State*, No. PD-0727-10, slip. op. at 35 (October 5, 2011) (internal citations omitted). In the past several years, the New York Court of Appeals has issued a number of rulings endorsing scientific research in the area and reversing lower courts' refusal to admit expert testimony. *See*, e.g.*, People v. LeGrand*, 8 NY3d 449, 452 (2007); *People v. Abney*, 13 NY3d 251, 267 (2009); and *People v. Santiago* 17 NY3d ___, 2011 NY Slip Op 07303 (2011).

Finally, courts that either lack the power to reconsider the entire legal framework or have yet to be presented with a case or controversy that raises the issue have indicated an interest in revisiting the existing legal framework. In a concurring opinion in *State v. Ferguson*, 804 N.W.2d 586 (2011), Minnesota Justice Anderson acknowledged the extensive science relating to eyewitness identification evidence, the problem of eyewitness misidentification, and discussed at length the New Jersey Supreme Court's decision in *Henderson*. Justice Anderson concluded:

> I hope that the district court will carefully consider whether the defects in the photo lineup procedure used here and the recent developments in social science require admission of eyewitness identification expert testimony and/or a cautionary jury instruction. Moreover, the court should look closely at New Jersey's safeguards and determine if those safeguards are appropriate here. Specifically, the court should consider the reliability of the eyewitness identification in light of the recent New Jersey Supreme Court decision, in addition to the factors our court has set out in *Miles* and *Helterbridle*. If the expert eyewitness testimony is not "otherwise appropriate," the court should consider alternative approaches to educating jurors on the variables that "can lead to misidentifications." As our courts and jurors grow to understand the science of eyewitness identification, we can better meet the "'twofold aim . . . that guilt shall not escape or innocence suffer.'"
>
> (*Id.* at 609–610).

State of New Jersey v. Henderson

In 2011, the New Jersey Supreme Court became the first court in the nation to reject the flawed *Manson* balancing test, finding that in “the 34 years since the United States Supreme Court announced a test for the admission of eyewitness identification evidence, which New Jersey adopted soon after, a vast body of scientific research about human memory has emerged. That body of work casts doubt on some commonly held views relating to memory. It also calls into question the vitality of the current legal framework for analyzing the reliability of eyewitness identifications.” *State v. Henderson*, 27 A.3d 872, 877 (NJ 2011).

The New Jersey Supreme Court’s decision was the direct result of the 1999 issuance of mandatory guidelines for conducting eyewitness identification procedures by New Jersey’s Attorney General. Office of the Attorney Gen., N.J. Dep’t of Law and Pub. Safety, Attorney General Guidelines for Preparing and Conducting Photo and Live Lineup Identification Procedures 1 (2001) (“Attorney General Guidelines” or “Guidelines”). Under New Jersey law, the Guidelines – which provided for the blind administration of identification procedures, the provision of instructions to witnesses, proper lineup construction (including minimum number of fillers, proper filler selection, one suspect per lineup), sequential presentation when possible, avoidance of feedback to the witness, and recording of the procedure, to include a witness confidence statement – were binding on all law enforcement agencies in New Jersey.

Henderson came to the New Jersey Supreme Court on appeal following a conviction for various crimes, including reckless manslaughter, aggravated assault, and various weapons charges, which arose out of a 2003 murder in a Camden, New Jersey, apartment. The primary evidence against Henderson at trial consisted of the statement of a single eyewitness and an investigating officer’s testimony about Henderson’s postarrest statement (*Id.* at 879–880). During the course of the investigation, the eyewitness – who, at the time of the crime, had been held at gunpoint in a dark, narrow hallway by a stranger – was presented with an eight-person photographic lineup by a blind administrator, consistent with the Attorney General’s Guidelines (*Id.* at 880). The witness was provided with instructions and viewed the lineup members sequentially, in keeping with the Attorney General’s Guidelines. The witness quickly eliminated five of the photographs, then eliminated a sixth, after which he said he “wasn’t 100 % sure of the final two pictures” (*Id*). At that point, the independent administrator left the room and the two investigating offers entered and conferred with the witness, thereby violating the Attorney General’s Guidelines that the identification procedure administrator be blind. Thereafter, the witness selected the police suspect’s photograph – that of Henderson.

When it reviewed Henderson’s appeal in 2009, the New Jersey Supreme Court declared that the trial record was inadequate to “test the current validity of [New Jersey] state law standards on the admissibility of eyewitness identification” and directed that a plenary hearing be held “[t]o consider and decide whether the assumptions and other factors reflected in the two-part *Manson/Madison* test, as well as the five factors outlined in those cases to determine reliability, remain valid and appropriate in light of recent scientific and other evidence” (*Henderson*, No. A-8-08, 2009 WL 510409, at *1–2).

The Court directed the parties, together with *Amici* Innocence Project and Association of Criminal Defense Lawyers of New Jersey, to participate in remand proceedings, which were presided over by Special Master Geoffrey Gaulkin, a retired New Jersey state appellate judge appointed by the New Jersey Supreme Court to handle the matter. Judge Gaulkin conducted the proceedings “more as a seminar than an adversarial litigation.” The parties submitted, and Judge Gaulkin considered, extensive scientific materials including more than 200 published scientific studies, articles, and books. Judge Gaulkin presided over 10 days of evidentiary hearings, at which seven expert witnesses – leading scientists in the field of eyewitness identification study – testified, and he received detailed proposed findings of fact and conclusions of law and heard oral argument. On June 18, 2010, based on his consideration of all of the information presented by the parties, Judge Gaulkin issued his report (the "Special Master's Report").

The Special Master's Report endorsed the remedy set forth by the Innocence Project in its proposed legal findings, "The Renovation of *Manson*: A Dynamic New Legal Architecture For Assessing and Regulating Eyewitness Evidence," as "wide-ranging, multifaced and highly detailed," and proposed that the current legal framework be modernized:

> to maintain the *Manson*/*Madison* principle that reliability is the linchpin of the inquiry, to expand that inquiry to include all the variables unaddressed by *Manson*/*Madison* and to assure that judges and jurors are informed of and use the scientific findings that bear on reliability

The Special Master's Report, at 84–86 (Citations Omitted and Emphasis Added)

The Special Master's proposed new design had two core elements: first, that courts treat eyewitness identification evidence as trace and scientific evidence, by placing the initial burden on the prosecution to demonstrate the reliability of the evidence, and second, to take "all available steps" to ensure that judges and juries are informed of and guided by scientific findings (*Id*).

In issuing its final decision in *Henderson*, 27 A.3d 872 (2011), the New Jersey Supreme Court adopted many of the recommendations set forth in the Special Master's Report. The New Jersey Supreme Court endorsed the scientific research considered by the Special Master, describing it as the "gold standard in terms of the applicability of social science research to the law" (*Id.* at 916).

Based on its review of the scientific research and the role of eyewitness misidentifications in wrongful convictions, the New Jersey Supreme Court took unprecedented action and became the first court in the nation to reject the *Manson* balancing test in favor of a totality of the circumstances test that would allow for the consideration of all relevant evidence – whether relating to system or estimator variables – when making a determination about the reliability of eyewitness identification evidence. (New York, Massachusetts, and Wisconsin follow a per se rule requiring suppression of out-of-court identifications that were the product of unnecessarily suggestive identification procedures. However, those courts then engage in a second step analysis to determine whether the in-court identification has a basis independent of the suggestive procedure for the identification. The independent basis test in these jurisdictions essentially mirrors the reliability factors set forth in *Manson*. Thus, it cannot be said that these jurisdictions have abandoned the *Manson* balancing test. *See*, e.g., *People v. Adams*, 423 N.E.2d 379, 384 (NY 1981); *Commonwealth v. Martinez*, 67 Mass. App.Ct. 788 (2006); *State v. Dubose*, 699 N.W.2d 582, 596 (Wise and Safer 2003) The revised legal framework set forth in *Henderson* has two principal features: pretrial hearings that are granted whenever a defendant can show "some evidence of suggestiveness that could lead to mistaken identification" *(Id.* at 920) and which will allow for the presentation of all system and estimator variables once the defendant has met this burden, and enhanced jury instructions that will seek to educate jurors about all aspects of eyewitness identification and memory, and may be given to the jury at the close of evidence as well as during the trial, at the time the witness testifies (*Id.* at 925–28). Additionally, the *Henderson* decision extended the court's prior decision in *State v. Cromedy*, 727 A.2d 457 (1999), in which the New Jersey Supreme Court held that jury instructions on the reliability of cross-racial identifications are necessary when "identification is a critical issue in the case" and there is no independent evidence corroborating the identification to require jury instructions on the reliability of cross-racial identifications "whenever cross-racial identification is in issue at trial." The *Henderson* court extended its ruling in *Cromedy* based on additional scientific research that emerged over the 12 years since the court had first considered the issue as well as the "more complete record about eyewitness identification in general" (*Id.* at 926). In considering remedies available at trial, *Henderson* also allows for the possibility of expert testimony at trial, provided it is otherwise admissible under New Jersey law (*Id.* at 878).

Finally, the *Henderson* opinion endorsed many of the police practices already required by the Attorney General's Guidelines and, through the court's supervisory powers, required additional police practices, including requiring that law enforcement inquire whether witnesses have had any communications with third parties concerning their observations and, if so, to take a written statement of the substance of those communications which must be disclosed to defense counsel (*Id.* at 909).

The *Henderson* decision has been hailed by the legal and scientific communities as a landmark ruling for its recognition that the *Manson* balancing test fails to achieve its objective and its attempt to offer a new approach that brings to bear the vast body of scientific research on the problem of assessing the reliability of eyewitness misidentification. Some have expressed concern with the court's reliance on enhanced jury instructions, as the scientific literature is sparse and somewhat mixed on the efficacy of jury instructions in educating jurors about complex aspects of memory and perception. The ultimate test of the success of the *Henderson* model will, of course, be seen in courtrooms throughout New Jersey in years to come.

Conclusion

More than 30 years of scientific research and more than 200 wrongful convictions confirmed by DNA make clear that the test for admissibility of eyewitness identification evidence in criminal trials cannot achieve its stated goal of ensuring reliability. Courts across the country, drawing lessons from scientific research and the cases of the wrongfully convicted, have begun to question the existing legal framework. Some have strengthened protections through expert testimony and comprehensive jury instructions. The New Jersey Supreme Court has rejected the *Manson* balancing test in its entirety and developed a new legal framework that holds enormous promise for improving both the collection of eyewitness identification evidence and the evaluation by courts and juries of the reliability of that evidence.

Acknowledgment The authors acknowledge and thank Ezekiel Edwards for his invaluable work in briefing *amicus* the Innocence Project's positions *State v. Henderson*, 27 A. 3d 872 (N.J. 2011), excerpts of which are included herein.

Overview

The following scene plays out in courtrooms around the world: from the witness box, an eyewitness is asked to look around the courtroom and indicate whether they see the person who committed the crime. The witness says she does, then outstretches her arm and points to the defendant. She is unequivocal, "That's the man. I'll never forget his face." Although the witness in this scene is absolutely certain that her identification of the defendant is accurate, a critical question remains: Does it also mean that she was right? Eyewitness researchers have studied this exact question for decades and have now identified many factors that influence both a witness' accuracy and confidence in their identification of the suspect. This entry will present the varying types of research methodologies that are conducted in the field of eyewitness identification, followed by a review of law enforcement procedures, known as system variables, that are utilized to secure the identification of police suspects and that have a direct impact on eyewitness accuracy and testimony: sequential lineup presentation, double-blind lineup administration, pre-lineup instructions, post-identification feedback, showups, the presentation of a suspect in multiple procedures, and co-witness contamination. Each identification procedure carries with it potential consequences (positive and negative) for an investigation and these will be discussed in turn.

Introduction to Eyewitness Research

In 1985, Kirk Bloodsworth was identified by five separate eyewitnesses in the murder investigation of a 9-year-old girl. Mr. Bloodsworth, a veteran with no prior criminal record, was swiftly convicted at trial and sentenced to death. After serving 8 years in prison, DNA testing on the forensic evidence in the case revealed that Mr. Bloodsworth was in fact innocent; all five eyewitnesses had been wrong. Kirk Bloodsworth's case was the first of 18 death penalty DNA exonerations in the United States, and it affirmed the harsh truth that eyewitness evidence is not infallible. In fact, an analysis of the more than 300 DNA exonerations in the United States reveals that mistaken eyewitness testimony played a role approximately 75 % of the time, making it the leading contributing factor of wrongful convictions. And like Kirk Bloodsworth's story where five eyewitnesses erroneously testified that he was the perpetrator, 35 % of the eyewitness exoneration cases had more than one eyewitness mistakenly identify the defendant at trial.

Although DNA exonerations show incontrovertible evidence of eyewitness error, they are only a small fraction of all identification cases, as it is rare to have DNA evidence in a typical eyewitness case. Therefore, eyewitness researchers turn to other sources of information, including archival and field studies, to help determine if eyewitness errors are common or rare occurrences in actual criminal investigations. In archival studies, police files from closed eyewitness cases are examined and the witnesses' identification decision from viewing a live or photo lineup are recorded. Archival research reveals a consistent and alarming pattern: approximately 20 % of all witnesses who view a lineup make a mistake and choose a lineup filler – one of the stand-ins who is known to be innocent of the crime. This statistic has also been replicated in field studies, where researchers gather data prospectively in ongoing criminal investigations.

Although the general public may be surprised by the high rate of identification errors in real cases, eyewitness researchers are not. Hundreds of eyewitness laboratory studies have also shown that nearly one in five identification decisions is an incorrect choice. Not only do the experimental laboratory studies confirm the actual data, but they also provide us with vital information that cannot be learned from actual cases and they allow us to make cause and effect conclusions about how identification procedures influence eyewitness accuracy. The accumulation of laboratory data over the last three decades has allowed eyewitness researchers to be in the position to make specific policy recommendations to law enforcement and legislators on how to increase the reliability of eyewitness testimony presented in court. To be sure, the "best practice" recommendations described in this entry have not been universally or equally embraced, but there has been a significant and enduring impact for those jurisdictions that have made the improvements to their identification practices.

Over a period of decades, researchers have established that when we experience an important event, we do not simply record it in our memory as a video recorder would. The situation is much more complex and most theoretical analyses of the memory process divide it into three major stages: encoding/acquisition, retention, and retrieval. First, the event is perceived by a witness and information is entered into the memory system. Next, some time passes before a witness tries to remember the event. Finally, the witness tries to retrieve the stored information. Psychologists who conduct research on eyewitness memory study and attempt to identify the factors that play a role in each of the three stages. In 1978, Professor Gary Wells, the leading researcher in the field of eyewitness identification, published an article that continues to guide the way in which eyewitness research is discussed and conducted. In that article, he introduced the terms "estimator and system variables" to refer to factors that typically relate to the encoding, retention, and retrieval stages of memory.

As it relates to law enforcement, research has shown that the procedures and practices that police use during the memory retrieval process can influence the reliability of an eyewitness identification and the witness' subsequent testimony. Examples of police procedures or system variables that can affect witness reliability include pre-identification instructions, the type of identification procedure administered (e.g., showup, simultaneous lineup, sequential lineup), whether the identification was conducted using a double-blind administrator, and the type of post-event information provided to a witness after their identification decision, to name a few. Each of the system variables listed above has received consideration in the eyewitness research community and will be reviewed below. Without question, however, two topics have received more attention and caused more controversy than the others combined: double-blind administration and sequential lineups.

Double-Blind Administration

At its core, the police lineup is akin to a scientific experiment, where a police officer tests the hypothesis that the suspect is the perpetrator. And thus, many of the principles that apply to conducting a research experiment similarly apply to the police lineup. Arguably the most important principle in this analogy is double-blind administration, where the person who is conducting the experiment does not know the "correct" answer and thus cannot consciously or unconsciously influence the participant or the outcome.

The impact of lineup administrator knowledge on witness decisions has been tested in laboratory settings and the results are consistent with the vast body of research on double-blind testing. One example is a study by Greathouse and Kovera (2009) which used witness-administrator pairs to test the hypothesis that an administrator could subtly influence the outcome of the procedure if they were aware who the suspect was. Administrators were given information about the case and told that they would receive a cash bonus if the witness selected the suspect, who was actually innocent of the crime. Half were then given the identity of the suspect. In this, non-blind, condition, 21 % of witnesses chose the innocent suspect, whereas only 9 % chose him in the double-blind condition. Greathouse and Kovera also surreptitiously video-recorded the interaction between the witness and the administrator and showed that even though the administrators believed they had not influenced the witnesses, their verbal and nonverbal behaviors suggested otherwise and were evident to those watching the videotape of the interaction.

As it pertains to police lineups, double-blind administration requires that the person who shows the lineup to a witness cannot know which person is the suspect and which are the fillers. This procedure eliminates the possibility that the detective hinted to the witness (consciously or not) which person to choose. This is a significant departure from the way in which law enforcement conduct lineup procedures and, not surprisingly, this recommendation has been met with resistance by many law enforcement agencies and prosecutors across the United States. A common (mis)interpretation of this recommendation is that detectives are being accused of deliberately leading witnesses and influencing the outcome of lineups. Although it is possible for deliberate influence to occur, eyewitness researchers believe this is rare. Instead, what is more likely to occur is the transmission of unconscious cues, such as nodding and smiling, when a witness is making their decision. The collective experience of many researchers is that after speaking with law enforcement and policy makers and educating them on the science and logic behind the double-blind administration recommendation, these groups are significantly more likely to embrace the reform. In addition to the International Association of Chiefs of Police (IACP) recommending double-blind administration, some states (CT, NC, TX) have changed their laws and now require that officers conducting identification procedures not know when the witness is viewing the suspect.

To be certain, there are, on the surface, reasonable objections to double-blind administration, including concerns regarding the additional cost of utilizing a separate person unfamiliar with the case or the logistics for smaller police departments who may not be able to find an officer who is not familiar with the case. In response to the latter concern, eyewitness researchers have recommended conducting the lineup in a "blinded" manner, where the officer is unable to see which photograph a witness is viewing at any particular time. This is typically done using the "folder shuffle method" where individual photographs are placed into unmarked folders. The folders are then shuffled, rendering the lineup administrator unaware of which lineup member is in each folder. The folders are then handed to the witness, one at a time, following the sequential procedure described in the next section. Blinded administration can also be achieved by using computer software to present the images in a random order and having the lineup administrator unable to see the screen. In the years to come, it is likely that more and more departments across the country will begin testing and using these methods.

Sequential Lineup Presentation

Perhaps equally controversial as the subject of double-blind administration is sequential lineup presentation. In sequential lineups, a witness views the suspect and fillers one at a time and makes a judgment about each person before the next is shown. In simultaneous or traditional lineups, the suspect and lineup fillers are presented at the same time and the eyewitness identifies which (if any) is the perpetrator. More than 20 years of laboratory research indicates that sequential lineups cut the rate of false identifications in half when compared to the traditional simultaneous lineup method (Steblay et al. 2011) and thus sequential lineups have become a recommended "best practice" (see Wells et al. 1998).

In addition to the results from laboratory studies, researchers have also compared (double-blind) simultaneous and (double-blind) sequential lineups using actual eyewitnesses to real crimes in ongoing criminal investigations. In a study sponsored by the American Judicature Society, Wells et al. (2011) found that sequential lineups produce fewer mistaken identification decisions than lineup procedures that present the photographs simultaneously. The study found that double-blind sequential lineups (compared to double-blind simultaneous lineups) as administered by police departments in four states across the country resulted in the same number of suspect identifications (27.3 % for sequential and 25.5 % for simultaneous) and fewer known-innocent filler identifications (12.2 % for sequential and 18.1 % for simultaneous).

One of the most notable results from the field study was that witnesses in these actual criminal cases who made positive identifications ("yes, that is the person I saw commit the crime") from a simultaneous lineup made an identification error 42 % of the time. That is, four out of every ten positive identifications that were obtained from double-blind simultaneous lineups were mistaken identifications of innocent lineup fillers. Even with the double-blind sequential procedure, three of every ten identifications were of an innocent filler. Thus, even when best practices are followed, identification errors are not entirely eliminated and witnesses can still be unreliable.

The dominant explanation for the difference in errors between simultaneous and sequential lineups is that witnesses who view simultaneous lineups – and do not immediately recognize anyone – are more likely to engage in a relative judgment process, whereby they compare the lineup members and choose the one who most closely resembles their memory for the perpetrator. Witnesses who view the images one at a time, however, are less able to engage in this comparison process and therefore are more likely to make an identification based on their memory rather than a combination of their memory and choosing the person who is the best option out of those presented.

The controversy over the use of sequential lineups arises from the finding that accurate suspect identifications are higher with simultaneous lineups than with sequential, and thus there is a concern that guilty suspects might "get away" if witnesses do not identify them. The concerns about sequential lineups were recently thoroughly vetted in several articles in the journal "Perspectives on Psychological Science," and the interested reader is directed to those articles for the full set of arguments. In summary, researchers who are cautious about recommending sequential lineups focus on the loss of correct suspect identifications (Clark 2012), and those who recommend sequential lineups ask "Why would a witness be unable to identify the suspect unless all of the lineup members were presented at the same time?" (Wells et al. 2012). In other words, if the witness has a great memory of the perpetrator and truly recognizes him, then she should be able to do so regardless if the lineup members are presented simultaneously or sequentially. Further, any loss in suspect identifications might be characterized as a loss of "lucky guesses" that resulted merely from relative judgments in the simultaneous procedure.

To date, there are several states and many jurisdictions that require the use of sequential lineup presentation. Thus, it appears that these groups who have considered the data and the "controversy" have been unmoved by the "loss of suspect identifications" argument made by those who question whether sequential lineups are superior to the simultaneous technique. Whether additional jurisdictions who are considering reform will be persuaded by these arguments is presently unknown. Whether new identification procedures can be developed to further reduce errors will likely be the subject of research over the next few decades. Until then, it is expected that more and more jurisdictions across the United States will adopt the sequential lineup procedure.

Pre-identification Instructions

Maybe the least contentious of all lineup reforms is the recommendation that witnesses be warned, prior to viewing a lineup, that the actual perpetrator may or may not be present in the procedure they are about to view.

Pre-lineup instructions have been studied by eyewitness researchers since the early 1980s (Malpass and Devine 1981). In this research, participants typically view a staged crime event and are then randomly assigned to an instructions condition. "Unbiased" instructions include wording to the effect that the actual perpetrator "may or may not be present," whereas biased (or standard) instructions provide no such warning. In the first study on this topic, Malpass and Devine found that witnesses who received biased instructions were 45 % more likely to make a false identification of an innocent person than were participants who were not told that the perpetrator may not be included in the array.

In 1997, Steblay published a meta-analytic review of the instruction bias literature and found, overall, a 25 % increase in eyewitness accuracy when unbiased instructions were provided to witnesses. Interestingly, Steblay also found that the mere failure to provide witnesses with a "may or may not be present" instruction had similar detrimental effects on accuracy as when witnesses were given some pressure to make a positive identification. Thus, failing to provide the warning is considered suggestive because it insinuates that the true perpetrator is in the lineup procedure. For these reasons, the National Institute of Justice Technical Working Group for Eyewitness Evidence (1999) included pre-lineup instructions in their research report titled *Eyewitness Evidence*: *A Guide for Law Enforcement*. In addition to discussing other eyewitness identification best practices, this report specifically recommended giving cautionary instructions to reduce the possibility that a witness would choose someone from the lineup merely because they expect that the police must have caught the perpetrator; otherwise, they would not be viewing an array. Some jurisdictions have gone further than the "may or may not be present" warning and now inform witnesses, among other things, that the investigation will continue even if the witness does not make an identification. These pre-lineup recommendations have been met with little resistance by law enforcement and others, and thus it is likely that this reform will continue long into the future.

Witness Confidence and Post-identification Feedback

Although there is a presumption among many actors in the legal system that there is a significant and positive confidence-accuracy relationship, serious questions about whether that is true have been raised by researchers within the law and psychology community. Decades of research show that there is only a small to moderate relationship between the accuracy of an eyewitness' identification and their confidence in that identification and that this relationship can be significantly affected by post-identification factors, making confidence highly malleable.

Confidence malleability refers to changes in a witness' confidence over time, generally as a result of events that take place after the identification. By the time a witness takes the stand at trial, their expression of confidence in their identification can result from multiple sources, including the strength of their memory of the person they saw but also a variety of system variables, such as learning that the person they identified has been charged with the crime or that other witnesses also identified the same person. For this reason, it is recommended that law enforcement ask witnesses, immediately after they make a positive identification, to state how confident they are in their decision. A statement of certainty at that point in time, unaffected by the passage of time and external influences, can be a more reliable indicator of accuracy than a statement taken months or years after the identification.

In their pioneering research on the topic of confidence malleability, Wells and Bradfield (1998) found that witnesses who were told that they had made a correct decision ("Good, you identified the suspect") were more confident than witnesses who were given no feedback. What was, and remains to be, surprising about this research, however, is that feedback has significant effects on a witness' recollection of other aspects of the event, including exaggerations in how much attention the witness paid to the perpetrator during the crime, how good a view they had, and so on. The results of this groundbreaking study have been replicated many times in both research labs (Bradfield-Douglass and Steblay 2006) and with actual witnesses in ongoing criminal investigations (Wright and Skagerberg 2007).

One of the explanations that have been proposed to explain the post-identification feedback effect, and its strong and pervasive influence on eyewitness confidence, is the theory of cognitive dissonance (Festinger 1957). In essence, this theory states that people are in a state of discomfort when they have inconsistent or contradictory beliefs, or when they have beliefs and behaviors that are inconsistent. As it relates to eyewitness identification, if a witness is confident in their identification, then they subsequently reason that they must have had a good opportunity to see the perpetrator. How else would they be able to "get it right"? A powerful example of cognitive dissonance is the DNA exoneration case of Dean Cage from Illinois. After Cage was exonerated in 2008, the victim refused to believe the accuracy of the DNA results and held on to her belief that Cage was guilty. Thus, cognitive dissonance was so powerful in that case that it was easier for the witness to believe that the DNA testing was flawed than to accept that she had made an error and identified an innocent person. Only after she was presented with independent results of the DNA testing did she come to accept that Cage was innocent and was not the man who had raped her in 1994.

The results of laboratory and field studies on post-identification feedback have led to the recommendation that law enforcement obtain a statement of witness confidence before any feedback about their decision is provided. Even then, it is not recommended that law enforcement tell witnesses that they were correct in their identification because of the pervasive influence feedback has on other memory-related judgments (attention, view, etc.) which could ultimately have an influence on a witness' credibility during their trial testimony.

Future research on post-identification feedback will likely examine whether there are ways to substantially mitigate the effect and protect the reliability of a witness' testimony while at the same time recognizing that actual witnesses will eventually receive information that the person they identified was charged with the crime and that the witness is needed to testify at trial. Steps have been made in this direction and the current recommendation of using double-blind administration – where the administrator cannot give meaningful feedback – appears to have some impact (Dysart et al. 2012).

Showups

The showup is an identification procedure in which law enforcement shows a single suspect – unaccompanied by fillers – to the eyewitness and asks them to decide whether the suspect is the perpetrator. Showups are generally conducted soon after the crime, and the suspect may either be viewed live (a "field" showup), the most common option, or the eyewitness may be shown a single photograph.

By definition, the showup is a suggestive procedure because only one person is presented to a witness and thus the identity of the police suspect is obvious. Showups can never be conducted double-blind; thus administrator bias is necessarily a concern with showups. Further increasing suggestiveness in police investigations is the fact that the suspect may also be handcuffed or seated in the back of a police car when the witness views him. Despite these reliability issues, showups are routinely used by law enforcement (between 30 % and 77 % of all identifications procedures in various areas of the country are showups, Dysart and Lindsay 2007) and largely accepted by the courts.

The research on showups is limited in contrast to lineups and much of the existing literature specifically compares accuracy between showups and lineups. A 2003 meta-analysis synthesized this research (Steblay et al. 2003) and highlighted a specific danger unique to showups: 100 % of identifications made from showups that contain an innocent suspect are false identifications. In lineups, however, filler identifications represent a measure of protection to a suspect. That is, if a witness was merely guessing in a lineup, they would have a one in six chance of guessing the suspect (in a six-person array). Innocent suspects presented in showups have little defense against a witness with a weak memory and a willingness to choose and are more likely to be falsely identified than if they were presented in an unbiased six-person array.

From a policy standpoint, there are two main reasons that showups continue to be used and that their use is likely to continue. The first reason is related to public safety. If police are not permitted to conduct showups, and yet have too little evidence to arrest a suspect, the guilty party may be set free to commit further criminal acts. The second reason is to allow innocent suspects to be cleared without undue delay. If the police have detained an innocent person, the sooner they present him to the eyewitness, the sooner he can be released, assuming the eyewitness correctly rejects him as the perpetrator.

Procedural issues and controversies regarding lineups have largely dominated the discussion about best practices in identification procedures, but, given the frequency with which showups are used by law enforcement, it is time for research and policy makers to pay greater attention to the showup procedure. A greater understanding is needed not only of how factors associated with reduced lineup accuracy affect showups but also how factors unique to the showup may affect the ability of eyewitnesses to make accurate identification decisions.

Co-witness Discussion

Co-witness discussion occurs when multiple witnesses to a crime speak with one another about what they viewed or heard. One of the reasons why co-witness discussion is of concern to researchers is that witnesses can incorporate information learned from other witnesses into their memory of the perpetrator and the event. As a result, the National Institute of Justice (1999) recommends that law enforcement, as part of their routine procedures, separate witness when they are being interviewed and when they view an identification procedure.

A particularly illustrative study on co-witness contamination was conducted by Hope et al. (2008), wherein participants viewed a videotaped event in pairs and then either discussed the event with the other person or answered questions about the video on their own with no discussion. The catch in the study was that only one member of each pair saw a theft take place because the event was filmed with two cameras from different angles and only one camera caught the critical theft. For participants in the study who did not see a theft take place, no one in the "no discussion" group reported seeing the theft but 50 % of those who had discussed the video with their partner reported a theft they in fact did not see. These witnesses were susceptible to misinformation from their co-witness and, as a consequence, produced less accurate recall accounts than participants who did not interact with another witness.

In another study, Zajac and Henderson (2009) showed that co-witness contamination can affect not only description accuracy but identification accuracy as well. In this study, research participants were paired with a research confederate whom they believed was just another participant in the study. Together, they viewed a video clip of a staged theft. Then, half of the participants were misinformed by the confederate that a target person in the video had blue eyes when in fact they were brown. Individually, participants then described the accomplice and viewed a lineup where the target person was not shown. In fact, all of the lineup members had blue eyes. Participants who had received the blue-eyed misinformation were several times more likely to describe the target as having blue eyes and twice as likely to falsely identify someone from the lineup.

In summary, the research literature on co-witness discussion/contamination shows that merely having a conversation with another person about an event can result in substantial changes to a person's memory and accuracy of that event. And thus, the recommendation that witnesses be separated and instructed not to speak with other witnesses is a critical element in assuring that the evidence a witness testifies to is from their own perceptions and has not been a result of contamination.

Multiple Presentations of the Same Suspect

The final topic that deserves attention within a discussion of system variables is the practice that law enforcement have of showing the same suspect to a witness in more than one identification procedure, such as mug book or a showup followed by a lineup. When this situation arises, it is important to consider the potential effects on reliability of having previously viewed or selected the suspect.

In research spanning three decades, investigators have examined the effects of repeated viewing of the same suspect and have identified two main effects: commitment and unconscious transference. Commitment occurs when a person who is selected from an earlier identification procedure is selected a second time in a subsequent procedure, regardless of if he or she is the correct person. Unconscious transference, on the other hand, occurs when an innocent person is merely viewed by a witness in one context and is only later selected as the target from a second procedure. The phenomenon of unconscious transference has likely plagued most people at one time or another as evidenced in the question "where do I know that face?" Witnesses that view a person in multiple identification procedures or in multiple contexts (e.g., in a photo array and then in court) are faced with a similar question. The correct answer is for the witness to say "I saw that face from several different contexts," but the erroneous conclusion is that the face is familiar **only** because it is the face of the perpetrator. The concern is that this sense of familiarity on the part of the witness may lead to an increased feeling of confidence in subsequent identification procedures. In fact, a meta-analysis on transference from viewing mug shot photographs confirms that witnesses are more likely to pick from a lineup a person previously viewed (Deffenbacher et al. 2006). Further, the 2006 meta-analysis confirmed that a person who has been identified in an earlier procedure is considerably more likely to be identified in a subsequent procedure.

Although it may seem obvious that a suspect should only be placed in one law enforcement identification procedure, the data from the United States DNA exoneration cases indicates that multiple identification procedures were used in a surprising number of those cases. It is also a relatively common practice for law enforcement to conduct a showup then a lineup, or a photo lineup followed by a live lineup procedure. Although this practice is common, research is very clear that one procedure can influence the reliability of the next and subsequent identification procedures should be viewed with great caution. Without a doubt, the practice of displaying multiple identification procedures to the same witness with the same suspect will be a subject of identification reform in the very near future.

Conclusions

Eyewitness errors are devastating. When an eyewitness makes an honest mistake and chooses an innocent suspect from an identification procedure, not only does that person suffer but the guilty person remains free, at liberty to commit additional crimes. However, research has shown that using modified techniques, such as the sequential double-blind lineup with pre-lineup warnings, will lead to fewer innocent people being convicted of crimes they did not commit. It is critical for eyewitness errors to be prevented in an investigation rather than litigated and disputed in court because both lab research and real-life cases have repeatedly shown that juries (and judges) are not able to distinguish between accurate and inaccurate witnesses. Instead, triers of fact are too often persuaded merely by a witness who appears confident but nonetheless has made a devastating error. Changes in law enforcement procedures with respect to eyewitness identifications, whether by choice or legislative mandate, are taking hold across the country with more reforms and changes to come.

Eysenck's Personality Theory

Adrian Furnham[1] and K. V. Petrides[2]

[1]Division of Psychology and Language Sciences, Faculty of Brain Sciences University College London, London, UK

[2]Research Department of Clinical, Educational, and Health Psychology, Educational Psychology Group University College London, London, UK

Overview

This entry looks at the research on personality correlates and determinants of crime following the influential views of the late Hans Eysenck.

Eysenck, a differential psychologist, made a strong theory and empirically based claim for the idea that personality factors of individuals make them more likely to take part in delinquent and criminal acts. The theory is reviewed and critiqued.

Introduction

Hans Eysenck was perhaps the most prolific psychologist of his day and is still one of the most quoted in the world. Prof. Jeffrey Gray, student of and successor to Hans Eysenck, once famously described his personality theory as akin to somebody finding St. Pancras Railway Station in the jungle. The station is an extremely impressive piece of highly elaborate, complex, and beautiful Victorian architecture situated in central London. What Gray meant was that Eysenck's theory stands out dramatically from all around it.

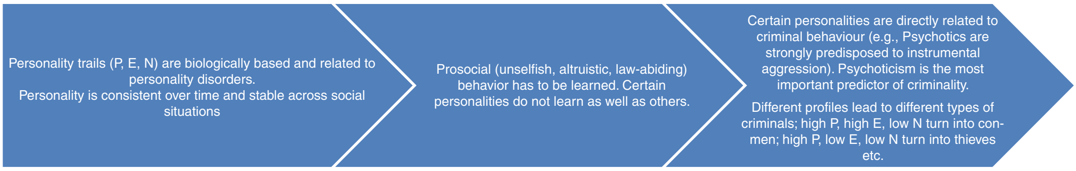
It has been argued that Eysenck's approach to science was characterized by very specific principles (Netter 2007). First, he always argued, even at a time when this was deeply unfashionable, that there was a physical/biological basis to personality. He maintained that taxonomization was the beginning of science and that personality research could not proceed without it. He insisted on a hierarchical model with highly specific behavioral responses at the lowest level, leading up to broad habitual responses at the facet level (e.g., sociability, liveliness, and excitability) and culminating into three giant super-factors at the apex of the hierarchy. He was one of the earliest theorists to advocate a biologically based theory of personality and to promote a continuous theory refinement approach in order to link up specific stimulus properties with general personality functioning.

The Taxonomy of Personality

At present, the Eysenckian model still has three – and only three – super-factors: Psychoticism, Extraversion, and Neuroticism (known as P-E-N). Eysenck was quite convinced that these three conceptual and descriptive categories are necessary and sufficient for a thorough understanding of individual differences in personality.

Extraversion is perhaps the best known of the three Eysenckian dimensions and is at the very "heart" of the model. Eysenck's cortical arousal theory of Extraversion has been extensively described in numerous books (e.g., Eysenck 1973), book chapters, and articles. Revelle (1997) succinctly summarized the classic Eysenckian hypothesis of arousal underpinning his Extraversion factor. "The basic assumptions were: (1) introverts are more aroused than extraverts; (2) stimulation increases arousal; (3) arousal related to performance is curvilinear; (4) the optimal level of arousal for a task is negatively related to task difficulty; and (5) arousal related to hedonic tone is curvilinear. Assumption 1 was based upon many studies associating EPI-E with (low) physiological arousal Eysenck (1967). Assumptions 3 and 4 were based upon the Yerkes-Dodson Law (Yerkes and Dodson 1908) and the subsequent support for it by Broadhurst (1959). Assumption 5 was founded on Berlyne's (1960) discussion of curiosity and arousal. Based upon assumptions 1–4, it can be predicted that introverts should perform better than extraverts under low levels of stimulation but should perform less well at high levels of stimulation. Similarly, assumptions 1, 2, and 5 lead to the prediction that extraverts should seek out more stimulation than introverts" (p. 199).

Neuroticism is based on activation thresholds in the sympathetic nervous system or visceral brain. This is the part of the brain that is responsible for the fight-or-flight response in the face of danger. Neurotic persons have a low activation threshold: when confronted with even mild stressors or anxiety-inducing situations, they quickly and easily experience negative affect and become upset. These manifestations can range from physiological changes in heart rate, blood pressure, cold hands, sweating, and muscular tension to feelings of apprehension and nervousness, to the full effects of fear and anxiety. In contrast to Neuroticism (or emotionally unstable and labile persons), their emotionally stable peers have a much higher activation



Personality trails (P, E, N) are biologically based and related to personality disorders.
Personality is consistent over time and stable across social situations
Prosocial (unselfish, altruistic, law-abiding) behavior has to be learned. Certain personalities do not learn as well as others.
Certain personalities are directly related to criminal behaviour (e.g., Psychotics are strongly predisposed to instrumental aggression). Psychoticism is the most important predictor of criminality.
Different profiles lead to different types of criminals; high P, high E, low N turn into con-men; high P, low E, low N turn into thieves etc.

Eysenck's Personality Theory, Fig. 1 Causal pathways in Eysenck's theory

threshold, and thus will experience negative affect only when confronted by major stressors. Such individuals tend to be calm even in situations that could be described as anxiety inducing or pressure laden. A full description of neurosis is provided by Eysenck in his 1977 book "You and Neurosis."

Psychoticism, the most underdeveloped and debated of Eysenck's three super-factors, was most fully described by Eysenck and Eysenck (1976) in the book "Psychoticism as a Dimension of Personality." High P scorers are predisposed to psychotic episodes but also tend to manifest a higher probability of engaging in aggression and demonstrating the kind of cold tough-mindedness that characterizes psychopathy and persons more likely to engage in crime (Eysenck 1977). While somewhat less fully described and with less empirical support than either E or N, the research that has been done has indicated that P also has a biological basis. The P factor is particularly relevant to crime and criminology. Indeed, the fact that criminals are overwhelmingly male was one of the key observations that Eysenck made in order to hypothesize that the biological basis of P may be related to androgens (e.g., increased testosterone levels).

The past 20 years has witnessed a protracted debate between pro-Eysenckians, who support various permutations of the Giant Three Eysenckian system, and those who support the various Big Five models. The two positions were clearly debated between proponents in conferences and journal articles. For those who were so fortunate to witness the debates between Eysenck and Costa, and others such as Goldberg (e.g., at the ISSID conference in Oxford University in 1991), these were truly akin to the "clash of the Titans." While the debate was always intense, each "proponent" bringing out more data to support their position, it was always respectful of each person's work and commitment as a scientist.

Costa and McCrae (1992) summarized the evidence for the validity of the five-factor model by stating the "four ways the five factors are basic." These were, *first*, that longitudinal and cross-sectional studies have shown five robust factors to underlie enduring behavioral dispositions; *second*, that traits associated with the five factors emerge from different personality data sources (self-reports versus other reports) as well as from studies of natural language (i.e., lexicon) conducted in many different countries; *third*, that the five factors are found in different age, sex, and ethnic groups; and *fourth*, that their heritabilities point to some underlying biological basis. Subsequently, further evidence demonstrated cross-cultural similarities and stabilities in the developmental and ageing trajectories of the five factors (Furnham et al. 2008).

Eysenck (1992) rigorously criticized five-factor models of personality. He suggested that the criteria set out by Costa and McCrae for accepting the five-factor model (some of which Eysenck had himself proposed and pioneered, such as heritability studies of personality) are necessary, but not sufficient for determining the essential dimensions of personality. He argued that Agreeableness and Conscientiousness are lower-level traits that can be conceptualized as facets of his higher-order factor Psychoticism. Additionally, he contended that Openness forms a part of Extraversion and (low) Conscientiousness a part of Neuroticism. Thus, O, A, and C were lower order, not super-factors. Incidentally, a new line of research focusing on the possibility of a General Factor of Personality has received its most emphatic support from robust intercorrelations between the supposedly orthogonal Big Five factors (Rushton et al. 2009).

Eysenck also pointed out the meta-analysis of factor analytic studies of personality, carried out by Royce and Powell (1983), which indicated a three-factor model similar to his own. Eysenck suggested that the five-factor model lacks a theoretical basis sufficiently grounded in empirical facts and is, therefore, arbitrary. He explicitly juxtaposed this arbitrariness against his conceptualizations of Neuroticism and Psychoticism, which were firmly rooted in mental health and clinical psychology research.

Eysenck (1992) argued that it is the nomological network in which a dimension is embedded that corroborates its validity. This network must include a detailed specification of a personality dimension's biological and psychophysiological origins, its cultural invariance, and its relationship to social behavior and psychological illness. Indeed, one of Eysenck's most significant contributions to personality research was his shifting of the field's agenda, from nebulous Freudian speculation to rigorous biopsychological integration (Eysenck 1967).

Eysenckian Measures

Eysenck devised and validated numerous inventories that are still widely in use. Furnham et al. (2008) suggested five reasons why these measures have stood the test of time:

(A) *Parsimony*. The P-E-N model offers a first-class conceptual foundation for the Eysenck Personality Questionnaire (EPQ), which is one of the most parsimonious and psychometrically robust personality inventories. It compares favorably with the 16 dimensions of Cattell's 16PF or the Big Five, Six, or Seven (there have been several attempts to expand Big Five models by adding allegedly new traits). In some ways, focusing on second-order factors is akin to the role of "g" in the measurement of intelligence. While some psychologists have argued through the bandwidth-fidelity debate for finer grain analysis at the facet (primary and lower-order) factor level, to some extent the Eysencks resisted this trend although the creation of measures such as the I_6 and I_7 did provide an assessment of several key variables including venturesomeness, impulsivity, and empathy. Recently, there has been a focus on primary factors and their acolytes started working with the EPP. More recently there has been considerable interest in the EPP and the facet/primary factor level of analysis (Jackson et al. 2000). While the Eysencks always measured super-factors or traits (i.e., the Gigantic Three), some researchers have argued that a finer-grained level of analysis (i.e., facet level) enables one to understand the nature of processes better (Petrides et al. 2003).

(B) *Explanation of Process*. More than any other test developers in the twentieth century, the Eysencks were not content to just describe and categorize traits: they constantly sought to escape tautological explanations. Eysenck's was the first counterintuitive theory of arousal to explain individual differences in Extraversion. Hans Eysenck showed, nearly a decade before the publication of the EPQ (Eysenck 1947), that his work and interests were solidly grounded in the biological basis of personality, which he set about exploring for the next 30 years (Eysenck 1967, 1982b). More than any other personality theorist, he was concerned with describing and explaining the mechanisms and processes which account for systematic individual differences. Eysenck's theory and model of individual differences is fully described in an earlier chapter by O'Connor and will not be repeated here; only a thumbnail sketch will be provided to provide the context for the development of the various personality measures developed by both Hans and Sybil Eysenck and colleagues.

(C) *Experimentation*: Eysenck was rigorously schooled in the experimental tradition at a time when behaviorism and psychoanalysis triumphed. He believed it essential that the correlational (individual differences) and experimental branches of psychology unite, so that personality effects will cease to be treated as error variance (Howarth and Eysenck 1968). This basic premise was the foundational underpinning for the creation of both the International Society for the Study of Individual Differences (ISSID) and also the Society's official journal, Personality and Individual Differences, arguably the leading journal in the field.

(D) *Wide Application*. The Eysencks were psychological pioneers as well as risk takers; they were eager to extend their research program to look at the significance of personality functioning in areas as disparate as sex, crime, parapsychology, astrology health, and behavioral genetics among many others. They were convinced that individual differences were systematically and predictably present in all facets of human functioning. To many, particularly those favoring sociological or more exclusively environmental perspectives (e.g., based on parenting styles or early childhood experiences), this was radical indeed.

(E) *Continuous Improvement and Development*. For nearly 40 years the Eysencks have engaged in a systematic research program aiming to improve, update, and validate their range of personality measures. Because their scales have been so widely used in research worldwide, they have been subject to detailed but, at times, ungenerous scrutiny by many people. Their observations and research studies, particularly those emphasizing a cross-cultural perspective, led to continuous improvements over time, with items being removed, changed, and replaced. Importantly, all of this psychometric development was guided not by commercial opportunities, but firmly by theoretical considerations and empirical evidence.

Personality Structure Cross-Culturally

Most personality theorists hypothesize that major individual differences variables, such as intelligence and personality, are universal constructs. While they may vary in their expression (phenotype) as a function of culture and other psychosocial factors, basic traits are common across humankind. Some psychologists would also argue that the measurement of their specifically described traits or constructs would be universal across all countries and cultures. Considerable research has been published over the years demonstrating the significant contribution that genetic, biological, neurological, and environmental factors make in shaping the expression of intelligence and personality.

For over 20 years, Sybil Eysenck published research comparing the results of studies on adults and children using the adult and junior versions of the EPQ. In 1981, the Eysencks summarized the results of 14 countries based on just under 15,000 subjects (Eysenck and Eysenck 1981). In 1985, they extended their analysis to 24 countries and in 1998 this was further extended to 34 countries (Barrett et al. 1998). As each national group was added, so inevitably the population sample increased, but more impressively so did the quality of the statistical analysis. Sybil Eysenck also published a dedicated book detailing specific studies of the Eysenck scales used in different countries with children and adolescents.

Personality and Crime

Perhaps the most robust and fecund of the theories of the criminal personality is that of Eysenck (1977). Feldman (1993) has noted: "One of the theory's great merits is that it makes predictions which are clear cut, testable and refutable" (p. 166).

The idea is beguilingly simple. Eysenck believed that sociological theory has little to offer society on the causes of crime, arguing that psychological theories have more explanatory power (Eysenck and Gudjonsson 1989). Criminal behavior is not the product of either environment *or* biology alone, but rather of a dynamic interaction between the two. This extends Eysenck's original hypothesis that biology played the largest part in determining criminality, expounded in his book "Crime and Personality" (Eysenck 1964). Eysenck suggested that some people are born with cortical and autonomic nervous systems that compromise their ability to learn from their environment and renders them susceptible to illegal and criminal acts.

Each of the three Eysenckian factors relates to some aspect of conditionability, notably the learning of rules of society.

Extraverts are social and impulsive. They are excitement seekers interested in novel experiences, which often leads them to be poorer learners than introverts at many tasks, including the acquisition of general social rules. They are somewhat more likely than introverts to become delinquents or criminals.

Neurotics are anxious, moody, restless, and rigid. They react strongly to threat often with great fear to painful stimulation. This means they too do not learn social rules well and are "inefficient learners" particularly with respect to punishment.

Psychotic (*tough-minded*) individuals tend to be aggressive, egocentric, insensitive, inhumane, uncaring, and troublesome, and they are far more likely than their tender-minded peers to engage in delinquent and criminal behavior.

Those who score high on the P-E-N end of the Eysenckian dimensions tend to be least socially conditioned and, hence, least socially restrained. They are aggressive, hedonistic, impulsive, and reckless. The Eysenckian view links personality and criminality with a simple mechanism: personality traits are linked to learning pro- and antisocial behaviors that are linked to delinquent and criminal behavior and recidivism.

Eysenck and Gudjonsson (1989) in summary note as follows:

1. There exists a general behavior pattern of antisocial behavior and criminality, marking the opposite end of a continuum that has prosocial and altruistic behavior at its other end.
2. Within the antisocial and criminal type of behavior, there is a certain amount of heterogeneity, marked particularly by the opposition between active and inadequate criminals (UNCLEAR), but probably also including differences according to type of crime committed.
3. Criminality is related to certain dimensions of personality, most especially Psychoticism, which is apparent across all age groups and conditions studied.
4. Extraversion is also linked to criminality, particularly in younger samples and among more active criminals; inadequate older criminals do not show high extraversion and may indeed be below average on this trait.
5. Most criminals are characterized by a high degree of Neuroticism, but this may not be found as markedly in children and youngsters.
6. Scores on the social desirability (L) scale are regarded in these studies as a measure of conformity (rather than of dissimulation) and tend to correlate negatively with antisocial and criminal conduct, in children, adolescents, and adults.
7. The criminality scale, made up of the most diagnostic items of the EPQ, discriminates reliably between criminals and noncriminals.
8. Primary personality traits, such as impulsiveness, venturesomeness, risk taking, and empathy correlate, in predictable directions, with antisocial and criminal conduct.
9. These relationships are observed also in research where self-reports of antisocial behavior are the criterion of interest. Thus, personality-criminality correlations are not confined to legal definitions of crime or to samples of incarcerated criminals.
10. The personality-criminality correlations have cross-cultural validity, appearing in different countries and cultures with equal prominence.
11. Personality traits characteristic of antisocial and criminal behavior also correlate with behavior that is not criminal per se, but is regarded as antisocial – whether legal or illegal (e.g., smoking and drug use, respectively). Studies show high P and N scores among drug users, although E scores are

elevated only among drug users who have also been convicted of other crimes.

> Eysenck and Gudjonsson (1989) concluded that "…psychological factors and individual differences related to the personality are of central importance in relation to both the causes of crime and its control. This does not mean to say that other factors, such as sociological and economic ones, are not important. Indeed, in many instances they are. We believe that sociological theories are particularly relevant in relation to victimless crimes and less so in the case of victimful crimes.
>
> Psychological factors in criminality, we argue, relate to genetic and constitutional causes and to personality and other sources of individual differences. This does not mean that some people are destined to commit crimes. Criminal behavior as such is not innate. What is inherited are certain peculiarities of the brain and nervous system that interact with certain environmental factors and thereby increase the likelihood that a given person will act in a particular antisocial manner in a given situation." (p. 247)

There are, of course, considered and extensive critiques of the Eysenckian approach to the understanding of criminals and crime frequently revolving around the points below:

- Self-report measures of both crime/delinquency *as well as of* personality are open to dissimulation, lying, denial, exaggeration, etc. In addition, their interrelationships may appear inflated in research investigations due to common method variance.
- Caught criminals are unrepresentative of the population. Most criminals are, alas, not caught.
- Criminals and delinquents are far from homogeneous (e.g., murderers are very different psychologically from con men).
- Incarceration may affect personality, notably increase Neuroticism and reduce Extraversion. Prisoners may change as a function of their imprisonment and, thus, there may be reciprocal links between personality traits and crime-related variables.
- Being nonexperimental in nature, personality research is unable to demonstrate unequivocal causal relationships between personality traits and outcomes of interest.
- Trait personality theories tend to underemphasize social and environmental factors, although recent advances in the field of multivariate statistics have allowed for more realistic conceptualizations combining all of these influences and countering objections by sociologists and educationalists.

Eysenck's position developed and changed over time. He gradually placed more emphasis on the role of Psychoticism and began to admit more freely the range of the social causes of crime. Nevertheless, he continued advocating a central role for personality traits, a position that has consistently received support over the years including from rigorous longitudinal (birth-cohort) studies. Thus, Caspi et al. (1994) and Wright et al. (1999) found replications in the Eysenkian hypothesized personality – crime relationships across country, gender, race, and method. As suggested by the theory, poor social control (impulsivity, hyperactivity, etc.) predicted weak social bonds, adolescent delinquency, and later criminality. In a large meta-analytic review, Miller and Lynam (2001) found that personality traits relate to antisocial behavior, in general, and to crime, in particular, in both distal and proximal ways. Thus, personality predicts how people react to situations, how other people react to them, and indeed the situations they find themselves in. Miller and Lynam concluded that individual differences variables can help account for the observed stability of antisocial behavior over the life-span.

Conclusion

It is perhaps still true that no psychologist before or after Hans Eysenck attempted to show and explain how personality variables relate to such a wide array of everyday social behaviors from aesthetic appreciation to sport and school success to sport. Among his interests was how personality, in terms of his Giant Three system, related to all aspects of crime. His first book, published nearly 50 years ago, set out a bold and clear theory linking personality to various aspects of crime. The book has been quoted over 1,200 times. It provoked criticism but galvanized differential psychologists into testing the theory. Both updates and reviews constantly appear (Blonigen 2010;

Levine and Jackson 2004). To some extent the early work rather overemphasized the role of personality variables in crime, probably in reaction to a domination of sociological and psychological theories of crime. His second book, coauthored with Gudjonsson – a clinical and forensic psychologist – was a more measured and better-referenced book on the topic.

Clearly personality variables must and do play a part in all aspects of criminal behavior. The question is how much of the variance they do explain apart from other demographic and social environmental factors.

False Confessions and Police Interrogation

Mark A. Costanzo[1] and Marina L. Costanzo[2]
[1]Department of Psychology, Claremont McKenna College, Claremont, CA, USA
[2]University of Colorado, Colorado Springs, CO, USA

Overview

False confessions are a serious problem in the USA criminal justice system, playing a role in about a quarter of all known wrongful convictions. False confessions can be differentiated based on whether they are voluntary or coerced and whether they are authentic or instrumental. Although the "third degree" was once common in the United States, police now rely on psychological techniques to extract confessions from criminal suspects. During interrogation, police strive to convince the suspect that the evidence against him is compelling and that admitting guilt is the only sensible course of action. When innocent suspects are subjected to psychologically powerful interrogation techniques, some will falsely confess. The vulnerabilities of individual suspects can also play a role in producing false confessions. Methods of reducing the risk of false confessions and identifying false confessions once they occur include mandatory electronic recording of interrogations, allowing expert testimony at trial, modernizing interrogation training, and reforming the interrogation process itself.

Introduction

A confession can be true, false, or ambiguous in veracity. We can often be sure that a criminal confession is true because the information revealed by the confessor is strongly supported by other evidences in the case. For example, there is often medical evidence, or DNA evidence, or fingerprints, or video recordings, or computer records, or multiple, credible eyewitnesses that confirm the account of the crime provided by a suspect in the interrogation room. True confessions disclose accurate details about the crime, often lead to the discovery of new evidence (e.g., where a body is buried), and reveal facts and information only the true perpetrator would know.

False confessions involve people admitting to crimes they did not commit or misrepresenting or exaggerating their role in a crime. We can know for certain that a confession is false when DNA evidence proves that someone else committed the crime, when the account of the crime given by the confessor clearly contradicts the physical

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

evidence in the case or when it can be shown that it was physically impossible for the confessor to have committed the crime (e.g., the suspect was in a distant location at the time of the crime). False confessions are generally not supported by other reliable evidences in the case. Usually, an account of a crime given by an innocent false confessor will not match the facts of the crime, will contain substantial errors, and will not lead police to new or missing evidence.

Some confessions are ambiguous in veracity – they can be proven neither true nor false. If there is a confession, but no other compelling evidence of guilt, it may be impossible to determine with certainty whether a confession is true. Confessions are a powerful form of incriminating evidence. Often, people who confess are convicted and sent to prison. In a study of *proven* false confessions, researchers found that 80 % of people who falsely confessed and pled "not guilty" were convicted at trial (Drizin and Leo 2004). Prisoners convicted of crimes may continue to proclaim their innocence from behind bars, but unless strong exonerating evidence is later uncovered or it turns out that it was physically impossible for the confessor to have committed the crime, we may never be able to verify whether a confessor is innocent or guilty.

A significant problem in distinguishing true from false confessions is created by the process of *contamination*. Too often, interrogators leak key details of the crime to the suspect being interrogated (Leo et al. 2009). Prior to or during the course of a long interrogation, police may disclose several critical elements of the crime (e.g., how and where the victim was killed). When a suspect later incorporates these key details into his or her confession, the result is a contaminated false confession that has the appearance of veracity. Because of the process of contamination, many proven false confessions contain details that only the actual perpetrator should know (Garrett 2008). As discussed below, without an electronic recording of the entire interrogation, it is usually impossible to assess whether contamination occurred during the interrogation process.

It is currently impossible to calculate the frequency or rate of false confessions. Police departments and state governments do not keep precise records of the number of interrogations conducted annually, nor do they keep detailed records of which confessions were proven to be true or false. Researchers have not been granted access to the records that do exist. And, of course, confessions that are ambiguous in veracity cannot be proven true or false. What we do know is that false confessions are far more frequent that was commonly supposed prior to the development of DNA identification technology. The Innocence Project, an organization that seeks to exonerate wrongfully convicted prisoners using DNA evidence, has found that false confessions were a critical piece of evidence in 25 % of wrongful convictions (Innocence Project 2012). It is critical to note that because the biological evidence (blood, semen, skin cells, hair, or saliva) which allows for DNA testing is only available in a minority of criminal cases, a large number of false confessions can never be *proven* false.

The Historical Context of Police Interrogations

Historically, physical and psychological torture have been the basic tools of interrogators, and, in many countries, torture remains a standard interrogation technique (Costanzo et al. 2010). In the United States, at least through the early 1930s, police used the "third degree," regularly threatening and physically abusing criminal suspects in an effort to extract confessions. As a result of the Wickersham Commission Report in 1931 (*National Commission on Law Enforcement and Observance* 1931), and a number of Supreme Court cases beginning with *Brown v. Mississippi* (1936), physical abuse of suspects began to decline in the 1930s, and, by the 1960s, such abuse appeared to be rare in the United States (Leo 2008).

In 1966, the US Supreme Court ruled that if a suspect is in police custody, police are required to issue several warnings prior to interrogation. Suspects must be informed of their right to remain silent, told that they have the right to appointed counsel and to have that counsel present during questioning. Suspects must be also be warned that anything they say can be used against them in court (*Miranda v. Arizona*, 1966). Somewhat surprisingly, *Miranda* warnings have proven to be only a weak safeguard against coercion. A large majority of suspects (estimates range from 78 to 96 %) relinquish their rights and therefore appear to consent to interrogation (Leo 2001). Police have devised several strategies to elicit waivers to the *Miranda* warnings. These include reading the *Miranda* warnings in a quick, confusing, or perfunctory manner; de-emphasizing or minimizing the significance of the *Miranda* warnings; obscuring the adversarial nature of the police-suspect interaction; and telling the suspect that the interrogator can help him only if he first waives his *Miranda* rights (Leo and White 1999).

In addition to the requirements that police "Mirandize" suspects and refrain from using physical force during interrogations, police are forbidden from making explicit threats of punishment or explicit promises of leniency.

To replace abusive practices, police developed more sophisticated psychological techniques. In 1942, Fred Inbau published the first edition of his seminal interrogation manual, *Lie Detection and Criminal Interrogation*. With John Reid and others, Inbau revised and expanded this training manual through several revisions. The most recent edition – *Criminal Interrogation and Confessions* by Inbau, Reid, Buckley, and Jayne – was published in 2001. The Chicago-based firm, *Reid and Associates*, transformed these manuals into a training program and, in 1974, began offering seminars to police and security professionals across North America. More than a quarter million police have now been trained in the Reid technique of interrogation. Undoubtedly, many more police officers have either read the training manual or have learned Reid tactics by observing or working with other interrogators. Research confirms that these tactics are frequently used by detectives in the United States (Leo 1996; Feld 2006). The use and effects of the Reid technique will be more fully discussed in the section on "The Process and Tactics of Interrogation."

Types of False Confessions

Several classification schemes have been proposed to differentiate between types of false confessions. Costanzo and Leo (2008) distinguished between four types of false confessions by crossing two dimensions: instrumental or authentic and voluntary or coerced. Instrumental confessions are those offered as a means to an end to achieve some goal. The goal of a suspect may simply be to end an extremely stressful interrogation. In contrast, authentic false confessions are the result of a confessor's genuine but false belief that he or she may have actually committed the crime. Voluntary false confessions are given freely by the confessor, while coerced false confessions are produced by psychological pressure (and occasionally physical pressure) from the interrogators.

Crossing the two dimensions yields four types of false confessions. *Instrumental – coerced* false confessions occur when, as a result of a lengthy or intense interrogation, suspects confess to crimes they know they did not commit. During the course of such an interrogation, the suspect becomes convinced that the only way to end the interrogation or to receive more lenient treatment is to agree with the interrogators that he or she committed a crime. This appears to be the most common type of false confession. *Instrumental – voluntary* false confessions occur when suspects knowingly implicate themselves in crimes they did not commit in an effort to achieve some goal. A member of a criminal gang or organization may falsely confess to a crime to protect someone higher up in the gang hierarchy. There have also been cases where parents have intentionally given false confessions to protect their children from being convicted of a crime. Indeed, people have voluntarily confessed to achieve a variety of peculiar goals – to achieve fame, to impress a girlfriend, to provide an alibi for one's whereabouts while having an affair, or to make police look incompetent (Gudjonsson 2003).

An *authentic-coerced* false confession occurs when, in response to a long or stressful interrogation, suspects begin to doubt their own memories and become convinced – at least temporarily – that they may have actually committed the crime. At the suggestion of the interrogators, the suspect may come to temporarily believe that he "blacked out" or "repressed" his memories of the crime. In a few exceptional cases, intensely coercive interrogations have caused innocent suspects to create false but vivid memories of crimes they did not commit (Wright 1994). Finally, an *authentic – voluntary* false confession occurs when someone who may or may not be a serious suspect confesses to a crime with little or no pressure from interrogators. In high-profile, well-publicized cases, police investigators sometimes receive multiple, unsolicited confessions from delusional or mentally ill people who appear to believe they have committed the crime.

Suspect Vulnerabilities to Interrogative Pressures

The majority of false confessions have come from adults with no significant mental problems. However, there are several suspect characteristics that raise the risk of false confessions. Risk factors attributable to the suspect include youth, mental impairment, personality characteristics, and temporary impairments.

Many of the best known examples of false confessions have involved juveniles or young suspects. In a large sample of proven false confessions, 63 % of innocent confessors were under the age of 25 (Drizin and Leo 2004). Juvenile suspects waive their Miranda rights at a rate about 12 % higher than adult suspects, making juveniles more vulnerable to false confessions (Grisso and Schwartz 2000). Research in developmental psychology demonstrates that children, adolescents, and even young adults differ from full adults in mental and social maturity. Cognitive neuroscientists have shown that key areas of the brain such as the limbic system and the prefrontal cortex continue to develop into the early 1920s (Steinberg 2007). Compared to adults, adolescents are more impulsive, more emotionally volatile, and less able to regulate their emotions. They tend to engage in riskier behavior and tend to make decisions based on immediate rewards and punishments rather than long-term consequences. This combination of attributes puts juveniles at special risk for false confessions (Redlich 2007).

Various forms of mental impairment including low intelligence or mental retardation appear to increase the risk of false confessions. About 22 % of known false confessors could be classified as mentally retarded (Drizin and Leo 2004). Mentally retarded individuals tend to be more acquiescent, more likely to agree with illogical questions, more likely to change their answers (especially in response to positive feedback), and more easily confused by the tactics of interrogators (Finlay and Lyons 2002). People with memory impairments are likely to distrust their own recollections and are therefore more likely to believe the account of events suggested by interrogators. Similarly, mental illness can make suspects more vulnerable to false confessions. Only 10 % of suspects who falsely confessed had been previously diagnosed with some form of mental illness, but others may have suffered from an undiagnosed impairment of some kind (Drizin and Leo 2004). Like mentally retarded suspects, mentally ill suspects may suffer from an inability to foresee the long-term consequences of admissions made in the interrogation room.

People vary in their ability to resist coercion and persuasion. Although there may be several aspects of personality that make people vulnerable to false admissions (e.g., need for approval or social anxiety), two traits – high suggestibility and compliance to authority – have been specifically investigated because of their relationship to false confessions (Gudjonsson 2003). People with these traits tend to be more uncertain about answers to questions asked by interrogators, tend to be more likely to trust interrogators' claims that they want to help, and tend to want to please interrogators. In addition to these stable personality traits, a variety of transitory states may increase the risk of false confessions. Sleep deprivation lowers our resistance to coercion, and drug or alcohol use makes us less able to evaluate the consequences of our actions. Grief and other strong emotional states have also been implicated in false confessions (Leo 2008). All of these temporary impairments create mental confusion and appear to weaken resistance to pressure.

The Process and Tactics of Interrogation

Interrogations in the United States tend to be based on the Reid technique and have been characterized as manipulative, guilt presumptive, and confrontational. Although interrogations vary in length, content, and intensity, all are designed to induce a guilty suspect to confess. Analyses of proven false confessions and experimental research demonstrate that the tactics described below sometimes induce innocent suspects to confess to crimes they did not commit (Russano et al. 2005; Drizin and Colgan 2004).

The interrogation process is designed to break the resistance of a suspect who knows he is guilty and to persuade him that the benefits of confessing outweigh the costs. The process of interrogation in the United States can be reduced to four broad tactics (Costanzo and Leo 2008). First, there is almost complete *control* of the process by the interrogators. Suspects are typically interrogated in a cramped, sparsely furnished room. The physical characteristics of the room, and more importantly, the nature, length and pacing of the conversation are under the control of the interrogators. The goal is to remove the psychological comfort of familiar surroundings and to communicate to the suspect that he has lost control of the situation. This loss of control disorients the suspect, raises anxiety, and creates a desire to escape the interrogation room. The second broad tactic that sets the stage for a potent interrogation is *social isolation*. Whenever possible, suspects are interrogated alone. Isolation deprives the suspect of emotional support. The presence of a friend or ally might bolster the suspect's resistance to persuasion and might lead to additional challenges to the interrogator's version of events. The combination of control and social isolation enables interrogators to create the social reality of the situation and to reshape the decision-making process of the suspect.

The two remaining tactics, certainty of guilt and minimization of culpability, are used to convince the suspect that offering an admission of guilt is their best available option. *Certainty of guilt* refers to the message – communicated in a variety of ways – that the suspect committed the crime and that the evidence against him is irrefutable. Although an innocent suspect will respond to this accusation with denials, interrogators are trained to challenge, cut off, and dismiss all denials. To convince the suspect that denials are futile and that certainty of guilt is justified, police are permitted to use a variety of *false evidence ploys*. Put more directly, police in the United States are permitted to lie about evidence against the suspect. Examples of false evidence ploys include untrue claims that others have implicated the suspect ("eyewitnesses saw you do it," or "others have told us you did it") and false claims that various forms of physical evidence (fingerprints, DNA, videotape from a security camera) clearly point to the suspect as the person who committed the crime. If the suspect offers an alibi, the interrogator may attack it as inconsistent, implausible, contradicted by the evidence, or simply impossible. These ploys often cause the disoriented suspect to conclude that he bears the burden of proving his innocence, that conviction is inescapable, and that further denials are futile.

Certainty of guilt is paired with *minimization of culpability* to move the suspect from denial to admission. Minimization of culpability involves offering "face-saving" justifications or excuses for the crime. For example, it might be suggested to a murder suspect that he killed the victim by accident or in self-defense. It might be suggested to someone suspected of theft that the money was stolen to pay for an important family expense or suggested to someone suspected of rape that he engaged only in consensual sex. These minimizing scenarios serve to morally, psychologically, and legally justify, downplay, or excuse a suspect's actions. Supplying a minimizing or exculpatory reason for committing a crime clearly implies that the offense may not be that serious and that anyone making a judgment about the act (e.g., a prosecutor, judge, or jury) would be likely to recommend lenient treatment. The interrogator suggests that the suspect will be charged with a less serious crime and receive a shorter prison sentence if he accepts responsibility, admits guilt, and expresses remorse (Leo et al. 2009). Conversely, continued denial will result in a more serious charge and a longer prison sentence.

The cumulative effect of these tactics is to persuade the suspect that he will almost certainly be arrested, convicted, and punished. Only by accepting a minimizing scenario can he improve his otherwise hopeless situation. Police often present an admission as an "opportunity" for the suspect to "tell his side of the story." Further, it is often presented as a time-limited opportunity that will vanish once the interrogation ends. During the interrogation, police may misrepresent themselves as allies instead of adversaries and suggest that they can and will help the suspect minimize the consequences of his crime. The pretense that interrogators are the allies of the suspect is the foundational lie of the interrogation process. Interrogators may explicitly tell a suspect that they can help him by how they write up their report, by what they tell the prosecutor prior to charges being filed, or by how they testify before a judge or jury at trial. Interrogators may even offer to help a suspect in ways that extend beyond the criminal justice system, such as arranging for counseling or assistance from social services. Of course, the catch is that these benefits can only be realized if the suspect complies with the interrogators' demands for an admission.

Reducing the Risk of False Confessions

Perhaps the most important goal of research on interrogations and false confessions is to suggest "best practice" reforms that reduce the number of false confessions while increasing the number of true confessions. Scholars have proposed several such reforms based on research findings. Some reforms aim to prevent false confessions from occurring, while others increase our ability to detect false confessions after they have occurred.

The most fundamental and frequently recommended reform is to require video recording of interrogations (Kassin and Gudjonsson 2004). Electronic recording of interrogations is required in some states and common in felony cases. Mandatory recording of interrogations creates an objective, reviewable record of what occurred in the interrogation room. Jurors, judges, lawyers, and experts are able to see and hear for themselves not only what was said but also how it was said. However, to provide an optimally useful record, the interrogation must be recorded in its entirety, and both the suspect and the interrogator should be visible. Recording the entire interrogation ensures that we do not rely on partial, selective, or biased records of what transpired. To assess whether a confession is coerced or contaminated, we need to be able to examine the entire interaction that preceded a confession. The requirement that both the suspect and the interrogator be visible follows directly from research demonstrating that only an "equal-focus" camera angle allows viewers to evaluate both the suspect's confession and the pressures exerted by interrogators (Lassiter and Geers 2004).

A second important reform is the use of social science expert testimony in cases involving a disputed interrogation or confession (Costanzo and Leo 2008). Such testimony is routinely offered in many states, and there is a substantial body of scientific research that experts can rely upon. When a disputed confession is introduced at trial, jurors will want to know why a possibly innocent person could be made to confess to a serious crime. Expert testimony can displace common misconceptions – for example, the belief that an innocent person will not falsely confess unless he is physically tortured or mentally ill. Experts educate the jury about the reality of false confessions, the psychological dynamics of the interrogation process, and the factors that increase the probability of false confessions. The purpose of expert testimony at trial is to provide an overview of relevant research and to assist the jury in making a fully informed decision about what weight to place on the defendant's confession (Costanzo et al. 2010).

A third set of reforms focus on modifying the training of interrogators to give more emphasis to the problem of false confessions. When asked about the possibility of false confessions, a common response of those who train interrogators is, "we don't interrogate innocent people" (Kassin 2005). In theory, police screen out innocent suspects through initial interviews and evidence gathering. In actual practice, however, the list of proven false confessions is replete with cases in which innocent suspects were subjected to highly coercive interrogation techniques based on little more than intuition or a misreading of a suspect's behavior as suspicious or deceptive.

In particular, interrogation training needs to make far more modest claims about the ability of police to correctly interpret behavioral cues to deception. Research shows that it is extremely difficult for observers to make reliable judgments about whether or not someone is lying (Vrij 2008). Further, research indicates that many of the behavioral cues used by interrogation trainers do not differentiate liars from truth tellers. The general finding is that both untrained observers and people with relevant professional training (e.g., police and polygraph examiners) perform only slightly better than chance. Where chance accuracy is 50 %, average accuracy is only about 54 % (Bond and DePaulo 2006). Although training to improve accuracy does not reliably improve the ability to detect lies, it does have effects: after training, people are more confident about their judgments, and they list more reasons for their judgments (Costanzo 1992; Kassin and Fong 1999; Kassin et al. 2005). When faulty cues to deception are combined with overconfidence by interrogators, innocent suspects can be subjected to enormous pressure. Some will falsely confess.

The most controversial, but potentially most effective set of reforms focus on the interrogation process itself. Because interrogations culminating in proven false confessions are significantly longer than average, some researchers have suggested time limits on interrogations (e.g., no more than 3 h). Longer interrogations appear to increase the risk of false confessions by producing stress and fatigue and thus impairing a suspect's ability and motivation to resist police pressures. Other limits on the interrogation process have been proposed. Following the lead of the United Kingdom, the United States could prohibit police use of deception and trickery in the interrogation process. Training manuals continue to insist that police lying about evidence does not produce false confessions. Yet many false confessions are the product of interrogations in which police lied to suspects, used false evidence ploys, and pretended to possess damning physical evidence against the suspect (Ofshe and Leo 1997; Drizin and Leo 2004).

As noted earlier, the dominant form of interrogation used in the United States is strongly influenced by the Reid technique, which presumes that the person being interrogated is guilty and will only respond to a confrontational and deceptive style. An alternative to this approach was developed in England and Wales in response to several high-profile false confessions that led to wrongful convictions. The PEACE model of interrogation (an acronym for Preparation and planning, Engage and explain, Account and clarification, Closure, and Evaluation) has been in use since the mid-1990s and has been adapted for use in several other countries (Gudjonsson and Pearse 2011). This alternative model emphasizes careful preparation for the interrogation and thorough knowledge of the suspect and the crime. The process of interrogation stresses finding the truth rather than obtaining a confession. Lying to suspects, false evidence ploys, manipulation, and strong pressure are avoided. All interrogations are electronically recorded. Use of the PEACE model appears to dramatically reduce the rate of false confessions while still producing a high rate of true confessions (Bull and Soukara 2010).

Careful analysis of proven false confessions and a growing body of experimental studies provide us with new insights on how interrogations go wrong. We need to translate these insights into reforms that increase the likelihood of producing true confessions while reducing the likelihood of false confessions.

False Memories

Overview

Memory is indispensable to the criminal justice system. Countless criminal cases are built around the things victims and eyewitnesses remember: details, faces, and circumstances of events that occurred weeks, months, and sometimes even years earlier. In an ideal world, a person's memory would work something like a video camera – capturing details in high definition and saving them to a memory card so they can later be retrieved and trusted as reliable. As it turns out, memory is less like a video recording and more like an active reconstruction of the past. It can be altered by even the subtlest of influences, and in some cases, even memories held with great confidence can be completely wrong. Errors in people's memories can be inconsequential, but they can also cause profound complications, particularly in the legal system where a defendant's guilt or innocence can depend on the precise details of another person's recollection. This entry explores the small and large ways that memory can depart from reality – how people can misremember details about an event and how they can come to remember whole events that never occurred.

Misremembering Details

In early 2012, Florida resident George Zimmerman called 911 from his cell phone and reported that a young Black man (later identified as Trayvon Martin) was behaving suspiciously inside the gated community where Zimmerman lived. With police en route, Zimmerman confronted Martin. An altercation ensued and ended with Zimmerman fatally shooting Martin in the chest at close range. When the police arrived, Zimmerman appeared injured and claimed that Martin attacked him and that he, Zimmerman, shot in self-defense (Kovaleski 2012).

Numerous eyewitnesses came forward with their accounts, but strangely, several of their stories seemed to transform over time. For example, a few days after the shooting, a woman recounted to the police that she saw two men running and then brawling in the street. A few weeks later, she said she saw just one man running, but couldn't identify him because she was not wearing her contact lenses. Another witness initially said she saw two men on the ground after the shooting, but could not tell which man was on top. Days later, after seeing Zimmerman on television and learning new details about the case, she said she remembered that Zimmerman was the one on top. Another witness said he saw Martin pinning down Zimmerman and punching him while Zimmerman called for help, only to later claim that he wasn't sure he saw any punches or heard any calls for help. Finally, a man who saw Zimmerman after the shooting first described him as looking bloody and dazed and later said he seemed calm and collected.

The shooting of Trayvon Martin and Zimmerman's subsequent arrest was covered incessantly by the American news media in the days and weeks following the event, so it is not surprising that witnesses to the incident were exposed to a bevy of reactions, opinions, imaginings, and speculations. But the question remains, how is it possible that two starkly different accounts can emerge from the same eyewitness? One possibility is that the eyewitness is not being truthful in one version of events. Another possibility is that some kind of post-event information *changed* the witness' memory. Psychologists have now studied this phenomenon, known as the misinformation effect, for several decades (see Loftus (2005) for a review).

In trying to understand how people's memories can become contaminated and distorted, researchers developed a simple experimental paradigm mimicking the sequence of events that could happen in an actual case involving eyewitnesses. First, research subjects are shown some type of stimulus (e.g., a video or a photo slideshow of a simulated crime). Next, they are exposed to some misleading information about what they saw, usually embedded in a lot of true information. Finally, their memories for the original source material are tested. In one study, subjects were shown a series of photographs depicting a man interacting with a woman on a city street, stealing her wallet, and hiding it in his jacket pocket (Zhu et al. 2010a). Later, subjects read narratives that described the photographs. For some of the subjects, however, the narrative contained bits of inaccurate information. These subjects were told, for instance, that the man hid the stolen wallet in his pants pocket. All subjects were then asked a series of questions about the original event they saw (e.g., Where did the man hide the wallet?). In hundreds, perhaps thousands of studies like this one, subjects who are exposed to inaccurate information frequently incorporate these inaccuracies into their memories of the original event, rendering them much less accurate than witnesses who were never exposed to misinformation.

When Is Misinformation Most Effective?

In any one specific instance, it can be very difficult to disentangle whether memories are based on true experiences and when they have been contaminated by erroneous information. However, knowing about factors that tend to promote or inhibit memory distortion might help to illuminate whether someone's recollection has been altered by post-event information. With this in mind, psychologists have worked at identifying circumstances that appear to facilitate the distortion of people's memories. For instance, studies have clearly shown that a person's memory is more susceptible to misinformation effects when more time has passed since the original event occurred (e.g., Loftus et al. 1978). This may be because memories fade over time; following longer retention intervals, misleading information may be less recognizable as false and more easily incorporated into the original memory. Other research has shown that misleading information has a stronger influence on memory when people are in certain states (e.g., under hypnosis; Scoboria et al. 2002) or when people believe they are in certain states (e.g., when they think they are intoxicated; Assefi and Garry 2002).

Another factor that can influence the power of misleading information on memory is the source of the information. Studies have shown that people incorporate false information more readily into memory when they perceive the source of the information to be trustworthy. For example, in a series of experiments, Unkelbach and Stahl (2009) showed that people were more likely to identify false statements as true when they heard a trustworthy source make those statements earlier in the study. Misinformation is also more likely to change a person's memory when they are exposed to it repeatedly. For instance, one study investigating the effects of hearing other witness statements (Foster et al. 2012) showed that people are more likely to incorporate other people's errors into memory when they hear the errors repeated multiple times. Interestingly, the repetition effect occurred whether the misinformation came from multiple witnesses or from just one witness multiple times. Even our own actions with misinformation can affect its strength. For example, people are more misled when they elaborate on misinformation by considering what it looked like or how it contributed to the overall meaning of an event (Drivdahl and Zaragoza 2001; Zaragoza et al. 2011).

An Ounce of Prevention

Can anything be done to prevent misleading information from invading memory? One approach has been to study the effects of warnings. That is, when people are made aware that they might be exposed to inaccurate information, are they better able to preserve the accuracy of their memories? Results from studies that have investigated this question have been mixed. If warnings are given before misinformation is presented, then they can help people detect errors in post-event information and ward off misleading details (e.g., Butler et al. 2009). But other research shows that warnings given after the misinformation have no effect at all (Greene et al. 1982). That is, after people have been exposed to misinformation, it is difficult for them to unwind the effects of post-event suggestion. Still other studies have shown that under some circumstances (e.g., when subjects are given a very specific warning straight after encountering misinformation), warnings following misinformation can help subjects maintain more accurate memories (Eakin et al. 2003).

Instead of alerting people to the presence of misinformation, other research has focused on developing interview procedures that would help preserve the integrity of a witness' memory. The *Cognitive Interview* (CI) is one such procedure. In the CI, people participate in an initial free recall phase and make use of contextual cues, temporal reordering of events, and recounting events from the perspective of other people. Interviewers are encouraged to avoid suggestive questioning, to discourage guessing, and to develop rapport with the interviewee. One study found that compared to a free-response control interview, subjects who were given a CI produced more correct details about an event they had seen and were better able to maintain accurate memories in the face of suggestive questioning (Memon et al. 2009). However, the CI had an effect only when it came *before* the misinformation. Of course in the real world, it is hard to know when misinformation is going to invade memory. Thus, to best protect memory, both warnings and interview approaches like the CI should be delivered soon after the event in question.

Taken together, these studies demonstrate that some precautions can be taken to prevent the contamination of a person's memory. However, it seems as though the timing of these interventions is crucial, and once a person has been exposed to misinformation (particularly without being aware that the information might be wrong), the damage may already be done. Also of note, even under conditions that were designed to protect people from misinformation – when people are warned that they might encounter inaccurate details – many subjects still showed evidence of memory distortion.

Are Some People Especially Susceptible to Memory Distortion?

Are certain types of people more vulnerable to misinformation effects than others? While misinformation effects have been shown in a wide variety of subject samples, there is evidence that some groups of people are especially susceptible. For example, young children and the elderly are more likely to have their memories contaminated by misleading information than adolescents and adults (see Davis and Loftus (2005) for a review). One explanation for this finding is that these groups are less skilled at tracking and making accurate judgments about various sources of information – for example, discriminating between details that were actually seen firsthand and those that were described by another witness.

Other studies (Zhu et al. 2010a, b) have shown that people who score higher on measures of intelligence, perceptual ability, working memory capacity, and facial recognition ability are especially resistant to misinformation effects. And certain personality factors, such as fear of negative evaluation and cooperativeness, are associated with susceptibility to false memories, particularly in individuals with low cognitive ability. An interpretation of these results is that when people are high in cognitive ability, personality variables are less useful in predicting whether misinformation is likely to creep in to memory. However, for a person who is low in cognitive ability, traits like fear of negative evaluation and cooperativeness may motivate them to pay closer attention to the post-event information in an effort to buttress the accuracy of their memories, only to fall victim to misleading details. While these studies imply that some individuals may be more suggestible than others, a broad survey of the literature reveals that no one is immune to memory distortion. That recollections can be molded and changed by suggestion and misinformation is simply a fact of human memory. This body of work demonstrates how true memories can be distorted and altered, but other research suggests that memory can be molded in more dramatic ways and people can come to remember entire events that never took place at all.

False Memory for Entire Events

During the 1980s, while seeking therapy for depression, Elizabeth Gale came to remember that she had experienced horrific acts of satanic ritual abuse. But years later, Gale realized that the memories she recovered in therapy were actually entirely false, and in 2004, she won a malpractice lawsuit against the mental health professionals who led her to recover the traumatic memories of horrific acts that never happened (Napolitano 2004).

Unfortunately, Gale's case was just one among a number of other similar cases. During the 1980s and early 1990s, other cases emerged where patients had gone into therapy and come out with memories of traumatic events from their past, only to later learn that the memories they had recovered were in fact false. Cases like these often had devastating consequences. Family members were accused of horrific acts. In some instances people ended up in court and behind bars based on a memory recovered during therapy that turned out to be not only inaccurate but also completely false (see Loftus and Ketcham 1994).

How could people come to remember entire events that never actually occurred? A common thread in many of these cases was that the patients were participating in Recovered Memory Therapy (RMT). Clinicians practicing this therapy – popular during the 1980s – believed that their patients were harboring repressed memories of trauma (memories that had been hidden away from conscious awareness). The goal of RMT was to help patients uncover these buried memories. With the best intentions, therapists encouraged patients to pursue buried traumatic memories using repeated retrieval attempts, guided imagery, imagination, dream interpretation, and in some cases hypnosis. It was already well established in the cognitive psychological literature that some of these techniques such as repetition, imagination, and imagery could promote false memories. But in those studies people misremembered words, shapes, and stories, not entire autobiographical events. It wasn't until the 1990s that researchers developed a paradigm to examine how the same techniques used in RMT could lead people to develop wholly false memories for an experience that never actually took place.

In this paradigm, subjects read four descriptions about childhood events and repeatedly try to recall them. Three of the descriptions are of true events provided by parents, but one of the descriptions is created by the researchers (e.g., getting lost in the mall) and documents an event that never occurred. The false event is altered for each subject so that it is filled with personal details and looks just like the real events provided by the parents. For example, in one study, a subject read that "You, your mom, Tien, and Tuan all went to the Bremerton K-Mart. You must have been 5-years old at the time. . .and somehow lost your way in the store. Tien found you crying to an elderly Chinese woman. . ." (Loftus and Pickrell 1995, p. 721). The key question is whether a false suggestion like the one described above combined with RMT techniques would lead people to remember an entire event that never occurred.

Over a number of studies, using a variety of RMT-like techniques that ranged from guided imagery, repeated retrieval attempts, and imagination, on average 36 % of people came to remember a false event that never happened (Newman and Garry 2013). Moreover, people falsely remembered all kinds of events; some were common, relatively benign experiences like getting lost in a mall. Others were less common but still relatively unemotional events like spilling a punch bowl at a wedding. Still others were traumatic and emotional, such as being saved by a lifeguard after nearly drowning or even being viciously attacked by an animal (for a review of these studies, see Garry and Hayne 2006). In other work, researchers have planted memories for events that are impossible like having a skin sample taken as a child – a national medical test that never took place.

Moreover, these memories were filled with details – people, places, and sensory and temporal information – that is, they contained many of the characteristics one would expect to see in a memory for an event that really did happen. In recalling the punch incident, one subject said, "…I definitely think it's a friend of my mother's for some reason, and the people I spilled punch on…I just picture him getting up and being kind of irritated or mad, then the woman, I see her in a light coloured dress that has like flowers on it, I think I see flowers on it and stuff, and I see like a big red punch thing down the front of them…" (Hyman and Billings 1998, p. 10). This subject's false memory looks just like a true memory.

In experiments like these, researchers know which memories are true and which are false, but in the real world, it is much more difficult to decipher which memories represent a veridical record of the past (see Bernstein and Loftus (2009a) for a review). Even some biological measures reveal very few differences between true and false memories. In one study, people who believed they had been abducted by aliens had a similar physiological stress reaction to patients – who had current PTSD – when they recalled their (highly improbable) traumatic memories (McNally et al. 2004). Taken together, these studies fit with the earlier work using words, shapes, and stories and suggest that RMT techniques not only lead people to agree that an event might have happened, but they can lead people to develop memories layered with detail, emotion, and even physiological responses that make them feel true.

Routes to a False Memory

In these memory implantation studies, subjects typically read through narratives ostensibly provided by family members before engaging in certain RMT techniques. One might wonder whether that is the only route to a false memory. Put another way, could other kinds of suggestion or therapeutic practices promote vividly detailed memories for events that never happened? The answer is yes. One does not need to read a description of a childhood event in order to develop a false memory. Reviewing family photos, receiving false feedback, and even imagining or paraphrasing how an event might have occurred can have similar consequences.

Photos. Sometimes clients are invited to review family photo albums to help cue their memory during therapy. But while this retrieval cue can help people remember real events, it can also help people build memories for events that never happened. For example, one group of researchers asked people to examine old family photos and try to recall events depicted in each photo (Wade et al. 2002). Just like the studies described above, one of the events was false and a photo was doctored so it looked like the subject experienced an event that they did not (e.g., it showed the subject as a child in a hot air balloon with their parents). After three interviews, and repeated recall attempts, 50 % of subjects remembered the false event. But people rarely encounter photos like these; family photos are usually a reliable record of events from our past, they are not doctored to mislead us. Would real undoctored childhood photos lead people to remember events that never happened? The answer is yes: simply reviewing an old class photo can lead people to remember doing things they never did in their childhood, such as hiding a slime toy in a teacher's desk (Lindsay et al. 2004). Other work suggests that these effects extend to more recent events too. When researchers doctored video footage to make it look like someone was cheating in an experiment, subjects were more likely to sign a form corroborating that cheating behavior, even though they witnessed the event differently themselves only 5–7 h earlier (Wade et al. 2010). Together these findings suggest that photographs and videos – even old class photos that seem harmless – can facilitate the recall of events that never took place.

Feedback. One especially controversial source of feedback were self-help books that offered people advice about buried memories of trauma. Some of these books offered a list of symptoms that authors suggested would help people assess whether they were harboring a repressed memory. Readers were informed that they might have a buried traumatic memory if they displayed a certain set of these symptoms. What are the consequences of this kind of feedback? Could feedback like this from a trusted source lead people to develop fully fledged false memories? Subsequent research examining the power of feedback suggests that the answer is yes. In one line of work, researchers demonstrated the influence of feedback using a simple three-stage procedure. In initial session, people completed a food history survey. In session 2, people received a personalized food experiences profile that provided feedback on a critical childhood event, e.g., that the subject got sick eating strawberry ice cream – in fact there was no evidence that this event occurred. In the final session, the experimenters measured the subjects' belief in having experienced the critical event by asking them to complete the food history survey for a second time. Receiving the false feedback led people to believe they had a bad experience as a child: over a number of studies, people remembered getting sick eating a variety of foods including strawberry ice cream, dill pickles, and egg salad sandwiches (for a review of these studies, see Bernstein and Loftus 2009b). Feedback like this can not only change people's memories and beliefs about the past, but it can change their behavior too. Subjects who received the false feedback about getting sick eating egg salad sandwiches were more likely to avoid eating them when they encountered that food later on (Geraerts et al. 2008). Moreover, other kinds of feedback such as dream interpretation can have similar consequences. In one study, some subjects' dreams were interpreted to mean that they experienced an upsetting event as a child (e.g., being lost in a public space), while others received no interpretation (Mazzoni et al. 1999). Those who received feedback via dream interpretation were more confident that the upsetting event happened to them. Taken together, this research suggests that feedback and interpretations offered by self-help books or even a well-intentioned therapist could be dangerous and unintentionally plant false memories.

Imagination. Even without a therapist, or photos, certain cognitive acts can lead people to build false memories. A range of studies show that spending time imagining a childhood event can lead people to become more confident that the event really did happen to them. Simply explaining or paraphrasing how a childhood event could have occurred can lead to a similar boost in confidence (see Garry and Polaschek (2000) for a review). All these behaviors likely lead subjects to generate a rich mental representation of the hypothetical event, adding sensory details and characteristics that make it feel like a real memory. Imagination can also lead people to falsely remember more recent events – even ones that are bizarre. In one study, subjects went on a campus walk and performed a series of actions. Later they imagined performing some actions, but not others. Imagination led people to misremember – only 2 weeks later – having performed actions they did not, even when the events were highly unusual (e.g., proposing marriage to a Pepsi machine) (Seamon et al. 2006).

Although generated as a consequence of suggestive retrieval techniques, false memories feel like true memories and they have real consequences. In cases similar to Elizabeth Gale, real patients pursued real criminal cases and real families were broken apart. That is, outside of the laboratory when it is more difficult for us to tell what is true and what is not, false memories wield similar power to true memories. So how do people confuse false memories that they generate themselves with ones that are the product of real experience?

How Do People Confuse False Memories with Real Experience?

People don't walk around the world mystified about what is real and what is not. Indeed, people usually remember correctly that they drove a car to work, that they ate breakfast, and that they had a conversation with a friend on the phone. But as described earlier, memory does not work like a camera capturing and replaying everything in high definition. Instead, when people retrieve information, they make a decision using a variety of characteristics to decide whether a particular mental experience is a memory, something someone else told them (a suggestion or piece of misinformation) or something they simply imagined (see Lindsay 2008). Sometimes these memory classifications are easy and people can quickly and accurately determine the origin of mental events. But sometimes these decisions are hard; mental events come to mind with characteristics that make them seem like a real memory. And techniques that encourage elaboration about suggested false events like imagination and guided imagery can artificially boost the characteristics people rely on to accurately classify memories – leaving people especially vulnerable to errors.

Moreover, when making these memory classifications, people can be swayed by where information came from. Recall that people are more likely to be misled by details provided by someone who is trustworthy. One explanation for this effect is that people are less inclined to scrutinize information that comes to mind when it was suggested by a reliable source. Thus, when inaccurate suggestions come from someone trustworthy, it makes it easier for false information to invade memory.

Summary

Although many have probably marvelled at the information and detail that can be retrieved from memory, the research reviewed here suggests that it is not a perfect retelling of the past. In the context of the criminal justice system, the fallibility of human memory is especially worrisome. Errors – small and large – can influence the outcome of a case and inevitably an individual's life. Indeed, people are especially swayed by an eyewitness or victim that describes their memory of an event in the courtroom.

In light of this, what tools are available to diagnose the accuracy of someone's memory? Some researchers have examined the characteristics of true and false memories by comparing the content and detail in true and false memory reports from experiments. Others have considered individual difference variables that might help determine which people are more vulnerable to memory errors (see Bernstein and Loftus (2009a) for a review). But more recently, scientists have investigated whether measurements of brain activity can help distinguish true from false memories. For instance, in one recent study (Stark et al. 2010), subjects viewed a series of photographs and then heard an audio narrative about the photos that contained pieces of misleading information. Later, they were given a memory test while in an MRI scanner. Results indicated that true and false memories showed similar activation patterns, but that true memories (which came from visual information) were associated with more activation in the visual cortex, while false memories (which came from auditory information) were associated with more activation in the auditory cortex. The results suggest that when misinformation is delivered in a different sensory modality than the true memory information, there may be detectable differences in brain activation patterns. However, we are still a long way away from being able to take a single memory report and use some physiological measure to determine whether it reflects an authentic experience or a false one. The research on these tools for trying to accomplish this is still in its infancy.

A different approach to the problem of memory in the courtroom has been to implement procedures and policies that bring many of the issues described in this article to the attention of jurors when cases they are hearing involve eyewitness or victim memory. For example, in a 2011 ruling, the New Jersey Supreme Court issued new rules for dealing with cases that include eyewitness evidence. Moving forward in New Jersey, when defendants present evidence that an identification may have been corrupted, the judge must hold a special hearing to consider the evidence and must give detailed explanations to the jurors about the relevant factors that may have interfered with the accuracy of the eyewitness' memory (Weiser 2011).

People's memories will remain a crucial part of the criminal justice system for the foreseeable future. While the courts continue to find ways to ward off questionable memory evidence, researchers continue to develop new ways to study the factors and processes that lead to inaccurate memories.

Overview

This entry describes the principles of third-party policing (TPP) on the example of the Family Engagement Strategy (FES). The FES is a police-led partnership approach, tailored to reduce the need for police interventions among high-risk families and juveniles. Key principles of TPP are described. Their application is illustrated on the example of the FES, to highlight some of the key benefits and challenges inherent to TPP. This entry highlights the usefulness of TPP principles to both high-risk target populations and agencies involved in TPP models.

Introduction

The Family Engagement Strategy (FES) is a police-led intervention that focuses on high-risk families that generate a disproportionately large number of crime incidents, calls for police service, and arrests. The FES is a police response to the long known fact in criminology that a small number of people are accountable for a disproportionately large number of recorded criminal offenses and civil code violations. These offenses include various forms of antisocial and criminal behavior, youth deviance, and family violence (Sherman 1992; Wolfgang et al. 1972). Research consistently shows that less than 10 % of the juvenile offender population account for over 50 % of police contacts and court hearings (Braga et al. 2001; Wolfgang et al. 1972). These high-risk juveniles are often embedded in families with a complex range of risks and needs (Moffitt and Caspi 2001) that not only absorb a significant amount of law enforcement resources (see Farrington & Welsh 2003; Mulder et al. 2011), but also drain other regulatory and non-regulatory support agencies (Farrington et al. 2001; Wolfgang et al. 1972).

In 2009, the Brisbane Metropolitan North District of the Queensland Police Service (QPS) in Australia initiated the Family Engagement Strategy (FES), a partnership response aimed at reducing problems associated with high-risk juveniles and their families. QPS officers examined their annual statistics for police contacts associated with particular physical addresses in the Brisbane Metropolitan North Region and, like thousands of other police agencies throughout the world, they found that a small number of private family residences were associated with a disproportionately large number of police contacts. In the majority of these "hotspot" residences, the police contacts related to an adolescent member of the family household engaging in behaviors that warranted police attention, such as truancy, public nuisance, and curfew violations. While these initial contacts with police did not always attract criminal sanctions, they consumed a large proportion of police resources due to their frequent occurrence. Notably, many of the high-risk families also had records of past interventions with a range of other service agencies.

The police used the key ideas of third-party policing (TPP) to develop the FES partnership approach. At the core of the FES is an interagency working forum of agency representatives that have access to various legal levers and diverse responsibilities for reducing the deviant behavior of highly troublesome family members. In this way, the FES is modeled after existing multiagency intervention strategies which rely on a variety of partnerships, including partnerships between different law enforcement agencies (see, e.g., Bond and Gittell 2010), partnerships between clusters of social support agencies (see, e.g., Stern and Green 2005), and partnerships between law enforcement and other support agencies (see Penfold et al. 2004).

This entry outlines the Queensland Police Service (QPS) Family Engagement Strategy (FES) as an example of third-party policing (TPP) applied to policing the problems associated with deeply troubled families. It describes the underpinning philosophies and principles of TPP and demonstrates how some of the key components of TPP were applied to the FES. It begins with a description of TPP and plural policing strategies in general and the specific challenges relating to partnership formation and agency buy-in. It then summarizes the key components of the FES and draws some conclusions around how the FES dynamics might inform future TPP approaches.

Fundamentals: Third-Party Policing

Buerger and Mazerolle (1998) first introduced the idea of TPP in the late 1990s. As a model of policing partnerships, it involves the strategic collaboration between local police forces and civil regulatory agencies to address and prevent criminal activities (Buerger and Mazerolle 1998; Mazerolle and Ransley 2005). In some jurisdictions, governments have actively issued a mandate for police to form collaborative partnerships with other regulatory and non-regulatory agencies to pursue problem-solving policing approaches (see, e.g., the United Kingdom; Fleming 2006). In others, including Australia, there is a greater reliance on "voluntary" partnerships between police services and other regulatory agencies (Fleming 2006). In both cases, the focus is on forming effective partnerships between agencies concerned with similar social issues and target groups, who share a mutual interest in preventing and addressing crime.

In the case of TPP, the partnerships operate on a spectrum from invited or encouraged partnerships at one end, to forced or coerced partnerships at the other end (Mazerolle and Ransley 2006). At the latter end of the spectrum, police use their coercive powers to "force" partnerships with non-offending third parties that are able to address particular crime problems, but who would not usually see this as their role. These approaches generally focus on crime control rather than prevention. At the front end of the spectrum, police invite third parties that share a mutual interest in addressing certain forms of crime or antisocial behavior to contribute to policing strategies, which are usually prevention focused (Mazerolle and Ransley 2005). While partnerships can be formed under very different circumstances, the objective remains the same from a police perspective; namely, to form partnerships with third parties that are able to regulate criminal or deviant behavior and share in the responsibility of addressing and preventing crime within the community (Braga et al. 2001; Buerger and Mazerolle 1998).

Past research on TPP reveals that the majority of partnerships initiated at the coercive end of the spectrum are formed to target street-level criminal activities, including the street-level drug market, street prostitution, shop lifting, and other forms of low-level property crimes

(Buerger 2007; Mazerolle and Ransley 2005). Under the model of TPP put forward by Buerger and Mazerolle (1998), "partnerships" are formed with proximate targets (third parties) to minimize opportunities for crime perpetrated by ultimate targets (individual offenders). Proximate targets are those non-offending parties who police choose to approach because of their access to regulatory powers, or so-called legal levers, that can be used to address the situational circumstances of crime. Proximate targets may include, for example, property owners renting properties to known drug dealers, or shop owners serving known drug dealers who tend to hang out outside the shop and use the street level as their market platform (Mazerolle and Ransley 2005). The regulatory levers available to the proximate targets are applied to reduce the occurrence of crime in a location-specific manner. While these levers are not accessible to the police, the formation of coerced partnerships with a relevant third party enables the police to indirectly access them. At this end of the spectrum of TPP, non-offending third parties are "coerced" into the partnership through the application of another level of legal levers in the form of applicable civil laws that can be used against the third party should the third party refuse to collaborate with the police. An example of applicable civil law codes that can be used as "legal levers" to "coerce" partnerships is legislation and regulations around unsafe or substandard rental properties. In an attempt to control criminal activities (e.g., drug dealing) that take place in substandard rental properties, the police identify agencies or individuals with access to civil law codes that can be applied to indirectly regulate and control these criminal activities. The police approach the relevant party (in this case the property owner or housing company) and ask them to perform their third-party role by applying tenancy laws that they can access – to terminate the tenancy agreement of the ultimate target. Should the third party be reluctant to carry out the eviction (e.g., fearing a loss of rental income), the police can utilize the legal lever which defines their responsibility as a homeowner in relation to unsafe or substandard housing conditions. The legal lever available to police can be escalated from an initial written request outlining the possible consequences in case of noncompliance on behalf of the third party – at the lower end of the "coercive pyramid" (Ayres and Braithwaite 1992), to a formal report to the Housing Commission, which is likely to result in the property being boarded up. This approach "encourages" the selected third party to take responsibility for their property and partner with the police in crime control and community safety (Green 1996).

In addition to the street-level TPP approaches, which predominantly focus on crime and place in a context of crime control, more recent forms of TPP have incorporated aspects of crime control and crime prevention through partnerships that are able to generate individual behavior change rather than opportunities that converge in space and time (Braga et al. 2001; Corsaro et al. 2009). These forms of TPP target problems such as youth deviance, child safety, and domestic and family violence. These forms of crime and antisocial behavior often attract the attention of multiple regulatory agencies which focus on individual behavior change and regulation. Notably, TPP approaches that focus on problem families and individuals differ from the more place-specific TPP approaches in the type of agency approached for the third-party partnership as well as the nature and duration of the intervention. While place-specific approaches of TPP are often formed with parties who manage certain locations but share no primary concern in individual crime control or crime prevention, person-specific approaches utilize partnerships with agencies that share a similar agenda in reducing and preventing crime and other potentially harmful behaviors (see, e.g., Braga et al. 2001; Mazerolle and Ransley 2005). While these agencies still require encouragement to take on certain policing roles in addition to their general agenda, their engagement as a third party predominantly takes place within their organizational aims and objectives. This will be illustrated through the example of the FES, which is built on police partnerships with agencies concerned with the well-being of high-risk families.

In practice, partnerships that aim to address a range of social and criminal issues are often marked by tensions between agencies that operate within different practical and philosophical frameworks. Having a legislative framework that lends itself to the formation of partnerships around issues of mutual concern is therefore only the first step in forming effective third-party partnerships that follow the principles of crime prevention. Most parties involved experience significant challenges throughout the partnership formation process as well as the intervention development and implementation phases. Challenges mainly arise from the diverse backgrounds and philosophical underpinnings of the different agencies involved. While parties may share a mutual interest in reducing crime and antisocial behavior, for example, police priorities focus on the end result (i.e., reducing police resources invested in addressing the issue), the primary focus of the third party often centers on changing the underlying causes of the issue (e.g., school failure, family conflict) (Bond and Gittell 2010; Fleming 2006; Sloper 2004).

In addition to the potential mismatch in underlying philosophies that drive different partnership approaches, police-led partnerships are prone to experiencing struggles around sharing the power and entitlement associated with crime reduction and related interventions. As described above, certain civil laws offer an opportunity for police to "coerce" rather than "invite" or "encourage" partnerships. This can lead to hostile and reluctant cooperation from the third party, and as a result, so-called partnerships can be fragmented due to actual and perceived power imbalances and a lack of mutual trust and respect between agencies and organizations (Fleming 2006; Loader 2000). While fragmentation and power imbalances can be managed through the approach taken by the police during the partnership initiation phase, the success of these (usually short-term) interventions does not depend on the level of buy-in from the third party since cooperation can be "coerced" by the police.

In contrast, invited or encouraged partnerships require a sufficient level of buy-in on behalf of the third party to be effective. The level of buy-in is strongly influenced by the level of mutual trust and respect generated during the partnership initiation phase. While this initiation phase is more time consuming than establishing short-term "coerced" partnerships, it is necessary to build a suitable foundation for interventions that aim to achieve long-term change and behavior improvement rather than short-term changes to spatial opportunities (Bond and Gittell 2010; Braga et al. 2001; Fleming 2006).

Both forms of TPP partnerships share a common overarching goal, namely, the sharing of police responsibilities around crime control and crime prevention with third parties that are in a position to enforce citizen compliance through regulatory statutes not available to the police (Buerger 2007; Green 1996; Mazerolle and Ransley 2005, 2006). The ultimate goal is to minimize the use of police resources for matters that can be controlled or addressed by other regulatory agencies (Mazerolle and Ransley 2005, 2006). In the case of the FES, this goal is expected to be achieved through invited partnerships with agencies that are able to regulate individual behavior of high-risk family members through the application of regulatory levers.

Partnership Policing: A Matter of Shared Roles and Responsibilities

Partnership policing builds on the idea of shared responsibilities for controlling and preventing crime (Loader 2000; Stenning 2009) such that crime problems are no longer the sole responsibility of those empowered by the State to regulate public behavior through the use of force and punitive reactions (Loader 2000). The increasing use of pluralized approaches to policing over the past two decades has created an extended "policing family" in modern societies. Today, policing responsibilities are shared between a number of different agencies and organizations to address a broad range of social issues and concerns (Fleming 2006; Loader 2000). Some jurisdictions, including Australia, rely on voluntarily initiated partnerships (Fleming 2006), while others, such as the United Kingdom, have clear mandates around partnerships designed to provide crime prevention and crime control strategies (Florence et al. 2011). Whether mandated or optional, most contemporary Western societies now take a pluralized approach to policing problem people (Bond and Gittell 2010; Braga et al. 2001; Corsaro et al. 2009), problem places (Weisburd and Green 1995), or criminogenic situations (Mazerolle et al. 2000).

Pluralized policing can take a number of different forms, including handing over traditional public policing roles to private security companies (see Bradley and Sedgwick 2009; Sarre and Prenzler 2000), networked policing models that bring together police and community partners (Crawford 2006; Shearing and Stenning 1983), and third-party policing approaches that involve police co-opting other entities to share the crime control load (Ayling and Grabosky 2006; Mazerolle et al. 2000). Examples of these pluralized approaches include private security companies supporting federal police terrorism control and peacekeeping missions (Loader 2000), private security companies taking on the responsibility of crime and crowd control at public events (Sarre and Prenzler 2000), private security guards patrolling public places or private properties (Bradley and Sedgwick 2009; Stenning 2009), and police partnering with community-based neighborhood watch groups to share responsibilities of crime control with individual community groups (Ayling and Grabosky 2006; Bradley and Sedgwick 2009; Kempa and Johnston 2005).

The third-party partnership approach also follows the principle of police working with other agencies to establish a shared and pluralized approach to reducing crime and the associated police workload (Ayling and Grabosky 2006; Mazerolle and Ransley 2005, 2006). The TPP partnership approach, however, differs from other forms of pluralized policing in the rationale that drives this partnership formation. Partnerships forged through TPP are explicitly sought based on the legal lever accessible to the partner but otherwise unavailable to the police. Rather than simply sharing policing responsibilities by handing certain roles over to another entity or agency, TPP seeks access to the legal levers that are thought to facilitate police efforts to control and prevent crime (Buerger 2007; Mazerolle and Ransley 2005). Police identify suitable third parties with access to regulatory levers unavailable to the police (e.g., levers to regulate substandard housing arrangements or matters around family violence and child abuse). This approach enables police to harness help while remaining involved as the lead organization in the intervention efforts (see, e.g., Braga et al. 2001; Corsaro et al. 2009).

While third-party policing partnerships hold value for the police (see Mazerolle and Ransley 2006), they do not come without their challenges. As discussed above, third-party partnerships are formed on a spectrum from invited to coerced partnerships, the latter leading to a range of challenges around establishing a sufficient level of agency buy-in and collaboration (Buerger and Mazerolle 1998; Mazerolle and Ransley 2005).

Most police matters relating to high-risk juveniles and their families also constitute grounds for intervention by other agencies. Mandatory notification between the police and other regulatory agencies when dealing with matters, including truancy, family violence, concerns around supervision and suspected neglect, require cross agency communication and ideally collaboration (Ayling and Grabosky 2006). Formalized partnerships to jointly address these issues share the policing workload and reduce the use of resources at either agency end, therefore seem an all too obvious solution.

The Queensland Police Service Family Engagement Strategy (FES)

The FES is a crime control initiative that focuses on the cooperative aspects of TPP partnerships. The FES comprises the following three key components:

1. Focuses on long-term behavior regulation
2. Addresses a complex variety of presenting issues within high-risk families
3. Creates a multiagency working forum with access to a range of legal levers

The following sections provide an overview of the FES target population, the range and role of invited third-party partner agencies, and the processes associated with forming these partnerships.

Target Population

Based on the information derived from internal police data reviewed during the planning phase of the FES, families with adolescent children who fall into the "top 100 list" of police contacts linked to their residential address in the Metropolitan North region during the previous 12 months "self-select" as the target population for the FES. The presenting issues identified from official police records for contacts with one or more of the relevant family members in each high-risk family/household range from noncriminal risk-taking behavior, including truancy, substance misuse, and curfew violations, to mental health issues, child abuse, domestic violence, and a range of officially recorded criminal activities.

The QPS FES Team

The FES is led by the QPS team based in the Metropolitan North Region. The team consists of the leading Inspector for the Metropolitan North Region, an unsworn project manager (with a degree in human services), and three front line sworn police officers from three different districts within the Metropolitan North Region. The leading Inspector and project manager were actively involved in the partnership formation and project planning phase and coordinate all working forums. The project manager is further involved in all initial client engagement. All three frontline officers are involved in the identification of suitable families for the FES in their relevant districts and accompany the project manager during the initial client engagement.

Voluntary Third-Party Partnership Formation

With the absence of mandated policing partnerships in Australia (Fleming 2006) and the lack of applicable legal frameworks to "coerce" partnership interventions around long-term behavior regulations as opposed to short-term spatial interventions (Mazerolle and Ransley 2005), the FES requires the voluntary buy-in from potential third parties to ensure their cooperation in taking on some of the traditional policing responsibilities as they relate to regulating antisocial behavior displayed by high-risk families.

In late 2009, the QPS invited a range of regulatory agencies to become involved in a third-party partnership approach to reduce the disproportionately high number of police contacts accumulated by a relatively small number of high-risk families. The overarching goal was to form partnerships designed to address long-term behavior regulation at an individual level. Given the level of required buy-in and long-term commitment to a variety of interventions offered as part of the FES, the partnership formation phase required a lengthy negotiation phase marked by various stages of protocol negotiations and renegotiations between QPS and the approached third parties. Overall, the partnership development and project planning phase of the FES lasted for 18 months from the initial invitations extended by QPS in late 2009. This lengthy process was required to ensure the expectations of the lead agency (i.e., QPS) were aligned with the organizational guidelines and legislative frameworks of each agency when acting as a third party in a multiagency TPP approach.

The key challenges that arose throughout the partnership formation process were associated with initial differences in perceived and promoted aims and objectives between QPS as the lead agency and some of the third parties. Both police officials and third-party representatives had to develop an understanding for each other's underlying goals, values, and organizational philosophies to negotiate terms of references acceptable for all parties involved. Ongoing protocol negotiations between all parties involved ensured the development of a trusting and respectful partnership between agencies that often had to overcome a history of hostile working relations marked by power struggles and poor communication (see Meyer and White 2011). The challenges observed throughout the FES partnership formation phase are not uncommon. Several studies examining the processes and outcomes of partnerships between the police and other regulatory agencies suggest that the development of partnerships marked by mutual trust and respect can be a lengthy and sometimes impossible process where historically poor working relations are involved (Bond and Gittell 2010; Fleming 2006; Rosenbaum 2002).

Forum Driven

A key component of the FES was the forum-driven multiagency nature of this approach. Instead of relying on a dyad relationship with a single third party, the FES used a multiagency forum approach that involved multiple third parties within the same TPP approach. This approach was necessary to address the complexity of presenting issues and behaviors to be regulated under the FES. Partnership negotiations and protocol renegotiations had to take place between the police and a broad range of regulatory agencies to ensure access to a diverse range of regulatory levers applicable to the high-risk families targeted by the FES. This component further contributed to the lengthy partnership development phase.

The initial call for interest in a TPP approach to high-risk families went out to a broad range of regulatory agencies operating at a state level in Queensland (Qld), Australia. Following an opt-in approach, these agencies were asked to indicate their initial interest and later confirm their commitment to the FES by agreeing to the project's terms of reference and data sharing agreement. Regulatory agencies (or their respective Departments) approached to form the TPP partnership included the following:

- Qld Department of Education
- Qld Department of Health, represented by the following subbranches:
  - Primary and Community Health Services
  - Alcohol and Drug Service
  - Mental Health Service
  - Children and Youths Mental Health Service
- Qld Department of Communities, represented by the following subbranches:
  - Child Safety Programs and Partnerships
  - Child Protection Development
  - Housing and Homelessness Services
  - Youth and Family Support Services
- Qld Department of Employment, Economic Development and Innovation
- Qld Department of Corrective Services (Probation and Parole)

The FES working forum was formed through preliminary electronic and in-person conversations between QPS and the approached agencies. While all 11 regulatory agencies and departments approached remained involved beyond the initial working forum planning phase, only 8 opted into a formal TPP partnership through signing the data sharing agreement. Three of the four branches under the Department of Communities stream (namely, Child Safety, Child Protection, and Housing and Homelessness Services) chose to attend only some of the working forums throughout the project planning phase and maintained an informal involvement in the FES. Their involvement comprised the provision of informal feedback at the working forums they were able to attend. Over an 18 months planning phase, working forums were held every 2 months to negotiate processes and protocols between QPS as the leading agency, each regulatory agency formally involved as a potential third party, and the University of Queensland as the evaluator of the FES. Initial and ongoing involvement of the evaluation team was crucial to ensure a sound methodology for the initial process and a long-term impact evaluation.

Multiple working forums were required throughout the project planning phase to give representatives of all partner agencies the opportunity to be actively involved in the planning and development of the FES prior to its implementation. The lack of formal engagement by some of the regulatory agencies initially approached for a formal partnership is not unusual for TPP approaches built on invited partnerships, that is, where there is no legal lever available to the police to "coerce" collaboration. While approaches like the ones described on street-level interventions to housing and drug sales (Mazerolle and Ransley 2005, 2006) offer an opportunity for police to coerce collaboration of proximate targets through threats of adverse outcomes in case of non-compliance, invited partnerships require the full buy-in of invited third parties. Full buy-in can best be achieved in partnerships between agencies that share a certain level of mutual trust and respect and pursue similar goals in crime prevention (Rosenbaum 2002; Sloper 2004). Once partnerships had been established, the monthly working forum discussions were used to drive the development and later implementation of the FES. This collaborative forum approach gave involved third parties an opportunity to shape the FES through equal involvement and decision-making powers. Past research has identified equal input and decision-making powers as one of the key factors contributing to the effectiveness of police partnership projects (Bond and Gittell 2010; Huey 2008; Stern and Green 2005).

Regulatory Agencies and Their Involvement

Due to the complex nature of risks and needs prevalent in high-risk families, the FES regulatory agencies have to contribute a broad range of legal levers as part of their involvement. The following three scenarios illustrate some of the key presenting issues, identify suitable third parties, and describe their regulatory involvement and the role of proximate and ultimate targets as they relate to the FES.

1. *Presenting issue: truancy*. A young person and his/her parent(s) may have agreed to regular school attendance under a FES Action Plan. In the case of unexplained absence coming to the attention of the Department of Education, the department may choose to issue an initial warning to the young person and his/her parent(s) in their role as the responsible supervisors. This warning can later be escalated into a fine (Ayres and Braithwaite 1992; Mazerolle and Ransley 2005) should the young person and his/her parent(s) engage in further non-compliance with the Action Plan.
2. *Presenting issue: absconding*. A family may have child safety concerns issued against an adult caretaker for exposing the young person to domestic violence where this exposure may lead to the young person running away from home and engaging in antisocial behavior while unsupervised. In cases where further incidents of domestic violence come to the attention of the Department of Child Safety, the department may choose to issue an initial warning, subject the parent to mandatory parenting training, or escalate the lever to the removal of the young person from the violent family household.
3. *Presenting issue: public rental property damage*. A young person may engage in frequent and severe forms of aggression against other family members, leading to property damage and police attention. In cases where further incidents of escalating violence and property damage come to the attention of the Department of Housing, the department may choose to apply its legal lever by issuing an initial warning which can later be escalated to an eviction notice should the property damage continue.

In all three examples, the initial third-party partnership between the police and a selected regulatory agency was extended to a “secondary third party,” namely, the adult caretaker of the young person as a proximate target of the overall intervention. While QPS formed the initial partnership with a regulatory third party to share their workload as it relates to high-risk families, the selected third party was then in a position to apply the traditional concepts of TPP and “coerce” parents as proximate targets into a partnership that seeks to regulate the behavior of the ultimate target, namely, the young person whose behavior attracts a disproportionately high number of police contacts.

The Role of Additional Non-regulatory Partners

In addition to the regulatory third parties invited to participate in the FES, the established FES working forum felt it was important to go beyond the traditional TPP partnerships with regulatory agencies and invite further community-based agencies relevant to addressing the needs of high-risk families. Past research has documented the effectiveness of such “mixed” partnership approaches. The “Boston Pulling Levers” project (Braga et al. 2001) followed a problem-solving

TPP approach that invited additional non-regulatory agencies to combine the key deterrence component with a rehabilitative intervention component that was able to address the underlying risks and needs of the target population. The impact evaluation of this mixed partnership approach found strong support for its effectiveness, leading to the replication of its framework in other sites in the United States (see, e.g., Corsaro et al. 2009). In relation to the FES, the rehabilitative component is to be understood in a criminal justice context. This component therefore includes agencies that support individuals in developing pro-social skill sets and protective factors, including but not limited to rehabilitation in a medical sense (e.g., from substance misuse). The non-regulatory agencies invited to provide a rehabilitative component to supplement the regulatory work of the controlling partner agencies in the FES include the following NGOs:

- Salvation Army Youth Outreach Services
- Drug Awareness, Rehabilitation and Management
- Domestic Violence and Family Counselling Program (SANDBAG)
- Employment Service Inc (EPIC)
- Northwest Aboriginal and Islander Community Association (NWAICA)

All five invited, non-regulatory partner agencies signed the initial data sharing agreement. Except for the culturally specific service, NWAICA, all other non-regulatory partner agencies are represented at most working forums. While their intervention contribution is designed to be supplementary to the regulatory components of the FES, all non-regulatory agencies were also given the opportunity of active involvement and input during the planning phase of the FES.

Data Sharing

A crucial component of the forum-driven multiagency TPP approach of the FES is the data sharing agreement set up by QPS, which had to be signed by each partner agency at the beginning of their involvement. This agreement enables QPS as the lead agency to identify relevant legal levers matching the presenting problems identified for each target youth and his/her high-risk family through access to third-party records. The data sharing agreement with non-regulatory agencies is of similar importance because it provides a broader background on participants' proven or suspected civil law violations, behaviors associated with an increased risk in civil and criminal law violations along with past interventions participants had been exposed to. While non-regulatory agencies are not in a position to apply a legal lever to control subsequent violations (e.g., in form of domestic violence or substance misuse), their record sharing provides QPS with more detailed information on each family's key presenting issues along with past (unsuccessful) interventions. Along with the information received from all regulatory partner agencies, this information facilitates the selection of the most appropriate third party in a position to regulate these issues.

While both the police and their partner agencies had to overcome some perceived barriers and challenges around understanding the value and importance of data sharing for TPP and multiagency approaches to high-risk populations, all parties involved eventually negotiated a process they felt met their ethical requirements without compromising their clients' right to privacy. The benefits of such data sharing approaches have been evidenced in past research results, which suggest that the needs of vulnerable and high-risk populations can be met more effectively through transparent communication between relevant support agencies. It is, however, not uncommon for this to be a lengthy negotiation process (Fleming 2006; Florence et al. 2011).

Conclusion

This entry describes the emergence of different forms of police partnerships with a specific focus on TPP. It introduces a TPP program known as the FES and draws on the relevant literature to demonstrate the application of key components of TPP to the FES. It illustrates the contributions TPP is able to make in the area of crime control that requires individual behavior change rather than short-term spatial interventions. The FES is a novel approach to TPP, which further advances the original components of TPP through multilayered partnerships that move beyond the original dyad nature of TPP partnerships. Through inviting partnerships with a number of agencies, the FES constitutes a crime control strategy that is able to address a complex range of social and criminal issues. It is the first TPP approach to target the small proportion of high-risk juveniles and families that are responsible for the majority of police and other agency contact. Through the regulatory partnership approach, with a supplementary rehabilitative component, the FES offers an opportunity to instantly regulate high-risk behavior while at the same time addressing the underlying issues which influence long-term behavior change. Such an approach holds great value in addressing the needs of its target population while at the same time reducing the resources invested by each individual partner agency.

FBI Influence on State and Local Police

William J. Vizzard
Division of Criminal Justice, California State
University Sacramento, Sacramento, CA, USA

Overview

This article reviews the history of Federal Bureau of Investigation (FBI) influence on US police agencies over the past 80 years. The FBI has exercised direct and indirect influence over American policing through a variety of activities, including the national fingerprint repository, the national crime lab, training for state and local police, the Uniform Crime Report system, the National Crime Information Center, direct investigative assistance, anti-crime task forces, and most recently, the national system for making investigative DNA comparisons. Perhaps of equal importance, the FBI was one of the leading agencies in the evolution toward professional policing, and was unparalleled in its focus on public relations and image management.

Before the Bureau

Formalized and structured policing did not develop in the United States until the mid nineteenth century. Initially only in a few larger cities, formal police departments spread rapidly to smaller cities after the Civil War. However, policing remained a city function throughout the nineteenth century. Although sheriffs and constables provided some level of law enforcement for rural areas, neither the states nor counties established formal police agencies during this period. Cities acted out of necessity, because rapid growth and immigration brought crime and disorder, and no other level of government was able or willing to assume the responsibility. American political culture and tradition combined with Constitutional restrictions to assure policing would be a local responsibility. The Tenth Amendment to the United States Constitution reserved all powers not specifically delegated to the federal government for the states or the people. Since policing is not even mentioned by the Constitution, this precluded the development of any type of national police agency. Even though the states were not precluded by any legal constraint from forming organized police forces, American preference for decentralized government and local control strongly favored local police.

The federal government did exercise some law enforcement powers. They had authority over crimes against the federal government, such as tax evasion and treason, and authority over crimes in the territories and on the high sea. United States Marshals were the first federal law enforcement officers followed by more specialized officers who protected the mail, enforce alcohol excise taxes and combated smuggling of goods to avoid tariffs. The first federal agency created solely for the purpose of investigating crimes was the United States Secret Service, established in 1865 to investigate and arrest counterfeiters. A bureau of the Treasury Department until 2002, the Secret Service was assigned the task of protecting the President after the assassination of President McKinley in 1901 because no other agency was available for the task.

The twentieth century brought widespread changes in American law enforcement and a greatly expanded role for counties, states and the federal government. By 1900 organized police forces were present in virtually every city of any size. As the century progressed two developments pushed states to begin organizing uniformed law enforcement agencies, the automobile and labor unrest. Rural areas still had little or no organized policing, so states established either state police or highway patrols. In the latter half of the century, most counties formalized their sheriffs offices into structured police agencies or formed county police to perform this function.

The federal government also expanded its role in law enforcement. Federal laws exercising control over narcotics and firearms were passed under the authority of the federal taxing authority in 1916 and 1934 respectively. These laws did not prohibit heroin or machine guns, they simply placed a tax that was higher than people were willing to pay. As tax laws, they avoided the restriction on federal authority (Vizzard 1997). In addition, from 1920 till 1933 federal law prohibited the manufacture and sale of alcoholic beverages as a result of the passage of the Eighteenth Amendment. Prohibition brought a wave of organized criminal activity and public corruption that generated demand for reform. Policing in the United States had been perceived as highly political and tainted by corruption from the beginning (Walker and Katz) and federal prohibition agents did not enjoy a better reputation (Okrent). Police reformers, such as Berkeley Police Chief August Vollmer had been campaigning for so called professional policing from early in the century. Their goals were the institution of civil service hiring, formal training and education, application of technology and science and independence from political control (Walker and Katz). The call for improved policing received national attention in 1931 as a result of the report from the Wickersham Commission, appointed by President Hoover to examine law enforcement in the United States (Walker and Katz).

J Edgar Hoover Assumes Control and Builds Mutual Dependence

In 1924, at the height of Prohibition, Attorney General Harlan Stone appointed John Edgar Hoover as Director of the Justice Department's Bureau of Investigation (BI). Originally formed in 1908, the BI was an obscure investigative unit with very limited jurisdiction and a poor reputation (Gentry). Hoover was a young lawyer who had worked at BI during World War I and the following years. Although very young and junior in the Justice Department, Hoover proved exceptional at bureaucratic organization. Over the next decade he survived two changes in administration while expanding both the size of the organization and its jurisdiction (Gentry). In 1935 the agency's name was finally changed to the current Federal Bureau of Investigation (FBI).

By aggressively pursuing real organizational reform and aggressive public relations, the FBI successfully developed a reputation for both honesty and efficiency that separated it from other law enforcement agencies from the 1930s through the early 1950s. Even though the law enforcement agencies of the Department of Treasury arrested and prosecuted far more offenders for violating federal law than did the FBI (Millspaugh), and local police continued to handle most crime, the FBI was seen by the public as what the FBI website describes as "America's premier law enforcement agency." This was accomplished by a combination of pursuing the most recent innovations in the applications of science and technology to criminal investigation, hiring well educated Special Agents, rigid discipline and rigid control of image. Hoover was obsessive in protecting the reputation of his agents and his bureau (Gentry; Powers 1983; Sullivan). This required that the FBI maintain a clear distinction from law enforcement in general, which did not enjoy a similar reputation. Yet, the FBI needed the support and assistance of local and state police. Police officials had considerable influence on politicians and local police had far more sources of information than the FBI.

The FBI pursued these goals in a number of ways. The Bureau of Investigation had assumed control of federal fingerprint files and consolidated them with a centralized file of prints taken by local police and maintained centrally by the International Association of Chiefs of Police (IACP) in 1924 (FBI). Although local police agencies had pioneered the use of fingerprints for identification, only a federal agency could provide the sort of central clearing house that would fully capitalized on their potential in a large and mobile nation. Contrary to the belief of many citizens, the FBI could not identify a person from latent prints left at a crime scene. A search of the files required a full set of rolled fingerprints and would continue to do so until computer technology developed to a level that allowed rapidly comparing a single latent fingerprint with the millions of individual prints in a file. But the centralized FBI file did allow the identification of persons in custody and provided a central library of prints from arrested persons. Once a potential suspect was identified, a latent print could be compared with the person's rolled prints. If the person had a local arrest record, the police could do this on their own. However, if the person had no such record, they were dependent on the FBI to make the comparison with the prints in the central file. This central finger print file created a symbiotic relationship between state and local law enforcement and the FBI unlike any relationship that had existed with a federal agency before. The FBI needed the cooperation of the police to build its fingerprint files by submitting fingerprints on all persons arrested, and the police needed FBI support in accessing the central file.

Technology and Training the Cornerstones

Although the fingerprint files created a mutual dependency, the FBI Laboratory did not. Initially established in 1932 to conduct research, the FBI Laboratory soon grew to become the largest and most diverse forensic laboratory in the country (FBI). The early technologies, such as fingerprint, tool mark and ballistic comparisons, had all been initiated by progressive local police agencies, such as Berkeley, California (Walker and Katz), but these technologies were not available to the majority of small or medium sized departments. Thus many of them came to depend on the FBI for support in the area of scientific investigation throughout the period from the 1930s through the early 1950s. The FBI laboratory served a variety of functions. First and foremost, it publicized and popularized the use of forensics in criminal investigation. Previously, police had to depend on eye witnesses or confessions to prove their cases. The dependence on confessions had produced a sordid history relating to police use of force during interrogations to extract confessions. In addition to popularizing "scientific investigation," the FBI provided direct service to police in the form of evidence examination as well as training and support for police personnel.

Training became a key component in the FBI support of local police. In 1935, the FBI established its National Academy (NA) to train local police officer. The NA would prove one of the FBI's most successful endeavors in building support among local police. Selected candidates attended classes in investigative techniques for several weeks at no expense to their parent agencies. Attendance at the National Academy soon became a status symbol for any ambitious police officer. The FBI focused on mid-level managers and followed up by making them members of the National Academy Associates. Special Agents were specifically assigned to facilitate and review applications. These same NA Coordinators arranged mixed training and social events that assured the NA graduates would remain connected to the FBI for their entire careers. Because police agencies routinely sent some of their most promising people to the NA and because NA attendance enhanced the graduates resume, the graduates routinely moved to the top positions in their respective agencies. Over time, this placed individuals with close ties to the FBI in charge of the majority of medium sized police agencies in the country. Although large agencies such as New York, Chicago and Los Angeles police departments tended to resist this trend, the NA and the accompanying follow up provided the FBI with substantial influence over and support from police. The NA also served to provide much needed training to key members of many police agencies in a time when such training was not available elsewhere. Although NA training may not seem advanced in the current era where universities and police agencies offer many options, it likely served as a key component of modernizing police before such options were available.

The FBI's training role did not stop with the National Academy. Over time, the FBI developed a cadre of skilled instructors, who provided training on a variety of subjects to local police. Up to the late 1950s only large police agencies and state police/highway patrols maintained formal training academies. Many officers learned on the job or received, at most, a short orientation upon employment. The FBI provided instructors for pre-service and in-service training, cost free. Surprisingly, the topics for instruction were not restricted to the areas where FBI expertise was greatest, such as law and investigation. Instruction ranged from unarmed combat to homicide investigation. For police agencies with limited budgets and staffing, this cost free training proved highly popular. Thus, cost free training was a critical element in maintaining FBI influence over local police.

The cost free nature of the FBI supplied training has been viewed as so fundamental to the FBI that the agency has even sought to undercut training offered by other federal agencies which involved cost sharing for fear that it would create a precedent. In 1992 this author was a member of the joint Justice Treasury Working Group to provide specialized training to local and state police at the Federal Law Enforcement Training Center. Although the FBI had a representative on the advisory board for the project and it was a Justice Department initiative, the FBI Assistant Director for Training openly urged members of the NA Associates to lobby Congress in opposition to the program.

Over time the FBI expanded its training role by developing both schools and field training cadres in a number of areas. One example is Special Weapons and Tactics (SWAT) tactical training. Although the SWAT concept was developed by the Los Angeles Police Department (LAPD) in the 1960s (Cannon), the FBI soon developed its own SWAT teams and SWAT school at the FBI Academy. By the early 1970s, the FBI became the dominate presence in SWAT training.

Field Operations and Investigative Support

Although these ancillary support functions constituted the core of the FBI program for supporting and gaining support from local police, some investigative functions also proved helpful. Federal criminal jurisdiction was greatly expanded during the 1930s as Congress began using the interstate commerce power granted by the Constitution to expand federal authority. Although the United States Marshals Service now takes the lead in apprehending federal fugitives, the FBI exercised this role for many years. While local agencies had limited interest in federal fugitives, they had much more interest in locating their own fugitives. Congress provided the FBI with a significant mechanism for assisting local police by passing the Unlawful Flight to Avoid

Prosecution (UFAP) statute. Although virtually never used to prosecute anyone, this law created federal jurisdiction for seeking and arresting violators of state law, who fled across state lines. Along with the Dyer Act making interstate transportation of stolen automobiles a federal crime, UFAP allowed the FBI to facilitate the return of both fugitives and stolen cars that would have otherwise presented a significant administrative problem for local police. In addition, the FBI routinely investigated bank robberies under federal jurisdiction because of government insurance and any kidnapping suspected of involving interstate movement. Practically speaking, the FBI often worked on kidnappings that involved no interstate movement. Many local agencies with limited resources were happy to turn most of these resource intensive cases over to the FBI.

Thus, three functions formed the basis for state and local police dependence on the FBI during the J. Edgar Hoover era: identification services, forensics and training. Concurrently, there were forces that generated competition and friction between the FBI and police. The FBI is charged with investigating violations of the federal civil rights laws. This sometimes places them in the position of investigating allegations against police officers. This became a particularly sensitive issue during the 1960s in the South when some police were directly involved in resisting racial integration (DeLoach). Another source of friction was Hoover's obsession with the publicity and fear of the FBI being blamed for the actions of other agencies. As a result, the FBI routinely announced the arrest of fugitives or other offenders arrested by local police and resisted working too closely with police investigators on crimes in which both agencies had jurisdiction. Many police officers tended to view the "feds" as either taking over their investigations or taking credit for their work. In addition, some prominent figures in policing, such as Chief William Parker of Los Angeles and Superintendent OW Wilson of Chicago, resented Hoover's high public profile as the "nations leading law enforcement officer."

The Police Pursue an Improved Image

Both the FBI and police reformers had adopted the ideas of the Progressives, who advocated de-politicizing governmental operations, recruiting the best personnel through competitive hiring, increasing efficiency of operations, standardizing procedures, adapting technology and providing managers authority to run their agencies. While the FBI received extensive laudatory publicity in magazines and books such as *The FBI in Peace and War* and films like *The FBI Story* (Powers 1983), local police reformers labored largely in obscurity. Throughout the first half of the twentieth century police were portrayed in the Boston Blackie and Thin Man films as well as print media as either irrelevant or incompetent in solving crimes. The literary tradition of private detectives being the solvers of crime the police were too dense or unimaginative dated back to Arthur Conan Doyle. The movies followed this pattern, but began to make exceptions for federal agents in movies like *G Men*, produced in 1935. In the period after World War II, FBI agents became the epitome of the clean cut, honest American hero in the popular media.

The first to break out of this pattern was William Parker. Parker assumed the position of chief in the LAPD in 1950. He instituted a program of reform reminiscent of Hoover's. Training and hiring standards were improved. Compliance with department rules, physical fitness and appearance were strictly enforced (Cannon). Unlike small suburban departments like Berkeley, LAPD was far more visible. This visibility was greatly enhanced by fortuitous geographic location, advancing communications technology and social change. In the early 1950s, America was shifting from radio to television as a primary source of home entertainment. One of the earliest scripted dramas to attain popularity was based on LAPD detectives. *Dragnet* was originally created by a young actor and producer, Jack Webb, as a radio show but soon made the transition to television (Cannon). Chief Parker provided support for the production on the condition of script review. The resulting series was the first of what would become known as police procedurals. Two LAPD detectives were portrayed as working diligently to solve crimes ranging from car theft to murder. As a result, Americans were presented with a very different view of local police than had been traditionally presented in films. LAPD went on to provide support and technical advice to numerous television series and films. Although the FBI's influence can only be implied, the pattern was clear. Law enforcement emulated the FBI's systematic efforts to shape an image of honesty, courage and technical efficiency through the popular media. This recognition of the importance of both media and public image, likely owe much to the successful model demonstrated by the FBI.

The Relationship Evolves

The relationship of the FBI with other law enforcement agencies underwent a significant change after the death of J. Edgar Hoover in 1972. The forces for change had already begun to reshape the relationship, but the rate of change greatly increased after Hoover died. Hoover had dominated the agency for almost 50 years. Virtually no agency head had every exercised such long or total control of a federal agency as Hoover (Lewis 1980). During the 1960s, local law enforcement had matured technically. Numerous states and local police agencies had opened their own forensic laboratories. In 1969 the Law Enforcement Assistance Administration (LEAA), an agency of the Justice Department, began granting money to states and local governments for the upgrading of police and other justice functions. As a result of LEAA support, states began to adopt police officer standards and training (POST) commissions, which established training requirements for new police officers (Walker and Katz). The POST model, developed in California during the late 1950s, (California POST) spread to all 50 states by the early 1970s. The combination of required training and selection standards and increased funding from LEAA radically accelerated the transition of police agencies to a more professionalized model. LEAA also provided forgivable loans for college expenses to those who entered law enforcement. Many police officers took advantage of this funding to return to school, and criminal justice programs in colleges and universities proliferated. Although the expansion of POST basic academies and advanced training increased the demand for FBI instructors, these changes also made the FBI only one of several entities engaged in training and professionalization of police.

Although Hoover had carefully built his relations with police and nurtured the dependence of police on the FBI, he had always kept his agents at arm's length enough from other law enforcement agencies to assure the FBI could retain full control over all its investigations and avoid any guilt by association from the actions of others. Although this approach served to protect the FBI from potential criticism and negative publicity, it also engendered a degree of mistrust and alienation. Police officers often expressed the view that FBI agents expected to receive information from local police, but would seldom share information. Although individual Special Agents often worked conscientiously to overcome this impression, it was wide spread.

After Hoover's death, power in the FBI became more decentralized, and procedures began to change. Hoover was replaced briefly by L. Patrick Gray, who resigned after failing to receive Senate confirmation as a result of accusations of aiding in the Watergate cover up. In 1993 Clarence Kelley was appointed director. Although Kelley spent 21 years as an FBI Special Agent and rose to the position of Special Agent in Charge, he subsequently served 12 years as the Kansas City, Missouri, Chief of Police. Under Kelley the FBI shifted its law enforcement emphasis to organized and white collar crime, began working undercover operations and began to work more cooperatively with other law enforcement agencies (FBI).

Hoover's death also marked a turning point in the FBI's image. Hoover had been largely successful in controlling any negative publicity regarding the agency and engineered substantial positive portrayals (Vizzard 2008). The combination of the Watergate investigations and later investigations by the Senate into intelligence gathering broke down the historic reticence of the media to criticize the FBI. Although this may have been viewed as negative within the agency, it removed the FBI from its pedestal; it likely reduced the police perception of the FBI as a privileged group somewhat separate from the rest of law enforcement. In subsequent years the FBI has been the subject of several serious exposés, including the conviction of Special Agents John Connolly for aiding Boston organized crime figure Whitey Bulger and Robert Hanssen for espionage, as well as criticism for numerous actions, including the Ruby Ridge and Waco sieges. However, the FBI has continued to thrive as an agency and build bridges to the police community.

A Partnership Evolves

Since the late 1960s the FBI has supported law enforcement through operation of the National Crime Information Center (NCIC). Although NCIC is governed jointly by state and federal representatives, its operation depends on the FBI. This system provides law enforcement with computerized, online indices of stolen property, wanted persons and criminal records. In addition, the system has been enhanced to provide computerized photographs and other identifying data. The FBI continues to maintain the national fingerprint files on arrested persons, and has established a centralized DNA file. The fingerprint file can be searched for a match with a single latent fingerprint. These centralized identification and information functions with records on millions of previously arrested persons, wanted felons, stolen property and missing children provide a critical link in the investigative and law enforcement functions. As has been the case from the inception of the FBI's fingerprint file, the FBI is as dependent on police agencies for submission of information as the police are on the FBI. In addition to continuing forensic science support, the FBI has provided police with investigative assistance from the National Center for Analysis of Violent Crime (NCAVC) which popularized behavioral analysis, or criminal profiling (FBI).

Although forensic advances such as DNA analysis and single fingerprint search have proven far more important in the solution of crime, behavioral analysis has captured the public imagination as criminal profiling. By applying inductive logic to evidence from the investigation using past offender patterns, behavioral profilers seek to describe identifying demographic characteristics and predict behavior of offenders based on their past patterns of activity. Because this process is expensive and only applicable in cases where significant unique information about the offender's actions can be developed from the investigation, most police agencies do not find it practical to employ behavioral analysts. The NCAVC also serves as a national clearing house for information on serial violent offenders and provides alerts to police via its Violent Criminal Apprehension Program (ViCAP). A number of localities have emulated these latter functions with regional centers that track violent serial offenses on a state or regional level (New Jersey State Police; New York State Police).

In addition to the National Academy, identification files and the laboratory, two other early FBI efforts at creating links to police have proven successful, the Uniform Crime Report (UCR) and the *FBI Law Enforcement Bulletin*. The UCR is a compilation of crime and arrest data from police agencies throughout the country. For many years the data in this report has constituted the "crime rate" for most of the public, policy makers and the media. Comparison of the UCR figures with those of the National Institute of Justice's National Crime Victim Survey (NCVS) clearly reveals that it does not fully count crime in the country, as many crimes are not reported to police (Clinton). However, it does reflect trends and has one significant advantage over the more accurate NCVS. The UCR data is reported by political jurisdiction; whereas the NCVS is national data drawn from sampling. Thus, the UCRs have long been a focus of police, who are organized by geography.

Neither police managers, local politicians nor the public are as concerned with national crime rates as they are with crime in their own community. Although the UCR does not fully report crime, it does allow for calculation of trends over time. These have had significant influence on police staffing, funding and administration, although the FBI is largely a passive agent in the process. Virtually all police agencies now track their own data, but are only able to compare that data to other political subdivisions by using the UCRs.

The *FBI Law Enforcement Bulletin* was begun in 1932 and is likely the most widely read publication among police. As with other FBI activities, it owes this largely to the fact that it has long been distributed widely to police agencies and officials at no cost to the recipient. Although the journal makes no pretense of being a scholarly journal, it provides readers with articles on law and police and investigative procedures. Articles are practical and applicable to daily police activities, thus likely to be read by working police officers.

Not all FBI influence on police results from the activities of FBI Headquarters. In the years since Hoover's death, the FBI has greatly increased its cooperative interactions with other law enforcement agencies. A variety of FBI task forces and fusion centers operate with FBI Special Agents and analysts working jointly with state or local police on investigations and information analysis. These task forces focus on areas such as violent gangs, computer crime, terrorism and organized crime and are often housed in a location away from the FBI office. Task forces allow the FBI to capitalize on the much wider coverage of a community enjoyed by police, who remain in one location and are far more numerous than FBI Special Agents. They also allow the FBI to largely shape the mission by providing resources and expertise not available to many police agencies. By working side by side with police officers, Special Agents build personal relationships which reduce the potential for police developing suspicion or resentment of the FBI. Although these joint operations have been widely welcomed by many police agencies, frictions have developed in some instances, particularly around the joint terrorism task forces (Levitt; Parascondola; Portland on Line; Yardley).

A final area in which the FBI has significantly influenced police is in the area of organized crime investigation. Until the late 1950s, the official position of the FBI was that the Mafia did not exist (Gentry; Sullivan). However, public disclosures of a disrupted 1957 conference of crime bosses in Apalachin, New York and the later testimony of former Mafia soldier Joseph Valachi resulted in a reversal of that position and the initiation of a major effort at investigating organized crime (Gentry). A combination of expanded federal statutes, significant resources and innovative investigative techniques has allowed the FBI to significantly disrupt organized crime, particularly in New York (Freeh). Only the FBI has the resources, jurisdiction and Justice Department support to pursue many of these cases. They have therefore had substantial influence over the investigation and prosecution of organized crime.

Thus the FBI has had a continuing influence on state and local policing in the United States, although the mechanisms and nature of influence have evolved over the past 80 years.

Fear and Punishment

Helmut Kury[1] and Annette Kuhlmann[2]

[1]University of Freiburg, Freiburg, Germany

[2]University of Wisconsin, Baraboo, WI, USA

Overview

Since the 1960s fear of crime and attitudes towards punishment have become increasingly pertinent to the field of criminology and criminal policy. The availability of new methodologies in the social science, such as victim surveys, made these phenomena measurable and thus allowed for comparisons between groups and across time. In some ways these research methods played an important role in creating these topics in the first place. Especially in the USA, but also in other countries, politicians discovered the use of fear of crime to govern and control people. Crime policy can be simple in so far as people who are "fearful" generally ask for harsher punishments of the offenders, particularly after severe cases of crime. Politicians argue for harsher laws and sentencing policies as the "solution," especially for violent or sex crimes. Studies have shown repeatedly that measurements of fear of crime and of attitudes toward punishment tend to substantially overestimate both traits in the population.

Introduction

During the previous four decades, fear of crime and, subsequently, attitudes toward punishment have become increasingly important research topics in criminology. This research served as a backdrop for discussions of punitiveness in Western Europe. Imprisonment rates, development of penal law, sentencing behavior of penal courts, and public attitudes toward punishment are key elements of punitiveness which exert strong influences on criminal-political decisions (Dijk 2011). The increase in the number of prisoners in some countries, particularly the USA, has to be seen as political decisions influenced by media reports of citizens' fear of crime, their attitudes toward punishment, and their demand for more severe penal policies. Empirical criminological research has documented these developments, and some studies have found that fearful citizens are more punitive; consequently, in conjunction with other variables, fear of crime creates harsher attitudes toward offenders.

This section provides an overview of the important research results on fear of crime and attitudes toward punishment from different countries. Both of these phenomena are complex, undertheorized, and often measured only through few survey items (see Matthews 2005). In western countries in recent decades, the broad discussion of fear of crime in criminology, but also in the media, has led some scholars to the conclusion "that fear of crime is now recognized as a more widespread problem than crime itself" (Bannister and Fyfe 2001, p. 808). Since the beginning of the 1990s, the ongoing discussion of related practical issues, such as community crime prevention in Germany, occurred against the background of an increasing awareness of fear of crime in the public. This discussion has to include a consideration of the problems inherent in the methodologies used so far in the measurement of fear of crime and attitudes toward punishment. As shown, the measurement of fear of crime is vulnerable to political manipulation. This contributes, as some authors point out, to a "governing through crime," discussed particularly in regard to the USA, but also in Western European countries (Baker 2010).

Empirical Research About Fear of Crime and Attitudes Toward Punishment

As Lee (2001, p. 467) points out: "Since the late 1960s the 'fear of crime' has progressively become a profoundly engaging field of study for criminologists and other social researchers." Meanwhile, fear of crime has become a subdiscipline of criminology with an extensive body of literature, special chapters in college textbooks, and summarizing publications. The discussion began in the United States in the context of race riots of the 1960s and 1970s and increasing problems with violence in large metropolitan areas, particularly in neighborhoods with predominantly ethnic minority populations. In the 1960s social scientists began to develop a new research method, that is, population surveys, to collect information regarding people's perception and emotional responses toward criminality, fear of crime, and attitudes toward punishment. It was relatively easy to formulate questionnaire items and to find people willing to respond since crime was and continues to be an intriguing topic. An increasing number of surveys on crime, victimization, fear of crime, and attitudes toward punishment among the public brought these topics to the center of attention. The increasing discussion about victims of crime led to the establishment of a new subfield, victimology, "But it was the victim survey that, by providing data about the extent and severity of such fear, pinpointed a new area for criminological enquiry" (Zedner 2002, p. 425). The problem with the construct of fear of crime can be linked to a weak cognitively anchored attitude, meaning that respondents are likely to have only a rather vague perception of "their" personal fear of crime or none at all. Therefore, when asked to answer items in a questionnaire regarding such issues, these people are responding from a basis of limited awareness or personal reflection.

By the late 1960s an increasing number of organizations began to ask individual people about their experiences with crime victimization and possible effects such as fear of crime or attitudes toward punishment focusing on particular groups such as the elderly, young people, women, or foreigners (Lee 2001, pp. 475f). These surveys revealed that the dark figure of crime is higher than previously assumed, and at the same time, they provided extensive new information about the "effects" of crime. The number of victim surveys increased particularly in the United States and regularly included questions regarding fear of crime and attitudes toward punishment. Already in 1965 the National Opinion Research Center asked a sample of as many as 10,000 households, followed by similar surveys conducted by the Bureau of Social Science Research in Washington 1967. Ennis (1967) discovered in the first nationwide representative survey in the USA results which were confirmed on the international level in subsequent decades – namely, that women and the elderly express more fear of crime than men or younger people. The US President's Crime Commission also engaged in crime/victim surveys with the result that the USA and other countries, such as Great Britain and the Netherlands, carried out regular National Crime Surveys. "Through these surveys the scope of public concern about crime was 'discovered' empirically for the first time" (Lee 2001, p. 476). Zedner (2002, p. 425) points out: "Ironically, carrying out victim surveys increases sensitivity to the risk of crime. Situating questions about fear within a survey may consequently elicit higher levels of anxiety than would otherwise be the case." Vanderveen (2011, p. 40) points out for the Netherlands that "'fear of crime' is rooted in statistics and surveys by the Dutch government: without statistics, there would be no 'fear of crime' in the Netherlands as we know it today." So the problem of fear of crime – and punitive attitudes toward punishment – was created, at least partly, by the research itself and by the manner in which the survey items were framed. The results of these surveys were discussed in the media, and so people "learned" how fearful of being victimized they really are. The media realized that such reports interest people, so they presented this information often in a distorted, sensationalized manner.

At the end of the 1980s, Dijk et al. (1990) founded the first international victim survey, the "International Crime Victims Survey – ICVS." This new data set represents significant progress since we now have reliable international comparative data available that include the dark figure of crime as well as fear of crime and attitudes toward punishment. So far this survey has been carried out five times, in 1989, 1992, 1996, 2000, and 2005 in a number of different countries using the same basic questionnaire and research methodology (Dijk et al. 2007).

As a result of these different ICVS surveys, extensive data sets on fear of crime and attitudes toward punishment are now available not only from the western industrialized world, but also from developing countries. Nevertheless, Arnold (1991, p. 87) cautions: "Although fear of crime has interested social scientists for over two decades, and despite the fact that considerable research work has been done in the field of correlates of fear of crime, results have been inconsistent, inconclusive, and far from unequivocal." The main reason for the different and partly controversial results in the data on fear of crime as well as in attitudes toward punishment can be seen in the unclear definition of these concepts and the differences in measuring it. “Even the understanding of the term fear of crime and how it should be indicated or measured is not commonly accepted” (Arnold 1991, p. 88).

Zedner’s (2002, p. 425) observation that “… although fear of crime is closely related to levels of crime and tends to increase as crime rises, it cannot be seen as a mere function of crime rates” has to be further specified. In fact, the correlation between fear of crime and crime rates has been shown repeatedly as being relatively low, with the exception of countries or cities with high rates of (violent) street crimes. On the background of the worldwide results of the International Crime and Victimization Surveys, Zvekic and Alvazzi del Frate (1995, p. 28) point out that “there is some correlation between the rates of assaults/threats and robberies and fear of crime… the higher the crime rates are, the higher is the feeling of insecurity” (here in regard to Sub-Saharan Africa and Latin America). This is not surprising as, generally, people are informed about developments of criminality through media which tend to present distorted and sensationalized views, focusing on extreme and rare cases of violent and/or sex crimes. Only in regions or cities where people experience victimization as part of their daily lives do we find a strong correlation between crime rate and fear of crime. For instance, Zvekic and Alvazzi del Frate (1995, p. 27) have found such results for specific cities with high rates of street crime, such as Rio de Janeiro or Johannesburg.

Dijk and Vollaard (2012) analyzed data from different waves of the International Crime Victims Survey (ICVS) for 15 countries and compared the actual rate of victimization of burglary against the perceived risk of burglary, that is, a cognitive aspect of fear of crime, for that year. These data provide the foundations for a model of “the aggregate crime rate as the outcome of an interaction between potential offenders and potential victims,” focusing on domestic burglary. The results of the study show that fear of crime is strongly related to the actual crime rate for burglary. They found a strong positive correlation between the rate of victimization of domestic burglary and the perceived risk of victimization. This relationship can be shown both across the 15 countries and over time within the different countries. Increasing rates of burglary had the effect of an increasing investment of people in home security. These higher levels of home security, in turn, are related to lower percentages of successful burglary attempts in the future. Therefore, the authors conclude that “precautionary behavior is an important factor in understanding aggregate crime trends.” A reduction in officially registered crimes can be a result of more effective preventive measures by citizens. “The empirical evidence suggests that regulating built-in security is not only an effective policy but also a relatively cheap way of reducing crime compared to more traditional crime policies such as strengthening law enforcement or rehabilitation of offenders” (Dijk 2008).

The concepts of fear of crime and attitudes toward punishment, as operationalized in most research, are influenced by a number of different variables. A representative survey, for example, from East and West Germany in 1991/1992, that is, just after the reunification of both parts of the country, showed that the fear of crime rate in the Eastern part was substantial and significantly higher than the rate in West Germany. At the same time the official crime rate in East Germany was about one third to one half of that in the western part. The results show clearly the weak influence of crime rates on fear of crime. Over subsequent years the official, registered crime rate increased significantly in the Eastern part of Germany until it reached the rate of West Germany in 2000 – at the same time the fear of crime rate decreased noticeably. Obviously other factors besides crime rates are influencing the fear of crime.

The same case can be made for attitudes toward punishment. The former German Democratic Republic (GDR) was, like other former Soviet states, rather punitive in comparison to West Germany or other western countries; the state propaganda taught people that it was necessary to be harsh toward offenders to reduce crime. The death penalty was abolished in GDR in 1987, in West Germany 1949. In contrast to western countries, only few alternatives to harsh sanctions, such as crime prevention or victim-offender restitution, existed and were seldom used. As Niggli (2004, p. 192) points out, punitive attitudes in the general public are to a large extent shaped by the values in the society, the prevalent practices of sanctioning, and the character of the public debate about the problems in society surrounding crime. According to Niggli, the new punitive turn in many countries is a response to far-reaching changes in the context of globalization, particularly the opening of borders in Europe and increased migration. In recent decades new problems emerged that led to a discussion of western societies as "risk societies." These problems include changes in the employment structure, an increasingly extreme income disparity, and a decline of the social security system (p. 196).

After German reunification western penal law was introduced in former East Germany which implied more lenient sanctions and corresponding reports in the media. The people had new experiences. Although the GDR experienced a significant increase in crime rates in the beginning of the 1990s, a decade later, fear of crime indicators as well as attitudes toward punishment had changed and become more lenient. However, some interesting exceptions illustrate the salient influence of public debate. Over the last three decades, a heated public discussion about rape in matrimony emerged, and stricter laws were enacted as a result. This was not the case in GDR. So after reunification West Germans were more punitive than the East Germans in this regard. Subsequently, East Germans were influenced by the media about this discussion and became more punitive as well. This development stands in contrast to a comparable debate on illegal drugs. Possession had been punished severely in the former GDR, whereas West Germany had more lenient penal policies, especially in regard to soft drugs. After reunification, as a result of public debate, East German attitudes also became increasingly lenient in this issue.

In contrast to countries like the USA, Great Britain, or the Netherlands, Germany has no regularly conducted representative crime or victimization surveys. There are only individual surveys with different samples and methods, so the results are only partially comparable. But there is a private insurance company which has conducted such representative surveys on "Fears of the Germans" using the same methodology every year since 1991. The survey inquires about different fears, including fear of crime (R+V Infocenter 2012). The results show that since 1991 the fear of crime is higher in the former East Germany than it is in the west of the country and this fear has been increasing over the last two decades. In 1991 24 % of West Germans indicated any fears (like unemployment, political situation, illness, or crime), while the rate for East Germany was 28 %. In 2011 the values were 42 % in West and 47 % in East Germany.

It is striking that out of the 16 registered fears, fear of crime has, over time, moved into the background, while other fears, such as increases in costs for living, unemployment, insufficient funds for retirement, or politicians' inability to solve the country's problems, moved into the foreground. In 2011, fear of crime, out of all fears, placed on the second to last position on this scale. So while other fears increased, the significance of fear of crime, as part of an overall sense of anxiety, diminished. Yet this interpretation of these empirical results requires caution. Zarafonitou (2011, p. 61) discusses Greece which, according the EU-ICVS, had a particularly high rates of fear of crime over the last two decades compared to other EU states. She points out that "significant social changes have occurred" in this country, "the most important of which were the mass entry of immigrants as well as the recent economic crisis."

During the Soviet era, former Soviet states had, in comparison to western countries, a significantly lower (official) crime rate, more punitive penal laws, and more severe sentencing policies. Also, the population had more punitive attitudes toward offenders; at the same time, the fear of crime rate was regularly lower than in western countries. After the collapse of the Soviet Union, the (official) crime rate increased in most countries, while the economic situation worsened, that is, the unemployment rate in many of these countries increased while the helping – as well as controlling – function of the state declined. With this background the fear of crime rate also increased significantly.

These results indicate that fears are more focused on general fears about the economic and political situation in a country, the living conditions, etc. and that fear of crime, as we measure it in victim surveys, is a mixture of these different fears – only part of it really is a fear of crime. Against the backdrop of the dramatic changes in the former Soviet countries, these fears are higher in those countries than in western countries, while their actual crime rate might be lower. The fact that East Germans voted for harsher penal laws to fight crime might not necessarily be interpreted as a higher level of punitiveness in the population, but rather as an expression of general dissatisfaction with the political and social situation.

As Krajewski (2006, p. 490) points out, the punitive attitudes in postcommunist countries are based on the strict sentencing practices of the courts as well as the generally conservative, rigid, and intolerant attitudes of the former Soviet system, which the regime presented to the public via the mass media. It is often overlooked that the "will of the society," which continues to be cited by communist politicians as the reason for their partially absurd ideas regarding penal policies, is a result of the propaganda in the media regulated by them (Krajewski 2006, p. 490). Klaus et al. (2011, p. 267) point out, "that communist criminal law was exceedingly punitive and penalisation was a basic means to counteract undesirable social problems." Reports about crime were seldom published in the media of the former Soviet countries, and, if so, the reports were one-sided and biased. Such politics promote the development of punitive attitudes.

A more punitive attitude toward offenders in the former Soviet countries is also illustrated in a number of different articles in a collection by Kury and Shea (2011). Krajewski (2006, p. 490) points out that intolerance and punitive attitudes are discussed in the scientific literature only very broadly. With regard to Poland he shows that according to surveys in 1987, 74 % of the population felt their country was safe. In 2004, this rate declined to 33 % (p. 489). According to the results of the ICVS (Dijk et al. 2007), Poland participated regularly in different waves of these recurring surveys. Since 1992, the surveys revealed increasing punitive attitudes in the population. In 1992, 31 % supported sentencing a juvenile recidivist burglar to a prison term. In 1996 the value declined to 17 % but increased again in 2005 to 34 %. In 1964, 50 % of the population supported the death penalty for severe offenders; in 2002 this percentage increased to 77 %. The new penal law from 1998 abolished the death penalty, but since then this new law has been strongly criticized by the media and by members of different political parties. This widespread and harsh critique continues today in the context of very conservative politics. The opponents of the new regulation postulate more repressive responses toward offenders similar to the practices in the USA and Great Britain. Politicians and the media publicize these demands regularly which exert an influence on the population. Consequently, in 1993 67 % of the public supported a reintegration of offenders into society as a central theme of crime policy. But in 2002 the percentage declined to 17 %. Likewise, 1993, the protection of human rights for prisoners was supported by 40 % of the public, but declined to 6 % 2002. According to Krajewski (2006, p. 504), there is no doubt that today the Polish criminal justice system is among the most punitive in Europe. Danilov et al. (2011) report a punitive tendency in Russia. Saar (2011, pp. 345f) points to high levels of punitive attitudes in Estonia. More specifically, the actual crime rate in Estonia increased significantly between 1991 and 2001, but decreased again from 2002 to 2009. At the same time, the fear of crime rate in Estonia decreased from 1993, when 49 % of those surveyed felt unsafe walking alone in the street at night, to 28 % in 2009 (p. 353). These results show high rates of punitiveness in these former Soviet countries which do not correlate with the actual crime rates. The penal practices of a country, that which are considered "usual" in sentencing and frequently discussed in the media as being a necessary reaction to crime, have an effect on the attitudes of the public. A conservative and restrictive Polish government has been asking for harsh punishment on crimes. It requires time, new experiences, and valid information to change the attitudes of people.

Criminologists were able to show in their research that a more detailed understanding of the background of criminal behavior and of offenders reduces harsh attitudes toward felons. Hough and Park (2002) in their research project asked people about possible ways to reduce crime. After completing a preliminary survey, the research subjects participated in a 2-day seminar where underlying reasons for crime and criminal behavior were discussed. Subsequently, the participants retook the survey and did so again 10 months later. In both times their punitive attitudes had declined substantially compared to the initial survey. This illustrates again the conclusions that more knowledge about crime and criminals reduces punitive attitudes.

In spite of a worldwide trend to reduce the use of the death penalty, some countries still practice it, among western countries most notably the USA. In Europe, only Belarus continues to use this form of punishment with support of the public. In the USA 34 states allow the death penalty, but the number of persons executed has declined from 99 in 1999 to 43 in 2011. A 2010 poll by Lake Research Partners "found that a clear majority of voters (61 %) would choose a punishment other than the death penalty for murder." The majority supported alternatives to the death penalty: 33 % voted for capital punishment, 39 % for life without parole plus restitution, 13 % for life without parole, and 9 % for life with parole (6 % no opinion) (Death Penalty Information Center 2012, p. 4). That means 52 % of the participants in the US survey voted for life imprisonment without any chance of release. Critics point out that life without parole is also an exceedingly cruel punishment, comparable to the death penalty. Consequently, the USA has to be seen as a particularly punitive country, in spite of the reduction in the number of executions in recent years. A disproportionate number of those executed are poor and African American.

While at the beginning of the twentieth century nearly all countries used the death penalty, today only 58 of them have such legal provisions. In 2010 only 23 countries worldwide actually executed people. A Gallup International survey from 2000 asked samples of the population in 59 countries about their attitudes toward the death penalty. Only 52 % of all persons surveyed supported capital punishment. Citizens from regions where the death penalty was used more often also supported capital punishment at higher rates: 66 % in North America, 63 % in Southeast Asia, 60 % in Eastern Europe, 54 % in Africa, 37 % in Latin America, and 34 % in Western Europe where this practice is fully abolished.

In West Germany the death penalty was abolished 1949. At that time, according to a 1996 survey by the Institut fuer Demoskopie Allensbach (1996), 74.8 % of the population supported the death penalty. Over subsequent years the support for the death penalty among the West German population declined to about 50 % in the 1960s and dropped further to about 30 % in the beginning of the 1970s. In the context of the murders committed by the Red Army terrorists, support for death penalty peaked at nearly 45 % by end of the 1970s and then declined again to between one quarter and one third today (Kury et al. 2004, p. 65).

The ICVS presents comparable data about fear of crime and attitudes toward punishment from a number of different countries. Zvekic and Alvazzi del Frate (1995) discuss the results for developing countries. According to their data in the 1990s, the "safest regions are Asia and North Africa, while the highest levels of insecurity were registered in Sub-Saharan Africa… and Latin America…" (p. 27). They also found "some correlation between the rates of assaults/threats and robberies and fear of crime… the higher the crime rates are, the higher is the feeling of insecurity (Sub-Saharan Africa and Latin America). However, high levels of precautions adopted when going out after dark (avoiding certain areas that are considered dangerous and asking somebody for company) do not necessarily mean that respondents feel unsafe and are also adopted in the low-crime regions. They may just as well reflect the cultural pattern of an outgoing style which is not directly related to fear of crime" (p. 28). This finding again calls attention to methodological problems in measuring fear of crime.

In regard to attitudes toward punishment, Zvekic and Alvazzi del Frate (1995, p. 48) summarize that "there is a high degree of agreement among the population in the developing world that the most appropriate sanction is imprisonment: more than 50 % in all the regions, and even more than 70 % in Sub-Saharan Africa and Asia." Despite some countries' favor for community service, like in Argentina and Brazil, "Punitiveness prevails in the developing world" (p. 48).

An analysis of ICVS results for 18 EU countries since 1992 found an average of 26 % of the sample, across all surveys and all countries included, felt unsafe walking in the street after dark in their own residential area (Dijk et al. 2007, p. 66). In 2005 this rate was more or less the same at 28 %. But the differences between the countries are immense. The highest rate of fear was found in Greece (2005) where 42 % expressed fear of crime. Also very high rates of fear were registered among the population in Luxembourg (2005, 36 %), Italy (2005, 35 %), and Portugal (2005, 32 %). On the other end of the spectrum were Finland (2005, 14 %), Denmark (2005, 17 %), and the Netherlands (2005, 18 %). In Estonia, Poland, the Netherlands, and Finland, the fear of crime rate decreased starting in the 1990s, but in the United Kingdom it increased (2000, 25 %; 2005, 31 %); the same occurred in Belgium (1992, 20 %; 2005, 26 %) and Sweden (1996, 11 %; 2005, 19 %).

In regard to attitudes toward punishment, the average percentage of the public in the different countries opting for imprisonment of the young recidivist burglar in 2005 was 24 % and for community service 49 %. So the majority supported alternative sanctions for the offender. But the difference between the countries was again very high. In the United Kingdom 52 % of those surveyed agreed with a prison sentence, while this percentage was only 38 % in Ireland and 34 % in Poland (here including labor camp). On the other end of the scale, the percentage in France was only 13 %, the same as in Austria, and 15 % in Portugal, while Germany's was 19 % (see also Dijk 2011, p. 218). At the same time, the rates for community service were highest in 2005 for France (68 %), Portugal (68 %), and Luxembourg (68 %) and lowest for Greece (27 %), United Kingdom (29 %), and the Netherlands (37 %). The development of community service orders shows some shift over time. "For instance, those in the Netherlands in 2000 were less in favor of a community sentence than they were in 1989. In contrast, there was more support in Belgium and Finland in 2000 than in 1989. Between the 1996, 2000 and 2005 sweeps, though, there was little change" (Dijk et al. 2007, p. 87).

Dijk et al. (2007, pp. 89f) compare national attitudes toward sentencing with rates of imprisonment for different countries. "In the Western world, those countries where the public clearly favors imprisonment, such as the USA and the UK, tend to have comparatively higher prisoner rates." The authors found on the basis of the ICVS data within the EU context, "a very weak and statistically not significant relationship between public opinion on sentencing and the actual level of prisoner rates. The three new member countries, Hungary, and especially Poland and Estonia, stand out with prisoner rates far above the EU average while public attitudes in these countries are only slightly above the middle range. In these transitional countries public attitudes have shifted over the past 10 years away from imprisonment toward community service orders. Public opinion in these countries is now broadly in line with the EU majority point of view. Actual sentencing policies seem still to be comparatively punitive, although... levels of conventional crime are not excessively high in any of the three countries."

Criminological research shows clearly that fear of crime rates and attitudes toward punishment have different trajectories in different countries, and both are particularly influenced by the political debate, the economic situation, and media reporting on crime – but also by the way of measurement.

Measurement Problems

Fear of crime and attitudes toward punishment are exceedingly complex concepts, yet they are measured in many cases with one or a few items only. The “standard item” for fear of crime is: “How safe do you feel walking alone in your area after dark?” Here crime is not mentioned so the background for the response can include other causes such as darkness or aggressive animals. But other surveys used different forms of assessment (Farrall and Ditton 1999, p. 58) such as the following: “In your everyday life, are you afraid of someone breaking into your home?” When the questions are framed so differently, the results are hardly comparable.

Attitudes toward punishment are also often measured by asking about the level of acceptance of the death penalty or by presenting a special criminal case and asking about suggested reactions (see the ICVS, Dijk et al. 2007, p. 98). Empirical explorations of complex concepts such as attitudes toward punishment cannot lead to any degree of precision nor provide any adequate results when assessed with one or a few items only. Even if the results of such polls do tell us something about the attitudes toward punishment, or at least about certain of its aspects, it is not clear to what extent these results apply. They certainly do not mirror “the” attitudes toward punishment, even if they are often presented as such (Kury and Obergfell-Fuchs 2008, p. 280). These items only embrace single aspects of the unclearly defined concepts. Mostly the authors of studies in this field lament the methodological problems, but nevertheless use the old items more or less in a similar way. Usually the questionnaires have to be short, so one or a few items are used to measure the concepts. Under these circumstances it is not surprising that the results of these surveys are often contradictory.

Farrall et al. (1997) have pointed out that the customary standard polling techniques, based on standard, closed questionnaires, have led to a significant overrating of the fear of crime. In particular, comparative qualitative studies, providing more thorough analyses of the indicated fear values, have called into question the results of quantitative questionnaire surveys. Farrall et al. (1997, p. 658) remark that from the outset fear of crime as well as victimization experiences have been almost exclusively the domain of quantitative studies, leading to results that suggest “that fear of crime is an overriding social problem.” It is only in recent years that these results have been increasingly questioned by more differentiated studies. On the background of their own research, using quantitative and qualitative methods, Farrall et al. (1997, p. 3) conclude that closed inquiry systems as used by most polls, especially by big-scale surveys, consistently and substantially overestimate fear of crime. Based on a comparative survey in Germany, Kury and Obergfell-Fuchs (2008) came to the same conclusions and were able to validate the English results. In another research project they found similar results concerning attitudes toward punishment (Kury et al. 2009). About half of the sample which had been classified as punitive based on a survey with a standardized questionnaire appeared nonpunitive in the face-to-face interviews. The research subjects responded with higher levels of punitiveness on the questionnaire to express other problems, which were outside the focus of the survey.

Some authors found a “risk-fear paradox” indicating that some population groups, such as women and the elderly, have low victimization rates but high levels of fear of crime, while men and the young generally have relatively high levels of victimization, but low levels of fear of crime. Some authors explain this paradox as a consequence of measurement problems. “Historically, victim surveys have produced problematic data that suggested a weak correspondence between fear and risk” (Zedner 2002, p. 426). Instead, over the last several decades, researchers have increasingly “attempted to identify the social structural causes of people’s fear” (Zedner 2002, p. 426).

Increasing numbers of studies over the last several decades have shown that “fear of crime” is related to general fears or feelings of insecurity which generally are not assessed separately in surveys consisting of standardized questionnaires.

What we call "fear of crime" is obviously a mixture of different types of fear, feelings of insecurity, worries, anxieties, or perception of various risks. "Fear of crime" emerges not only through reports about or experiences of (severe) crimes, but also through the socioeconomic situation in the neighborhood, living conditions, or signs of increasing incivility. "Fear of crime may operate as a 'sponge,' absorbing all sorts of anxieties about related issues of deteriorating moral fabric, from family to community to society. People may use the language of 'worry' and 'crime' to express connecting conflicts, insecurities, and anxieties" (Jackson 2006, p. 261). As the German surveys by R+V Infocenter (2012) clearly show, since 1991 fear of crime has moved increasingly in the background and other "fears" related to social changes and living conditions in society increased. Zarafonitou (2011, p. 50) discusses the background of high rates of fear of crime in Greece in comparison with other EU countries and points out that the "research evidence in Greece reflects the association of citizens' insecurity with the perception of the quality of their everyday life as degraded as well as their dissatisfaction with the state services, and in particular with the police effectiveness, in this field. In this context, the interpretation of the examined phenomenon will be based on the fundamental assumption that a feeling of general social insecurity is expressed through fear of crime."

The same conclusion holds true for attitudes toward punishment. Here also the standardized polling of attitudes toward punishment, used in virtually all victim surveys, raises considerable methodological problems. Kury et al. (2004) proved in his experimental research project that survey results are influenced by the order and number of alternatives provided to a question about sentencing. In a randomized sample of three groups, each group was presented with the same questions about sentencing of different crimes. Only the possible options for responses to the questions differed. Group A was presented with five different sanction alternatives ranging from lenient to punitive and was asked to choose one of them (the options included private restitution, mediation by an official mediator, punishment with or without restitution). Group B was presented with the same questionnaire, but with the options listed in reverse order (from punitive to lenient). Group C was presented again with the same questionnaire as the first group, but with three additional options (no reaction to the crime, fine, imprisonment). The effects of the different methodologies on the results of the surveys were so pronounced that the results were not comparable, especially in criminal cases that were not severe. For example, in the case of theft, 72.4 % of group A voted for alternative sanctions, but only 20.8 % in group C did so; instead, 22.5 % of this group C voted for no reaction, an option not provided for the other two groups. In case of homicide 38.1 % of group A voted for alternatives as did 18 % of group B, but only 7.5 % did so in group C; again, their options for alternative measures were different. In the case of using public transport without paying for the ticket, 58.1 % of group A and 53.5 % of group B voted for alternative sanctions, in contrast to only 4.2 % in group C and of those 36.7 % opted for "no reaction." These findings show that the answers are influenced significantly by the way the items are presented; if we do not present "no reaction" as an option in the survey, the participant cannot inform us that he/she does not really suggest any alternative reaction, but to simply do nothing.

Political Relevance of Fear of Crime and Attitudes Toward Punishment

With fear of crime among the citizenry political actions can be initiated and justified, that is, the research results on this topic have tangible consequences. Fear of crime is, since we measured it, a very politicized topic. This can be seen in the development of the discussion and changing reactions to crime in the USA since the beginning of the 1970s (Lee 2001). Against the backdrop of a "perceived growing lawlessness in the USA," the public "was becoming anxious about the steadily climbing crime rate." Criminologists measured this development and "calls for tougher action in terms of policing, disciplining and punishing criminals began to grow" (Lee 2001, p. 476). All over the world and throughout history, the most favored reaction to crime has been (stricter) punishment. The USA had a dramatic increase of punitive reactions toward crime, and consequently, penal laws and sentencing policies became stricter with the effect that the incarceration rates climbed as did the costs of the criminal justice system. Meanwhile, the USA has the highest incarceration rate in the world.

In 1965 President Johnson set up the Commission on Law Enforcement and Administration of Justice (LEAA) "that was supposed to produce solutions to the crime problem in a non-political, non-partisan environment" (Lee 2001, p. 477). The commission was charged with investigating the reasons for the crime increase at the time and with discerning the societal factors responsible for it. The 1967 report of the commission, "The Challenge of Crime in a Free Society" (Harris 1969, p. 15), emphasized the "real" background of an increasing crime rate which was neglected in subsequent decades by politicians in favor of increasing stricter reactions to crime. "To speak of controlling crime only in terms of the work of the police, the courts, and the correctional apparatus is to refuse to face the fact that widespread crime implies a widespread failure by society as a whole" (Harris 1969, p. 16). The background of crime was seen here first and foremost as rooted in the social conditions, but over the following decades the causal attribution moved to the offenders themselves who were now seen as individually responsible for their behavior.

In the USA fear of crime, individual responsibility for (criminal) behavior and socioeconomic status, as well as penal policies are highly racialized. Young black males are particularly feared, yet they are also the most victimized group, that is, their homicide victimization rate is five times that of whites. Penal policies, particularly the war of drugs, have led to disproportionately high incarceration rates among this group; that is, it is currently seven times higher than that for whites, or one in three African Americans ages 20–29 is under some form of correctional supervision (Kuhlmann 2011). Sheldon (2010, p. 92) has called this new racial disparity in prisons "the New American Apartheid."

Fear of crime, combined with the historical mythology of the American West and corporate interests such as the National Rifle Association, contributed to constitutionally secured gun laws which allow individuals in many states not only to own and carry guns but to do so while concealing them. This mixture has proven particularly disturbing recently in the two shootings of black youths by private white citizens who felt threatened by the young men. It is unlikely that the white shooters will be convicted or even go to court.

Lee (2001) explains the development of the politics of crime over subsequent decades in the USA when politicians "learned" to use fear of crime as a tool for governing. It became popular to announce ever harsher punishment as a means to reduce the (severe) crime rate and to use the population's "fears of crime" to win elections. Thus, "governing through crime" became a pattern of penal politics not only in the USA but, as Garland (2001) demonstrates, also in Great Britain. The effect was that penal law became increasingly harsh in most western industrialized countries, a development which also applied to sentencing (the criminal justice systems in Eastern European countries were already much more severe) (see the chapters in Kury and Shea 2011). People ask for harsher punishment, politician creates stricter laws, and, as a result, people "learn" that they are right and the politicians have "understood"; this is a self-sustaining feedback loop (Lee 2001, p. 480). The resulting high levels of incarceration created economic and political interests groups, the prison-industrial complex, which includes not only construction businesses for the large number of new prisons but the producers of technologies, products, and services required to operate these. Defense industry giants like Westinghouse are retooling and lobbying Washington for their share of the domestic law enforcement market, for many rural area prisons are becoming the primary form of economic development, and advertising industries have found a new market. These businesses are so successful that they were identified as the sixth fastest growing industry in the USA in 2010.

Over the last few years, a debate erupted in Germany concerning the question of a "punitive turn," the possibility of a "new Punitiveness" in that country (Pratt et al. 2005). There are, in fact, a few signs for a "governing through crime," but overall, the attitudes toward punishment in Germany have been relatively stable over recent years; in comparison to previous decades, people express more lenient attitudes today (Kury and Obergfell-Fuchs 2011).

The discussion about more punitive attitudes toward crime regularly starts after particularly serious crimes, such as the cases in Oslo, Norway, or London, England, in 2011 or in Toulouse, France, in 2012. The Norwegian President reacted with a cautionary message of not allowing this crime to diminish the freedoms in the country and for the population and politicians to react quietly and rationally. In contrast, the prime reactions in Great Britain and France were to create stricter penal laws and to increase the penalties. Without considering if this reaction actually was the best way to reduce such types of crime, politicians assumed that this was what the people wanted to hear most – after all, the population generally is un- or misinformed and the politicians tell them what the right reaction is supposed to be.

Discussion

Beginning in the late 1960s, western countries have been involved in an expanding discussion about fear of crime. Evolving new research methodologies made comparisons between different groups and countries possible. Early on in this debate, politicians found ways to use this fear to further their own interests, especially to win elections. Crime policy in this context is simple: especially after the occurrence of a severe crime, a discussion starts about increasing punishment; people become more punitive and believe that crime can be reduced through more severe reactions to it.

Because fear of crime has such a strong impact on crime policy, it is important that criminological research results are valid and methodologically sound. The research experiences on this topic over the last decades reveal that the results for fear of crime and also for attitudes toward punishment are not always exact. Methodological studies show clearly that surveys with standardized questionnaires, often measuring fear of crime and attitudes toward punishment with single items, strongly overestimate the "fear of crime" rate and the desire for harsher punishment. These results are used to support wrong political actions, namely, harsher penal policies. What we measure with "fear of crime" is often more or less a mixture of different fears, insecurities, and worries about social conditions. If people are better informed about the underlying causes of crimes and the effects of punishment, as well as the resulting costs of imprisonment, fear of crime is reduced and attitudes toward punishment become less punitive. Citizens need to be informed that some level of crime is a "natural" aspect of each society and cannot be completely eliminated; instead, fears can also protect people from dangerous behavior. Criminologists have a responsibility to produce valid results to facilitate rational discussions about these topics. There needs to be more information available to the public as to the actual reasons for the prevalent crime rates as well as possible ways to reduce crime to rational levels. Stricter penal policies generally do not lead to this goal; instead people need to understand the connection between societal conditions and crime.

Anxieties about crime; Psychology of risk; Risk perception; Worry about crime

Overview

Research on the fear of crime has developed slowly but surely since the early 1960s, providing a rich interdisciplinary literature of empirical, conceptual, and methodological interest. But studies often lack theoretical reach and ambition. In an attempt to stimulate interdisciplinary work that spans psychological and sociological modes of analysis, this entry tries to reframe the fear of crime literature according to psychological insights into social and risk perception.

Framing Fear of Crime and Risk Perception

The first section reviews psychological work on emotional reactions to the anticipation of victimization and risk perception.

Emotion

Emotional reactions and perceptions of risk lie at the heart of fear of crime, and one way to approach the link between them is to focus on "worry" not "fear." There are two reasons for this.

First, fear inadequately captures most people's emotions about the threat of becoming victims of crime (*see* inter alia Warr 2000; Gray et al. 2011). Fear is a strong physical response to an immediate and proximate threat, and while fear may be a good descriptor of some people's emotions in some situations (e.g., in the presence of immediate signs of danger), people's emotions about crime are often closer to some kind of rumination or anxiety about risk and uncertain threat (i.e., in the absence of immediate signs of danger). People can respond to an immediately threatening environment, but they can also worry about distant potential harm.

Worry about crime, by contrast, captures people's assessment of proximate *and* distal threat. Worry is both an evaluation of an immediate situation (one can worry about the threat of victimization indicated by close cues in the environment) and the rumination about future outcomes (an anxiety-producing concern about distal and future events yet to transpire). According to Berenbaum (2010, p. 963), worry can be described as repetitive and anxiety-producing thoughts that have three characteristics: "…(1) the repetitive thoughts concern an uncertain future outcome; (2) the uncertain outcome about which the person is thinking is considered undesirable; and (3) the subjective experience of having such thoughts is unpleasant."

Second, there is a good theoretical framework for the processes by which worry about crime starts, continues, and finishes. Berenbaum's (2010) *initiation-termination two-phase* model draws our attention not just to the links between perceived threat and emotion, but also to worry as a dynamic process that unfolds over time. On the one hand, worry is initiated by perceptions of threat which comprise the perceived probability of undesirable future outcomes, their cost, and the salience of risk and threat.

On the other hand, people continue to worry unless they can accept the uncertain future possibility of a threat, and have taken whatever efforts they can to prevent or cope with it. Conversely, they stop worrying if they become comfortable with the possibility that the threat might still be realized. In Berenbaum's (2010) model, this acceptance of threat – that often leads to the termination of worry – is linked to one's desire for certainty (i.e., the intolerance of uncertain situations and events), beliefs about the value of worrying (i.e., positive beliefs that some individuals hold about worry, such as perceiving it as an effective way of problem solving or an indicator of high levels of responsibility), a perseverative-iterative style (i.e., the tendency to focus on an object of concern by repeatedly thinking about the next possible step in a chain of connected outcomes), and a sense of closure in one's role to prevent or cope with the threat (i.e. the sense that every possible preventative or coping action has been taken).

Need for cognitive closure may be especially relevant to fear of crime (Jackson 2013). Kruglanski and Webster (1996, p. 278) define it thus:

> . . .a desire for definite knowledge on some issue and the eschewal of confusion and ambiguity . . . need for closure is presumed to exert its effects via two general tendencies: the urgency tendency, reflecting the inclination to attain closure as quickly as possible, and the permanence tendency, reflecting the tendency to maintain it for as long as possible

People with a high need for cognitive closure have difficulty accepting the prospect of the uncertain outcome; they exhibit a general intolerance of uncertainty and prefer predictability, structure, and quick decision-making. Imagine a group of people who all believe that falling victim of crime is a significant personal threat and all have a high need for cognitive closure. They are less able to live comfortably with non-negligible risk and cannot reach some sort of acceptance of the existence of possible harm, so they continue to worry in a persistent fashion.

Cognitive and Affective Assessments of Risk

The distinction between *risk as feeling* and *risk as analysis* (Loewenstein et al. 2001) may also be important to fear of crime. According to this perspective, there are two types of information processing that drive how people make sense of risk. On the one hand, *risk as analysis* involves a more formal, logical, and numeric style of reasoning. A style more applicable to quantitative and cognitive assessments of crime risk, *risk as analysis* typically involves a rather dispassionate assessment of likelihood and consequence via more logical and numerical assessments of risk. If people are using such a type of information processing regarding crime risk, then emotion is less likely to accompany and shape the resulting representation of potential threat.

On the other hand, *risk as feeling* involves more intuitive and experiential type of thinking in which emotion is particularly important. *Risk as feeling* brings in more qualitative aspects, like the vividness with which consequences can be imagined, one's mood, and prior experience with the event. For Slovic et al. (2004), the "experiential" system is affect-laden rather than formally logical like the "analytic system," involving rapid processing and the encoding of reality in images and metaphors rather than abstract symbols and numbers.

Importantly, affective reactions and appraisals of risk can often hold sway over more dispassionate perceptions (Loewenstein et al. 2001). For example, when the outcome is vivid and affect-laden, then an individual will be relatively insensitive to probability variations. Applied to fear of crime, people who process crime risk in affective and imagery-laden ways may be rather uninterested in the actual probability of victimization. They may focus instead on its imagined outcome.

Feelings about a risk object can also shape more cognitive and numeric appraisals of risk and benefit. The *affect heuristic* describes how a representation that is tagged with affect – a good or bad quality – can be influential in overall judgements of risk (Slovic et al. 2004). Vivid and emotion-laden representations of an outcome (i.e., a particular image of crime) may thus shape numerical assessments of probability (cf. Jackson 2011).

Availability Cascades

The *availability heuristic* (Tversky and Kahneman 1974) predicts that the probability of an event tends to be judged by the ease with which instances of it can be retrieved from memory. People tend to overestimate the frequency of very rare, spectacular events and underestimate the incidence of more frequent, less spectacular events. Applied to crime, the *availability heuristic* predicts that when individuals hold a particularly resonant and vivid image of a risk object (of a given crime, say), they judge its likelihood to be especially high: they substitute a relatively difficult question (e.g., how likely is it that I will become a victim of crime?) with a relatively easy question (e.g., how easy can I imagine becoming a victim of crime?).

Why can some people easily imagine becoming a victim of crime? Potentially relevant here is Sunstein's (2005) notion of "availability cascades," which posits that hearing about events via interpersonal communication and the mass media can have an impact on public perceptions of risk, partly through an interaction between availability and particular social mechanisms:

> [there may exist] social cascades, or simply cascades, through which expressed perceptions trigger chains of individual responses that make these perceptions appear increasingly plausible through their rising availability in public discourse. Availability cascades may be accompanied by countermechanisms that keep perceptions consistent with the relevant facts. Under certain circumstances, however, they generate persistent social *availability errors*—widespread mistaken beliefs grounded in interactions between the availability heuristic and the social mechanisms we describe. [emphasis in original] (Kuran and Sunstein 1999, p. 685)

Applied to fear of crime, circulating information about crime may shape people's emotional and cognitive representations of personal risk, in part by increasing its cognitive availability. Fear-inducing accounts of events – such as the Boston Marathon bombing in May 2013 and the incident in 2002 in Virginia when two snipers killed ten people – may be highly publicized, noticed, and repeated, leading to cascade effects as the event becomes available to an increasing number of people.

Sunstein (2005, p. 93) also speculates that existing predispositions can determine in large part what individuals pay attention to. One example he gives relates to genetic modification of food. Those who are predisposed to be fearful of this issue are more likely to seek out information about genetic modification. Furthermore, "group polarization" describes how, when individuals discuss with each other certain events and risks, they typically end up with a more extreme view (p. 98).

The subjective threat of crime may thus become enhanced in people's minds. Vivid and dramatic images may raise subjective probabilities, in turn initiating worry. Frightening images may then lead some people to process risk information in more rapid and basic ways that are sensitive to the vividness and associations that a given risk evokes. The emotional impact of the associated outcomes of victimization may shape cognitive assessments of probabilities, and emotional appraisal of risk may hold sway over cognitive assessments – when emotions and thoughts diverge – in shaping people's behavior. If individuals find it difficult to accept the threat, then worry will continue in a persistent fashion over time (cf. Berenbaum 2010).

Criminological Work on the Fear of Crime

This section reviews how criminological research has defined and measured emotion and risk perception, before then addressing how criminological studies have explored the links between the two.

Risk Perception, Vulnerability and the Fear of Crime

Criminological studies typically ask individuals about the intensity with which they worry about falling victim of crime (Hough 1995) or the extent to which they are fearful of falling victim of crime (Ferraro 1995) – although some continue to use single indicators of subjective safety in the home and streets. Asking individuals how "afraid" or "worried" they are about crime, surveys direct people to their emotions about future harm. But worry (or fear) may be rarer than one might think. In a study based on British Crime Survey (known as Crime Survey for England and Wales since April 2012) data, more people expressed concern about future harm (i.e., they said they were worried at the time of the interview) than had worried recently (Farrall et al. 2009). A good proportion of individuals who said that they were "very" or "fairly" worried also reported that they had not worried even once over the past twelve months. Asking about *frequency* may thus be a useful supplement to asking about the *intensity* of worry or fear (Gray et al. 2011).

Criminological research typically measures perceived risk as solely subjective probability. Survey respondents are asked how likely they think it is that they will become a victim of crime (e.g., in the next year). But a number of studies have widened the focus beyond perceived likelihood. Drilling into perceptions of the possible impact and seriousness of crime and victimization (Warr 1987; Jackson 2011) as well as the sense of control over the event (Jackson 2009); such work shows the relevance of people's perceptions of the seriousness of the consequences *if they were to fall victim* and people's sense of control *over its occurrence*.

This work suggests that worry about crime is partly generated and sustained by a sense of risk, threat and vulnerability, comprised of perceived likelihood, consequence and control (*see* Killias 1990; Gabriel and Greve 2003; Farrall et al. 2009; Jackson 2009, 2011). Consistent with Berenbaum's (2010) account of the initiation of worry, people start to worry about crime when they see significant threat. And critically, subjective threat may extend beyond the chances of an event happening, to include its controllability and possible impact. The heterogeneity of different types of crime with regard to "relevance, explanation and consequences" (Gabriel and Greve 2003, p. 6) may mean that the same crime could have a different anticipated resonance or impact for one individual compared to another.

Introducing the notion of "perceptually contemporaneous offences," Warr (1984) posited that some criminal events are viewed as more dangerous than others by particular segments of the population (typically women and the elderly) due to the crimes they imply. As such, "... circumstances or events that appear innocuous or comparatively minor to males or younger persons are apt to be viewed as more dangerous to females and the elderly because of the offences they imply or portend" (Warr 1994, p. 19). Similarly, Ferraro (1995, p. 87) argued that sexual harassment "... may shadow other types of victimization among women. Rape may operate like any other master offence among women, especially younger women who have the highest rate of rape, heightening fear reactions for other forms of crime."

Relatedly, Warr's (1987) model of "sensitivity to risk" predicts that the influence of likelihood on fear is moderated by perceptions of seriousness of the given type of crime. Analyzing US data, he found that when people judged crime to be especially serious in its effect, a lower level of perceived likelihood was needed to stimulate some level of personal fear. Individuals were more "sensitive" to a given level of perceived risk when they viewed the consequences of victimization to be especially serious. The risk sensitivity model suggests that once individuals associate a risk with high personal consequences and low personal control, only a relatively small level of perceived likelihood is needed to elicit a strong emotional response (Jackson 2011).

There is a clear overlap between the notions of perceived risk and vulnerability (or susceptibility) to crime. According to Killias (1990), there are physical, social and situational dimensions of vulnerability, related to three aspects of threat: "exposure to non-negligible risk," "loss of control," and "seriousness of consequences." Crucially, perceived risk may mediate the association between markers of vulnerability (typically sociodemographic variables, such as gender and age) and expressed emotion. For example, Jackson (2009) found that females tend to worry more frequently than males partly because (a) they feel less able to physically defend themselves, (b) they have lower perceived self-efficacy, (c) they have higher perceived negative impact, and (d) they see the likelihood of victimization as higher for themselves and for their social group. Those with fewer resources – typically posited to be females, the elderly, and those in lower socioeconomic groups – may feel less able to protect themselves and deal with the consequences, and therefore they may be more likely to report being worried or fearful over falling victim of crime.

Applying the work on *risk as feeling* and *risk as analysis* to risk perception and fear of crime, one individual may associate burglary with the risk of physical or sexual assault, while another individual may associate burglary with the loss of material goods and a great deal of inconvenience. For the first person, the risk of burglary may be appraised through the affective route (in part because of the severe consequences and sense of uncontrollability of the perceptually contemporaneous offence of assault) leading to a feeling of vulnerability and susceptibility to crime. Risk in this case may be constituted by the resonance of the consequences, the uncontrollability of the outcome, the vividness of the event, and the ease with which one can summon up a frightening image. Such imagery of consequence and control may then raise the subjective probability of burglary. But it may also interact with the perceived likelihood to produce a strong emotional reaction (cf. Jackson 2011). By contrast, the second person may think about burglary more through the cognitive route, with the subjective likelihood being relatively low, and less influential in shaping emotion than some resonant image of the impact of the event and its controllability.

Risk Perception and Circulating Media Representations of Crime and Danger

One might assume that personal victimization experience is the main source of people's personal sense of vulnerability and risk. People may feel threatened about crime in part because they have recently been victimized. It may be, for example, that people who have been burgled have a strong sense of the severe consequences, can easily imagine it happening, and know something about its controllability.

Yet victimization experience is not a strong predictor of fear of crime (*see* inter alia Hale 1996). This may be because of what Winkel (1998, p. 477) calls "active adaptational coping," whereby the experience of victimization simultaneously raises one's perception of the likelihood of it occurring and lowers their perception of its negative impact if it were to occur again (e.g., the reality of burglary may not be as frightening as one imagines). More work is clearly needed, however, and Berenbaum's (2010) model of worry may be a helpful orientating framework for research into the effect of victimization on fear of crime, capturing the process of its initiation and continuation or termination over time.

If it is not (primarily) personal experience of criminal victimization, what drives people's perceptions of risk? Why does crime become a vivid, accessible, and easy-to-imagine prospect for some people, involving a sense of severe personal consequences, uncontrollability and unpredictability?

Clearly, the media are a primary source of information about the extent, nature, and seriousness of crime in most countries across the world. The media tend to report shocking but rare criminal events that are intriguing, dramatic, and sensational (*see* inter alia Weitzer and Kubrin 2004; Surette 2011). In a study of the reporting of murder in the UK, for example, Gekoski et al. (2012, p. 17) found that journalists tend to "…believe that certain types of murder – involving 'ideal' victims, unusual features, extreme brutality and serial killers – are almost always of interest to the public, while certain other types – involving 'undeserving' victims in commonplace circumstances – are almost always not."

Crucially, the mass media and interpersonal communication may be an important backdrop for a widespread psychological proximity of the threat of crime. While the fear of crime literature lacks a clear and robust evidence based on the relationship between media coverage and risk perception (although *see* Chiricos et al. 1997), it does seem plausible that people develop personalized images of risk partly as a result of hearing about specific events of crime via the media. High levels of coverage – biased towards the dramatic and sensational – may make the events cognitively available to people. Personal images of risk may develop, and through the media's focus on the highly consequential and uncontrollable, crime reports may end up stressing certain attributes of the criminal event which only increase the vividness of the representations. If many people develop their own sense of risk, based on common imagery of particularly frightening crimes, then it may not be very surprising that they worry about crime: they receive dramatic images of risk that become cognitively available and are processed in a more intuitive and experiential manner, which stresses affect, images, and vividness.

People might, for instance, come to associate burglary with violence in part because they receive and process striking reports of especially serious burglaries from the newspapers, television and other media. Hearing about specific (and local) events of burglary – which are brought home in a very vivid way, "as if it could happen to me," that resonate with their own experience (*see* inter alia Chiricos et al. 1997) – may then explain why people develop these personalized representations of the risk of crime, with all the attendant sense of severe consequences, loss of control, and high likelihood (Jackson 2011).

Risk Perception and the Social and Physical Environment

What about the neighborhood in which someone lives and resides? Does the social and physical environment matter?

Here the fear of crime literature is relatively strong. First, a number of studies have used multilevel models to situate individuals in their specific neighborhood context (e.g., Wyant 2008; Brunton-Smith and Sturgis 2011). Focusing on people's expressed feelings of local safety, Wyant (2008) found significant neighborhood-level clustering in Philadelphia. Similarly, Brunton-Smith and Sturgis (2011) found significant area-level clustering in worry about crime in neighborhoods across England and Wales.

It clearly matters where one lives. But what explains this neighborhood-level clustering? Perhaps the most complete study in this regard is that of Brunton-Smith and Sturgis (2011). Examining neighborhood effects across a full national distribution of neighbourhoods in and around a range of different urban, rural, and metropolitan contexts, they found that recorded crime, neighborhood structural characteristics, and visual signs of disorder (derived from survey interviewer ratings rather than respondent assessments) all had direct and independent statistical effects on the expressed intensity of worry about crime. Additionally, neighbourhoods predicted crime-related worry in more subtle ways, moderating the statistical effects of its individual-level causes: between-group differences in expressed worry about crime were both exacerbated and ameliorated by the characteristics of the areas in which people live.

Second, one's neighborhood matters but so also does one's adjacent set of neighborhoods. People seem to draw on environmental cues not just from their own immediate environment, but also from neighboring local areas, basing their judgements of risk on both the characteristics of their local neighborhoods and the characteristics of the areas visited during their routine activities. In statistical terms, this manifests itself as spatial autocorrelation, with higher than average similarities amongst neighbourhoods in closer proximity to one another, signalling the existence of shared characteristics and joint influences.

Wyant (2008) incorporated this additional spatial structure in an assessment of neighborhood effects on fear of crime. Across 45 local neighborhoods in Philadelphia, Wyant reports significant spatial autocorrelation in his measure of neighborhood fear. Analyzing data from the Crime Survey of England and Wales, Brunton-Smith and Jackson (2012) found that worry about crime was weakly related not just to levels of crime and disorder in one's own neighborhood but also to crime and disorder in adjacent areas. By incorporating information about those areas that surround each neighborhood, it was possible to estimate the extent of these shared influences as well as the extent to which individuals base their judgements on the broader local environment.

Third, people's *perceptions* of their neighborhood are key. The aforementioned work used recorded crime levels, neighborhood structural characteristics and visual signs of disorder to help explain some of the (immediate and adjacent) neighborhood effects. But many more studies have addressed people's perceptions of the immediate environment, investigating how individuals variously make sense of neighborhood disorder and collective efficacy. Importantly, disorder is any aspect of the social and physical environment that indicates to the observer

(a) a lack of control and (b) the values and intentions of others that share the space (*see* inter alia Skogan and Maxfield 1981; Ferraro 1995). Ferraro (1995) analyzed data from a nationally representative survey of US citizens, finding that people's perceptions of incivilities predicted their perceptions of the chances of victimization, which in turn predicted people's expressed fear of crime.

Farrall et al. (2009) found similar results, this time analyzing data from the British Crime Survey. Although they did not use a multilevel framework, their analysis did link neighborhood-level characteristics to worries and anxieties about crime through two layers of mediation: individual perceptions (of disorder and collective efficacy) and risk perception (i.e., subjective probabilities). The statistical effects of social and structural characteristics of the neighborhood seemed to be mediated through people's reading of social organization and disorganization.

The Social Perception of Disorder

People thus seem to "read" the character and intentions of certain individuals and groups – and the presence or lack of local social control – from the level of social disorganization in their neighborhood. But importantly, two individuals living in the same environment can come to quite different conclusions about the same environmental cues. A good deal of work suggests that people's perceptions of their neighborhood are dependent not just on the social and physical cues in the local environment but also on the respondent's *relationship* to that environment and others who inhabit it (e.g., Sampson and Raudenbush 2004). Some individuals judge certain stimuli as "disorderly," while other individuals in the same environment might not, with people ascribing meaning to disorder they see in front of them (see Wickes et al. 2013).

An individual's existing attitudes, beliefs, or prejudices seem to provide a filter through which they experience and interpret their environment. Ambiguous cues need to be defined by the observer as "disorderly" *in the first place*. Exploring the basis on which individuals formed perceptions of disorder, Sampson and Raudenbush (2004) reasoned that citizens interpreted objective signs of disorder (measurable signs of litter, vandalism, graffiti, etc.) through existing and historical stereotypes of race and deprivation (see also Chiricos et al. 1997). Their work suggested that observers in Chicago not only infused disorderly cues with notions of race and deprivation; they also had existing cognitive representations or stereotypes that linked disadvantaged minority groups with "social images, including but not limited to crime, violence, disorder, welfare, and undesirability as neighbors."

Jackson (2004) also found that some people judged particular ambiguous stimuli as "disorderly" and representational of criminal threat, while other people in the same environment judged the same stimuli as benign and unthreatening. Respondents who held more authoritarian views about law and order, and who were concerned about a long-term deterioration of community, were more likely to perceive disorder in their environment. They were also more likely to link these physical cues to problems of social cohesion and consensus, declining quality of social bonds and informal social control (cf. Farrall et al. 2009). The symbolic nature of social order seemed to generate meaning in the context of their relationship to long-term social change and people's anxieties about cohesion and moral consensus.

In an important qualitative study, Carvalho and Lewis (2003, p. 791) explored how reactions such as fear, safety, and anger were dependent on personal distancing from issues of crime and disorder:

> The more distant the relationship, the less salient these problems, as dangers, are in the context of daily routines and the less they intrude in one's life. With close relationships, crime and incivilities occupy a central position in one's daily life. These problems appear isolated, detached from other domains of life, imposing themselves onto the person as dangerous (raising fear) or as bothersome (raising anger). With distant relationships, on the other hand, crime/incivilities are peripheral to the person. The dangers of these problems are part of life, and qualities other than their dangerousness are apparent. Peripheral relationships with crime/incivilities accompany a neutral reaction of safety (neither fear nor revolt).

Carvahlo and Lewis's (2003, p. 791) data suggested that individuals can neutralize dangers when they view crime/incivilities as "banal events . . . Dangers are contextualized temporally, referred to the past, with the idea that they have been there, they have existed, and they are ordinary." Dangers might also be neutralized when they are "delimited": "when they lose their random character (thus, the potential to affect just anyone) and become restricted to certain places of the neighbourhood and times of the day (physical delimitation), or to groups of people (social delimitation)" (p. 794).

Final Thoughts and Future Directions of Research

More work is needed on the links between emotion and risk perception in fear of crime. Studies need to address how people develop a sense of threat and psychologically try to manage that threat. The distinction between *risk as feeling* and *risk as analysis* may be especially important, exploring whether risk, circulated chiefly by the mass media and interpersonal communication, may be judged cognitively *and* emotionally. People may process information from the mass media (and interpersonal communication) using both analytical and associational routes. When the emotional appraisal of the threat of crime (using a more associationist rather than formal mode of information processing) differs to a cognitive sense of its likelihood, feelings may hold sway, and if crime is judged to have severe consequences and the outcome is vivid and affect-laden, then an individual may be insensitive to probability variations. That individual is thus unlikely to feel better if she or he is told that their chances of victimization are rather slight.

A feedback system might also mean that someone already emotionally animated by risk builds over time a more extensive and vivid image of the risk event, fleshing out effects, protagonists, and relevant causes and circumstances. This might then make the risk more substantial, structured, and relevant to that individual. Emotional systems may lead to the structuring and differentiating of risk images, personalizing them, fleshing them out, and bringing affect into the picture (Jackson 2011, 2012).

In addition, more work is needed to explore neighborhood context, social perception, and circulating images of crime in the context of the links between emotion and risk perception. Studies need to address the particular set of evaluative activities that links crime – in the eyes of observers – with certain individuals or groups that are judged to be (a) hostile to the local social order, (b) untrustworthy, and (c) representative of some sort of social breakdown. Such work should assess how the risk of crime is projected into a given environment and elaborated with a face (the potential criminal) and a context (the place it might happen). It should consider how emotion and risk perceptions disclose a whole host of subtle evaluations of and responses to the social world – a way of responding to variable levels of social order and control, a sense of unease in an unpredictable environment, and the association of particular individuals or conditions with deviance and hostile intent. Fear of crime may thus be both an expressive and experiential phenomenon (Jackson 2004).

In this respect, perceptions of crime risk may reveal processes of designation (where certain groups, behaviors or community conditions are labelled as potentially criminal and dangerous). Crime may be used as a way of articulating evaluations of people, community conditions, and social control, a lens through which people understand social order, low-level deviance, and diversity. The identification of dangerous individuals may operate to establish "moral communities" by locating "immoral communities." Stereotypes of particular groups may operate as distancing strategies for placing others, perpetuating normative boundaries of social conduct, roles and judgements, and strengthening one's own social identity. They may reinforce the boundaries and identity of a given community by identifying what that community is against, e.g., certain troublesome individuals or particular groups defined by their social class or their ethnicity. Social psychology shows that the identification of an out-group can act to strengthen in-group solidarity. Scapegoating may also arise, where one group comes to embody a particular social problem. Such evaluative activity, if this analysis is correct, reveals how people define social order and what they think is hostile to social order. It also means that risk is culturally conditioned: what one defines as dangerous depends on where one stands.

Criminological research shows that the fear of crime is a complex social phenomenon and a multi-faceted construct. Fear of crime clearly expands far beyond direct victimization experience and probabilistic evaluations of its occurrence, comprising multiple psychological and social phenomena – such as wider worrying mechanisms, perceptions of one's physical and social environment, and individuals' prejudices and stereotypes. But more work is needed to capture the complexity and multi-dimensionality of this important social and political phenomenon. Bridging sociological and psychological modes of analysis can open up new avenues of research, providing us with more powerful analytical perspectives to understand the causes, nature and effects of fear of crime.

Feminist Criminological Theory

Amanda Burgess-Proctor
Criminal Justice, Oakland University, Rochester, MI, USA

Overview

Informed by the observation that feminist criminology is *both* readily embraced by the discipline *and* still isolated from "core" theoretical knowledge, this entry examines two areas in which cutting-edge feminist scholarship is occurring: advancements in feminist criminological theory and feminist refinements of traditional criminological theory. The first half of this entry considers innovative applications of the intersectional theoretical framework to several areas of feminist criminological scholarship, with a particular focus on studies examining violent victimization among girls and women of color. The second half of this entry highlights efforts to infuse gender into mainstays of criminological theory from which gender has long been absent, including life course, social control, and social learning theories. Taken together, the exemplary studies highlighted in this entry demonstrate the important scholarly developments occurring within contemporary feminist criminological theory.

> If a prominent goal in much of the criminological enterprise is the creation of general theories. . ., feminist criminology has not been particularly successful. However, it is precisely feminist understandings of gender that require us to move beyond what broad, global explanations can provide. (Miller and Mullins 2006, p. 221)

Introduction

In her 1998 commentary on gender, crime, and criminology, Daly identified two distinct and divergent areas of theoretical development that served as sources of "field expansion" in criminology: criminological scholarship largely uniformed by feminist knowledge and feminist scholarship largely uninformed by criminological knowledge (p. 86). As Daly noted at that time, "Some feminist scholars in criminology straddle both sources of knowledge, and others may work from the second source to challenge criminological thought and to build from feminist theories" (p. 86). In the 15 years since that writing the gulf between criminology-proper and feminism-proper has narrowed, allowing contemporary feminist criminologists less time for straddling and more time for advancing knowledge. Indeed, recent theoretical innovations continue to push feminist criminology in new directions and into new applications, and this work is published in a previously unthinkable number of outlets (including the journal *Feminist Criminology*) to a seemingly ever-expanding and ever-receptive audience.

Though narrowed, the troublesome divide between criminological and feminist knowledge persists,and this disjuncture is driven more by perceived ideological differences than actual theoretical or empirical differences. Feminist criminological theories still routinely are positioned in opposition to "traditional" or "mainstream" theories. This is problematic because the characterization of feminist perspectives as "nontraditional" or "nonmainstream" risks giving the impression that they are nonnormative or lack the empirical rigor of those dominant theories, as some critics have (wrongfully) claimed. Still, the distinction between "traditional/mainstream" and "feminist" theories in criminology is perhaps best understood, to use an illustrative shorthand, as the difference between theories occupying the bulk of undergraduate theory textbooks and those relegated to a chapter or section at the end.

This delicate reality – that feminist criminological scholarship is simultaneously far more enthusiastically embraced than ever before, while still regularly positioned outside fundamental, core sources of theoretical knowledge – puts contemporary feminist criminology in a somewhat precarious position. Using the feminist "both/and" concept (Collins 2000; Daly and Stephens 1995), one may consider feminist criminology to be *both* a legitimate source of theoretical knowledge *and* auxiliary to core criminological theories – and, therefore, denied a position of theoretical privilege in the discipline.

Of course, feminist perspectives were developed to correct the absence of gender from the long line of traditional theories representing the pillars of criminology. Feminist criminologists have criticized the long-standing exclusion of girls and women – indeed, of *gender* – from nearly every theory developed to explain offending (Belknap 2007; Daly and Chesney-Lind 1988; Miller and Mullins 2006; Simpson 1989). Even today, "key contemporary schools of thought in criminology have yet to adequately incorporate gender" (Miller 2010, p. 136). Feminist criminologists' response to this oversight generally has taken two forms: (1) efforts to advance feminist, gender-specific criminological theories, and (2) efforts to refine "traditional" theories of offending using feminist insights (e.g., see Daly and Chesney-Lind 1988). These strategies raise an obvious question: "[g]iven that traditional criminological theories are posited to be gender-neutral (and universal) yet have been developed without consideration of how gender structures human behavior, what are the implications of theories that ignore gender in the face of real-life gender inequality and discrimination?" (Burgess-Proctor 2010, p. 433).

Informed by the observation that feminist criminology is *both* readily embraced by the discipline *and* still isolated from "core" theoretical knowledge and guided by the two approaches feminist scholars have taken to address the absence of gender from mainstream criminological theories, this entry examines two areas in which cutting-edge feminist scholarship is occurring: advancements in feminist criminological theory and feminist refinements of traditional criminological theory. Importantly, these two areas reflect Daly's (1998) conceptualization of efforts to advance feminist criminological scholarship from either its criminological or its feminist source.

Cutting-Edge Advancements in Feminist Criminological Theory

In their recent commentary offering an evaluation of feminist theory in criminology, Miller and Mullins (2006) draw upon Daly's (1998) conceptual schema to identify three core areas of feminist criminological inquiry: (1) *gendered pathways to lawbreaking*,

(2) *gendered crime*, and (3) *gendered lives*. First, *gendered pathways* research explores how men and women differentially initiate, continue, and terminate offending trajectories. Second, *gendered crime* research examines the types, contexts, and consequences of men's and women's offending behaviors, as well as the extent to which criminal justice processing of those offenses also is gendered. Third, *gendered lives* research examines how gender structures the broader lived experiences of girls and boys, which may facilitate (or protect against) victimization and offending opportunities. These three areas of inquiry are useful for evaluating cutting-edge work in contemporary feminist criminological theory.

Perhaps the most important advancement in feminist criminological theory has been the development of intersectional scholarship that simultaneously attends to the interlocking and interacting forces of race/ethnicity, class, gender, sexuality, age, and other systems of power (see Burgess-Proctor 2006 for a review). Both intersectional scholarship and feminist criminology share common goals: (1) to develop theoretical frameworks that account for structuring forces like gender, race/ethnicity, and class; (2) to utilize methodologies that give voice to groups whose experiences previously have been overlooked; and (3) to bridge theory and practice with an eye toward improving social justice for marginalized groups (Burgess-Proctor 2006). Indeed, intersectionality is particularly relevant to feminist criminologists because it considers how intersecting systems of race, class, and gender make marginalized groups more vulnerable to criminal legal system control (Sokoloff and Burgess-Proctor 2011).

Intersectional scholarship perhaps most closely aligns with the *gendered lives* area of inquiry, which Miller and Mullins (2006) note has been least empirically examined but may be most ripe for exploration. Contemporary feminist criminologists are performing intersectional analyses of a range of important criminological issues, including gender violence in the lives of urban girls of color, marginalized women's experiences with intimate partner abuse (IPA), and other areas beyond women and girls' violent victimization.

Girls of Color and Urban Gender Violence

Two recent works exploring how inner-city Black girls' victimization and offending experiences are simultaneously raced, classed, and gendered are good examples of cutting-edge, intersectional feminist criminological theorizing. First, Jody Miller's (2008) book *Getting Played* examines the lives of Black girls in impoverished St. Louis neighborhoods. Miller interviewed 75 youth (35 girls and 40 boys) ages 12–19 about their experiences with three types of gender-based aggression: sexual harassment, sexual coercion and assault, and dating violence. Summarizing her findings, Miller writes: "Urban African American young women face widespread gendered violence that is a systematic and overlapping feature of their neighborhoods, communities, and schools. In addition, while young women employ a variety of strategies to insulate themselves from such violence, they do so in a context in which ideologies about gender work against them at every turn" (p. 192). By virtue of their race and class status, and the structural inequalities that contribute to the impoverished communities in which they live, these girls "have limited support and few avenues – institutional or otherwise – for remedying the systematic nature of the gendered dangers present in their daily lives" (p. 192).

Second, targeted at the same population of girls in Philadelphia, Nikki Jones' (2010) book *Between Good and Ghetto* offers a similarly nuanced portrait of how race, class, and gender shape inner-city Black girls' lived experiences. The result of 3 years of ethnographic field work and research, Jones' analysis uncovers how deeply entrenched and intersecting systems of race, class, and gender shape the ways girls vacillate between conforming to ("good") and violating ("ghetto") expectations of Black femininity and respectability. Jones writes: "Inner-city girls who live in distressed urban neighborhoods face a gendered dilemma: they must learn how to effectively manage potential threats of interpersonal violence…at the risk of violating mainstream and local expectations regarding appropriate feminine behavior. This is a uniquely difficult dilemma for girls, since the gendered expectations surrounding girls' and women's use or control of violence are especially constraining" (p. 9).

Both studies uncover similar findings that significantly illuminate our understanding of how urban gender violence is simultaneously raced and classed, making them important contributions to feminist criminological theory. First, violence is endemic to the lived worlds of inner-city Black girls; they experience violent victimization and exposure to violence at home, in their neighborhoods, and in their schools. Second, the social mechanisms governing whether, why, and to what extent inner-city Black girls use and receive interpersonal violence are highly gendered, raced, and classed. Third – and this is perhaps the most distressing finding of both books – inner-city Black girls often are left to navigate, negotiate, and survive the violence in their lives by themselves. Finally, inner-city Black girls are forced to adopt survival strategies, including "situational avoidance" (Jones 2010) and isolating themselves in their homes (Miller 2008), that are damaging, disruptive, and likely to serve them poorly later in life. These maladaptive survival strategies may disadvantage girls who go on to experience intimate partner abuse (IPA) – a second source of cutting-edge intersectional feminist criminological theorizing.

Marginalized Women's IPA Victimization

An increasing body of intersectional scholarship in feminist criminology addresses marginalized women's experiences with IPA victimization. Feminist scholars who study IPA have advocated for intersectional theoretical models of both men's battering and women's responses to victimization that include, but do not prioritize, gender (e.g., see Sokoloff and Pratt 2005). For example, Potter's (2006) Black Feminist Criminology perspective aims to identify the structural, cultural, and familial forces that shape Black women's responses to IPA. Potter (2006) describes her perspective as moving "beyond traditional feminist criminology to view African American women (and, conceivably, other women of color) from their multiple marginalized and dominated positions in society, culture, communities, and families" (p. 107). This observation echoes findings from Miller's (2008) and Jones' (2010) research, which unsurprisingly documented high exposure to IPA among their samples. And, as Miller (2008) notes, even instances of IPA among adults outside youths' own families of origin (e.g., between neighbors, acquaintances, or even strangers) are still important modeling opportunities for children who witness them. Thus, the experiences of women – particularly marginalized women – with IPA victimization are most appropriately theorized using an intersectional framework, as recent feminist criminological scholarship demonstrates.

Beyond Violence: Other Applications of Intersectionality

Finally, contemporary feminist scholars are applying an intersectional race/class/gender framework to criminological topics that go beyond women and girls' violent victimization experiences. For example, Sokoloff and Burgess-Proctor (2011) use an intersectional lens to examine how contemporary US drug policy – specifically, the mass incarceration of drug offenders and restrictive ex-offender policies – disproportionately disadvantages poor women of color. Meanwhile, Erez and Berko (2010) draw upon an intersectional framework to explore the pathways to crime and imprisonment of Arab/Palestinian women living in Israel. Finally, Benson and Simpson (2009) use a race/class/gender perspective to consider a subject typically outside feminist purview: how opportunities for white-collar crime are differentially distributed across groups in society. As these examples reveal, contemporary feminist criminologists are using an intersectional framework to perform cutting-edge research and theorizing on a wide range of important criminological topics.

Efforts to Refine "Traditional" Criminological Theories Using Feminist Insights

Whereas the examples in the previous section are best thought of as existing within the feminist body of knowledge, cutting-edge feminist theorizing also is occurring in the criminological body of knowledge. Efforts to impart feminist insights into mainstream criminological scholarship are evident in recent feminist refinements of the life course theoretical model, as well as social learning and social control models.

Life Course Theoretical Model

In recent years, one framework in particular has been notably expanded and advanced by feminist scholars: the life course theoretical model. As its name suggests, the life course model examines the development of human behavior over time and in the context of historical and situational events and is characterized by "the notion that changing lives alter developmental trajectories" (Elder 1998, p. 1). Within criminology, the life course model is used to examine patterns of offending and desistance over time. The last two decades have seen a proliferation of life course criminological research. Perhaps the best known and most influential application of the life course model in criminology is Sampson and Laub's (2003, 1993) research on Boston-area delinquent boys using data originally collected by Harvard researchers Sheldon and Eleanor Gleuck (see Sampson and Laub 2005 for a review).

Broadly, feminist refinements of the life course theoretical model in criminology have taken two forms. The first type of feminist refinement is feminist pathways research. The Feminist pathways model is an extension of the life course criminological framework that examines women's and girls' offending behaviors in the context of their past victimization experiences. The feminist pathways and life course models share many similarities, including a focus on trajectories of behavior like offending and desistance and the role of transitions in altering or shaping those trajectories. While both models attempt to explain and predict offending over time, the feminist pathways model specifically considers how women's (and girls') prior victimization experiences initiate or facilitate offending pathways (Burgess-Proctor 2011; Gaarder and Belknap 2003; McDaniels-Wilson and Belknap 2009).

The second type of feminist refinement might be loosely termed "gendered pathways." In contrast to feminist pathways research that specifically considers the role of women's victimization experiences in their subsequent offending, gendered pathways analyses view life course processes through a gendered lens; in other words, these analyses seek to uncover how, why, and in what ways gender structures motivations and opportunities for both offending and desistance. (Of course, when gendered pathways studies examine only women's experiences without also including the experiences of men, the extent to which the processes they uncover are accurately termed "gendered" remains unclear.) While these analyses may be less likely to bear the "feminist" label than studies using the feminist pathways model, they nonetheless accomplish a primary objective of feminist criminology: exploring the meaning and nature of gender relations (e.g., see Miller and Mullins 2006).

Cutting-edge feminist pathways research in criminology continues to proliferate. Much of this scholarship highlights how women's trauma histories initiate subsequent offending pathways (Gaarder and Belknap 2003; McDaniels-Wilson and Belknap 2009; Simpson et al. 2008). For example, Simpson et al. (2008) found that girls who were sexually abused before sixth grade and who had consensual sex before age 13 were three and a half times more likely than other women to be childhood onset offenders. Another good example is Caputo's (2008) *Out in the Storm*, an ethnographic study of 38 drug-addicted women living as shoplifters and sex workers. In a succinct summation of the feminist pathways approach, Caputo notes of her participants: "Childhood trauma occurring within the home resonates as the first important part of women's journeys to drugs and crime... This [trauma] triggered a wave of negative reactions, a misdirected coming of age during the women's adolescence that would carry through life" (pp. 27–28). Finally, still another refinement comes from feminist efforts to apply the life course model to *non-offending* outcomes. For example, the feminist pathways model has been used to explain how battered women's past victimization experiences can initiate help-seeking trajectories that guide their response to IPA over time (Burgess-Proctor 2011).

Likewise, it is easy to find examples of cutting-edge gendered pathways research in criminology. At the forefront is Peggy Giordano's (2010) magnificent *Legacies of Crime*, a longitudinal study of children whose parents were incarcerated as teens. Giordano uses three waves of data collection: (1) initial interviews with teenage offenders at the time of their incarceration, (2) follow-up interviews with the now-adult participants 14 years later, and (3) subsequent interviews with participants and their children several years after that. The study explores both the gendered and "generic" family dynamics that foster the intergenerational transmission of offending, violence, substance abuse, and other antisocial behaviors over time.

Giordano's (2010) analysis constitutes cutting-edge feminist theorizing because it imposes a gendered lens on the traditional life course approach to studying the intergenerational transmission of violence and offending:

> If an essential theme within the mostly male tradition of life-course research is that of continuity and change, core concerns within the gender and crime literature are questions of similarity and difference. Thus, researchers continue to grapple with the issue of whether and to what degree theoretical perspectives, and even basic facts about crime that developed largely around male-focused studies, "fit" with the life experiences of women and girls...Focusing only on [generic, as opposed to gendered] features of the women's lives, however, ignores many of the realities that have been effectively depicted by feminist researchers. (pp. 19–24)

These gendered realities, Giordano notes, necessarily shape a young woman's family environment as well as her parenting practices – both of which have implications for the intergenerational transmission of antisocial behavior (p. 24).

There are other noteworthy examples of gendered pathways research. For example, several recent studies have attempted to predict women offenders' recidivism risk over time using a gendered pathways approach (Huebner et al. 2010; Reisig et al. 2006). Likewise, Block and colleagues (2010) do a masterful job of exposing the absence of gender in life course criminology by evaluating whether Farrington's (2003) "widely accepted conclusions" about criminal career research are applicable to, or reflect the experiences of, female offenders. Examining offending pathways of a nationally representative sample of offenders in the Netherlands, the authors found that women were significantly more likely than men to begin offending in adulthood (mean age of onset: 21.5 for men versus 29.3 for women). Noting that age of onset is a key indicator in criminal careers research, the authors caution: "the findings of significant gender differences in age of onset...not only challenge widely accepted conclusions of developmental life-span criminology but also require us to rethink life-span patterns in and out of crime for women" (p. 93). Finally, examining how the consequences of incarceration are gendered, Block et al. (2010) observe that imprisonment is not just damaging to the woman herself but also to the loved ones for whom she cares. This observation echoes Giordano's (2010) conclusions about the gendered impact of parental (and especially *maternal*) incarceration on young people's criminal propensity – both observations not easily made without a gendered pathways perspective.

Social Learning and Social Control Theories

The life course model is not the only criminological theory to have undergone feminist revision in recent years. Feminist scholars have offered refinements of two other titans of criminological theory: social learning theory and social control theory.

Throughout criminology, social learning explanations of offending have been rooted in "differential" models, including differential association and differential reinforcement. These theoretical models propose that individuals learn criminal behavior through exposure to some pro-crime, learning-facilitating mechanism. In Sutherland's (1924) differential association theory, that mechanism is definitions favorable to lawbreaking; in Akers' (1973; Burgess and Akers 1966) differential reinforcement model (often referred to in criminology simply as "social learning theory"), that mechanism is crime-reinforcing stimuli. In other words, differential exposure to these mechanisms distinguishes between people who learn to commit crime and people who do not (i.e., whose exposure was insufficiently high).

In contrast, social control theories start from the opposite approach: social control theorists assume that lawbreaking is a natural tendency and that, absent sufficient controls, people left to their own devices will become deviant. Therefore, social control models seek not to explain offending but rather to explain conformity – that is, what allows law-abiding people to resist their natural desire to offend. Arguably the most well-known social control theory in criminology belongs to Hirschi (1969), who theorized that strong bonds to pro-social others facilitate conformity. As any undergraduate theory student can no doubt recite, Hirschi (1969) articulated four elements of a social bond: attachment, commitment, involvement, and belief. For Hirschi – at least until the emergence of his later, self-control model (Gottfredson and Hirschi 1990) – people with attachment to law-abiding role models, commitment to pro-social goals, involvement in pro-social activities, and belief in good citizenship are predicted to experience sufficient social control so as to keep them from engaging in deviance.

As with the life course model discussed previously, both the social learning and social control models have undergone feminist reinterpretation in recent years. In fact, Giordano's (2010) aforementioned study is theoretically important for a second reason: it offers a gendered refinement of the traditional social learning model. While Giordano explicitly states that traditional frameworks like social control and social learning should not be abandoned, she recognizes that "attention to gendered processes" also is crucial for developing comprehensive, integrated, and fully realized theoretical explanations of girls' and women's criminal involvement (p. 21). Indeed, Giordano's revision of the traditional social learning model incorporates elements of symbolic interactionist and feminist theory to identify three concepts that are particularly relevant to girls' offending pathways: self and identity, agency, and emotion (p. 30).

Recent scholarship has likewise offered a gendered refinement of the traditional social control model. Notably, Zimmerman and Messner (2010) explore the effect of neighborhood disadvantage on the gender gap in adolescent violent crime. Using data from Chicago neighborhoods, the authors found that, as expected, exposure to violent peers increased (for girls and boys alike) as neighborhood disadvantage worsened, but the effect of violent peer exposure was more pronounced for *girls* than boys. Thus, their original social control explanation – that informal social control is a stronger buffer against violent peer influence for girls than boys – was not supported. Instead the data suggested a more "complex causal chain," leading the authors to "reaffirm the fundamental premise of feminist perspectives: explaining social phenomena requires an understanding of 'gendered lives'. . .Such variation likely reflects the different ways that gender organizes" daily life (p. 974). As with social learning theory, then, social control theory also has undergone refinement by contemporary feminist scholars.

Conclusion: Making Connections to Narrow the Theoretical Divide

The examples in this entry make clear the abundance of truly innovative and impressive theory development that is occurring in contemporary feminist criminology. While it is true that cutting-edge feminist theorizing may be broadly divided into efforts to *advance feminist criminological* *theory* and efforts to *refine mainstream criminological theory*, these initiatives do not operate entirely apart from one another's influence. Indeed, as these two bodies of scholarship share a common goal – the infusion of gender (and other social systems) into contemporary criminological theory – there are plentiful examples of cross-fertilization between the two. As each enterprise necessarily informs the other, a series of theoretical and empirical questions remain.

For example, given that Black girls living in distressed urban neighborhoods are highly likely to experience sexual victimization (Miller 2008), and that sexual victimization is an important predictor of women's later offending (McDaniels-Wilson and Belknap 2009; Simpson et al. 2008), how do we contextualize poor, Black women's offending? Moreover, given that their social marginalization sharply limits the survival strategies of inner-city Black girls to include primarily isolation and social withdrawal (Jones 2010; Miller 2008), how can we better understand their responses to intimate partner victimization later in adulthood (Burgess-Proctor 2011; Potter 2006)?

Additionally, delinquent peers are a demonstrated risk factor for youth-onset offenders (Simpson et al. 2008). How does this finding square with Zimmerman and Messner's (2010) findings about the effect of delinquent peer relationships on girls versus boys? How are the processes governing the effects of delinquent peer attachment gendered (and/or raced and classed)? Does delinquent peer attachment vary according to peer group sex composition (Zimmerman and Messner 2010)? Further, in light of evidence suggesting gender differences in adult-onset offending (Block et al. 2010), how do peer influences shift and change over time, and how does their relevance differ for boys and girls versus adult men and women?

Answers to these questions and other similar inquiries will no doubt be the focus of cutting-edge feminist criminological theorizing in the coming years. But what will be the status of feminist theory in the overall discipline a decade from now? Despite over 40 years of scholarship, "traditional" and "feminist" theoretical frameworks today still are cast in opposition to one another. Acceptance of this (false) dichotomy remains an entrenched problem in criminology.

For example, in the introduction to their comprehensive anthology assessing the current state of criminological theory, Cullen et al. (2006) remark: "Because they [were] invented by males, written about males, and originally tested on males, feminist scholars see traditional or core theories as 'men's theories' that do not capture the special circumstances inherent in women's criminality" (p. 15). Leaving aside the troubling assumption that only feminist scholars can "see" the problem with compulsory generalization to women of theories developed for and tested exclusively on men, the most vexing aspect of this statement is the positioning of life course, social control, and social learning theories as "core" frameworks to which feminist perspectives stand in opposition. As the examples offered in this entry reveal, cutting-edge work in feminist criminological theory engages and uncovers social mechanisms that cut to the very core of criminological and sociological theorizing, despite their continual categorization as derivatives of mainstream theory. Hopefully, as exemplary feminist scholarship continues to inform, refine, and reconceptualise both "traditional" and feminist criminological theories, the latter will come to be viewed by the discipline as "mainstream" explorations. Indeed, perhaps feminist criminological scholarship will truly have found its cutting edge when the theoretical and ideological divide between mainstream and feminist bodies of knowledge has disappeared altogether, and feminist perspectives are presented as core theoretical contributions in their own right.

Feminist Theory and Domestic Violence

Jo Dixon
Department of Sociology, New York University,
New York, NY, USA

Overview

For much of the past, US society turned a blind eye to violence between intimates. However, with the emergence of the progressive movement in the early 1900s and the women's movement in the 1960s, domestic violence began being constructed as a social problem worthy of attention by academics, policy makers, and the criminal justice system. Feminist constructions of domestic violence as a social problem vary and range from early constructions focusing on family preservation to later ones emphasizing mental illness, sex differences in intersubjectivity, male domination, family conflict, and survival. Portending to reduce and/or punish domestic violence, concomitant state social control mechanisms emerged. This entry traces the feminist constructions of domestic violence as a social problem as well as the relationship of these constructions to the social control mechanisms employed by state institutions, especially the criminal justice system.

Domestic Violence: Preserving Family and Disciplining Poor Families

Prior to the 1870s domestic violence in the USA was constructed as a private family matter, and the major social control mechanism was the interwoven fabric of family, church, and state constituted by Christian morality. The legal system of this period was a combination of English common law and the Holy Bible. While Puritan church courts tried domestic violence cases, the focus was on preserving the family rather than punishing wrongdoing. Moreover, most congregations accepted a sinner's confession, and only a few dozen cases per year involved any type of discipline (Pleck 1987). Although the Massachusetts Body of Liberties of 1641 and the 1672 law against spouse abuse made wife beating illegal, society accepted hierarchical relationships and the use of physical force by parents, husbands, and masters (Pleck 1987). By the 1700s the "rule of thumb" principle was established by an English judge and reinforced in the early 1800s by Southern appellate courts ruling that a husband could beat his wife as long as the beating tool was no thicker than a man's thumb.

In the late 1800s and early 1900s, the women's progressive movement lobbied for women's participation in the public sphere, but they did not place the private sphere and domestic violence as a high priority among their legislative and judicial agendas. However, there were indirect campaigns against domestic violence through the temperance, child-welfare, and purity movements aimed at disciplining minority, immigrant, and the working class families. One of the institutional legal developments during this period was the court of domestic relations, a tentacle of the early welfare state and the forerunner of today's family court. The domestic relations court personnel consisted of welfare officials, social workers, police, and prosecutors involved in the protection of dependent mothers and children. The court's main agenda was to discipline poor families and force husbands to be sober, work, and financially support their dependent wives and children (Willrich 2003). While police often encountered domestic violence, unless the violence was extremely severe, they would not arrest anyone. In some states, severe cases of domestic violence were punished via the whipping post. However, since forcing husbands to financially support wives and children was central, neither wives nor the state showed much interest in the imposition of jail or prison for domestic violence offenders. Throughout this period, some legislatures advanced making domestic violence illegal, but the criminal justice system turned a blind eye when it came to arresting and prosecuting batterers. Thus, domestic violence remained a private family affair to be ignored or resolved by informal dispute resolution in civil domestic relations courts.

Domestic Violence: Mental Illness

With the development of psychoanalytic theory in Europe and the USA, a construction of domestic violence as mental illness emerged in the 1940s. While male batterers were labeled as emotionally disturbed, the primary focus centered on female victims whose victimizations were attributed to sexual problems or a masochistic personality whereby victims provoked violence and subsequently remained in violent relationships. Only psychoanalytic therapy could uncover the unconscious motivations that led battered women to search for and stay with their batterers. Alternative psychological constructions challenged Freudian theories and linked domestic violence to cognitive or behavioral processes that could be diagnosed and treated by other forms of therapy. Feminists in the American Psychological Association opposed including the masochistic personality disorder in the DSM (Diagnostic and Statistical Manual of Mental Disorders) which was becoming the major diagnostic tool used by psychologists, psychiatrists, and insurance companies. While the masochistic disorder was blocked, an alternative category called the self-defeating disorder was included.

One of the major feminist opponents to the masochistic or self-defeating constructions of battered women was Lenore Walker (1979) who called the psychological effects of the trauma produced by domestic violence “the battered women’s syndrome.” Unlike earlier psychological perspectives arguing that women with particular psychological pathologies enter into battering relationships, Walker proposed a feminist theory arguing that psychological pathologies followed the trauma of battering. As an expert legal witness, Walker became instrumental in promoting feminist therapy and changing the image of battered women in the legal system. Nonetheless, supporters of psychological constructions of domestic violence as mental illness advocated individual and couples therapy as the appropriate mechanism for alleviating domestic violence.

Domestic Violence: Institutional Sex, Family and Legal Inequality, or Family Conflict

In the 1980s feminist theories of violence against women grew (Gilligan 1982; MacKinnon 1987), and in the 1990s feminist sociologists and criminologists began conducting empirical studies to identify the demographics of battering. Though domestic violence occurs across all race, class, educational levels, and age groups, sociological studies consistently showed that violence, whether it be in the public or private sphere, is more likely to occur among those who are black, lower class, less educated, and young (Fagan and Browne 1993; Kruttschnitt 1993). However, the most contentious debate focused on whether domestic violence, like crimes in the public sphere, was sex asymmetrical with men being more likely to engage in violence or whether men and women equally engage in violence in the private sphere.

Domestic Violence: Female Victims of Sex, Family, and Legal Inequality

During the 1980s radical and cultural feminist constructed domestic violence as a binary sex asymmetrical social problem caused by sex differences and sex inequality in the social institutions of sex, family, and law. Because both cultural and radical feminist theories of domestic violence constructed domestic violence in terms of group membership and focused on the patriarchal institutions of sex, family, and law, the issue of male victimization was ignored. Cultural feminists attributed violence against women to sex differences in intersubjective understandings of males and females (Gilligan 1982) with the males' voice being dominant in institutions, while radical feminists pointed to the role of violence and sex inequality in the male domination of women (McKinnon 1987). However, unlike those who focused on mental illness, both viewed cultural and structural changes in sex, family, and legal institutions as the social control mechanism for dealing with domestic violence. Cultural feminists argued for consciousness-raising about domestic violence and rallied for more sex equality by introducing the *female voice* in institutional reforms of sex, family, and law, while radical feminists lobbied for institutional reforms in sex, family, and law that created more sex equality by reflecting women's *interests*.

Along with grassroots organizations, cultural and radical feminists viewed domestic violence as a public rather than private family matter. Thus, they supported state aid to women's shelters where battered women could escape their battering, engage in female consciousness-raising about domestic violence, and increase their economic independence. A small number of feminists argued for more criminal justice involvement such as battering programs and rehabilitation *or* arrest and incarceration. However, most feminists were skeptical of criminal justice interventions, maintaining that victim empowerment would be better served by paying attention to the interests and voices of battered women. In addition, most believed that arrest policies without economic resources for victims would keep women in abusive relationships or lead them and their children to a life of poverty if they left their batterers.

Domestic Violence: Male and Female Victims of Family Conflict

While radical and cultural feminists continued to lobby for judicial and legislative reforms that would improve the status of women as a class, liberal feminists and researchers were busy arguing that domestic violence was individual and sex-neutral. Unlike radical and cultural feminist theories of domestic violence characterizing sex, family, and law as unequal patriarchal institutions where men use violence to dominate and control women, liberal feminist theories focused on individuals and family conflicts whereby both men and women used violence to deal with the conflicts and stresses associated with intense emotional relationships. Murray Straus (1980), the most vigorous proponent of the liberal feminist perspective, constructed domestic violence as a sex symmetrical family conflict problem rather than a sex asymmetrical woman's problem. He argued that the emotional intensity of marriage coupled with the stresses of family life leads to frustrations and aggressions for married men and women such that sex differences in the rates of violence found in the public sphere are absent in the private sphere. In 1975 Straus, Gelles, and Steinmetz interviewed a large sample of married and cohabitating couples to assess their use of violence in conflict resolution. Results from this study (and a later study in 1985) indicated that the number of acts of aggression committed by men and women was the same and that females were slightly more likely than men to be perpetrators of severe acts (Straus et al. 1990). The family violence construction of domestic violence turned attention away from a sex-specific focus on wife abuse to a sex symmetrical focus on family violence. The victim status reserved for women by cultural and radical feminists was extended to men, and the problem changed from a woman's problem to a family problem.

As family conflict constructions of domestic violence became more pervasive, the limited state support for battered women's shelters and victim's services declined and was replaced with informal conflict resolution intervention by police and family courts. As in the Progressive Era, the social control mechanisms employed for domestic violence based on liberal feminist family violence constructions focused less on welfare and services for women and, instead, on family conflict resolution in civil family courts.

Liberal feminist family violence theories of domestic violence gained momentum during the era of rehabilitation in criminal justice. Consequently, police crisis intervention and court diversionary programs became the predominant social control mechanisms for dealing with family violence. By 1980, most spousal assault cases brought to the attention of the court were handled in civil family courts (Dobash and Dobash 1992). Once again, domestic violence was regarded as a private family matter to be resolved through informal court resolution rather than a public matter to be adjudicated by criminal courts or resolved by welfare state shelters and victim services providing battered women with the economic resources to leave their batterers.

Domestic Violence: Female Survivors of Sex, Family, and Legal Inequality

For some feminists the radical and cultural feminist constructions of domestic violence as sex asymmetrical with women construed as passive victims without agency were uncomfortable. Equally uncomfortable was the liberal construction of domestic violence as conflict between individuals with agency in families or intimate relationships without regard for sex inequality in existing social institutions.

Taking both agency and institutionalized sex inequality in intimate relationships into account, some feminists constructed a view of domestic violence as sex asymmetrical with battered women being perceived as survivors (Hoff 1990). This type of construction led feminists to focus on the social context and survival strategies of battered women, especially women using self-defense against their batterers (Dobash and Dobash 1992; Maguigan 1991; Schneider 2000; Dixon 1995; Ferraro 1989). Another more nuanced position supported by research argued that a large number of families suffered from occasional outbursts of violence from either husbands or wives (common violence) while a significant number of other families experienced systematic violence from husbands engaged in patriarchal terrorism (Johnson 1995).

This genre of feminism presented a more complex construction of domestic violence which viewed women as active agents attempting to survive the inequality in sex, family, and legal institutions. This construction attempted to grapple with the issue of agency for battered women without denying the issue of inequality in social institutions. The feminist constructions of domestic violence that viewed battered women as survivors provided the basis for significant changes for cases involving battered women who killed their assailants. The sex symmetrical survival construction of battered women led to statutory and case law reforms that expanded self-defense options for battered women.

Domestic Violence: Intersection of Sex, Sexual Orientation, Race, and Class

As feminist scholarship and legal practice in the area of domestic violence expanded, criticisms began to emerge focusing on the lack of attention to the race, class, and sexual orientation contexts of domestic violence. Critical race theorists noted that existing feminist theories of domestic violence reflected the experiences of white battered women with little attention to the experience of black battered women or to the intersection between sex and race in battering (Crenshaw 1989). Similarly, feminists interested in issues of class inequality suggested that current feminist theories limited their analysis to battered women without recognizing social class variations or the intersection of sex and class in domestic violence. Lettie Lockhart's (1991) cross-racial perspective on domestic violence was one of the few empirical studies that examined the intersection of sex, race, and class in domestic violence.

Domestic Violence as Crime: Arrest, Prosecution, and Specialized Courts

Increasing crime rates in the USA during the 1970s and 1980s led to a situation whereby the criminal justice system began to criminalize many social problems once belonging to the private sphere such as drugs and domestic violence. Earlier debates over the merits of constructing domestic violence as a public offense adjudicated and punished in criminal courts or a civil offense handled by conflict resolution resurfaced.

After the results from the Minnesota Domestic Violence Experiment showed that arrest provided a significantly greater reduction in domestic violence than informal conflict resolution by police (Sherman 1992), some feminists joined hands with the criminal justice system to advocate mandatory arrest as the appropriate social control mechanism for dealing with domestic violence. Six replications of the original Minneapolis experiment were commissioned by the National Institute of Justice. Although some analyses yielded modest support for the deterrent effect of arrest found in the Minnesota study (Maxwell et al. 2002), other results suggested that deterrent effects varied across settings (Garner et al. 1995), and offender characteristics linked to stakes in conformity such as marital status and employment (Sherman and Smith 1992). The finding that arrest decreased future violence against women when offenders were married and employed but increased future violence when offenders were unmarried and unemployed produced a dilemma for feminists who construed women as a universal category. Some feminists also pointed to the absence of gays and lesbians in studies of domestic violence.

Research showing that female victims were more likely to use police in the future if offenders were arrested in accordance with the preferences of victims also called into question the degree to which mandatory arrest was empowering to women (Hickman and Simpson 2003). However, by this time the train had left the station. Mandatory arrest had become the predominant criminal justice policy in the USA. When research reported that prosecutors were dropping domestic violence cases even after mandatory arrest policies were initiated, many prosecutors followed with mandatory prosecution. Some feminists applauded mandatory prosecution (Wills 1997), while others argued that it empowered the criminal justice system while disempowering battered women (Ford 1991).

After the development of specialized problem-solving drug courts and the passage of the Violence Against Women Act (1994), the federal government provided money for the development of innovative criminal justice policies for dealing with domestic violence cases: specialized domestic violence prosecution bureaus, no-drop prosecution policies, specialized domestic violence court, victim advocacy programs, and court-community partnerships. Feminist debating the merits of mandatory arrest began debating the merits of mandatory prosecution and specialized domestic violence courts, i.e., criminal justice ownership of the domestic problem.

Domestic violence is no longer ignored or constructed as a private family problem. It is now constructed as a public crime problem solvable by criminal justice agencies. However, what is not clear is whether the specialized domestic courts will operate in a manner that empowers victims or, like the early domestic relations and later family courts, will operate more as an institution to discipline and control poor and minority family life by punishing poor minority men while limiting state resources for female victims.

Synonyms

Feminist theory in the context of rape; Sexual assault and violence against females

Overview

Feminist theories offer significant contributions to the field of criminology, especially to the understanding of sexual violence since it was first introduced into the field approximately 40 years ago. Since their initial appearance, feminist theories have matured and grown. While some continuity is found among feminist theories, great variation exists in their underlying assumptions, approaches, and goals. This entry describes feminist theories in the context of sexual violence and is structured as follows. First, the background in which feminist theories emerged is described. Next, feminist theories of sexual violence are introduced. This entry then describes some specific integrative theories of sexual violence that are informed by the feminist paradigm. Subsequent sections address myths and controversies, as well as questions that remain unanswered in the literature. This entry concludes with a list of relevant references germane to feminist theories of sexual violence.

Introduction

Perhaps more than any other theoretical tradition, feminist theories greatly changed our understanding of sexual violence. Prior to their introduction, criminological research and theories were androcentric, having been shaped and informed solely by male understandings, perspectives, and experiences. Initial criminological understanding of victimization and offending focused almost entirely on male behavior and perceptions, and when attention was given to females, it was generally through the lens of sexism, misogyny, and the view of females as male property. Females who engaged in nontraditional behavior (i.e., deviance or criminal) were negatively characterized as morally corrupt, devious, manipulative, and even ill. And females who were victimized were similarly viewed as flawed, devious, and the sole cause of their victimization.

One of the most important contributions of feminist theories was to recast assumptions and understanding of criminal behavior and victimization, especially as it relates to sexual violence. Feminist theories introduced a more complete understanding of sexual offending and victimization because they started to take account of the actual experiences of females and highlight the considerable influence of gender (versus sex) as a construct on criminological behavior and victimization. However, feminist theories offer far more than a focus on the offending and victimization experiences of females and the effects of sexism. Feminist theories represent a reconceptualization of key concepts and ideas. They focus on how gender organizes the field of criminology, our understanding of offending and victimization, and the structure and functioning of criminal justice institutions. That feminists prioritize gender is widely established, though it is important to emphasize that "gender" is not equivalent to or interchangeable with "sex." Gender is the "sociocultural and psychological shaping, patterning, and evaluating of female and male behavior" (Schur 1984, p. 10). Sex is a biologically based and stable characteristic identified with two categories: male and female. Before discussing contemporary feminist theories of sexual violence, it is important to first define feminist theories, and to consider the theoretical context in which these theories emerged.

Background Description

Attempts to define a singular feminist theory is both naïve and incorrect because there is no "feminist theory" that is based on a single paradigm. Recent literature indicates at least 12 variants of feminist theory, though not all address sexual violence.

As such, the phrase "feminist theories" refers to a decentered and diverse collection of perspectives and methodologies based on various ideas about the basic assumptions regarding inequality, the role of gender and gender relations, the issues and problems requiring attention, and the methods needed to address these issues and problems. More succinctly, feminist theories are "woman-centered description[s] and explanation[s] of human experience[s] and the social world" and they are guided by the notion that "gender governs every aspect of personal and social life" (Danner 1991, p. 51).

There are common elements shared by the various feminist perspectives that distinguish them as a group from traditional criminology theoretical orientations (Daly and Chesney-Lind 1988). First, they view gender as a complex, social, historical, and culture product and not a natural fact. Second, gender and gender relations are fundamental organizers of social life and institutions. Third, gender relations in society and the role of masculinity and femininity are not equal or symmetrical. Rather, masculinity and femininity are used to organize and subordinate females based on male superiority. Fourth, traditional criminological theories are based on a gendered perspective that reflects solely a male's perspective of the criminological world. Fifth and finally, feminist theories agree that females should not be invisible, subordinate, peripheral, or viewed as appendages to males. Instead, feminist theories argue that females should be at the center of theory development, research, and intellectual inquiry.

Before turning to a description on how feminist theories inform sexual violence, it is important to describe the "traditional" criminological perspective as well as Liberal feminist theory that it led to. It is in this context that contemporary feminist theories focusing on sexual violence emerged.

Background Historical Context

Androcentric Theoretical Tradition

Traditional criminological theories virtually ignored the presence and experiences of females. Theories were based on male experiences and intellectual views, and these male-centered theories and understandings were generalized to the population at large – including females. When females were addressed in theories focused on criminology, it was assumed that male and female differences stemmed from biological differences. Evidence of this is found in Durkheim's work on homicide in which he described the importance of biological differences between males and females. He noted that females have smaller brains, smaller overall size, lesser strength, and were simply more primitive and less socialized than males. Further, Durkheim argued that these differences between males and females grew as societies evolved (DiCristina 2006). Pollak's (1950) views on the criminality of women also highlighted the importance of biological factors. He indicated that female criminals have an excess of male biological and psychological characteristics and make them more similar to male criminals than to female criminals or non-offenders. In general, this early work failed to consider external influences such as social or economic forces. In general, when these traditional perspectives discussed "gender differences," it was done in a way to highlight differences and deny the presence of gender inequality. For instance, disparities in strength and in aggression (in general) between males and females and the greater innate nurturing and care-giving behaviors (in general) found among females compared to males were seen as reflecting the natural order of things.

Given the belief that gender differences reflected the natural state of affairs and were biological imperatives, few scholars drew attention to strategies for social change until the introduction of Liberal feminist theory. Although this theory does not offer direct insight into sexual violence, it is important to understand the background role it plays in the emergence of contemporary feminist theories that do.

Liberal Feminist Theory

Liberal feminist theory challenges the notion of the natural state of biological imperatives that long kept males and females in separate spheres. This perspective holds that socially created, rather than biologically based, gender inequality underscores discriminatory social policies that maintain separate and distinct spheres for males and females, including the socialization of specific and distinct gender roles for males and females. Liberal feminist theory argues that both females and males are socialized and indoctrinated to believe that females are not capable of, or appropriate for, participating in intellectual activities, in physical activities, or in roles with a public presence; rather, a female's natural and proper role is one behind the scenes, subordinate to males, and outside of paid labor. Thus, Liberal feminist theory contends, it is not through a biological imperative that males and females are found in different spheres, but rather through the process of socialization and laws that this segregation and structural inequality takes place.

The work of Liberal Feminists was used as a way of organizing our understanding of *offending* and did not address sexual violence. This is not surprising given the timing of its emergence. Liberal Feminism emerged in the late 1960s into the 1970s during a time when little was known about sexual violence as it was widely considered a private or personal matter. On the rare occasion that sexual violence found its way into the public domain, the victim (generally female) was blamed for her victimization.

Liberal feminist theory does not hold that the *system* is inherently unequal, but rather, the policies by which it operates are. Thus, while not explicitly noted, proponents of this perspective would likely argue that sexual violence could be addressed through policy/legal changes (e.g., divorce laws, restraining orders, marital rape laws, and domestic violence laws) and structural changes which would address women's abilities to be socially and financially independent (e.g., equal opportunity laws, affirmative action, and equal rights).

While policy change approach with the goal of gender equality is an important advancement, it proved problematic in practice. First, a focus on equal treatment uses males as the yardstick by which females are treated; and in a practical sense, this approach has been shown to exacerbate problems and ultimately work against females.

Today, the approach for equality has been largely dismissed by newer more radical variants of feminist theory focused on parity. Parity allows for sex-based differences in treatments and policies. These newer more radical perspectives currently dominate research and theory within the feminist paradigm, and it is among these perspectives that a focus on sexual violence is found.

State of the Art: Feminist Theories in the Context of Sexual Violence

While sexual violence is heavily researched, it receives comparatively little theoretical attention even among feminist perspectives. This section addresses two theories that most often form the basis of inquiry into sexual violence. Following this presentation, the discussion moves to describing some feminist theoretical perspectives focused specifically on sexual violence.

Radical Feminist Theory

Radical feminist theory views "male power and privilege as the source of all social relations, inequality, and violence against women" (DeKeseredy 2011, p. 298). It identifies *patriarchy*, especially in terms of controlling and exploiting female sexuality, reproduction, and familial relations, as the root of gender inequality and ultimately sexual violence. Other characteristics such as class are of secondary importance. One very important and critical way in which Radical feminist theory differs from other feminist theories is that it rejects official notions and definitions of violence because extant definitions and ideas of violence are male centered and fail to incorporate the full range of female victimization experiences. Instead, Radical feminist theory conceives of a broad definition of sexual violence, which places this violence on a continuum ranging from sexual harassment (less severe) to violent completed rape (most severe). This sexual violence continuum does not reflect what males embedded in a patriarchal social structure view as sexual violence; sexual violence is based only on the experiences and notions of females. By reconceptualizating sexual violence in a broader sense, Radical feminist theory clearly indicates that sexual violence is a means of social domination and not merely random acts of aggression.

Patriarchy is the core concept in this perspective and refers to the belief that society views women as the property of males, and therefore, societal norms convey that females are subject to male control. Because males, in general, are larger and more powerful than females, males are able to use aggression and power to subordinate and control females in every sphere of life.

Radical feminist theory identifies *sex* as the arena in which females are controlled. It is not necessary that all females be sexually victimized, nor is it necessary that all males offend against females. It is only necessary that acts of sexual violence be well known so that fear of this violence keeps females in a subordinated position. Thus, rape, sexual assault, and intimate partner violence stem from patriarchy and represent a form of social control. The continual threat of sexual violence serves to perpetuate male domination over female minds and bodies by force.

Radical feminist theory contends that the end of patriarchal relations and the elimination of oppressive social structures are the only means to end the gender inequality and the resulting sexual violence. This can be accomplished by providing females sexual, reproductive, and familial autonomy.

An important early work representative of Radical feminist thought is Brownmiller's (1975) work on rape. This revolutionary work brought the Radical feminist perspective to the forefront of research and reframed our understanding of rape. Brownmiller's work recast rape as a crime of power and control and a part of the arsenal of tools used to control, dominate, and subordinate females. Previously, rape was considered a crime of passion or an erotically driven act. Her work identified the patriarchal system of gender inequality and how it controls and subordinates females, condones sexual violence, and encourages and justifies sexual coercion. By moving the conversation of rape as a sexual crime to rape as an issue of power and control, greater understanding about the motivation and consequences of rape and sexual assault were made. Contrary to traditional views, it is now established that rape and sexual assault are acts of violence, sex is the weapon, and offenders are motivated by power, control, and anger. Further, current understanding includes that victims of rape and sexual assault do not incite an offender, nor does this violent act occur only to "bad" females (or males). This shift in perspective changed policy as well. Until the late 1970s, most states did not consider spousal rape a crime. It was believed that a wife could not be raped by a husband as their marriage formed a contract meaning the wife had to submit herself to her husband. Currently, rape of a spouse is a crime in all states as well as the District of Columbia.

A second important example of research informed by Radical feminist thought is Kelly's (1988) seminal work on sexual assault. In *Surviving Sexual Violence*, Kelly interviewed 60 females to examine the range of sexual violence they experienced over their life course. The interviews provided groundbreaking information on how females defined their sexual violence, the strategies they used to resist this victimization, and finally how they coped with their experiences. Using this information, Kelly conceptualized sexual violence broadly and placed it on a continuum. She concluded that several changes were needed. First, females need to recognize their experiences as sexual violence. Second, sexually victimized females need to view themselves as survivors rather than victims. Further, Kelly argued that women need to work together to end sexual violence. Since the presentation of these early classics, a wide range of research on sexual violence, rooted in the Radical feminist school, has been conducted. Areas covered in this body of research include behaviors that disproportionately victimize females such as pornography, domestic violence, incest, and sexual harassment.

Marxist Feminist Theory

Marxist feminist theory posits that *class* is the primary basis of gender inequality and sexual violence and *gender*, or male-to-female relations, is a secondary basis for inequality and sexual violence disproportionately experienced by females. From this primary perspective, gender inequality is based on class differences stemming from private property ownership and the inheritance of property – social phenomenon enjoyed primarily by males. Because females as a sex class were historically excluded from working in the labor force (except as a reserve army of labor), owning property or inheriting private property, they were disadvantaged and placed in weak/powerless economic positions that increased their vulnerability to exploitation including sexual violence. Yet another way, Marxist feminist theory contends that class forms the base for female disadvantage is the master–slave relationship found between husbands and wives in traditional marriage. In a traditional marital relationship, a wife serves as unpaid and exploited laborer to the benefit of her husband.

Marxist feminist theory recognizes that violence against women in not equally prevalent in all societies and that high rates of rape and sexual violence are found among modern capitalist societies. This results directly from the history and culture found in exploitative class relations that characterize a capitalist society. A classic and cornerstone treatment of sexual violence rooted in the Marxist feminist tradition is found in Schwendinger and Schwendinger's (1983) *Rape and Inequality*. Their research indicates that rape is not present in all societies, but rather that it varies based on gender equality. Based on an historical, cross-cultural, and anthropological analysis, the authors find that rape rates are highest in capitalist societies precisely because of gender inequality. Specifically, the inequality bred by a capitalist society enhances the conditions for female subordination and sexual violence. In contrast, they find that in noncapitalist societies, rape is rare, and egalitarianism between males and females high.

To end this class inequality which disadvantages females and enhances the conditions for sexual violence, the Marxist feminist perspective stresses the need to transform the capitalist societies to noncapitalist societies. The elimination of a class-based society will remove the power and privilege enjoyed solely by males (i.e., wealthy white males) and benefit females who will be freed from economic dependency on males. In a society free from gender and class stratification, females would be able to participate equally in the public and private sphere activities including paid labor, housework and child rearing. And finally, this change argues for the abolition of traditional marriage which views females as the private sexual property of males. These changes designed to end class stratification will in turn end or greatly reduce sexual violence.

Feminist Theoretical Offerings on Sexual Violence

The previous section offers an overview of two major perspectives of feminist theory and how they address sexual violence. In reality, the parsing of feminist theories is not so neat and theoretical contributions in the literature are more often integrative. The next section presents several theoretical contributions by feminists valuable for our understanding of sexual violence.

A Feminist/Male Peer Support Model of Separation and Divorce Sexual Assault

Until the presentation of this model, DeKeseredy and Schwartz (2009) noted that there were no theories specifically designed to address why males sexually assault female partners who end, or wish to end, their relationship. While much work has produced important information on risk factors of sexual violence, none has offered a unified model to address this particular form of sexual violence.

This model is grounded in the notion that divorce/separation sexual assault is an expression of the broader societal forces including societal patriarchy and male proprietariness. Societal patriarchy is defined in the model as "male domination at the societal level" (DeKeseredy and Schwartz 2009, p. 35), and it is composed of structure and ideology. Based on the work of Wilson and Daly (1992, p. 85), male proprietariness is defined as "the tendency [of men] to think of women as sexual and reproductive 'property' they can own and exchange."

Exiting a relationship (whether physically or emotionally) is also a component of this model. Exiting a relationship cannot in and of itself be the cause of sexual violence, but it can and does contribute to the likelihood of sexual violence. Additional forces are necessary and this model indicates those forces are "patriarchal male peer support" and "threats to masculinity and patriarchal control." Male peer support is defined as the "multidimensional attachments men form to male peers who themselves sexually assault women, provide resources that perpetuate and legitimate such assault, or both" (DeKeseredy and Schwartz 2009, p. 41). Extant research demonstrates that male peer support is a powerful determinant of sexual violence: A connection with an all-male group tends to support and justify the commission of sexual violence against females. Further, an all-male support group can bolster the idea that a female who exits her relationship damages a male's masculinity. In an effort to restore threatened or damaged masculinity, males engage in sexual violence against their partners.

Masculinities

Messerschmidt's Masculinities (1993) theory is greatly informed by feminist theoretical perspectives and is valuable in understanding sexual violence. Building on earlier theoretical work, Messerschmidt contends that masculinity is not an inherent or fixed characteristic of males, but one that must be continually *accomplished* in every social role. Further, how a particular male accomplishes masculinity is directly based on his position in society (employment, stable family life, race, class, etc.). Thus, males are not uniformly afforded the same opportunities to accomplish masculinity. A wealthy white male may have opportunities unavailable to a poor, black male. His theory also contends that not all males share the same conception of what being male means.

For males who do not have legitimate means of accomplishing masculinity because they are positioned in the powerless underclass, criminal behavior and sexual violence against females is one way to accomplish gender and masculinity. Thus, violence – including sexual violence – is a method for some males to demonstrate their masculinity.

Though males do not share a singular method to demonstrate masculinity, all males do act within the confines of "hegemonic masculinity." Hegemonic masculinity emphasizes masculine practices toward control, independence, emotional restriction, self-reliance, active homophobia, aggressiveness, and the capacity for male perpetrated violence. Further, hegemonic masculinity socializes males into believing that they can accomplish masculinity by ridiculing, dominating, and subordinating all that is female. This includes sexual violence.

While a valuable approach in that it recognizes gender as a product of social action in everyday life, and that there exists a variety of masculinities (and femininities) shaped by structural positioning, it is not without criticism. Miller (2002, p. 437) argues that the perspective can be strengthened with careful attention to four issues: avoiding tautology; challenging gender dualism; accounting for stratification, hierarchy and power; and conceptualizing the complexities of agency and social practice.

Gendered Social Bond/Male Peer Support Theory of University Woman Abuse: New Insights

This particular feminist approach to understanding sexual violence integrates Hirschi's social bond theory (1969), feminist male peer support theory, masculinities, and other critical perspectives to present a theory of conformity used to explain sexual violence against university females. In this work, Godenzi, Schwartz & DeKeseredy (2001) invert Hirschi's social bond theory by asserting that it is precisely the social bonds with conventional institutions and peers that *encourage* sexual violence against females in university settings. This approach, in combination with the male peer support theory, offers an explanation about why men who are associated with patriarchal peer groups commit sexual violence against females.

Important in this explanation is the role that attachment plays. The greater the emotional ties males have with other male peers in a hypermasculine subculture, the greater the likelihood of sexual violence against females. A second critical element identified is commitment which suggests that males will conform to the patriarchal social order based on a strong loyalty. This can manifest itself by regular relations with females regardless of the circumstances involved. Through this activity, one can accomplish masculinity and demonstrate commitment to the patriarchal social order. Next the model addresses inverts Hirschi's proposition about the relationship between involvement and offending. Specifically, the more time spent with patriarchal peers – in activities like drinking and watching pornography – the more likely it is that men will perpetrate sexual violence against females. And finally, Hirschi's theory notes that those with a belief in the legitimacy of patriarchy and masculinity are most likely to follow it. In this case, following it can lead to sexual violence against females.

This integrative theory offers a rationale for why males engage in sexual violence against females. They are engaged in accomplishing masculinity and demonstrating attachment, commitment, loyalty, and involvement in a patriarchal system that both condones and encourages sexual violence. This integrative model offers several benefits to extant theories. First, it includes the role of gender making up for a flaw in social bond theory. Second, it includes the role of social group processes, also neglected in social bond theory. As noted by the authors, each perspective used makes up for weaknesses in the others.

Left Realist Gendered Subcultural Theory

Left realism is an example of critical criminology which has its roots in Marxist feminist theory. It however differs from traditional Marxist thought in that Left Realism addresses the Marxist shortcoming of being gender blind. In this particular perspective, DeKeseredy and Schwartz (2010) consider the role of economic policies, social exclusion, and sexual violence. This theoretical offering on sexual violence focuses on the criminogenic subcultural development and destructive economic policies that have characterized the last several decades, and continues today. Together, these two forces have increasingly made difficult male attempts to accomplish masculinity – at least in legitimate ways.

DeKeseredy and Schwartz argue that in the last several decades, employment opportunities have diminished greatly especially from the working class. This loss of employment opportunities for these males frustrates the accomplishment of masculinity as opportunities to be a breadwinner and demonstrates self-reliance is greatly diminished. A second result of this deindustrialization and loss of employment opportunities is an increase in male connection to peer groups that tout violent, macho, sexist, and patriarchal ideals. The growth of such peer groups is indicative of an increasing hegemonic masculine subculture. Thus, males without legitimate means of accomplishing masculinity come together with other similarly frustrated males to form subcultures. These subcultures then encourage and condone sexual violence against females, as it is one "legitimate" way to salvage their hegemonic masculinity.

The Influence of Feminist Theory in the Context of Sexual Violence

The influence of feminist theories in addressing sexual violence is widespread. Research informed by feminist theories is responsible for changes in the criminal justice system making it more responsive to the victimization of, and domination experienced by, females. Research based on feminist theories has resulted in important and rapid changes in policies and laws designed to address many forms of sexual violence. For example, it is responsible for the reformation of state rape laws including marital rape laws, and the adoption of and further inquiry into mandatory and pro-arrest intimate partner violence laws. Still, it is clear that much remains to be done given the problems that remain in the legal treatment of sexual violence.

Feminist approaches have also increased our understanding of the victim-offender overlap in sexual violence. Consider, for example, that research now routinely considers the influence of prior sexual and physical violence against women and how it influences future offending. Research routinely finds that many females, in escaping from victimization, turn to deviance and offending (e.g., running away) which in turns enhances victimization risk – especially sexual victimization risk. Research repeatedly indicates that adult and juvenile female offenders in the criminal justice system report higher rates of prior physical and sexual victimization than non-offenders. This series of behaviors – referred to as "criminalizing girls' survival" illuminated by feminist perspectives – offers better understanding of the experiences of females, especially as it relates to sexual violence.

Contemporary research also routinely considers the role of sexual inequality, prior sexual victimization, sexism, and patriarchy in sex work by females. A growing body of research indicates that a substantially greater proportion of prostitutes experienced childhood sexual abuse compared to non-prostitutes. Further, attention has recently been given to juvenile sex workers who traditionally have been framed as criminal offenders. In contrast, these juveniles – many of whom are being exploited and dominated by males – are now being seen as sexual violence victims.

Controversies in the Literature

Despite theoretical and research advances, considerable controversy remains over some very basic questions about sexual violence. For example, how much sexual violence is there? How should sexual violence be defined? Should a victim who believes she was not raped be counted as being raped? Does the victim or the surveyor determine who was raped? These simple, yet controversial, questions are best exemplified by a series of studies published by Koss (1988), Gilbert (1993), and others.

Koss (1988) directed a study on college campuses widely referred to as the "*Ms.* Report" given it was funded by *Ms.* Magazine. The research was grounded in the belief that rape is an extreme behavior on a continuum of normal male behavior and utilized a broad definition of rape. To capture the concept of rape, ten questions were used in the survey. For instance, one question asked respondents if they were physically restrained and forced to have sexual intercourse. Another question queried respondents about threats and/or forced sexual intercourse that occurred after they had been given drugs or alcohol by a male.

After interviewing more than 3,000 randomly selected college women in the nation, it was concluded that 15.4 % of females had been raped and an additional 12.1 % experienced an attempted rape. From the same study, Koss (1988) concluded that 27 % of the 15.4 % who had been raped did not consider what happened to them as rape. From this work, the *Ms.* Report reported that "one in four" women had been raped.

This statistic was widely reported and accepted in the media, and it was used to direct policy although it was substantially higher than official statistics and estimates found in previous academic research focused on rape. This discrepancy brought attention from many, including Gilbert who reviewed Koss' research and concluded that the numbers were exaggerated. For instance, he found that including females who answered "yes" to the question "have you had sexual intercourse when you didn't want to because a man gave you alcohol or drugs?" lacked rigor and exaggerated the problem. He contended that by including this question as a measure, Koss' definition of rape included regretted sex. Further, Gilbert was troubled by the fact that the majority of women Koss et al., classified as rape survivors did not believe they had been raped at all. Is it appropriate to reject the judgment of females who do not believe they were victimized? Should the law or a researcher's beliefs override a female's experience?

While some scholars and activists have "sided" with Koss' methodology, others find her estimates exaggerated and the definitions she used overly broad. In general, research generates controversy, but the controversy generated by this issue has been extreme. Researchers and experts have been called traitors, shunned from universities, and in the case of Gilbert, threatened with calls to "Kill Neil Gilbert," and for him to "cut it out, or cut it off." In one instance, the director of the California Women's Law Center stated that they wished that Gilbert would himself be raped.

Open Questions

As is true with any theoretical tradition, many open questions characterize feminist theory especially as it relates to sexual violence. The purpose of this section is to outline some of these open questions.

One open question focuses on the value of feminist theory for understanding criminological phenomenon outside of sexual violence. The connection between feminist theory and sexual violence has been present since at least the 1960s. However, the use of feminist theory continues to remain predominantly in the area of sexual violence. Calls for its widespread use in criminology have been made since at least 1988 when Daly and Chesney-Lind noted that criminology in general – with the exception of feminist treatments of rape and intimate violence – has remained untouched by feminist theory. Why does feminist theory continue to be found primarily in the domain of sexual violence? If feminist theory is a powerful explanation of violence, why is it not more prevalent in understanding other types of violence such as stranger robbery or homicide?

A second set of questions pertain to the preeminent role given patriarchy in some variations of feminist theory. First, does the emphasis on patriarchy mask the important influence of other phenomena? Second, how can one recognize and measure greater and lesser degrees of patriarchy? Third, how can patriarchy explain sexual violence among same-sex partners?

Can feminist theory focused on patriarchy explain same-sex and heterosexual relationship violence equally? And finally, how does patriarchy help explain female perpetrated violence against males?

Third, what is the most effective way to treat offenders? If as feminist theories indicate problems are systemic (e.g., patriarchy) what approach is best for addressing offenders? If the problem is structural, do individual-level treatments help? Can restorative justice be a safe and effective way of dealing with sexual violence? Do the potential benefits of such an approach exist only in theory? How does the role of an apology – a component of restorative justice – work within the context of intimate partner violence when an apology is considered a form of coercion in violent relationships? Some work offers some insight into these questions though additional research is warranted. Research by Daly and Curtis-Fawley (2006) concluded that a majority of victims in their study benefitted from a restorative justice proceeding instead of a court proceeding. While this approach is characterized by some problems (e.g., victim safety, manipulation of the process by offenders, pressure on victims, etc.), victims benefitted in that they felt heard, participated in a communicative and flexible environment in which the offender took responsibility for the offense.

And finally, could the more equal standing and greater opportunities available to females today, compared to decades gone by, be a basis for greater, not lesser, sexual violence? In the past, when it was more widely accepted that females were the domain and property of males, sexual violence was not needed to maintain the dominance over females. Today however, less subordination may give rise to some to demonstrate dominance over women via sexual violence. How do feminist theories address this possibility? Have changes in policy actually minimized what would have been a great increase in sexual violence? In other words, had policy changes offering greater opportunities to females never been enacted, would sexual violence rates be substantially greater?

Fencing/Receiving Stolen Goods

Mike Sutton
School of Social Sciences, Nottingham Trent University, Nottingham, UK

Overview

The Industrial Revolution, beginning in Britain and gathering momentum in the eighteenth Century, enabled widespread ownership of desirable, mass produced, identical goods. This changed the characteristics of general theft whereby it switched from being motivated predominantly by a desire to take often unique property for personal consumption to stealing to sell standardized goods once more destined for the personal enjoyment of others.

While weight and portability of items is considered by thieves (Felson and Clarke 1998), this most usually happens, at least where prolific thieves are concerned, only if they believe the goods will be saleable once removed (Sutton 1995); at which time, considerations regarding weight and portability, and even danger of removal, will be balanced against prices. Therefore, the issue of demand and supply by theft is important because the most valid predictor of items that most thieves will choose to steal is whether or not they believe they can be sold easily for a good price. For example, the recent meteoric rise in scrap metal theft is fuelled by a global metals shortage caused by the high demand for raw materials that are essential for the expanding industry, cities, and infrastructure of China. High prices motivate thieves to remove heavy lead flashings from the roofs of high buildings or risk electrocution stealing heavy and difficult to remove live copper cable. Globally, scrap metal copper prices have doubled since 2004, followed worldwide by a significant number of electrocution fatalities at substations, railways, oil wells, overhead power lines, industrial buildings, and other places by thieves attempting to steal live copper cable.

Understanding more about the various markets for stolen goods presents a challenge for criminology and the criminal justice system that is relatively overlooked by the conventional tight-focus upon only the thief and the act of theft. Yet, arguably, mankind cannot adequately understand the prevalence and incidence of theft of different goods without understanding how different types of stolen goods markets operate to influence demand and supply, who deals in them and why. Worldwide, societies that actively detect and punish thieves, seek to target harden property, or otherwise increase its capable guardianship all virtually ignore the large number of citizens who purchase stolen goods at bargain process, notwithstanding that all those who buy motivate thieves to supply by theft.

Background to the Problem

Thieves are seldom found living in, or otherwise owning, an Aladdin’s cave of stolen goods. A safe assertion, therefore, is that most prolific thieves seek to raise money by selling whatever they steal. And the type of goods most frequently stolen is determined by the level of demand for them. Prolific thieves are generally very good at gauging this because most sell stolen goods within 30 min of their theft (Sutton 2010).

Most burglars and other thieves steal because they want money, and Clarke (1999) explains that offenders have a hierarchy of goods that they prefer to take. Top of their list is cash, followed by items that can be sold easily for relatively high prices – such as jewelry and desirable high-technology equipment. Stolen goods markets and knowledge of what can be sold in them motivate many thieves. This explains why societies have experienced different crime waves comprising targeted theft of very specific items and commodities.

The prolific and successful thief must complete one or else two objectives while evading detection and apprehension. The first objective is to steal cash or else saleable commodities. If something other than cash is stolen, the second objective is to either sell or else trade the goods stolen. Where goods are stolen, typically, police, prosecutors, and criminologists view this behavior as comprising the two distinct crimes and actions of stealing and then of selling stolen goods. From the thieves' perspective, however, these one or two objectives need to be completed in order to achieve their main aim, which is usually to acquire whatever it is they initially needed or wanted to buy before embarking on the crime.

Criminologists and crime scientists focusing upon the act of theft typically seek to understand the causes of, and find solutions to, the first objective. But the wider aims and objectives of theft from the perspective of the thief include selling, fencing, and receiving stolen goods (the second objective). In effect, the offender is following a crime script that begins before and continues after the act of theft. Seeing this wider picture can help to increase depth of understanding of acquisitive offending and possibly reveal innovative and promising avenues for seeking to tackle it.

Dealers in stolen goods have most probably existed for as long there have been laws against theft and a demand for stolen goods. The fence is a middleman between the thief and the consumer of stolen goods.

Through the act of buying stolen goods as a trusted criminal middleman, the fence allows the thief to avoid the risk of being caught in the act of trying to sell their loot directly to untrusted strangers. Hence, the origin of the word fence is widely believed to stem from the shortening of "defense" during the seventeenth century as a common understanding of the dealer in stolen goods being the thieves' defense from detection.

The role of historical and contemporary fences as protectors of the secret of thieves' identities is perhaps most plainly highlighted by what is known about theft in the time of slavery. For example, Williams' (1963) translation of a letter written by the Archdeacon of Hispaniola to the Council of the Indies in 1542 reveals that trusted fences served as a safe and ready market, thereby protecting numerous slaves from being linked directly to their crimes through selling goods they stole in slower and more risky ways. Money from the fence was then paid by the thief to his "master" in order to buy off his otherwise callously enforced labor. Likewise, slaves who were fences bought their own way out of the same exploitation through trading in stolen goods:

> The Negros are already doing business and trading among themselves to an extent involving great value and cunning, and as a result, big and notable robberies are committed on all the farms in the country... Some steal to pay for the day's work which they have agreed to give their masters... Night and day they rob and steal anything in the country, including gold to be melted. These thefts are concealed with the assistance of two or three hundred Negros called "fences", who go about the city seeking to make profits as I have said...and to pay the daily wage in exchange for each day or month or year, that they are at large and travel about the island. They take away stolen goods for sale and carry and conceal all that they are accustomed to conceal...

As well as providing protection for thieves, fences are conveniently sited to provide information to assist their arrest and prosecution. Although it has long been suspected that disingenuous police officers might allow fences to continue trading in exchange for intelligence about the thieves who supply them, there is no published evidence that this actually happens. Perhaps the only published evidence of such things happening in the past can be found the case of Jonathan Wild. In the eighteenth century, Wild, the most notorious fence in history, presented himself as a public hero, arresting so many thieves that he earned the title Thief-Taker General. Yet all the while, Wild secretly led a gang of thieves, regularly received stolen goods, manipulated victims to offer a reward for their return, and then pretended to track down the goods he already illegally possessed to claim the reward. Unsurprisingly, the question of the degree of guilty mind of the receiver has, for centuries, occupied legal scholars (e.g., Colquhoun 1796; Hall 1952), but astonishingly few contemporary criminologists are concerned with criminal career ethnographies of successful fences (Steffensmeier 1986) or understanding the wider dynamics of the trade (Sutton 1998).

Stolen Goods Market Types: Guilty Minds and Offending Dynamics

The London magistrate Patrick Colquhoun (1796) was concerned with the guilty knowledge of people buying stolen goods at bargain prices. His threefold typology consists of:

1. Criminal receivers (professional fences who deliberately encourage theft)
2. Careless receivers (have a reckless disregard for the origin of the goods)
3. Innocent purchasers (believe good were legitimately purchased by the seller)

A new typology was created 156 years later by the jurisprudentialist Jerome Hall (1952), who set out to emphasize the role of the professional fence in marketing stolen goods with another threefold typology:

1. The professional receiver (fence who deals in stolen goods)
2. The occasional receiver (buys for resale but does so only infrequency)
3. The lay receiver (buyer and consumer of stolen goods)

Even professional fences operate at different levels, as can be seen in the following three-tier fencing level typology first outlined by Lewis (2006):

- *Level-1 fence*: The thief sells to a level-1 fence (often a storeowner such as a pawnbroker or jeweler), who then sells the goods in his store or else sells them to another fence.
- *Level-2* (wholesale) *fence*: This fence buys from a level-1 fence and then often cleans up and/or repackages the goods to make it look as though they came legitimately from the manufacturer. These are very clandestine operations that are perhaps most likely to be found by police officers working back from an investigation of a level-3 fence operation. Those who operate stolen car rings also fall within this subtype.
- *Level-3 fence*: A level-3 fence takes repackaged goods from a level-2 wholesale fence and diverts them to retailers. At times, major retailers find themselves innocently purchasing the very goods that were stolen from them. Level-3 fences have been known to sell perfume, cosmetics, razor blades, and shoplifted designer goods in this way.

Being human constructs, all typologies tell us as much about those who create them as they do about their subject matter. Hall's typology, for example, was purposely designed to emphasize the role of the professional fence in the marketing of stolen goods, because he sought to bring about a change in US law that would see professional fences treated with greater severity. Lewis's three-tier fence model is concerned only with describing the hierarchy and marketing dynamics of fences dealing in goods stolen in organized retail theft.

Seeking to classify the various ways that the most commonly stolen goods are sold, Sutton's original (1998) fivefold typology of handling dynamics, updated to six to incorporate later knowledge of eSelling (Sutton 2010), describes how thieves sell, dealers deal, and the public buys stolen goods. No one of Sutton's six market types is known to be more serious or important than any other in terms of the role it plays in promoting theft by motivating thieves, fences, and the buying public. Moreover, research suggests that thieves and dealers regularly use more than one type (Sutton 1998):

1. *Commercial Fence Supplies*. Stolen goods are sold by thieves to commercial fences operating out of shops such as jewelers, pawnbrokers, and secondhand dealers.
2. *Commercial Sales*. Commercial fences usually pose as legitimate business owners while secretly selling stolen goods for

a profit, either directly to the (innocent) consumer or more rarely to another distributor who thinks the goods can be sold again for additional profit.

3. *Commercially Facilitated Sales* (modified here from eSelling). This market type involves either the thief or a residential or commercial fence knowingly selling stolen goods through classified advertisements in traditional newspapers and magazines, through traditional auctions, or online through classified sales websites such as Craig's List or Preloved.co.uk. They may also sell stolen goods on Internet auction sites such as eBay.
4. *Residential Fence Supplies*. Stolen goods (particularly electrical goods) are sold by thieves to fences, usually at the fence's home. The fence may be drug dealer and may be a prolific dealer in stolen goods or may deal only occasionally.
5. *Network Sales*. Stolen goods are passed on, and each participant adds a little to the price until a consumer is found. This may involve a residential fence or commercial fence selling to other fences. Alternatively, the buyer may be the final consumer or may sell the goods on again through friendship networks.
6. *Hawking*. Thieves, or their friends, sell stolen goods directly to consumers on the street or in places such as bars and pubs or door to door in residential areas (e.g., shoplifters selling cigarettes, toiletries, clothes, or food).

Thieves tend to be flexible and may trade in several different markets depending upon where they are, the time of day, what they have for sale, and how quickly they need to sell it.

Thieves do not simply respond to requests to steal certain types of goods to order, because many *steal to offer* goods to total strangers, which can lead to the thief directly motivating members of the public to become regular customers in *Hawking* markets and tempting previously straight business owners to become fences by way of *commercial fence supplies* (Sutton 1998). Experienced commercial fences, in turn, use their respectable business *fronts* to recruit inexperienced thieves who come in to offer them stolen goods. Commercial fences sometimes mix stolen goods in with their legitimate stock. Somewhat perversely this helps to sell legitimate stock, because some people think they are getting a real bargain if the shop has something of a reputation for selling high-quality goods suspiciously cheaply as opposed to cheaply made legitimate merchandise.

Research suggests that stealing to order is not as common as *stealing to offer* (Sutton 2010). And thieves' knowledge of the "standing demand" for particular types of stolen goods influences the types of goods that are stolen, which can lead to crime waves when thieves target particularly hot products. Past crime waves of this kind have included theft of lead, copper, aluminum, bronze, silver, gold, color television sets, hi-fi equipment, videocassette recorders (VCRs), motor vehicle radio-cassette players, computer memory chips, mountain bikes, laptop computers, digital versatile disks (DVDs), games consoles, mobile phones, and in-car satellite navigation devices.

The Basic Principles of Fencing

According to the US Senate's comprehensive review of fencing operations, the overwhelming majority of fences in the North America operate legitimate businesses (Sutton 2010). To operate successfully and avoid detection, the criminal dealings of the fence must be much less visible than the offenses and offenders that initially supply stolen goods. To achieve this, the fence must coach thieves to avoid detection, conceal his own trading behind a legitimate front, remain willfully ignorant of the provenance of goods bought from other fences, avoid storing goods to avoid detection but know how to safely store them if necessary, be wary of working with police informants, and limit the number of people who know what he is up to. He must never admit to knowingly trading in stolen goods if questioned by detectives, and he must have money for a good lawyer in case of arrest (Steffensmeier and Ulmer 2005).

Thieves and dealers in the UK and USA at least operate a "two- and three-way split" whereby experienced thieves selling to fences ask for between half the wholesale price and a third of the fences' selling price. This tends to vary though depending upon whether or not items are in high demand as fast-moving consumer goods or high end luxuries. Thieves selling stolen cigarettes, for example, are generally paid between 30 % and 40 % of the retail price. Shoplifters selling stolen clothes, meat, and bottles of alcohol such as vodka, whisky, and brandy directly to consumers tend to receive half the retail price. Other stolen but used items, like electrical goods stolen from house burglaries, are usually sold by the thief for a third of the retail value. If a fence sells directly to someone who knows the goods are stolen, then they sell for half the retail price. If the fence is a businessperson selling stolen goods to innocent customers through a shop, then the goods are usually sold for two-thirds of the retail value. Gold jewelry is different, however, in that it is sold by thieves to jewelry shops for the going rate for scrap gold. Presumably that same rule applies for scrap metals of all kinds. Where other stolen goods are concerned, this two- and three-way split on prices appears to be cast in stone, not least because several writers have documented these pricing practices existing for well over 100 years (Quennell 1958; Steffensmeier 1986, Sutton 1998). Perhaps this is because it is simple to understand and operate by those motivated to make quick but regular profits in illicit markets.

The Seller's Dilemma

Devising and testing creative ways to increase the difficulties and dilemmas faced by those dealing in stolen goods might be a useful approach in designing theft prevention and control strategies. The stolen goods seller's dilemma, whether she is the thief or a dealer (the fence), is that to increase her profit, she has to increase her risks of getting caught. The seller can choose to sell only to people that she knows, which reduces her risks of being ripped off or detected but restricts her sales and buying opportunities. The thief can sell to strangers, which allows her access to more potential customers, but also increases her chances of being arrested or robbed. This dilemma applies to both the thief and the dealer, but the business-owning commercial fence must also simultaneously nurture the confidence of thieves with whom they deal while projecting a legitimate trading image.

These conflicting demands of access and security determine to a large extent the structure of local stolen goods markets. The small size of most fencing operations, uniformity in pricing, and limited profit making from theft should come as no surprise since competitive options are limited by virtue of there being only so many ways of doing things efficiently and effectively in any kind of illicit market. This is because advertising, marketing, warehousing, transportation, and expansion options are necessarily avoided, or else extremely limited, in order to avoid detection and regulation (see Reuter 1985).

Prevalence

Few estimates of the amount of trading in stolen goods markets exist, but an exercise conducted by the British Government to inform the UK National Accounts (1997) claimed that in 1995, thieves selling stolen goods within Britain cleared between £900 million and £1,680 million (net) and that fences cleared between £450 million and £875 million (net) through selling stolen property.

The 1994 British Crime Survey (Sutton 1998) found that over the previous 5-year period, 11 % of the population of England and Wales admitted buying stolen goods, which they knew or believed to be stolen; 70 % thought that at least some of their neighbors had stolen goods in their homes; and 21 % thought a lot of them had the same. Looking back at just the previous year, rather than the last five, the British Offending, Crime and Justice Survey (Sutton et al. 2008) found that 7 % of adults in England and Wales admitted buying stolen goods while 2.7 % admitted selling them. Furthermore, almost half of males aged 16–24 had been offered or else bought stolen goods. Comparing males with females, this research suggests that it is possible that more than twice as many males buy. In the poorest neighborhoods, 40 % of males bought stolen goods compared to 17 % of females. Even in the most affluent neighborhoods, 7 % of people bought stolen goods. Incredible as they are, these figures could be an underestimate if some respondents were reluctant to admit buying stolen goods and others forgot that they did so.

The importance of the stolen goods market problem is further highlighted by Graham and Bowling (1995) who found that handling stolen goods was the most prevalent crime admitted by their respondents, with 49 % of offenders admitting to having done it in the past year.

Responses to Stolen Goods Markets

A consistent theme in the social sciences and the multidisciplinary areas of criminology and criminal justice is the unintended, sometimes ironic, consequences of purposive action. This theme, which is central to Merton's (1949) self-fulfilling prophecy, is reflected in the rationale behind the market reduction approach to theft (Sutton 1998). Specifically, those who buy stolen goods unintentionally support a market supplied by theft for their own future victimization.

Since the existence of "safe" and ready stolen goods markets is a difficult to disentangle, downstream consequence of theft, as well as one causal factor behind the motivation for theft, knowing more about stolen goods markets, in order to seek to reduce them and make it more risky to deal in them with situational crime reduction approaches, might provide one potentially promising avenue. The market reduction approach (MRA) (Sutton 1998; Sutton et al. 2001) is designed to do this. Although it is recommended as promising practice on official websites supported by government agencies in the UK, USA, Australia, and New Zealand, the MRA remains as yet unproven (Hale et al. 2004) avenue for reducing acquisitive crimes.

A comprehensive review of promising policing and multi-agency partnership responses to stolen goods markets, including those known to have limited effectiveness, was commissioned by the US Department of Justice (Sutton 2010). The review examines various crackdowns on stolen goods markets that have been tried out in the UK and USA with various degrees of success. One important conclusion reached is that even the most apparently successful schemes prove difficult to maintain over time with the traditional focus on the theft act taking priority in the allocation of scarce resources (Walsh 1976). Moreover, limited research in this area reveals that what works and does not work in tackling stolen goods markets is complex and at times counterintuitive. Research findings – however limited – are particularly valuable, therefore, in helping police services avoid repeating past mistakes. Clandestine police storefront antifencing sting operations, for example, can have the unintended effect of generating theft in the surrounding area to meet the demand they have unintentionally created (Langworthy and Lebeau 1992). Furthermore, despite being a favorite crime reduction activity in many police services, property marking has never been proven to reduce theft largely because thieves steal both "invisibly" and clearly marked property and fences and citizens will buy it (Sutton 2010). Therefore, the oftentimes bold assertions made by commercial companies for the success of their expensive property-marking products have never been confirmed by independent academic research (Knutsson 1984; Sutton 1998; Harris et al. 2003; Hale et al. 2004).

Explaining the Relative Importance of Stolen Goods Markets: Why the Market, Not Opportunity, Makes the Thief

Property thieves, particularly prolific ones, are generally perceived to be "bent" offenders whose predation upon "straight society" can be explained by their relative poverty, subculture, wider cultural influences, poor socialization, substance addiction, or individual pathology acting alone as significant causes or else together as a combination of forces that interacts with so-called opportunities for theft. Here, current criminological understanding of the crime act has been shaped by the current criminological notion of “opportunity” that is classically defined in Crime Opportunity Theory as what happens when a relatively more capable and sufficiently motivated “likely” offender succeeds against a target or victim – thereby proving that they were capable offenders against relatively incapable or absent guardianship. However, this crime as “opportunity” explanation does not at the time of writing provide discoverable and measurable quantifiable values that would enable criminologists to predict and test individual or general victim or target vulnerability relative to actual or potential capable offender motivation or guardianship abilities (Clarke 1984). This same limitation applies in the area of repeat victimization and within various types of high crime environment or in crime hot spots. It is a truism therefore that capable and suitably motivated offender components of current notions of “crime opportunity” cannot be discovered and objectively measured in nature or society before a successful crime happens – only afterward. This limitation means that “crime opportunity,” as the “almost always, elements of a criminal act” described in the Routine Activity Theory (RAT) crime triangle by Felson and Boba (2010, pp. 28–40), and in the description of crime as opportunity that is classically outlined by Mayhew et al. (1976), is the essential data of a successfully completed crime in commission. In other words, it is always knowable – but only ever after the event – that the crime happened because the offender could successfully commit it or else failed because he could not.

Logically, therefore, “crime opportunity” cannot be a cause of crime because Crime Opportunity Theory merely describes whether or not offenders were in fact more capable than the crime target’s guardianship. It follows, therefore, that until a crime is successfully completed or fails in the attempt, the current notion of “crime opportunity” cannot be known by offenders to exist in advance of the crime being completed or failing. This is because no potential thief could know for sure that they would be more capable than any guardian or that guardianship would remain absent. After all, if that was possible, there would be no reason for so many failed criminal attempts.

The RAT “crime opportunity” incorporates the commonsense premise that before stealing, most offenders rationally weigh up what they perceive to be risks versus rewards. However, this explanation of perceptions in the so-called crime opportunity event does not include human guardian perceptions of their own relative capabilities. Offender and guardian perceptions aside, if the current notion of crime opportunity, which combines RAT with the known successful criminal outcome described in the classic crime triangle, could somehow exist in advance of the crime actually being accomplished, then it would logically follow that every successfully completed crime and every offense of attempt would be the cause of itself, which is clearly impossible according to the scientific laws that govern the universe above the subatomic level. Therefore, the widely cited claim that “opportunity makes the thief” (Felson and Clarke 1998) is undoubtedly logically flawed (see also Sutton 2012).

Consequently, this notion of opportunity is neither a rational framework nor model for theory building. Nor is it a stand-alone theory of crime causation (e.g., see Felson and Clarke 1998, p. 9; Tilley and Laycock 2002; Felson and Boba 2010, p. 47) nor any kind of *measure* of differential vulnerability (see Clarke 1984), because it does not quantify levels of vulnerability. What is more, this notion of “crime opportunity” does not even fit common understandings of opportunity because it does not describe any kind of realistic pre-crime situation formed by a juncture of circumstances favorable to crime. Logically, therefore, there is no opportunity in Crime Opportunity Theory.

The current classic RAT and situational crime prevention notion of “crime opportunity” (perhaps ratortunity is a better word for it) is an elegantly precise, perhaps perfect, post hoc description of any successfully completed criminal act, which makes it a veracious, and therefore important, description of what has happened. But descriptions, no matter how elegantly described, cannot explain the reasons for the data. It follows, therefore, that precise descriptions of the components present at every crime act cannot explain the cause of the crime. This is true for all descriptions and the data they describe (Shermer 1991). Just as a fossil embedded in the geological fossil record, no matter how precisely and elegantly described, cannot explain itself without a separate theory – such as Darwin's theory of evolution.

Criminology requires a crime theory to explain why, in all successfully completed crimes, offenders are sufficiently motivated to prevail against protective measures. Simply saying, for example, that successful offenders were sufficiently motivated to overcome levels of guardianship, perhaps even ones that had deterred them in the past, because they rationally reevaluated the risks and rewards (Felson and Clarke 1998) does not explain at what point and why the rewards and risks switched to make a once adequately protected target become sufficiently vulnerable. In order to do that, criminologists need to look for more promising explanations that are separate from the data and descriptions of criminal acts they seek to explain. One potentially promising avenue here is to focus upon precisely how variations in demand for particular stolen goods differentially influence the motivation of thieves and their perceptions of risks versus rewards. This is why the strangely neglected area of stolen goods markets deserves more attention.

In the case of theft, changes in technologies, cultures, consumption patterns, and the economy of a nation state can sometimes act as a spur for new crime motivating markets, leading to increased levels of theft of particular types of property and changes in ways and methods of offending (e.g., Mann and Sutton 1998). Future research in this area will most certainly build upon existing knowledge and seek to understand more about the role that stolen goods markets play in motivating people to begin and continue stealing. One thing waiting to be discovered is information about exactly how and why an increase in demand for particular things can change them from "warm" to "hot products" (Clarke 1999) and hence increase both licit and illicit prices (Sutton 1995). If future research could find and then attach a quantifiable value to the "sufficient motivation switching point" for offending (if indeed there is such a thing) as a sufficient condition for theft, then criminologists would be in a better position to predict acquisitive crime waves. Perhaps one day criminologists will be able to accurately predict the likelihood of the next otherwise unexpected crime wave before it becomes a crime harvest. Forewarned with such knowledge, it would be possible to take preventative action, rather than merely explaining why the crime wave happened and seeking to prevent individual repeat occurrences. Understanding more about the role of stolen goods markets in theft, therefore, offers further promising incremental advances and perhaps, potentially, a monumental breakthrough in criminological knowledge, crime reduction policy making, and policing.

Conclusions and the Way Forward

Little is known about the factors that influence demand for stolen goods, what impact ready markets have on potential and persistent property thieves, and what might be the most promising ways to tackle effectively the crime of knowingly buying stolen goods. One thing is certain though: if more goods are stolen from people on the street or from their houses and cars, then they are normally purchased by other people to enjoy on the street or in their own houses and cars.

Surprisingly little research has been conducted into who buys stolen goods and why. Accordingly, compared with other areas of criminology, such as ethnographic and subcultural analysis of various different types of theft and thieves, the subject of stolen goods markets is a weirdly neglected area. Despite the fact that fences and consumers create much of the demand for stolen goods that is met through supply by theft, policing and crime reduction initiatives remain for the most part heavily focused upon thieves alone. Given the pervasive nature of stolen goods markets and the fact that the stolen goods trade is, when compared with acts of theft, afforded far less resources and attention, a most telling question is whether it is evenhanded or particularly efficient criminal justice policy or policing practice to focus so much attention on property thieves, rather than those who buy from them.

Knowing what research reveals about adults who motivate young thieves to steal by fencing or otherwise criminally receiving stolen goods and considering the number of thieves occupying prison systems throughout the world reveals a telling question, namely, *why do so few receivers of stolen goods share prison time with their regularly incarcerated suppliers*? The answer lies partly in the fact that gathering sufficient evidence to prosecute fences is difficult because they conceal stolen goods trading behind legitimate business fronts. Professional fences are expert at this and can remain undetected for years. In addition, members of the general public who buy directly from thieves for their own consumption do not do so as prolifically as individual thieves tend to steal. Consequently, their risk of detection is lower. Furthermore, public tolerance toward those who deal out of their cars and houses, often using networks of contacts in the community, is high because these dealers are seen by their customers as providing a kind of community service by way of essential or expensive luxury items at bargain prices.

If fences and the general public who buy stolen goods are responsible for creating markets for everyone's potential victimization, then finding effective ways to reduce such markets appears to be a logical and compelling way to reduce theft. Detecting those engaged in handling stolen goods and applying legal sanctions against them ensures that thieves and handlers have less chance of profiting from the misery of victims of burglary and other thefts, which is arguably an important criminal justice end in its own right and perhaps one that criminologists should not lose sight of in pursuit of measurable theft reduction. That said, it is not possible to predict accurately how different populations might respond in the event they were significantly deprived of stolen bargains.

Since theft remains a problem to be solved, criminologists will continue to make progress in the area. The logical impossibility of "crime opportunity" being a cause of crime brings us to a nexus where the next fundamental breakthrough in understanding the causes of theft may possibly be a new hypothesis proposing an explanation for how "demand" for hot products interacts with human actors to cause a "switching point" in offender motivation with the effect that what was previously capable guardianship of valuable products becomes inadequate when their trading value increases to a certain level, which is exactly what happened when electricity first ceased to be a capable guardian of live copper cable when global copper prices rose significantly in 2004 and thereafter. If such a hypothesis is formulated, criminologists and economists will do their best to disprove it through a process of prediction and observable outcome. If disconfirming evidence is not forthcoming, then the issue of fencing and receiving stolen goods may no longer remain so strangely ignored because it might enable criminologists to better forecast crime waves. The theft reduction potential of adopting such a market reduction approach is huge.

Fines in Europe

Tapio Lappi-Seppälä
National Research Institute of Legal Policy,
Helsinki, Finland

Overview

Fine is the most used criminal sanction – both in history and in present. It is also one of the most neglected topics in textbooks and criminal policy analyses. The use of fines and other financial penalties has expanded during the last decades, as a result of several simultaneous changes. The growth of mass infractions in traffic and elsewhere has led to a differentiation of criminal fines into court-fines and summary fines (imposed either by the police or the prosecutor). Also the system of administrative monetary penalties has differentiated into fixed penalties for mass infractions and substantive penalties imposed for large-scale illegal economic activities and corporate fines.

Fines have several benefits which increase their potential as penal sanctions, also for middle rank offenses. This has been acknowledged especially by those jurisdictions that have adopted a day-fine (unit-fine) system. Under this system, the gravity of the offense is reflected in the number of imposed fine-units, while the monetary value of each unit is reflected by offenders' financial means. Thus, two offenders, sentenced for similar offenses, receive fines that are experienced as equally severe, despite the differences in wealth and income. The available (albeit fairly meager) evidence suggests that fines are generally followed by somewhat lower reoffending rates compared to more substantive sanctions.

Not all fines are paid voluntarily, and a backup system for fines is required. The benefits of monetary penalties are lost, if unpaid fines need to be converted to imprisonment. Unfortunately, many jurisdictions have resorted to default imprisonment as a backup sanction. However, there are signs of a wider adoption of new community alternatives to serve this purpose.

History

In tribal societies, injuries were sanctioned either by vengeance or by settlement between the injurer and the injured. The Barbarian Codes (from the fifth century onwards) fixed the amount which can buy off vengeance. The victim (his/her relatives) had the option either to accept the offer or to resort on retribution. These sums cannot be defined as punishment in the modern sense, as there was no third authority to compel the parties to agree with the proposed compensation. It was only through the formation of state and central power that made it possible to establish a public criminal justice system where the ruler had the powers to dictate the sanctions for offenses. In Europe, this period starts around the middle of twelfth century (the establishment of "King's Peace"). This was also the birth of fines as a criminal sanction.

Throughout the history, fines have retained a central position as criminal punishment. Fine was the principal punishment for most offenses in the Nordic codes, the earliest dating from mid-thirteenth century. The amount of fines was also fixed in detail according to the consequences of the acts, and in some cases also the mental state of the offender.

Still, the establishment of justice from above was a slow process. Private vengeance continued to be practiced throughout the later Middle Ages. In addition, fines, even after being authorized and confirmed by the state, served not only punitive but also private compensatory functions. This was also reflected on the way fines were divided in the Nordic codes into three parts: one third to the victim or his/her relatives, another to the King (central power), and one for the Church. Subsequently, punitive and compensatory elements were differentiated from each other, and fines became a matter of public criminal justice belonging to the central power alone. Alongside fines there grew a civil compensation to cover the damages and the losses of the victim.

European criminal codes grew gradually more punitive during the later Middle Ages. As a result, fines lost space to corporal punishments, especially in Central Europe and in England, where the administration of criminal justice came close to state-run terror in the sixteenth and seventeenth century. The eighteenth century witnessed the social and political revolutions across Europe, instigated and inspired by the writings of the enlightenment philosophers. Much of that criticism was a criticism against the brutality and severity of criminal justice of the ancient regime. The use of capital and corporal punishments was restricted and replaced by imprisonment, which came to form the backbone of the European criminal justice systems of the nineteenth century. But along with imprisonment, fines also retained a principal role as a basic sanction for minor and middle rank offenses, especially in the Nordic countries. Practical advantages of pecuniary penalties were recognized also by reformers like Montesquieu, who was among the first to recognize the need to grade the fines according to the financial situation of the offender.

> Our fathers the Germans admitted almost none but pecuniary penalties. These men, who were both warriors and free, considered that their blood should be spilled only when they were armed. The Japanese, by contrast, reject these sort of penalties on the pretext that rich people would escape punishment, But do not rich people fear for the loss of their goods? Cannot pecuniary penalties be proportionate to fortunes? And, finally, cannot infamy be joined with these penalties?
>
> Montesquieu, The Spirit of the Laws. Book VI, Chapter XVIII.

The practical use of fines was conditioned also by general economic conditions. According to Rusche and Kirchheimer (1939, p. 167), the poverty of lower classes remained as a central obstacle for the expansion of fines till the middle of the nineteenth century, whereafter their use has expanded, much caused by the decline of unemployment and the general rising of living standards. For example, in Finland and Sweden, over 90 % of cases dealt by the courts in the end of nineteenth century were punished by fines. Though often overlooked by historians and legal textbooks, fines remained the most used criminal sanction also during the twentieth century in several common offenses (see Table 1).

Fines in Europe, Table 1 The use of fines in 1930s (percent of all punishments)

	France 1933	Belgium 1930	Sweden 1934	Germany 1933
Assault (intentional)	68.9	79.3	97.9	62.2
Damage to property	63.1	79.3	97.9	62.2
Larceny	15.5	24.4	25.1	29.3
Fraud	10.5	10.7	46.9	34.2
Adultery	99.5	83.0	70.9	58.1

The System of Financial Sanctions

Fines can be ordered by the courts or through simplified process by the prosecutor or the police. The expansion of mass-criminality in the form of new traffic offenses and the growth of petty property offenses (resulting from the change of opportunity structures) has led to an ever-widening adoption of summary proceedings. Today the majority of fines in most jurisdictions are imposed either by the police or the prosecutors.

Alongside "penal fines," there are other kinds of financial sanctions with punitive and preventive functions, and which are sometimes hard to distinguish from penal fines. Continental legal theory makes a clear distinction between criminal and administrative sanctions. This distinction has also far-reaching consequences for the imposition and enforcement of sanctions. For example, administrative matters are dealt with by administrative courts and criminal matters in criminal courts. The use of criminal punishments is tied by much stricter legal safeguards and procedural guarantees, including requirements of guilt, presumption of innocence, and the principle of proportionality.

The growth of administrative sanctions alongside is based on two distinct reasons. Criminal law with all its legal safeguards has proven to be too expensive and heavy measure to deal with bagatelle-offenses. For reasons of procedural expediency, many countries have developed own administrative sanction systems to deal with traffic-offenses, minor infractions against public disorder, etc. The German system of "Ordnungswidrigkeit" has served as a model for several jurisdictions in the continental Europe.

On the other hand, criminal law has proven to be ineffective and impractical when it comes to dealing with large-scale economic activities where the magnitude of possible gains from illegal activities may be counted in millions. The establishment of corporate liability and corporate fine to control large-scale illegal economic activities may have been arranged either inside criminal punishment (with the requirement of criminal guilt) or outside criminal law (as an administrative sanction based on objective responsibility).

In addition to fines based on national corporate liability, there are an increasing number of economic sanctions based on the need to protect supranational market interests (EU fines). The EU Commission has set up guidelines on the method of setting fines imposed on firms which infringe European Union (EU) rules, prohibiting cartels and other restrictive business practices and abuses of dominant position (article 23(2)(a) of Regulation (EC) No 1/2003). The basic amount is calculated as a percentage of the value of the sales connected with the infringement, multiplied by the number of years the infringement has been taking place. Additional factors in setting the fine include the gravity of the infringement and possible previous infringements. The maximum fine for each firm remains 10 % of its total turnover in the preceding business year (Regulation EC No 1/2003, http://europa.eu/legislation_summaries/competition/firms/l26118_en.htm). While traditional penal fines are counted in hundreds or occasionally even in thousands of Euros, EU-corporate fines are easily counted in millions.

In all, the present system of financial sanctions may be divided into three main groups (with considerable jurisdictional variations). (1) Fines defined as criminal punishments and imposed for natural persons, either by the courts or by other criminal justice agencies (prosecutors or the police). (2) Administrative penalties imposed for natural persons for mass infractions (parking tickets, etc.). (3) Substantial financial penalties/fees imposed for illegal economic activities for natural persons or for companies (corporate fine), either under national or supranational (EU fines) rules. The following part of the entry discusses mainly about penal fines imposed for natural persons (group 1).

The Benefits of Fines

The benefits of fines over other penal sanctions are generally known (see, for example, Gordon and Glaser 1991). Fines are generally less costly to administer and can provide revenue that, in some cases, exceeds their administrative costs. Secondly, monies paid to the court can be redirected to the victim of an offense in order to pay financial restitution for any physical or psychological harm incurred. Fines are a flexible penalty that can be adjusted to reflect both the severity of the crime and the offender's financial circumstances (see below). Finally, the use of financial penalties avoids many of the debilitating social costs that are attached to incarceration (including the loss of job and leaving dependents with reduced income and labeling and making it more difficult for the offender to successfully return to the community). Fines permit the offender to remain in the community and in employment, and, in doing so, reduce the need for social support. Much of these benefits are dependent on the way the setting and enforcement of fines is arranged.

The Day-Fine System

Equal treatment of offenders requires that penalties for the same offense should be equally severe for different offenders. The same sum of money means different things for the rich and the poor, and it is an elementary requirement of social justice that people should be treated in the same manner despite the differences in wealth and economic resources.

Most fining systems have tried to meet the demands of equal impact by developing counting rules for balancing the differences in economic wealth. The Scandinavian day-fine system has proven to be the most successful in this respect. The day-fine system was adopted first in Finland in 1921, with Sweden and Denmark to follow in 1931 and 1939.

The origins of the system go back to the discussions in the International Association of Criminalists and their Nordic counterparts in the shift of the century, while the term day-fines was coined by a Swedish law professor Johan C.W. Thyrén. The introduction of the day-fine system was motivated by three main reasons. Firstly, it provided a mechanism to ensure equal impact of sentence severity for the rich and the poor. Secondly, since the amount of fines was tied to the level of income, fines were more or less untouched by the changes in the value of money. And since this made it possible to maintain the level of fines high enough, fines could serve more effectively as alternatives for the much discredited short prison sentences. The Scandinavian day-fine system has served as an influential model for a number of European jurisdictions. During the last decades, countries such as Germany (1975), Austria (1975), France (1983), and Switzerland (2007) have adopted the system with success.

The main objective of the day-fine system is to ensure "equal severity" of the fine for offenders of different income and wealth. In this system, the number of day-fines is determined on the basis of the seriousness of the offense while the amount of a day-fine depends on the financial situation of the offender. The total sum of a fine is reached by multiplying the number of day-fines with their monetary value. The technical counting rules vary within each country, but the basic principle remains the same. It is also very much a matter of domestic penal (and social) policy whether income is counted before (brutto) or after (netto) taxes, and whether there exists a definite ceiling for the value of a single day-fine. In Finland, for example, the amount of the day-fine equals roughly half of the offender's daily income after taxes (and without any upper limit; in Austria, the limit is 5,000 Euros and in Germany 30,000 Euros). The exact amount results from a rather complicated calculation. However, the officials (police, the prosecutor, and the courts) have in their hand a handbook which makes it easy to count the amount of day-fines. Also the number of day-fines varies in different systems: in Finland from 1 to 120, but in Austria, Germany, and Switzerland from 1 to 360.

> *An example from Finland*: The typical number of day-fines for drunken driving with BAC of 1,0 o/oo would be around 40 df. The monetary value of one day-fine for a person who earns 1,500 euros/months would be 20 euros. For someone with a monthly income of 6,000 euros, the amount of one day-fine would be 95. Thus the total fine for the same offense would be for the former person 800 euros and for the latter 3,800 euros.

Not all countries have followed this line. Most common law countries, including the USA, implement tariff fines, which leave much less – if any – room for the adjustment of fines according to the financial means of the offender. England and Wales adapted the system of "unit-fines" based on the day-fine principle in 1991. However, after a heavy media-driven criticism, the government repelled the system in 1993. As noted by a leading legal commentator:

> [T]o sweep away the whole edifice and to return to a system that promises, on the Governments own view, less fairness, fewer fines, and greater difficulty to enforcing them, . . . is eloquent testimony to the power of short-term political gain over sound penal policy. (Ashworth and Gibson 1994, Criminal Law Review 1994, 101 ff)

The failure of the unit-fines system in England and Wales in 1991 was basically a political one. It can be attributed mainly to the UK government's inability to defend a sound system against ill-founded public pressure and misplaced criticism. As reported in surveys post the reform, courts that followed the unit-fines process were more consistent in their fining practice and they graduated the fines more proportionally according to the level of income. In short, their fine setting practice met the requirements of both equality and proportionality better, compared to courts that followed the old system (see Charman et al. 1996).

Despite the defeat in the UK, there have been ongoing efforts to expand the day-fine system in other common law countries. In the USA, this system has been renamed as "structured fines." The first structured fine project demonstration in the United States was designed and operated by the Vera Institute of Justice in Staten Island, New York, between 1987 and 1989. Soon after, several other US jurisdictions had started to implement similar programs. But as it was also noted, these programs required well thought-out policy formulation and program planning, as well as a strong collection system. As the situation stands to days, a growing number of US jurisdictions are experimenting with structured fines (see Bureau of Justice Assistance 1996: How To Use Structured Fines (Day Fines) as an Intermediate Sanction, https://www.ncjrs.gov/pdffiles/156242.pdf).

Institutional Requirements for Effective Enforcement

Effective enforcement of fines requires centralized and well-functioning enforcement organization. Fines need to be collected, which may sometimes need several consecutive acts by the state authorities and/or local municipalities. The authorities need to contact the debtor and, in case of nonpayment, enforce the payment, for example, by drafting a payment plan which allows payment by installments. The credibility of fining systems depends much on the effectiveness of this organization. Low payment rate undermines the credibility of the whole system. It reduces the public confidence of fining and it diminishes the willingness of the courts to use fines as sentencing options. The Nordic countries report fairly high collection rates (for example Sveri 2005, 376 reports that 90–95 % fines are paid in Sweden within 5 years). However, exact comparisons between different systems are complicated due to differences in counting methods.

As regards the day-fines system, key requirement for its effective implementation is that those responsible in setting the fines (whether the police, prosecutor, or the courts) have reliable information about the offenders' income and financial situation. This can be ensured in several ways. In most Scandinavian countries, the criminal justice authorities (including the police) have access to previous year's taxation files. More specifically, the police can receive on request last year total annual income via protected SMS data from the taxation officials. Should that option not be available, other sources for correct income data may be needed. In 1999, Finland criminalized giving false information of one's income for the police in order to reduce the amount of fines. (However, after the establishment of the SMS link, the criminalization of "fine deception" became obsolete, with only two or three convictions per year).

Default Penalties

The credibility of fines as criminal sanction requires a backup system, which will be enforced in the case of nonpayment. The standard default sanction for unpaid fines has traditionally been imprisonment. In the course of history, default imprisonment has – from time to time – become one of the major causes for locking up people. In the 1930s, half of the males and two thirds of females were in English prisons due to unpaid fines (Rusche and Kirchheimer 1939, 169). In Finland, during the last prohibition years in the late 1920s, four out of five admitted prisoners were taken in custody because of unpaid fines.

If fines are converted to custodial sanctions, the original benefits of monetary penalties are lost. One may also end up using prison for trivial offenses, and for offenders whose major fault is that they are too poor to be able to pay their fines.

Fines in Europe, Table 2 The use of default imprisonment for unpaid fines in Europe

	Fine defaulters (1 September 2009)			
	Abs	% of prisoners	/pop	/10,000 fines
Denmark	0	0.0	0.0	0.0
Sweden	0	0.0	0.0	0.0
France	6	0.0	0.0	0.2
Belgium	1	0.0	0.0	0.3
Scotland	4	0.0	0.1	0.7
England and Wales	113	0.1	0.2	0.9

Germany	4197	5.7	5.1	72.0
Poland	3302	3.9	8.6	106.6

Source: Compiled from European Sourcebook 2010

The discriminatory nature of default imprisonment has been acknowledged for long, and most countries have made efforts to restrict the use of default imprisonment, however, with different results. Some jurisdictions have adopted community alternatives as default penalties (such as supervised attendance orders in Scotland, community service in Germany, or the newly adopted "fine service" in Norway). Other countries have just simply ceased to impose default penalties for unpaid fines, as was done in Sweden in the 1980s. More recently also Denmark has practically ended the use of default imprisonment in the late 2000s. Finland, with probably the highest number of imposed fines in Europe, has also had the largest number of fine defaulters in the Nordic countries. However, in 2006–2009, the average number of fine defaulters in prisons (at any given day) has been reduced from around 200 to 50, removing all prosecutors' fines outside the default system (Table 2).

As shown in comparative analyses, default imprisonment has practically disappeared in Denmark, Sweden, France, Belgium, and Scotland. In Poland, Germany, and the Netherlands, about 5 % of prisoners are in custody for unpaid fines. However, also in Germany, a considerable reduction of fine default imprisonment has been achieved by extending community service schemes in some federal states (see Dünkel 2004).

Fines in Practice

Criminal justice systems vary in their ways to deal with minor infractions. Some include even the most common traffic offenses (as is done in Finland) in criminal code, other exclude not only traffic offenses, but also many other minor infractions from their criminal justice statistics. With these caveats in mind, Table 3 makes effort to highlight the use of fines in European countries.

First column displays the number of all imposed sanctions (convictions) either by the court or prosecutor. All offenses and infractions are included. Comparison with column D (convictions excluding traffic cases) shows how much each nation's criminal justice statistics are affected by traffic violations. Finland has the highest overall conviction rate (4,158), but three out of four convictions are for traffic cases (non-traffic convictions: 1,413). England and Wales, in turn, reports only non-traffic cases, as is done also by the Czech Republic, Latvia, and Cyprus. One must therefore look at the overall number of imposed fines (B) with caution. They reflect for some countries mainly traffic offenses, for others something else.

Some of these difficulties may be overcome, once the use of fines is analyzed separately for different offenses. Table 4 lists imposed fines and other sanctions/pop by countries and regions.

The average number of sanctions imposed for theft in 21 European nations was 153, of which 34 (22 %) were fines and 119 other types of penalties. For assault, the corresponding figures were 72 (all) 22/31 % (fines) and 50 (other sanctions).

The Nordic countries impose the largest number (300–600) of sanctions for theft offenses (together with Scotland and Hungary). However, in Finland, 9 out of 10 theft offenses are dealt with fines. This leaves around 52 other sanctions than fines imposed for theft in Finland, which, in turn, is considerably lower than the European

Fines in Europe, Table 3 The use of fines in Europe 2006

	General application of fines (all offenses)			
	A All convictions/ pop	B All imposed fines/ pop	C Fines of all convictions %	D Non-traffic convictions/pop

average (119). Finland has the second highest number of convictions also in assault (207), after Scotland. More than half (112) of these are fines, which is five times the European average (22). This indicates that Finland imposes monetary sanctions for both offenses in a much larger scale than any other country (while the victimization rate for theft in Finland is well below the European average and for assault little above the average). The alternative explanation is that minor forms of property and assault offenses are in other countries dealt by sanctions that are not included in the European Sourcebook statistics.

There are marked differences between the countries and it is hard to discern clear patterns. However, with the exception of Hungary, fines are much rarer in the Eastern countries, while the overall level of imposed sanctions is fairly high in these countries, especially in theft offenses. Scotland imposes a large number of sanctions both for theft and assault offenses. Also fines are used in a high scale. Switzerland imposes a very low number of sanctions for both offenses, and uses practically no fines. Whether the use of fines is connected with the extent of imprisonment will be discussed next.

Fines as an Alternative to Imprisonment

Fines provide one alternative to short-term prison sentences. Finland has been, perhaps, more consistent with her efforts to expand the use of fines over other type of sanctions. After the adoption of

[a] The low number of fines in Switzerland does not match with the data from official sentencing statistics (see http://www.bfs.admin.ch/bfs/portal/de/index/infothek) which indicates that fines (especially suspended fines) play an a substantial role in sentencing (in 2010 total number of convictions 98,200, of which suspended fines 71,881, partly suspended 1,050, and unsuspended 11,554). It is possible that formerly used (prior the day-fine reform) lump-fines (Busse) have not been included in the table

[b] The low number of assaults in England and Wales compared to earlier editions suggests that the definition in the statistics has been changed in a manner that prevents reliable comparisons

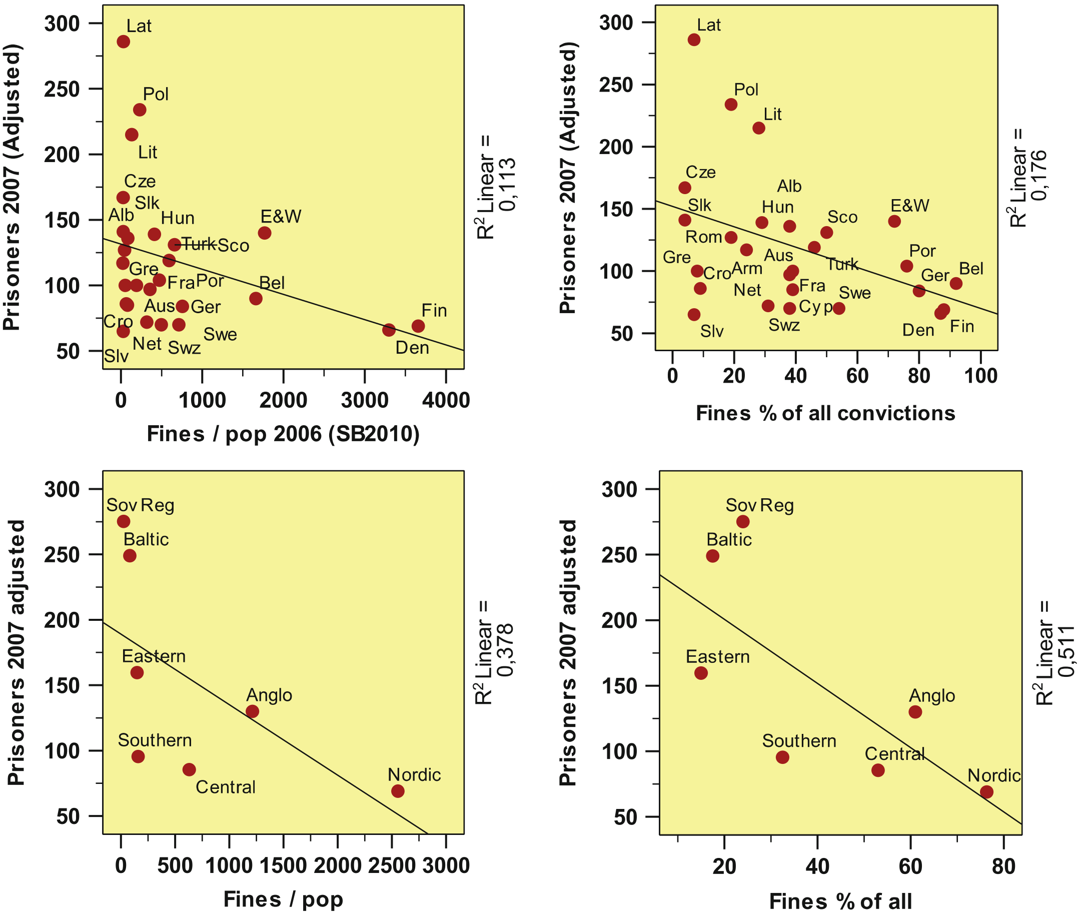
day-fines in 1921, the next major reform took place in Finland in 1977 as a part of a general prison reduction program. The monetary value of day-fines was increased, thus making fines a more credible alternative for short-term prison sentences. As the follow-up studies show, this aim was largely achieved also in practice (Lappi-Seppälä 2011). Similar results were gained also in Germany in connection with the replacement of short-term prison sentences (up to 6 months) by fines in 1969 and the adaption of the day-fine system in 1975 (see Dünkel and Morgenstern 2010).

The association between the use of fines and national incarceration rates is examined in figure below (Fig. 1).

There is a clear inverse correlation with the overall use of fines relative to population, even though this correlation is much dominated by high rates from Finland and Denmark. The same applies to the share of fines and incarceration rates, with much more even distribution. Regional analyses reveal the exceptional position of the Nordic countries. They use much more frequently fines, and they have much lower incarceration rates. Eastern countries represent the other end of this scale with high incarceration rates and scarce use of fines.

Effectiveness

It is generally known that offenders receiving fines have the lowest recidivism rates. For example, in Finland, about 25 % of those receiving fines became reconvicted for some form of penalty during the following 5 years whereas the figure for those receiving prison sentence was as high as 75 %. But as the initial recidivism risk in these two groups is totally different, these figures



Fines in Europe, Fig. 1 The use of fines (/pop and as % of all convictions) and imprisonment rates by countries and by regions (Source: European Sourcebook 2010)

cannot be used as a basis for comparisons. Unfortunately, there is fairly little systematic research with control groups on the effects of fines on recidivism.

A study published in the USA in 1991 (Gordon and Glaser 1991) compared recidivism after different combinations of fines and other sanctions. Supervision with fines led to lower recidivism (25 %) than mere supervision (36 %). Equally short-term imprisonment with supervision and fines led to lower recidivism (37 %) than mere supervision and fines (50 %). However, the detected associations were statistically nonsignificant (Table 5).

A methodologically more advanced US study based on randomized experiment (Turner and Petersilia 1996) compared day-fines with flat-rate fines (no difference according to income). It turned out that the day-fine group had a lower recidivism rate (11 % vs. 17 %) and less technical violations (9 % vs. 22 %) than the control group (latter differences were statistically significant).

The third study is a meta-analysis covering 18 studies (Gendreau et al. 2000). The overall effects size in these 18 studies was −0.04. In other words, after groups had been matched, those receiving fines showed a 4 % lower recidivism rate than those receiving other types of penalties.

The impact of the size of fines on reoffending was examined by a large-scale study carried out

Fines in Europe, Table 5 Recidivism rates after fines

Study	Results
Gordon and Glaser (1991) USA	Supervision and fines (25 %)
No data on the matching of the groups	Only Supervision (36 %), nonsignificant
	Supervision, prison, and fines (37 %)
	Supervision and prison (50 %), nonsignificant
Turner and Petersilia (1996) USA	Arrests
Randomized experiment	Day-fines (11 %)
	Control group (17 %), nonsignificant
Poor data of treatment of control group	Technical violations
Consists of fixed fines	Day-fines (9 %)
	Control group (22 %), significant
Gendreau et al. (2000) Canada	Meta-analysis (18 studies)
	Effect-size −0.04 (= 4 % difference)
Moffatt and Poynton 2007	Reoffending was uninfluenced by the size of fines imposed for driving offenses
Marginal (specific) deterrent effect of the size of fines on recidivism	
Two-stage regression model	

in Australia by the NSW Bureau of Crime Statistics and Research, see Moffatt and Poynton (2007): 70,000 persons who received a court-imposed fine for a driving offense between 1998 and 2000 were followed for a period of 5 years to see whether they committed another driving offense. After controlling for a wide range of other factors likely to influence reoffending, a no relationship between the magnitude for the fine imposed and the likelihood of a further driving offense was found. The same negative result was obtained for drink-drive (PCA) offenses, drive while disqualified offenses, exceeding the speed limit and "other" driving offenses. The results are in line with the general findings that suggest that increased sentence severity does not go along with lower reoffending rates. However, the results leave the question of relative effectiveness of fines open.

Public Acceptance of Day-Fines: A Case Study from Finland

Fines are vastly the most extensively used criminal sanction. At least one out of ten Nordic citizens receives each year either a fine or a corresponding administrative sanction, usually for a traffic violation. As pointed out by a Swedish professor in criminology:

> There are many reasons why we should be more interested in the use of fine. We should never forget that more people are getting into contact with the legal system by being fined than by any other means. And because of this the way fines are handled by the representatives of the state will forever be remembered by the citizens. (Sveri 2005)

Smooth functioning of fining system is dependent on its legitimacy and public acceptance. Unfortunately, there is only limited research on the legitimacy and public perception of fines. The English government withdrew the unit-fine reform partly with reference to lack of public support – whether real or just printed in headlines. For this, the Finnish experience with another day-fine reform forms an interesting contrast.

In the shift of the millennium, the Finnish fining system received worldwide attention, thanks to extraordinary large traffic fines imposed for offenders with extraordinary high income. The Finnish law does not recognize any upper limit for a day-fine, and if the offenders' annual income is counted in millions, the fines may well be counted in thousands of Euros – or even more.

The other source for criticism was the worry expressed by the conservatives that a system based on gross-income instead of net-income leads to unjustly severe fines in general in higher income levels. Under the conservative coalition government, gross-fining was changed to net-fining in 1999 with the aim, "to introduce a more just fining system, whereby the size of the fine is perceived as fair among different income-groups" (Government Bill 74/1998).

A follow-up research was carried out in order to measure the degree of perceived fairness of the fining system. A total of 2,966 persons were interviewed at four different stages before and after the reform during the years 1999–2001. Key findings included the following (see Lappi-Seppälä 2004):

- In general just below 60 % considered traffic fines generally to be fair, about one fifth considered them too low, and about one sixth too severe.
- Three out of four considered that the system with day-fines was in general fair.
- When asked whether speeding fines should be graded according to the drivers' income, or whether the fine should be the same for all drivers, four out of five preferred differentiation according to income.

The assessments of fairness varied in different respondent groups. Not surprisingly, those who did not drive considered the system with day-fines to be fairer than those who drove (still, 70 % of drivers considered the system as fair). Men were more critical of the system with day-fines than women. Women would often be more apt to demand more severe traffic fines than men. As one could anticipate, respondents' critical attitudes toward the day-fine system grew along with income-level.

Several of the findings were in clear contradiction with general presumptions about the public support of the fining system. Evidently the fears of the perceived unfairness of the fining system were grossly exaggerated. The reform of the fining system introduced in 1999 did not as such bring about any significant change in public opinion, once measured before and after the reform. Neither seemed the stirring fines imposed in summer 2000 appear to have affected the public's confidence in the fining system for traffic offenses.

But as it also turned out, the general public was poorly aware of the rules concerning fines for traffic offenses. The fact, whether fines were counted on the basis on net-income or gross-income, turned out to be completely irrelevant for the perceived fairness of the fining system.

One major lesson was that the images of the public opinion, as expressed by the media and the politicians, may have very little to do with the views shared by the "silent majority." Not surprisingly, the perceptions of fairness and the proper amount of control depended heavily on the respondents' personal circumstances and financial situation: Those who do not drive wish more control and stiffer penalties, those who drive are less satisfied with the fining system, and those who have the highest income-level are the least satisfied with the day-fine system. Envy and self-interest are also essential elements in public opinion.

It seems that the legislators' attempt to "gratify" the well-off offenders by moving from "gross-fining" to "net-fining" did not succeed. Paradoxically, after the reform, the discontent of the fining system grew, especially among respondents in the highest income-level. In other words, those who benefited most from the new net-fining were the least satisfied with the changes brought by the reform. Either they had misperceived the content of the reform, or they were unhappy with the fact that giving false information to the police of their income had become a criminal offense (for the criminalization of fine deception, see above).

Surveys leave the door open for different interpretations. One fairly plausible conclusion could be that a clear majority of Finnish people consider the day-fine system and the fines imposed for traffic violations as reasonable fair and just. This was the case before and this was also the case after the reform (which, in fact, largely passed their attention). Another conclusion could be that the assumptions of the contents of "public opinion" may rest on a shaky basis – as may also lay the efforts to please this (assumed) general opinion.

Overview

This entry will provide an overview of the stages leading to fingerprint identification, including the enhancement of marks deposited at crime scenes, obtaining images of the enhanced marks that are suitable for identification, and the methodologies that are used during the identification process itself. The range of enhancement processes that can be used to reveal marks is described in detail, showing how different constituents of deposited marks can be progressively targeted to maximize the number of marks recovered. This entry also addresses some of the recent research associated with the fingerprint identification stage, including the possible influences of cognitive bias and the use of probabilistic approaches to describe fingerprint identifications in place of 100 % certainty.

Fundamentals

Definitions

In this section, the term "fingerprint" will be used to describe impressions of the ridge patterns on fingertips that have been taken under controlled conditions, for example, inked or digitally enrolled ten-print sets. The term "finger mark" is used to describe the marks recovered from articles or surfaces at crime scenes.

"Finger mark recovery" is defined as the process by which finger marks present on articles and surfaces are revealed and captured. The output of the finger mark recovery process is an image of the mark that can be submitted for comparison and identification.

"Fingerprint identification" is defined as the comparison of finger marks against sets of fingerprints, or two sets of fingerprints against each other, so that it can be established that they originate from a common source.

Finger Mark Recovery

Introduction

The finger mark recovery process begins with an initial examination of an article or surface where it is suspected that finger marks may be present. In some cases marks may already be visible during the initial examination, either because they have been deposited in a visible contaminant ("patent" marks) or because they have left permanent impressions in a soft surface ("plastic" marks). The majority of marks present on the surface are not visible during this initial examination, and some means of enhancement will be required to make them detectable by an eye or an imaging system. These marks are known as "latent" marks.

One of the principal differences between finger marks and other types of forensic evidence is the wide range of mark enhancement techniques that are available, and the fact that it is possible to use several of these techniques in sequence. The sequential application of enhancement techniques, commencing with nondestructive processes and progressing to techniques directly reacting with constituents of the mark, maximizes the chances of their recovery.

A wide range of optical, physical, and chemical techniques are available for the detection and enhancement of latent finger marks. The choice of the best sequence of techniques will depend on several factors that include the following:

- The nature of the surface and the presence of any particular contaminants
- Environmental factors
- The likely age of any evidential finger marks
- Investigative priorities
- Other forensic evidence

The techniques that are used for finger mark enhancement all have the same purpose, which is to increase the contrast between the finger mark ridges and the surface they have been deposited on to an extent where the mark can be readily seen and captured. Many different properties of the mark may be used to achieve this contrast, including optical properties, adhesive properties, chemistry of the mark, and electrical properties. The chemistry of finger marks is usually a complex one, and the chemicals that may be present in marks include constituents of eccrine, sebaceous, and possibly apocrine sweat, contaminants from any substances handled, and substances significant at crime scenes such as blood. If additional information can be obtained about the likely composition of the finger marks (e.g., contaminants that may be present), this will assist in the selection of the most appropriate enhancement techniques.

When considering which enhancement techniques should be applied to a particular article or surface, the nature of the surface and the environment it has been exposed to should also be considered. Surface characteristics such as porosity, texture, and color will all influence what happens to the mark post-deposition and, thus, will influence the selection of the most appropriate technique(s). This will be equally true of any known environmental conditions such as exposure to water and high temperatures. The initial examination stage should be used to obtain as much of this information as possible so that the selection of enhancement processes is optimized.

Finger Mark Enhancement Techniques

The sections below give an overview of some of the finger mark enhancement processes that are available, together with some indication of their potential applications. Many other processes have been reported, those outlined below cover a representative range.

Nondestructive Processes

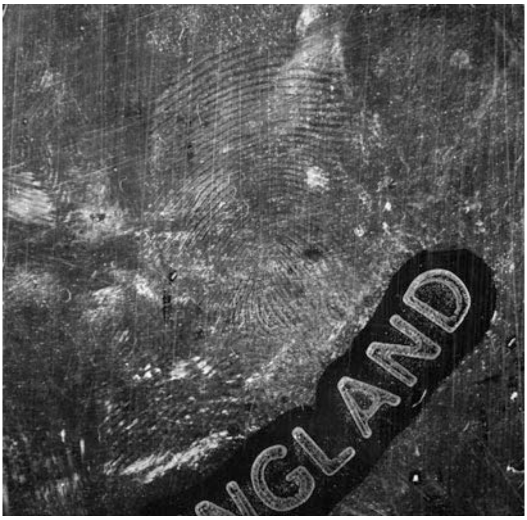
Visual Examination Visual examination utilizes differences between the optical properties of the mark and the surface to provide contrast. The surface is illuminated with a light source, and the angle and proximity of the light source to the surface varied until optimal contrast is obtained. The process is most suited for greasy marks and marks in dust on nonporous surfaces.

Fluorescence Examination Fluorescence examination is performed by illuminating the surface with a high intensity light source and viewing any fluorescence through a filter that blocks the illuminating wavelength range (Menzel 1999). It can be used to detect latent finger marks on both porous and nonporous surfaces, or to enhance marks developed using other techniques. Contrast is obtained by either the mark or the background fluorescing, and the other component absorbing the incident light. When used to detect latent marks, any fluorescence observed in the mark is most likely to arise from the presence of contaminants although some natural constituents may fluoresce.

Ultraviolet Imaging Ultraviolet imaging is a specialized technique that requires an imaging system sensitive to short wave ultraviolet radiation. The surface is irradiated with short wave ultraviolet, and the outcome is viewed through the imaging system. On porous surfaces, marks may absorb radiation and the surface may reflect it, and on nonporous surfaces marks scatter radiation to a greater extent than the surface (Creer 1995). Both mechanisms may give sufficient contrast for the marks to be revealed. The short wavelength of the ultraviolet radiation is scattered more than visible wavelengths, meaning that fainter traces of marks can be detected. The technique should be used with caution because short wave ultraviolet is harmful to both skin and eyes, and can destroy DNA evidence.

Selective Deposition Processes

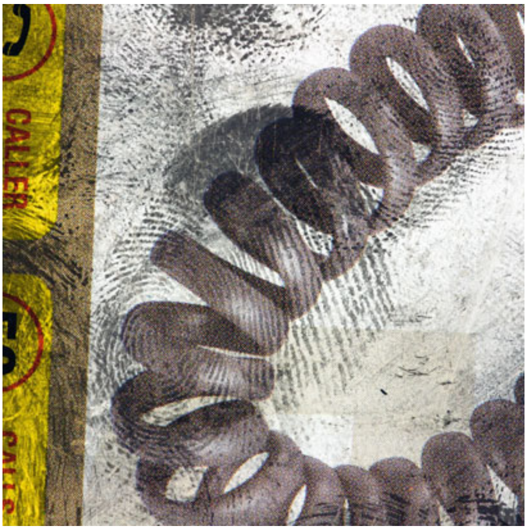
Powders Powdering is one of the oldest finger mark enhancement techniques. Finely divided powders are applied to the surface using a brush (or an equivalent delivery system such as a magnetic applicator), and some of the particles selectively adhere to the ridges of the mark, making it visible (Fig. 1). A variety of adhesive mechanisms may operate, including wetting by capillary action and physical adhesion due to the "sticky" nature of the mark. A wide range of powder types are available, and the most appropriate should be selected taking into account factors including the surface texture and color.



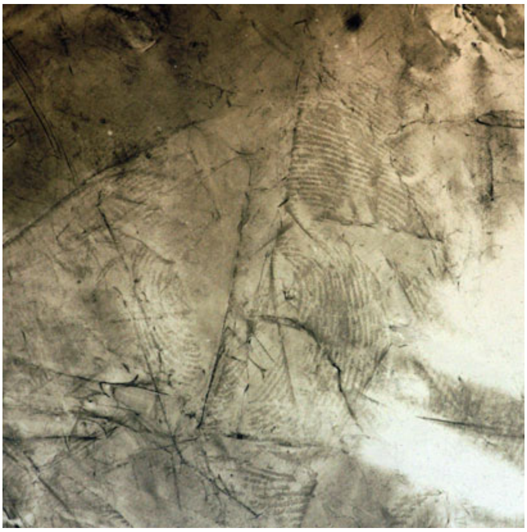
Fingerprint Identification, Fig. 1 A mark developed using aluminum flake powder and lifted using transparent tape

Small Particle Reagent Small particle reagent formulations utilize a dilute mixture of particulates (most commonly molybdenum disulphide) in a water/detergent solution. The detergent molecules form micelles around the particles, the lipophilic molecules in the micelles causing the particles to preferentially attach to the lipids in the mark. The article being treated is immersed in an agitated solution of the small particle reagent, and the particles are allowed to settle onto the article. Excess particulates are gently washed from the surface to reveal the mark. The technique is suited for use on nonporous surfaces and can be used on articles known to have been wetted.

Powder Suspensions Powder suspensions are very similar in nature to small particle reagent, but consist of a much more concentrated mixture of powder (either carbon, iron oxide, or titanium dioxide) in a detergent/water mixture. This is painted onto the surface using a brush and then washed off before it can dry. Some constituent of the mark (thought to be eccrine constituents held in an insoluble matrix) destabilizes the micelles and causes particles to preferentially settle on the ridges. The technique can be used on nonporous surfaces, adhesive surfaces (Bratton and Gregus



Fingerprint Identification, Fig. 2 Marks developed on a semi-porous printed cardboard box using black powder suspension



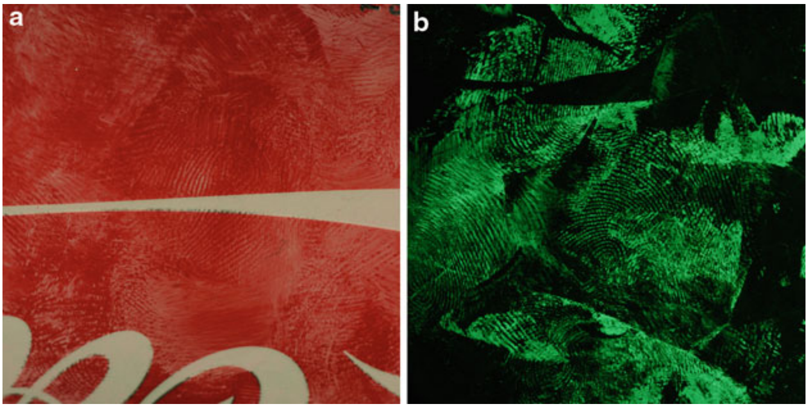
Fingerprint Identification, Fig. 3 A mark developed using vacuum metal deposition on a polyethylene bag and imaged using transmitted light

1997), and semi-porous surfaces, including those that have been wetted (Fig. 2).

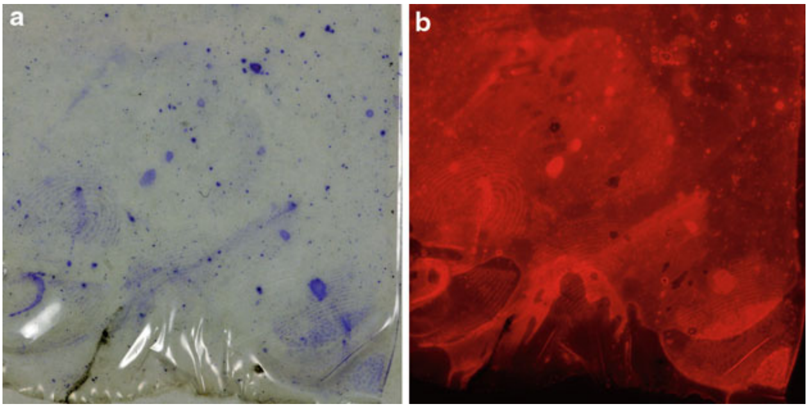
Vacuum Metal Deposition Vacuum metal deposition reveals marks by selective deposition of metal onto the surface. Vacuum is required to reduce the metal vapor pressure to a point where it can be readily evaporated. The most commonly used process involves an initial evaporation of a small quantity of gold, which deposits all over the surface as small clusters. The size and distribution of these clusters is influenced by the nature of the surface, and often differs between the ridges and the background. A second evaporation of zinc is then conducted, zinc relying on the presence of gold clusters to initiate and grow as a film on the surface. Differences between the growth rate of zinc on the ridges and background regions make the marks visible (Kent et al. 1976). Vacuum metal deposition is most suited to nonporous surfaces but can also be used on semi-porous and porous surfaces including fabrics. It can be used to develop marks on nonporous surfaces that have been wetted (Fig. 3).

Multimetal Deposition Multimetal deposition is a liquid phase deposition process. The article is first exposed to an acidified colloidal gold solution. This causes constituents of the finger mark ridges to become charged, and colloidal particles are attracted by and bound to the mark. This is not sufficient for the mark to become visible, so the article is exposed to a second "physical developer" solution consisting of a silver-iron redox combination. Silver particles are preferentially deposited on the gold already bound to the ridges, and the mark becomes visible as a consequence (Schnetz and Margot 2001). Multimetal deposition can theoretically be applied to both nonporous and porous surfaces but in practice is most suited to nonporous surfaces, in particular plasticized polymers such as "cling film."

Cyanoacrylate Fuming Cyanoacrylate fuming reveals marks by selective polymerization of cyanoacrylate monomer vapor on finger mark ridges. Vapor can be produced in several ways, but is most commonly achieved by evaporation of liquid cyanoacrylate monomer from a dish placed on a heated stage. The resultant polycyanoacrylate deposit appears white and may give sufficient contrast for marks to be seen on dark surfaces. However, subsequent enhancement techniques are often used to increase contrast, such as staining the polymer deposit with



Fingerprint Identification, Fig. 4 Marks developed using cyanoacrylate fuming (**a**) marks on a drinks can viewed using white light, (**b**) marks on a black refuse bag, dyed with basic yellow 40 and viewed under fluorescence



Fingerprint Identification, Fig. 5 Marks developed on adhesive tape using basic violet 3 (**a**) viewed using white light, (**b**) viewed under fluorescence

fluorescent dyes (Fig. 4). The polymerization reaction is initiated and catalyzed by the presence of finger mark constituents including salts (especially sodium chloride) and some other eccrine constituents in the presence of moisture (Wargacki et al. 2007). Fuming cabinets may be humidified to supply this moisture in a controlled manner. Cyanoacrylate fuming is generally used on nonporous surfaces, but is not suitable for use on wetted surfaces because the eccrine constituents that initiate polymerization are dissolved.

Staining Reagents

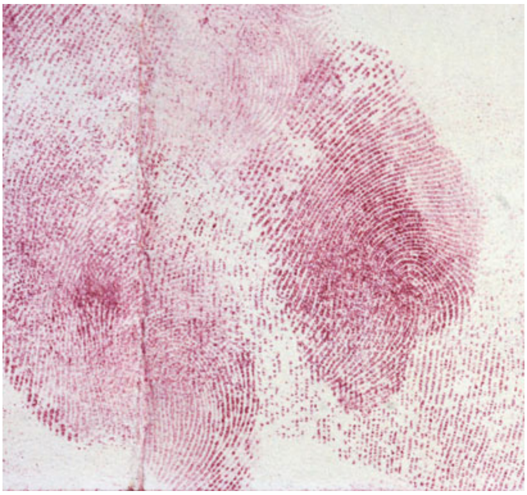
Basic Violet 3 Basic violet 3 is a dye that can be used to preferentially stain lipids, greasy contaminants, and epithelial cells sometimes shed within finger marks (especially on adhesive tapes). The dye molecules preferentially transfer from solution into any compatible constituents that may be present within the mark, staining them violet. Excess dye is then washed from the surface. The dye is also fluorescent and marks that are not stained sufficiently for them to be detected visually may become visible when examined using fluorescence. Basic violet 3 can be used on surfaces contaminated with grease, and on nonporous and adhesive surfaces. On nonporous and adhesive surfaces, it is generally used last in a sequence because it may cause heavy staining, but is capable of developing reasonable numbers of additional marks. The dye and solvents used do have health and safety issues associated with them and use should be restricted to small articles under controlled conditions (Fig. 5).

Solvent Black 3 Solvent black 3 is another dye that is used to selectively stain the lipid constituents of finger marks together with greasy contaminants. The article being treated is exposed to the dye solution until staining has occurred and then the excess washed from the surface, leaving the marks stained a deep blue/black. Its operational use tends to be confined to nonporous articles known to be contaminated with grease or drinks residue. It is nonfluorescent and nontoxic, although difficult to clean from scenes.

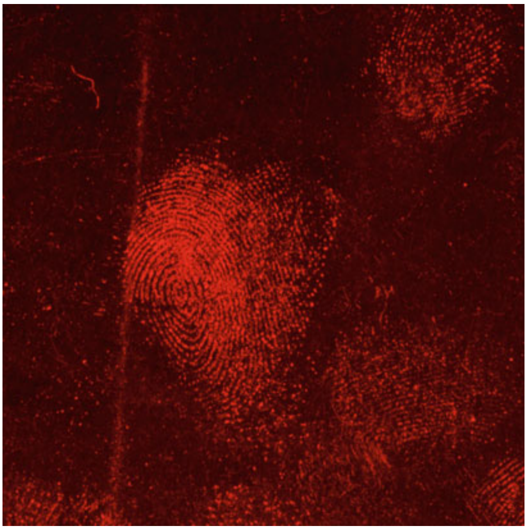
Amino Acid Reagents

Ninhydrin Ninhydrin is one of the mostly widely used finger mark enhancement techniques worldwide. It is most suited for use on paper articles but can be effective on other porous surfaces including matt painted walls and untreated wood. Ninhydrin is an amino acid reagent and reacts with the amino acids present in finger marks to give a purple reaction product (Oden and von Hofsten 1954). The surface or article to be treated is exposed to the ninhydrin solution by dipping or brushing, and is then allowed to dry. Small articles can then be exposed to elevated temperature (~80 °C) and humidity (~65 % relative humidity) which accelerates the reaction so that the product is visible in <10 min (Fig. 6). When ninhydrin is applied to large areas such as walls, this is not possible and marks are then allowed to develop at room temperature, which may take over a week.

1,8 Diazofluoren-9-one (DFO) DFO is another amino acid reagent, although in this case the reaction product formed between amino acids and DFO is fluorescent and fluorescence examination is required to visualize the marks (Pounds et al. 1990). Illumination in the green region of the spectrum is required, and the fluorescent marks appear orange (Fig. 7). DFO is more sensitive to ninhydrin, detecting lower concentrations of amino acids, but is less widely used because of the additional time taken to detect marks. DFO is applied in a similar way to ninhydrin, that is, by brushing or dipping, and exposure to temperatures >100 °C is required to develop marks in a reasonable time (20 min at 100 °C). For this reason, DFO cannot easily be used at scenes. DFO can be used in a sequential treatment routine before ninhydrin, which may develop additional marks when used after it.



Fingerprint Identification, Fig. 6 Mark developed on white paper using ninhydrin



Fingerprint Identification, Fig. 7 Mark developed using 1,8 Diazafluoren-9-one on paper viewed under fluorescence

1,2 Indandione 1,2 Indandione is a more recently introduced amino acid reagent which is displacing DFO from some applications. The is now general consensus that 1,2 Indandione develops more, intensely fluorescent marks than DFO, but it has still not be determined whether the DFO-ninhydrin sequence remains more effective than a sequence of 1,2

Indandione-ninhydrin. 1,2 Indandione is applied and processed in the same way as DFO. Bright pink visible marks are occasionally developed, but the reagent is most effective in fluorescence mode where it is illuminated with green light and produces a yellow-orange fluorescence (Hauze et al. 1998).

Chloride Reagents

Silver Nitrate Silver nitrate is a long recognized enhancement chemical that targets the chlorides present in finger marks and is most suited to use on porous surfaces. A solution of silver nitrate is applied to the surface, which is then allowed to dry in the dark. The dried surface is then exposed to light (with ultraviolet giving most rapid development), and a reaction occurs which first converts to chlorides to silver chloride, and ultimately to silver. Developed marks appear dark brown and darken to gray/black with time. A disadvantage of the technique is that the background also progressively darkens and will ultimately obscure the marks. In common with the amino acid reagents, silver nitrate cannot be used on wetted surfaces because these constituents are water soluble.

Other Processes for Porous Surfaces

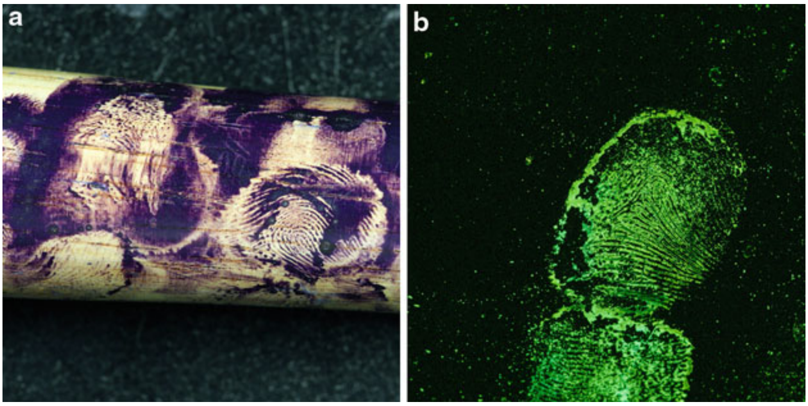
Physical Developer Physical developer is the most widely used reagent for porous surfaces that have been wetted. It consists of an unstable silver-iron redox solution, which certain constituents in the finger mark (thought to be eccrine constituents bound in an insoluble matrix) can locally destabilize resulting in the precipitation and growth of fine silver particles on the ridges. Because certain alkali fillers added to paper can also cause precipitation of silver, the paper is first immersed in a weak acid bath until all reaction with these fillers ceases, then immersed in the physical developer solution (Ramotowski 2000). The technique can develop addition marks if used sequentially after DFO and ninhydrin. It can also be used on other porous surfaces such as raw wood.

Oil Red O Oil Red O is a lipid stain that has been proposed for use on porous surfaces such as paper, in particular those that have been wetted. The article to be treated is immersed in a solution of Oil Red O until strong staining of the mark is achieved. This may take up to 90 min. The article is then transferred to a buffer solution, which stops the staining action and removes excess dye from the background (Beaudoin 2004). Because the process targets different constituents of the mark from DFO and ninhydrin, it can potentially be used in sequence after them and before physical developer. However, the lipids most strongly stained by Oil Red O break down with time and the effectiveness of the technique is significantly reduced on marks over 4 weeks old.

Iodine Iodine is possibly the oldest reported chemical enhancement technique for finger marks. The traditional means of applying iodine is as a fuming process, enclosing the article to be treated in a chamber with fumes of elemental iodine. The iodine fumes are preferentially adsorbed into the ridges of the mark, staining them a brown color. This coloration will gradually disappear unless a fixing agent is applied, the most commonly used being a solution of α-napthoflavone which stains the developed mark blue. Iodine can also be applied as a solution, with the fixing agent incorporated into the formulation. Blue marks are rapidly developed as the solution evaporates from the surface. Iodine is most commonly used on porous surfaces but can also be applied to nonporous surfaces, including those contaminated with grease. The principal constituent of natural secretions targeted by iodine is squalene, which is rapidly lost from the finger mark. As a consequence, iodine tends to be ineffective on marks more than a few days old.

Blood Dyes The reagents used to enhance marks in blood fall into two principal categories, protein stains that selectively stain the proteinaceous constituents of blood, and reactive dyes that are catalyzed by the heme constituent. Both types of dyes are outlined below.

Acid Dyes Acid dyes operate by selectively staining the proteins present in blood.



Fingerprint Identification, Fig. 8 Marks in blood enhanced using acid dyes (**a**) marks on a baseball bat handle enhanced with acid violet 17 and (**b**) marks on black plastic piping enhanced with acid yellow 7 and viewed under fluorescence

They require the blood to be first fixed, either by the application of heat, drying using methanol, or application of a fixing agent such as 5-sulphosalicyclic acid. Once the mark has been fixed, a staining solution containing the dye is applied, and the dye molecules become selectively bound to the proteins giving them a strong coloration. The excess dye is then washed from the surface using a destaining solution. A range of acid dyes have been used for this purpose, including acid black 1, acid violet 17, acid violet 19, and acid yellow 7 (Sears et al. 2005). All of these dyes are suitable for use on nonporous surfaces and most are suitable for nonporous surfaces although some dyes (e.g., acid yellow 7) cannot be easily washed from the background (Fig. 8).

Leuco Dyes Leuco dyes are the principal type of reactive dye that is used for enhancement of marks in blood. They are made into solutions in their colorless form, and when applied to marks in blood a reaction is catalyzed by the heme molecule which results in the formation of the colored form of the compound, thus making the mark visible. The two dyes most commonly used for this purpose are leuco crystal violet, which stains marks violet, and leuco-malachite green, which stains marks a green-blue. The reagents are most commonly applied in the form of a fine spray and are more suited to speculatively searching for marks in blood than the acid dyes.

Because there is more protein than heme present in blood, the acid dyes are expected to be more sensitive in this application. However, both types of reagents may give false-positive reactions with certain substances.

Enhancement of Developed Marks

Once marks have been enhanced, there may be sufficient contrast for them to be easily imaged. If this is not the case, then it may be possible to apply filtration or use more advanced imaging processes to make the mark sufficiently visible for imaging. Some of the means by which this can be achieved are described below.

Color Contrast Filtration If the mark is difficult to visualize, and either the mark or the background is colored, it may be possible to use colored filters (or a colored light source) to increase the contrast between the mark and the background. Where the mark is colored, but too faint to distinguish from the background, a filter of contrasting color can be used to increase visibility of the ridges. An example of this is the green filter sometimes used to improve the contrast of marks developed using ninhydrin. Color contrast filters can also be used to improve visibility of marks developed on light-colored surfaces using enhancement techniques such as white powder suspensions. In this case, the contrast filter darkens the background and the mark remains light.

Infrared Imaging Infrared imaging can be considered in cases where developed marks are obscured by patterned and/or multicolored backgrounds. Marks developed using a metallic or inorganic deposition process (e.g., powders, powder suspensions, physical developer) will remain visible when viewed in the infrared region of the spectrum, whereas many backgrounds printed in inks based on organic compounds become transparent. As a consequence, the effect of the background is suppressed, and the mark can be clearly seen. This technique requires an imaging system that is sensitive in the infrared region of the spectrum, a long pass filter blocking visible wavelengths and transmitting infrared placed in front of the imaging system, and a light source with significant intensity of output in the infrared.

Imaging of Developed Marks

Once marks have been enhanced sufficiently for ridge detail to be visible, and it is considered that sufficient ridge detail is present for a potential identification, it becomes necessary to capture an image of the mark.

To meet the requirements for fingerprint identification, it is essential that any image taken provides identification experts with all the information necessary to make decisions on identification/exclusion. The image of the mark should therefore ideally contain all features of significance captured at a resolution appropriate to that feature type, and have clear distinction between what constitutes a fingerprint ridge and what constitutes "background."

Imaging was traditionally carried out using film photography, although this has now almost entirely been replaced by digital imaging in many countries. Cameras and other digital imaging equipment such as scanners may be used for image capture. Alternatively, for marks developed using powders, a "lift" taken from the surface may occasionally be submitted to the bureau as the "image."

Digital images can be enhanced post-capture using image processing tools. If this is to be carried out before the image is submitted to the bureau, it is essential that a "master copy" of the originally captured image is retained, together with an audit trail of the modifications that have been carried out to the image submitted for identification.

The output of the finger mark recovery process is therefore an image of the mark that is submitted for comparison with fingerprints taken from suspects. This image may be in the form of an electronic image viewed on screen, a photograph printed from a negative, an image printed on a digital printer, or a physical lift from a powdered mark. In all cases, the identification specialist receiving the image should be given as much information as possible about the mark, including the location and surface it has been developed on, the technique(s) that have been used to enhance it, any modifications that have been made to the image, and any methods used to produce a hard copy. This information will all assist in the subsequent comparison and identification process, which is outlined in the following sections.

Future Trends in Finger Mark Recovery

There is a continued drive to increase the number of finger marks that are recovered from articles, whether it be to identify the optimum technique for "low yield" surfaces such as cling film and fabrics, or to investigate novel chemistries that can interact with constituents of the mark that are not currently targeted. Of particular note is ongoing research using nanoparticles, which can be chemically modified to attach themselves to specific finger mark constituents or suspect contaminants such as drug metabolites.

The compositional analysis of finger marks using advanced analytical techniques such as matrix-assisted laser desorption/ionization (MALDI) and attenuated total reflection Fourier transform infrared spectroscopy (ATR-FTIR) is also generating much interest, as this may offer a means of providing additional contextual information about the donor of a mark. Information that it may be possible to obtain includes the sex of the donor, the approximate age of the mark, and what the donor may have been handling (e.g., drugs or explosives). For these techniques to be truly effective, they will need to be integrated with conventional development techniques.

Fingerprint Identification

Introduction

The premise of fingerprint identification is that the fingerprints of each individual are unique and are persistent throughout their lifetime. It is therefore possible to identify an individual by comparing marks deposited at crime scenes with sets of prints obtained under controlled conditions. By finding sufficiency of agreement between the mark and the corresponding print, and an absence of any unexplained differences, identification is deemed possible. Although it is true that no two individuals have ever been found with the same fingerprints, the marks left at scenes often present partial, smudged, and distorted representations of the fingertip, and therefore, the role of the latent print examiner is to satisfy themselves that there is sufficient information present in the mark to individualize.

The fingerprints found on the tips of each finger consist of patterns formed by ridges in the surface of the skin. These were traditionally grouped into three general types of pattern, the whorl (where the central ridges complete a full revolution), the loop (where ridges enter at one side of the finger, curve back on themselves without touching, then exit at the same side), and arches (where ridges run from one side of the finger to the other without any backward turn). In practice, there are subdivisions of each pattern type, and other more complex pattern types may be found (Fig. 9).

Latent print examiners should assess holistically all features within a fingerprint from which to make conclusions as to identity. These features are broken down into three levels of detail. Level one refers to the basic pattern of the print outlined above, level two refers to the Galton details that consist of discontinuities in the ridge flow, and level three refers to the configuration of sweat pores and shapes of the ridge edges (edgeoscopy and poroscopy) (Fig. 10).

Under a magnifying glass, friction ridges are not uniform in configuration, nor do they necessarily flow in predictable direction or flow. Friction ridge skin has breaks and interruptions within the structure known as Galton details (Galton 1892; Ashbaugh 1999), also known as ridge characteristics or minutiae.

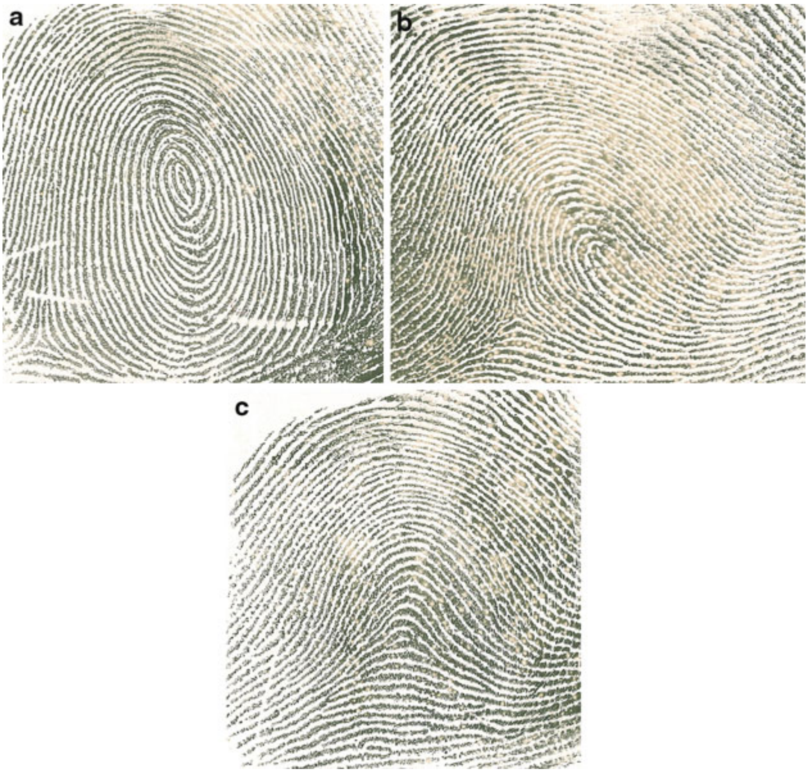
It is these characteristics that, when visible to the examiner, provide the principal means to make a determination of individualization for a latent crime scene finger mark against a suspect's ten-print card. There are two primary classifications of the characteristics, namely, ridge endings (A), where ridges stop abruptly, and bifurcations, where a ridge divides into two (B) (Fig. 11).

In this instance, the ridges running parallel to this feature diverge to accommodate the ridge division. There are variations of these primary characteristics. For example, a lake is where two bifurcations join together (C); an independent ridge is a short ridge that is divorced from any other ridge (D). A spur (E) is a combination of a small independent ridge and a bifurcation and a crossover (F) as the name suggests is a small ridge joined at each end to two parallel ridges.

Every feature and characteristic in friction ridge skin is readily identifiable and identification can be made so long as there are sufficient characteristics of acceptable quality present. It is possible to match very small amounts of friction ridge skin from a crime scene mark against the prints of a suspect, so long as there is sufficient clarity upon which to rely upon the permanence and reproducibility of visible features.

Identification Methodologies

When comparing detail between a crime scene mark and a ten-print exemplar, a generic methodology has been adopted known as ACE-V (Ashbaugh 1999). In order to make a value judgment on any identification, the examiner must first **assess** (or **analyze**) the friction ridge detail in the scene mark so that useful reference points can be identified in the next phase. Next, there must be a **comparison** of the mark features with that of features within the reference print. Then there must be an **evaluation** of the findings, from which conclusions as to identity must be derived. Finally, as in all scientific methods, there must be an element of peer review, known as **verification,** to repeat the ACE process independently to arrive at the same conclusions as that of a colleague.



Fingerprint Identification, Fig. 9 Types of fingerprint pattern, (**a**) whorl, (**b**) loop, and (**c**) arch

During the **Assessment** (or **Analysis**) phase, the fingerprint examiner will look for the following:

- Distortion
- Development methods and medium used to visualize latent material (chemicals and powders, etc.)
- Deposition pressure to highlight areas of possible distortion
- Anatomical attributes (features)
- Clarity

During the **Comparison** phase, the examiner will look for similarities in the following:

- Pattern
- Ridge path
- Ridge shape
- Pore positioning

During the **Evaluation**, the examiner will look to form an opinion in the following:

- Can the mark be eliminated?
- Is there sufficient information available to individualize?

During **Verification**, an independent assessment of the casework is undertaken to see whether the ACE process has been correctly executed and that the conclusions reached are consistent with the original findings. In the UK, for a crime scene mark to be identified, the comparison must be undertaken three times. One check will be made by the original examiner, then verification by two further experts who must come to the same conclusions independently.

In some countries, there are a minimum number of features that must be found in agreement between the crime scene mark and the print for the identification to be confirmed. For example, in many European countries there is a requirement for 12 features to be found in agreement with none in unexplained disagreement for an identification to be confirmed. In other parts of the world, including the USA and the UK, there is no longer any “standard,” and it is the responsibility of the examiner to satisfy themselves that the holistic information present justifies the decision that is made.

Automated Fingerprint Identification Systems

The role of automated fingerprint identification systems (AFIS) in the identification process is to provide the identification expert with a selection of candidate prints against which to compare the crime scene mark. It does not replace human opinion in the decision-making process. The algorithms used in AFIS convert images of fingerprints to wire drawings, identify the positions of level two features such as bifurcations and ridge endings, and store information relating to these locations and their spatial relationship to each other.

When a crime scene mark is input into an automated system, it is possible to "auto-encode" it, by allowing the database algorithms to go through the same conversion process and automatically mark the estimated position of ridge endings and bifurcations. In practice an expert will generally review this encoding and locate the positions of these level two features manually, removing any false features such as scratches in the image. The marked positions and spatial relationships of the level two features are then searched against those of the prints in the database, which displays the images associated with the most closely matching feature sets.

The examiner can then review the displayed images to select those that most closely correspond with the crime scene mark, and subject these prints to greater scrutiny in the ACE-V process. The human interpretation of the mark and print therefore remains essential to the decision-making process.

Scientific Validity of Fingerprint Examination and Human Error

Because the decision-making process during fingerprint examination depends on human opinion, the important question of the reliability of fingerprint examiners in making correct judgments when conducting fingerprint comparisons using ACE-V must be raised. Within the science of fingerprint examination, nobody really knows how often examiners make an erroneous decision. It is the examiners (and not necessarily the underlying biological science behind fingerprint identification) that are the potential weak link in the evidential chain.

Fingerprint examiners can make a false-positive judgment (an erroneous identification). However, there is also what is known as a false-negative decision (a missed identification). While the fingerprint profession prefers to weight the relative importance of such errors, preferring to insist that to have an "erroneous identification" is the most problematic mistake because a person has been wrongly brought into custody, one cannot ignore the "missed identification" errors, as they represent the majority of all known errors in the profession and as such are just as relevant because they relate to a failure in the human actor to apply methodology and skill to arrive at a correct conclusion. Whether the mistake is to erroneously identify a perpetrator of a crime or to erroneously exclude another person, the latter is potentially just as serious and no less a mistake. To wrongly exclude a perpetrator may leave him or her free to commit more crime, perhaps even to kill. One problem with knowing the true scale of the rate of error arising from a missed identification is that by the very nature of the error, a "miss" is only known about when circumstances permit that error being found. In so far as the erroneous identification has more potentially immediate and public ramifications, this has much to do with the rationale for the profession that regards errors in positive identification as being more serious than the missed identification. But in reality, both are technical mistakes arising from the same methodological failings.

The McKie case in Scotland (Campbell 2011) is perhaps one of the most notorious of all the recent controversies in latent print examination. Shirley McKie was arrested for perjury for stating under oath during a murder trial that a thumbprint, which was matched to her during routine elimination checks, was in fact not hers. McKie was vindicated after latent print examiners from other agencies around the world challenged the validity of the identification made by the Scottish Criminal Records Office (SCRO). To this day, there are experts in latent fingerprint analysis who still disagree as to whether it is a correct match or not. This inability to reach a consensus raises a number of fundamental issues associated with the reliability and repeatability of ACE-V as practiced by fingerprint examiners.

The erroneous fingerprint identification of Brandon Mayfield by FBI latent print examiners in response to the forensic investigation of the 2004 Madrid Bombings was another highly controversial case (Stacey 2004). Mayfield's fingerprints were alleged to have been identified against those found on a bag of detonators found in Spain after the bombings took place. However, subsequent reanalysis carried out after the Spanish authorities questioned the accuracy of the identification. The FBI fingerprint experts had to concede they had been incorrect in their original analysis.

These cases, as well as other errors and controversies, have resulted in fingerprint analysis coming under attack from both the judiciary and the academia. Some (Saks and Koehler 2005) have questioned the very underlying scientific assumptions made by fingerprint experts. The profession has built up over many decades a principle of infallibility around the methodology used to compare fingerprints that has delivered into the public domain a mantra that training and peer review through verification of findings are enough to ensure that erroneous identifications will not only be extremely rare, but that such occurrences will rarely if ever reach the courts.

Fingerprint examiners and law enforcement maintain that fingerprint evidence has unrivaled power within the judicial system. Fingerprint examiners also hold to a rigidity of thought around the clarity and unambiguousness of their work. In comparing fingerprints, there are limited choices an examiner can make. The only possible conclusions are it is a match, not a match, or there is insufficient detail upon which to make a conclusive decision (Bain 1985). However, the Evett/Williams report suggests that when many fingerprint experts use the term exact science (where conclusions are binary, it either is a match or it isn’t), this is a contradiction in terms, science is not exact (Evett and Williams 1995). This has now been endorsed by the recent findings of Sir Anthony Campbell who chaired the Fingerprint Inquiry (Campbell 2011) looking into the erroneous fingerprint identifications in the McKie case in which one of the key findings was that fingerprint experts should not use statements of fact over fingerprint identification, but rather should use statements of opinion instead. Without assessing every set of human prints in the world either alive now, or have ever lived, there can be no way of truly knowing whether fingerprints can ever be unique to the degree of having a categorical belief that two prints match one another.

Future Directions in Fingerprint Identification

Probabilistic Approaches

There has been a growing body of opinion that a statistical presentation of fingerprint evidence may be both valid and necessary (Champod and Evett 2001). For fingerprint evidence to be held up as an infallible science may be to overstate the power of the evidence and could, on occasions, misguide the pursuit of accurate and fair assessment of the case evidence by the jury.

Expressing fingerprint evidence in probabilistic terms would bring it in line with other types of evidence such as DNA, and may also enable probabilities of matches to be proposed for partial marks containing few features that would otherwise be disregarded. In probabilistic terms, examiners could testify that, for example, there was a one in a billion chance that the mark was left by someone other than the defendant.

This approach requires the position and spatial relationship of features to be marked on the crime scene mark, which would be compared to data on how often these feature combinations occur across large populations of fingerprints. Corresponding data is required on how the position and spatial relationship of these features is reproduced within a number of marks deposited by the same finger under different conditions. This enables the likelihood that the feature set in the crime scene mark was deposited by the finger of the suspect to be compared with the likelihood that it was deposited by any other person.

Probabilistic models have been developed by several different research groups, and work is underway to provide the supporting data sets to enable such analyses to be performed. It should, however, be noted that there is still much opposition from the fingerprint examiner community regarding the presentation of fingerprint evidence in this way.

Cognitive Bias

Examiners explore several different rhetorical strategies to appear to be demonstrating validity, while in fact demonstrating other things. These include "the fingerprint examiner's fallacy" (if the ACE-V methodology is followed, error cannot happen) and "the casework fallacy" (over 100 years of fingerprint examination only a handful of errors have been recorded). In essence, whenever an error is highlighted in the profession, it is invariably the case that the hierarchy blames the practitioner. It is the fault of the person doing the analysis and that the methodology is sound, even if human factors contributing to the error proved to be unavoidable and to a large extent unconscious to the individual. To date, it has been very rare for the profession to investigate possible factors other than practitioner incompetence for the occurrence of error. This is unfair to the practitioners and deflects away from the more serious underlying need to investigate the factors that contribute to error in the first place.

Validity research is rare in the fingerprint domain. Perhaps one of the reasons why validity studies are so rare is that there is a real fear of undermining the long-held core values and beliefs that underpin the dogma within the profession, and that to question the reliability of the method or to assess wider cognitive issues impacting upon practitioners is deemed both dangerous and by some, unnecessary. Fingerprint practitioners for the most part are simply not aware of the dearth of scientific support for their discipline's core assumptions.

There have been legal challenges for many years in the USA to the acceptance of fingerprint science as a valid methodology. In the landmark motion to exclude fingerprint testimony, (State of Maryland v. Bryan Rose K06-0545), the defendant contended that ACE-V was not a valid methodology which has been subjected to scientific testing and that the error rate in latent print identifications is unknown. It was asserted that in the absence of an error rate, the reliability of the methodology remained unproven. A fundamental problem, according to the defendant, was that the subjective comparisons in ACE-V involve psychological phenomena known as "confirmation bias." Further, the defendant argued that the "standards" for latent fingerprint identification are inadequately defined. The lack of error in certain fields of inquiry often derives from the nonexistence of methodological research into the problem and merely denotes a less advanced stage of that profession (Risinger et al. 2002).

There are examiners who are prepared to look at the issues of error rate and to investigate the methodology as well as human factors, and to suggest ways of mitigating potential weaknesses. Wertheim and Langenburg (Wertheim et al. 2006) showed in their research results that errors can and do occur. A study by Schiffer and Champod (Schiffer and Champod 2007) suggested that context may have an impact on practitioners dependent upon where in the ACE-V process the fingerprint analyzer found themselves. Latent print examinations are currently performed by human examiners, and human examiners are fallible, no matter in what domain they work. Therefore, the examinations are only as valid as the examiner performing the task and the conditions under which the tasks were conducted. Measuring and enhancing fingerprint expert performance is a challenging task. However, for any expert domain, be it medical experts, military fighter pilots, police officers, or forensic experts, one must study and understand the underlying expertise. Results obtained in law enforcement generally demonstrate that investigating police officers' judgments (this may include latent print examiners) are malleable and susceptible to influence from extralegal factors (Ainsworth 2005).

Enthusiasm to seek answers to these questions is gaining in strength (National Academy of Sciences 2009). The fingerprint community must be willing to subject established beliefs to verification and peer review (Busey et al. 2008).

There is now a substantial body of psychological research illustrating the tendency for human beings to engage in motivated reasoning or to be affected by contextual knowledge to a point where decision thresholds and even decision outcomes can be altered (Dror et al. 2006; Dror and Charlton 2007; Dror and Fraser-Mackenzie 2008). Such biases may be present in the work of latent print examiners. However, the extent to which cognitive bias creates the danger of erroneous interpretations in real-world circumstances has not yet received significant research attention. Continued research about the presence or absence of such biases in the latent print domain and the extent of any impact on accuracy and reliability is needed. However, given the decades-long research into the significant effects of cognitive bias in other domains, it would seem appropriate to minimize the potential for such biases in latent print interpretation now.

Given the genuine dangers of cognitive bias, examiners should be protected from inadvertent bias by shielding them from information that is clearly unnecessary and not relevant to their assessment. If examiners routinely receive extraneous, domain-irrelevant information, forensic service providers should examine whether they can modify their procedures to shield examiners from this unnecessary and potentially biasing information (Kaye et al. 2012).

Focused Deterrence and “Pulling Levers”

Edmund F. McGarrell
School of Criminal Justice, Michigan State
University, East Lansing, MI, USA

Overview

The last few decades have witnessed considerable developments in both research and practice with respect to both offender- and place-oriented strategies aimed at reducing crime and violence. One such offender-oriented approach is based on the concept of focused deterrence and includes what is sometimes referred to as a pulling levers strategy. This entry describes the focused deterrence pulling levers strategy, reviews the research suggesting its capacity to affect levels of crime and violence, and poses a series of practical and research questions related to the model.

One of the most consistent findings of criminological research has been that a relatively small number of people and a relatively small number of places generate a disproportionately large amount of crime and calls-for-service to the police. The focus on recurring places such as street block segments and particular businesses has resulted in a variety of intervention strategies that research suggests have crime prevention and control efficacy. Similarly, recent years have witnessed the emergence of offender-oriented strategies that follow a focused deterrence logic model and demonstrate promise for violence and crime prevention and control. One particular strategy that has emerged has become known as the “pulling levers” approach.

Foundations

In the early to mid-1990s, officials in Boston began experimenting with a new approach to addressing the very serious issue of youth violence and youth gun violence in particular. Like many cities in the USA, the period coinciding with the crack cocaine epidemic generated elevated levels of homicide and gun crime, much of which involved youths in their teens and early twenties. To address this problem, Boston convened a multiagency working group consisting of federal, state, and local law enforcement; the US Attorney’s and the District Attorney’s Offices; probation and parole; street outreach workers; a coalition of faith leaders; and community leaders. Also included was a team of researchers from Harvard’s Kennedy School of Government. The working group agreed to follow a problem-solving approach that would begin with systematic analysis of the youth gun crime problem.

The analysis proved to be very insightful and ultimately shaped the offender-oriented pulling levers strategy. Specifically, gun violence in Boston was largely concentrated among a small group of chronically offending youth estimated at 1–3 % of the youth population. Further, these violence-involved youths were typically part of loosely organized gangs and street crews. Finally, these youthful offenders had long histories of involvement in the juvenile and adult criminal justice systems and homicide victims, and offenders often were mirror images of one another (Kennedy et al. 2001).

The strategy that emerged was based on these findings. First, the concentration of violence in a small subset of youth meant that a surgical intervention aimed at high-risk individuals would likely be more effective and generate fewer collateral costs than large-scale crackdowns affecting large proportions of the youth population. Second, extensive criminal histories meant that these individuals were subject to the sanctions and coercive power of the criminal justice system. For some this equated to incapacitative sentences; for others it meant that the criminal justice system had credible leverage over their behavior. Third, the group or network structure meant that it was possible that influencing a subset of the individuals involved in these social networks could have a broader impact on the larger group. Additionally, it might be possible to impose "group accountability."

The actual strategy involved delivering a highly focused deterrence message to youths involved in these violent street groups. Analysis would reveal groups currently believed to be involved in violence. Intelligence would identify members of the groups on probation and parole. These probationers and parolees would be ordered to attend what has come to be known as a "notification" or "call-in" meeting. At the meeting, a specific and focused deterrence message would be communicated to these individuals. Essentially, police, prosecutorial, and/or probation and parole staff would inform the attendees that officials know who they are, believe that they are at high risk for being involved in violence based on their behavior and their associations, and inform them that the violence must immediately stop or the task force will do everything possible, pull every lever, to try and get them off the streets. Attendees were reminded that as convicted felons they were prohibited from possessing or carrying a firearm and that there were severe sanctions in the federal system that would be imposed on felons in possession. For example, simple possession by a felon could carry a 5-year sentence in the federal system, along with no right to bail before trial and an anticipated time served of 85 % of the sentence. If the firearm was used as part of a drug trafficking operation or in the commission of a violent crime, much more substantial sentences were available in the federal system. Although there is significant variation across the states, typically the federal sanctions are more severe than those in the state court system. The message sought to gain credibility, and shift the perceived threat of sanction, by using examples of similar individuals often from the same network of street crews who had received stiff sentences.

An additional unique feature of the call-in meeting strategy was that the focused deterrence theme was coupled with two other key messages. The first involved the expression of the community voice. Typically community members would express their concern for the well-being of the attendees, their exasperation with the level of neighborhood violence and the loss of young people to violence and prisons, their hope that the attendees would go in another direction, and their support for the police and prosecutors. The community voice was considered important for "resetting" and clearly communicating community norms. The second key message was an offer of support from various social service providers. The social service providers and the community would typically describe various supports available (mentoring, housing, drug treatment, vocational and educational programs, work preparedness, etc.) should the meeting attendees seek assistance.

The community voice and the expression of social support were considered important in terms of increasing the perception of fairness and legitimacy of the overall stop the violence message. This was based on theory and research findings that compliance with the law increases with perceptions of fairness and legitimacy (Tyler 2003).

The Boston Ceasefire focused deterrence pulling levers approach has received significant attention for its apparent impact on youth homicide and shootings. A series of studies demonstrated that there was an approximate 63 % reduction in youth homicides and substantial declines in shots fired (−32 %) and gun assaults (−25 %) (Braga et al. 2001). These findings were contrasted with trends in other Massachusetts cities as well as major US cities, and Boston was distinct in terms of the timing and magnitude of the reduction.

The Diffusion of an Innovation

Although the peak of the homicide epidemic was ending, in many cities and for the country as a whole, homicide and gun homicide in particular remained at very high levels as news about the Boston Ceasefire program and its apparent impact began to spread. One of the first manifestations was US Department of Justice support for what became known as the Strategic Approaches to Community Safety Initiative or SACSI. SACSI provided technical support and research funding for ten participating cities. The sites received training in the Boston Ceasefire model including the research-based problem-solving process as well as the focused deterrence strategy involving offender notification meetings and the pulling levers approach. Overall, the SACSI evaluation team found that the SACSI cities experienced a reduction in violent crime compared to other US cities (Roehl et al. 2008).

One of the participating cities, Indianapolis, implemented an approach and strategy very similar to Boston Ceasefire. Employing a very similar analytic approach, the Indianapolis researchers found that after a crackdown on one violent street group and a series of offender notification meetings had occurred with probationers and parolees involved in gangs and violent street groups, homicide declined by approximately 34 %, and this decline was greater than that experienced by other similar size Midwestern cities (McGarrell et al. 2006). Subsequent analyses revealed that the reductions were highest for gang homicides (Corsaro and McGarrell 2009) and for the groups most at risk for homicide victimization, in the case of Indianapolis, this involved young African-American males in five specific hotspot areas (Corsaro and McGarrell 2010).

Another DOJ-funded site during the SACSI period, Los Angeles, followed a similar approach to address homicide and gun violence largely associated with gangs. Although the East Los Angeles site struggled with implementing all components of their strategy, they did implement a focused deterrence approach targeted at two rival gangs. Their evaluation found evidence of at least short-term declines in violence when comparing this target area to other parts of Los Angeles (Tita et al. 2003).

The positive findings from the SACSI jurisdictions seemingly had a policy impact as the Department of Justice developed a new initiative in 2001 that became known as Project Safe Neighborhoods (PSN). The PSN program incorporated elements of Boston Ceasefire and SACSI but also provided more flexibility to task forces operating out of each US Attorney's Office to adapt the strategy based on local problems and resources. Among the elements incorporated were the creation of multiagency teams, adoption of a problem-solving approach based on analysis of the local gun crime problem, and the incorporation of research partners into the PSN task forces. Two additional components related to Boston Ceasefire but also were influenced by an initiative developed in Richmond, Virginia, known as Project Exile. Whereas Boston had utilized selective federal prosecution of gun offenders as example for other potential felons, in the Exile program there was a commitment on part of the US Attorney's Office to prosecute as many illegal gun possession cases in the federal court as possible. Similarly, whereas Boston sought to communicate a deterrence message to at-risk individuals through call-in meetings, Richmond officials utilized a broad public education campaign involving multiple forms of media (radio, television, billboards, bus posters, etc.). PSN task forces were encouraged to use any and all of these strategies.

Several of the PSN sites followed the Boston Ceasefire model fairly closely and generated evaluation findings that suggested an impact. Although initiated before PSN, Stockton, California, worked with one of the original Boston researchers and followed a very similar approach focused primarily on gang homicide and violence. This study found a significant reduction in gun homicide that was much greater than that observed in eight comparable California cities (Braga 2008). Officials in Lowell, Massachusetts, followed the offender-oriented pulling levers approach to reduce youth violence. An interesting twist in this initiative was that Lowell officials applied an additional lever to adult offenders involved in illegal gaming activities with the goal of having the adults exert influence over youths involved in street violence. The results of an evaluation indicated a reduction in gang violence that was much greater than that observed in other Massachusetts cities (Braga et al. 2006). One of the most sophisticated evaluation designs was utilized in Chicago's PSN initiative that targeted specific geographic areas of the city. A twist on the pulling levers strategy was that Chicago included former inmates returning to the target areas in its offender notification meetings. The researchers found that homicide declined approximately 37 % in the PSN target areas. Further, they reported that the evidence suggested the most influential component of the strategy was the impact of the offender notification meetings (Papachristos et al. 2007).

Several additional jurisdictions, some involved in PSN and others distinct from PSN, also observed declines in homicide and/or gun crime following the implementation of the offender-oriented pulling levers strategy. Most of these studies employed limited designs involving pre-post trend analyses with either no comparison group or a weak comparison (e.g., remainder of city). However, the consistency of these findings from cities including Minneapolis, High Point, Baltimore, Greensboro, Omaha, and Winston-Salem was at least suggestive of impact on homicide and gun crime.

As would be anticipated given the latitude provided, there was considerable variation across PSN sites in terms of the implementation of the Ceasefire model generally and the pulling levers components specifically. All of the PSN task forces reported establishing new criminal justice partnerships although there was considerable variation in density and scope. All of the task forces received funds for a research partner. Officials from the majority of sites reported that the research partners brought value to the task force, though there were task forces where research was never integrated and it was difficult to discern a strategic problem-solving model. An estimated 45 % of the PSN task forces reported using offender notification meetings. The vast majority (98 %) reported increased federal prosecution of firearms cases and over 90 % utilized joint federal-local prosecutorial screening of gun cases, although the analysis revealed considerable variation across the 94 districts in terms of levels of federal prosecution of gun crimes. Over 40 % of the task forces reported other components of the Operation Ceasefire approach with respect to probation/parole home visits and firearm supply side interventions. Finally, approximately 58 % reported using directed patrols in hotspot locations and over 40 % utilized street-level firearms enforcement units, interventions that might be part of a "pulling levers" strategy (McGarrell et al. 2009).

Consequently, across the 94 PSN task forces, there were components of Boston's Operation Ceasefire's pulling levers strategy. The evaluators of PSN also found that there were significant differences across the task forces in the implementation dosage of three components: level of federal prosecution of gun crime, integration of research into the task force, and partnerships. Further, these implementation levels related to differences in the trend of violent crime with PSN target cities in high-dosage districts experiencing a significant decline in violent crime when compared to target cities at lower levels of dosage as well as with non-PSN target cities (McGarrell et al. 2010). Given that PSN was not implemented with a randomized design, the researchers were not able to exclude the possibility that some other characteristics of these high implementation cities produced the decline, but the results did appear to be consistent with the prior research on offender-based deterrence strategies.

As is evident in the above review, almost all of the research that has examined the offender-oriented pulling levers strategy has focused on the impact at an area level (either the entire city or particular neighborhoods or police districts). Two studies have included a focus at the individual level. The first is an ongoing study conducted by Papachristos and colleagues in Chicago. The results are not yet available. The second was an extension of the above-described Indianapolis initiative conducted by Chermak (2006). In 2002 Indianapolis conducted an experiment to assess the impact of two types of pulling levers meetings compared to traditional probation supervision. The first meeting was modeled on Boston Ceasefire and included the criminal justice deterrence message coupled with a message of opportunity provision. The second meeting was a type of meeting that had been developed by community groups who sought to deliver their own message urging participants to stop the violence and emphasizing the social support message. Probationers were randomly assigned to the three conditions. The population consisted of all felony probationers convicted of specific violent, drug, gun, and property offenses. There were a total of 540 probationers in the study with180 probationers in each group (Boston Ceasefire-style meeting, community support meeting, traditional probation). Interviews revealed that both types of meetings made an impression on the probationers and, consistent with the goal of the meetings, the Ceasefire meeting attendees were most likely to report that law enforcement was cracking down on violent crime and they were more likely to believe that illegal possession of a firearm was likely to result in stiff sanctions. Meeting attendees also reported that they discussed the message with their friends. Despite these differences in perception of message, no differences were found between the treatment groups and the control group on re-offending using both self-report and criminal history records. Caution was urged in interpreting these findings, however. There were two critical distinctions between the Boston Ceasefire and earlier Indianapolis pulling levers strategy and what occurred in the experiment. First, the selection of participants in the experiment was based on their probation status as opposed to their selection as being at high risk of violence based on their behavior and their group affiliations. Second, the study found that there was very little follow-up when violence occurred that may have involved meeting attendees and their associates. Similarly, there was very little follow-up in terms of delivery of service. Thus, although there was a threat of pulling levers and an offer of assistance, there was little actual implementation of either component.

Extensions of the Model Beyond Gun and Group Violence

As noted above, one of the first cities to implement the Boston Ceasefire pulling levers approach to addressing gun and gang violence was High Point, North Carolina. High Point followed virtually all of the components with a multiagency team of criminal justice, social service, and community partners, a research team, a data-driven problem-solving orientation, and the use of offender notification meetings. Having experienced what the police department and community partners considered success in addressing violent group crime, High Point extended the approach to addressing other problems. This, in turn, has resulted in innovative adaptation of the pulling levers approach in other communities as well.

On the basis of continuous monitoring and analysis of crime patterns, the High Point Police Department (HPPD) decided that the next major problem driving crime, violence, and disorder was overt drug markets. The analysis suggested that drug market activity was creating such problems in specific neighborhoods. Detailed analysis, street-level intelligence, and subsequent undercover operations revealed that a relatively small group of offenders were responsible for these discrete drug markets. Specifically, in the initial four markets targeted for the pulling levers approach, the number of identified dealers ranged from a low of 13 to a high of 26. This finding has since been replicated in over 20 communities where the number of individuals involved in the drug market has ranged from a low of 7 to a high of 59 and an average of 27 (Hipple et al. 2009). This manageable and specific network of street drug dealers suggested that the pulling levers approach had merit.

The main distinction between the drug market approach and the gang and group-based approach was that many of the dealers were not on probation or parole so the question arose of how to get them to attend the offender notification call-in meeting. The strategy that emerged involved a traditional undercover operation in which undercover buys would be made from all, or as many as possible, of the individuals believed to be involved in the specific market.

Following the undercover operation, police and prosecutors convened to decide who would be subject to aggressive prosecution and who would be called-in to a meeting and offered a second chance. The criteria agreed to by the High Point team were based on prior involvement in violence as well as extensive criminal histories for drug selling and other serious offenses. Individuals with histories of violence and gun use as well as chronic offenders were prosecuted as would normally occur. These individuals comprised the "A list." They would serve as examples for those diverted from prosecution. The diverted individuals, without histories of violence, were often the retail street-level sellers and lookouts who could be expected to continue to sell and to "backfill" for the drug-selling network as others were removed from the community. This group comprised the "B list."

Adopting the same approach as developed in Operation Ceasefire, the B list group was invited to attend a call-in session along with "influentials" in their lives. Here they were presented with the evidence against them, often including video of their drug sales, and informed that the drug market was closed. Continued involvement in drug selling and other crimes would result in arrest and prosecution similar to that of the A list. The meetings included opportunities for the community to express their exasperation with drug dealing and its impact on the neighborhood, their support for the criminal justice authorities, and their support for the individuals attending the meeting and being offered a second chance. The meeting also included social service representatives describing available services and offering support to the attendees.

Following the call-in meeting the police would provide an increased presence for a short period of time to send the message that dealing would no longer be tolerated. Substantial effort went into community engagement with the idea that the community would ultimately be responsible for asserting informal social control that would preclude the reemergence of the drug market (Kennedy 2009).

An evaluation of the High Point experience with the implementation of what has come to be known as the Drug Market Intervention (DMI) in the initial four neighborhoods found evidence of impact on violent crime. Using trajectory models that compared chronic high crime street blocks in the DMI target areas with comparable high crime street blocks in the remainder of the city, there was a significant decline in long-term violent crime trends in the DMI areas (Corsaro et al. 2012).

Given the frustration with traditional drug enforcement efforts, the High Point DMI has generated significant interest. The Bureau of Justice Assistance has supported training and technical assistance on the DMI model to 24 communities and at least 33 communities have implemented or are in the process of implementing the DMI approach. In addition to the High Point evaluation, studies have been completed in Rockford, Illinois, and Nashville, Tennessee. Both studies compared the pre-post trend in crime in the drug market target area with the trend in crime for the rest of the city. In the case of Rockford, there was a large decline in violent, property and drug crime following implementation. A careful evaluation utilizing growth curve modeling indicated that the target area had a statistically significant decline in property crimes relative to the rest of the city and a decline, though not statistically significant, in violent crimes (Corsaro et al. 2009). In Nashville, there were large declines in all offenses, although when compared to trends in the remainder of the city and controlling for preexisting trends, only the reduction on drug crime was found to be statistically significant (Corsaro et al. 2010). In both Rockford and Nashville, interviews with residents of the target neighborhood suggested perceived improvements in the quality of life, levels of crime, and support for the police. Given these promising findings the National Institute of Justice awarded the RAND Corporation a grant to carefully evaluate the DMI model. That study is ongoing.

High Point also extended this approach to the problem of street robbery when they experienced an increase in street robberies. Crime analysis and street-level intelligence identified groups involved in these robberies. Individuals involved in the groups under probation or parole supervision were ordered into very similar call-in meetings. Although no formal evaluation was conducted, HPPD officials report that the spike in street robberies declined soon after these call-in sessions.

An additional adaptation of the offender-oriented, focused deterrence model has involved former inmates returning to the community. Indianapolis was the first known community to implement this approach. The model was based on findings that a significant proportion of homicide victims and offenders had previous prison and parole experience. The meetings were organized geographically so that a group of returning former inmates from the same part of the city would be invited to a call-in meeting. A pilot evaluation of the project compared recidivism for former inmates attending a call-in meeting with similar former inmates in other neighborhoods who were not afforded this treatment. The results indicated a potential delay in the time to re-offending, although the results were not statistically significant in a multivariate analysis (McGarrell et al. 2003).

The most promising results suggesting the potential use of call-in meetings with returning former inmates comes from the previously mentioned Chicago PSN program (Papachristos et al. 2007). This program included returning parolees in the PSN target areas, and these areas experienced very significant declines in homicides and gun crime. As noted above, there is an ongoing analysis that is assessing the impact of the meetings on individual re-offending. A similar approach in Boston found very positive results in terms of reduced re-offending (Braga et al. 2009).

Finally, although it has not been evaluated, another variation of this approach in the reentry context comes from the PSN program in Dallas. Very large numbers of probationers and parolees (N = 400–500) from throughout the city are invited to an offender notification meeting. The message delivered is very similar to that of the smaller call-in meeting and includes the deterrent threat, the "felons cannot possess a gun" message, and the offer of social support.

Summary of the Research Findings

In the late 1990s when the results from Boston Ceasefire first came to the attention of the research community, the findings seemed too good to be true. A 60 % reduction in youth homicide and a city going two and a half years without a youth homicide caught the attention of researchers, policymakers, and law enforcement leaders. Yet it stood as one city's experience. Since that time a number of other studies of the group-based violence reduction strategy have been completed from cities including Baltimore, Chicago, Greensboro, High Point, Indianapolis, Los Angeles, Lowell, Minneapolis, Omaha, Stockton, and Winston-Salem. The evaluations associated with these efforts have varied in terms of approach and methodological rigor but have been consistent with an interpretation of the pulling levers approach having a desired impact on levels of homicide and gun violence. Although the research base is much more limited, the studies of the pulling levers extension to drug markets conducted in High Point, Nashville, and Rockford are also encouraging, at least for some types of offending. The results from the PSN research are also encouraging although more difficult to interpret given the multiple components of the interventions and the variation across cities.

Importantly, a systematic review of the focused deterrence model has been conducted as part of the Campbell Collaboration. This review was based on ten quasi-experiments and one randomized controlled trial. Although noting the need for more rigorous testing, the authors found an "overall statistically significant, medium-sized crime reduction effect" for these focused deterrence strategies (Braga and Weisburd 2012: 324). At a minimum, this series of studies suggests at least a short-term impact on lethal violence at the community level. Given the human, social, and fiscal costs associated with homicide and gun violence, these are important findings.

The research assessing the impact at the individual level is even more limited and leaves in question whether the pulling levers approach can significantly alter individual level patterns of behavior.

Limitations and Issues for Further Study

Despite this promising evidence, there remains uncertainty and perhaps skepticism that the pulling levers strategy has been the cause of the reductions that have been observed in these studies. One of the reasons for this skepticism is that the period during which this research has occurred has witnessed an overall decline in homicide and violent crime since the peak levels of the early 1990s. Given that the strategy was often implemented when a particular jurisdiction was experiencing a "homicide problem," the question arises whether there was a "regression to the mean" coupled with the long-term reduction in violence observed throughout the country. A number of the studies employed statistical techniques that are designed to minimize the impact of preexisting trends in the crime patterns but that cannot completely rule out the possibility that the decline would have occurred absent the intervention.

These concerns relate to the limitations of the evaluation designs that have been employed in the various studies. Although a number of the studies have employed quasi-experimental designs that provide a comparison group, they have not involved a true experimental design that can eliminate the threat that the decline in crime is based on some unmeasured factor rather than the pulling levers strategy.

Questions also arise due to the complex nature of the intervention. For example, one study comparing three strategies that emerged in the mid-1990s, Boston Ceasefire, Richmond Exile, and New York City's Compstat, found evidence that both Ceasefire and Exile were associated with reductions in violence (Rosenfeld et al. 2005). Similar results emerged in Exile-type strategies in Mobile and Montgomery, Alabama (Hipple 2010). Given that both Ceasefire and Exile included the threat of federal prosecution for illegal gun possession and use, it becomes difficult to disentangle the impact of the role of focused federal prosecution of gun crime from the impact of the pulling levers meetings.

Finally, a common threat to interpreting a series of studies like those described above is "publication bias." It is more likely that evaluations finding an impact for a strategy like pulling levers will be written up and published than evaluations that did not find an impact. Given the attention to the group-based pulling levers and Drug Market Intervention programs, it is possible that jurisdictions have implemented these strategies without an evaluation component or where the findings were ambiguous and did not show an impact and thus never made it to the research community.

In addition to these methodological questions, a series of theoretical issues arise. The theoretical foundations of the pulling levers strategy are multifaceted and include focused deterrence, procedural justice, social support, and community coproduction of order (Kennedy 2009).

The focused deterrence component is based on the idea of a small group of individuals being responsible for a large amount of crime and being subject to a direct message that may shift their perceived risk of sanction. The procedural justice component is based on research that finds that compliance with the law is most likely when individuals believe that they have been treated fairly and with respect (Tyler 2003). Social support links to the procedural justice component but also may include psychological, social, and tangible resources that may reduce strain or increase incentives to comply with the law. It may also involve informal social control as those most influential with the target population are included in the process. This aspect of informal social control includes both the network associated with individuals deemed at risk and the role of the broader community in coproducing order. This component involves collaboration with individuals, networks, and institutions in the community to increase the collective efficacy within the neighborhood (Sampson et al. 1997).

The logic model of the pulling levers approach builds on these multiple theories (see Rivers et al. 2012), yet there is very little research actually testing these theoretical components in the context of the offender-focused pulling levers strategy.

In addition to further research on the theoretical foundations of the offender-oriented, focused deterrence model, there are several areas deserving of further investigation.

As noted above, one of the lingering questions is the impact of the offender notification meetings on those selected to attend. A parallel question is the impact on their associates. From a human capital standpoint, the hope is that the meetings will result in reduced levels of offending, reduced levels of serious and violent offending, and reduced victimization among meeting attendees and their associates. At this point the evidence simply does not exist to answer whether this is the case. Having said this, if research continues to point to significantly reduced levels of community violence, then the approach may be considered successful even if there is minimal impact at the individual level of meeting attendees.

A second question relates to the sustainability of the violence reduction. Other types of police crackdowns have generated short-term declines but that were not sustained over time (Sherman 1990). Both Boston and Indianapolis experienced increases in homicide years after their initial findings of reduced violence. In contrast, High Point officials report sustained declines. At this point, there is insufficient research evidence to clarify whether implementation of the offender-oriented, focused deterrence strategy can yield long-term sustained reductions. There appear to be two sets of questions related to sustainability. The first is theoretical. Can this approach produce a long-term shift in perception about the relative costs of criminal justice sanctions and victimization risk, or are the findings to date driven by short-term impact that decays in the period after the offender notification meetings? The second question relates to the system capacity to sustain the efforts. By their very nature, the multiagency partnerships are fragile and can suffer from turnover at both the leadership and implementation levels. Responsibilities for intelligence gathering, undercover operations, organizing call-in meetings, and community collaboration are diffused across organizations and often are “add-ons” to the normal responsibilities of the various actors. Action may be driven by a sense of crisis, such as that generated by high levels of youth homicide in Boston and record levels of homicide in Indianapolis, but may be difficult to sustain when peak violence levels decline. Thus, research is needed both on the capacity of the model to have long-term impact and on the system capacity to sustain these strategic, data-driven, multiagency coalitions.

As noted above, prior studies found evidence that both Boston Ceasefire and Project Exile were associated with declines in homicide and violent crime (Rosenfeld et al. 2005). The PSN research found that case studies consistent with both approaches (Ceasefire and Exile) showed evidence of violence reduction. Both strategies include a focused deterrence message supported by the actual and threatened use of federal prosecution for very select behaviors (illegal gun possession and use). From this point the approaches diverge with Boston Ceasefire relying on direct communication of the message to at-risk groups and Exile using a broad public media campaign to communicate the message. Boston Ceasefire also placed greater emphasis on community engagement. The existing research, however, cannot distinguish which of these various components are critical for impact. Is the threat of federal prosecution a necessary ingredient? Is the direct communication of the message in face-to-face meetings the necessary ingredient? Does the community actually change in terms of increased collective efficacy and informal social control, and if so, is this a critical ingredient in violence reduction? Is it the combination of deterrence threat and social support that generates the impact, or can one or the other component have a similar impact alone? How do all of these components relate to the sustainability issue? Ultimately, multisite investigations with longer-term follow-up are needed to address these types of issues and to inform policymakers and professionals on the key elements needed to maximize violence reduction.

The focused deterrence approach is largely a people-based strategy. During the same years that these models have emerged, there has also been progress in the development of place-based strategies (Braga and Weisburd 2010). Both people- and place-based approaches are based on principles of situational crime prevention (Clarke 1997). Given that violence is highly concentrated in terms of both people and places, an extension of the offender-oriented focused deterrence model might attempt to link this people-based strategy with a variety of place-based interventions. In reality this may already be occurring. For example, Rockford, Illinois, included a place-based intervention focused on problem properties following its initial call-in meeting with individuals involved in street-level drug dealing. Similarly, Milwaukee, Wisconsin, and Roanoke, Virginia, conducted code enforcement surveys and landlord education sessions along with their offender call-in meetings. Although this further complicates evaluation issues, it does seem to offer a promising set of interventions based on research understanding of crime patterns (Tillyer and Kennedy 2008).

Summary

The National Academy of Sciences review of strategies intended to reduce violent crime noted that Boston Ceasefire represented a promising intervention that deserved further research (Wellford et al. 2005). The accumulation of evidence of the impact of the offender-oriented, focused deterrence model since the initial findings of Boston Ceasefire warrants at least a label of "promising," if not "evidence-based," practice. For police and criminal justice officials and their various community partners, these strategies offer an approach to reducing violence that offers significant promise for reducing high levels of violence, at least in the short-term. Further, there is some evidence that the greatest impact will be on those communities that suffer the most from high levels of violence. For scholars, it is an approach that also offers a host of unanswered research questions. Answering these questions will not only advance theoretical knowledge about violence and violence prevention but will also likely contribute to practice in ways that further maximize the likelihood of violence reduction.

Forced Migration and Human Rights

Wenona Rymond-Richmond
Department of Sociology, University of
Massachusetts Amherst, Amherst, MA, USA

Overview

Being forced to leave one's home or homeland constitutes a gross violation of human rights. Tragically, over 60 million people worldwide have been forcibly removed from their homes. The causes of forced displacement are diverse and include natural or manmade disasters, human trafficking, war and civil war, genocide, development projects, evictions, and political, social, ethnic, or religious persecution. According to recent figures published by the United Nations High Commission for Refugees (UNHCR 2010), over 43.3 million people worldwide have been forcibly displaced due to conflict and persecution.

The sheer enormity of these numbers should imply that forced displacement is central to discussions of human rights. Yet, forced displacement has not received the same attention as other human rights violations in public discourse in academia and "often seems to be accepted as a sad but inevitable consequence of war" (Hollenbach 2008: 2). Furthermore, the study of refugees is often overlooked in academia. Demonstrating the slow pace in which academics focused on refugees, the interdisciplinary field of "refugee studies" did not emerge until the early 1980s. Further, it was not until the late 1990s that a significant number of academic reviews of internally displaced people (IDP), individuals who are forcibly displaced and remain inside their original country, were published.

Criminologists should have much to contribute to the study of forced displacement and the relationship between crime, human rights, and social justice. However, the discipline of criminology has been remarkably unresponsive to examining the role of the state in acts of persecution and crimes committed by the state more generally. Inherent to the definition of refugee is recognizing either a state's crime against its citizens, the state's inability to protect its citizens, or the state's willingness to turn a blind eye on crimes committed against its citizens. For the most part, the discipline of criminology has failed to incorporate forced displacement into their research agenda. Instead, criminologists are primarily concerned with interpersonal acts of violence such as homicide, rape, and robbery. In other words, the focus of mainstream criminology is predominately the individual or possibly the neighborhood rather than the state as a unit of analysis. One notable exception is critical criminologists who are attentive to state crimes and crimes of the powerful more generally. Similar to criminologists silence on the topic of genocide is their silence on the topic of forced displacement (Hagan and Rymond-Richmond 2008).

Causes of Forced Displacement

According to recent figures published by the United Nations High Commission for Refugees (UNHCR 2010), over 43 million people worldwide have been forcibly displaced due to conflict and persecution. The causes of forced displacement are diverse and include natural or manmade disasters, human trafficking, war and civil war, genocide, development projects, evictions, and political, social, ethnic, or religious persecution. The focus of this entry is forced displacement due to conflict and persecution rather than forced displacement due to natural or manmade disasters.

While evictions might not initially register to some as a form of displacement resulting from conflict and persecution, human rights violations may occur during the process of urban redevelopment. Forced displacement and human rights violation can occur when individuals or families are forcibly evicted. This may occur because of urban redevelopment, "beautification" projects, gentrification, or as a side effect of development. Like other displaced people, those who are forcibly evicted may experience trauma from being forced out of one's home and or community. In recent years, the United Nations human rights program has become more attentive to examining human rights violations that occur in the practice of forced evictions. One example from the United Nations in regards to human rights violations and evictions comes from Miloon Kothari, the United Nation's highest-ranking expert on housing issues. After visiting a public housing development in Chicago that was slated to undergo demolition and redevelopment, Kothari stated that "evictions of public housing residents in the United States clearly violate international human rights, including the International Convention on the Elimination of All Forms of Racial Discrimination and the International Covenant on Economic, Social and Cultural Rights" (Hagedorn and Rauch 2007: 451). Under these guidelines, some public housing residents could qualify as internally displaced people (ibid).

Definition of Immigrants, Refugees, and Internally Displaced Persons

Defining and classifying who is and who is not a refugee has serious consequences for individuals and families. For some, being defined as a refugee can be a matter of life and death because with refugee status comes international protection. The legal definition of refugee was established in the 1951 United Nations Convention Relating to the Status of Refugees and its 1967 Protocol:

> Any person who owing to well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable, or owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence, is unable, or owing to such fear, is unwilling to return to it.

There are significant critiques and debates regarding the definition of refugee. First, is a dispute regarding whether immigrants and refugees are fundamentally distinct categories. Refugees and immigrants share common disadvantages including high levels of poverty and discrimination in their home country. Nonetheless, some argue that significant differences exist. One the one hand is the realist perspective, which suggests that the groups are distinguished by whether the migration was by choice or not. For refugees the migration is not by choice but due to social, cultural, or political pressures, which forced them out of their native country. For immigrants, the migration is by choice and typically for economic opportunities. Additional distinctions are made between the categories based on their likely ability to return to one's homeland and their relationship to the state (see Kunz 1973). On the other hand is the nominalist perspective, which suggests that the binary categories are blurry, are socially constructed, used to advance state interests, and mask the similarities between immigrants and refugees.

Among the debates regarding the definition of refugee is whether the definition is too broad or too narrow. Those who find the definition to be too broad emphasize that individuals defined as refugees have exceptionally diverse historical and political origins. Individuals' cultural, psychological, economic, spiritual, and personal differences may be minimalized as they are collectively subsumed under the label of refugee. Others assert that the definition is too narrow because the focus is on individual persecution rather than generalized persecution resulting from violence and war. Two legal documents that attempt to rectify this limitation are the 1969 Organization of African Unity Convention Governing the Specific Aspects of Refugee Problems in Africa and the 1984 Cartegena Declaration on Refugees. Both of these regional legal instruments broaden the definition of refugee to include persons who "have been threatened by generalized violence" (1984 Cartegena Declaration on Refugees).

The legal definition of refugee is further critiqued for being too narrow because it excludes individuals who were displaced from their homes for similar reasons as refugees, but have not left their country of origin and crossed an international boarder. The term used for this exceptionally large group of individuals is internally displaced persons (IDP). Approximately 25–30 million IDP's were displaced because of conflict. While there is no legal definition of IDPs, the Guiding Principles on Internal Displacement provides the following definition:

> internally displaced persons are persons or groups of persons who have been forced or obliged to flee or to leave their homes or places of habitual residence, in particular as a result of or in order to avoid the effects of armed conflict, situations of generalized violence, violations of human rights or natural or human-made disasters, and who have not crossed an internationally recognized State border.

Rather than adjudicate between these positions, the purpose here is to highlight controversies surrounding the definition of immigrants, refugees, and internally displaced persons and to examine human rights violations of forced migration.

Legal Violations and Rights of Forcibly Displaced People

The rights to freedom of movement, rights to choose one's residence, rights to security of the person, rights to life, and rights to freedom of expression are recognized in many international laws and national constitutions. In particular, forced displacement violates a number of international laws including the Universal Declaration of Human Rights (art.25, para.1), the International Covenant on Economic, Social and Cultural Rights (art. 11, para. 1), the International Covenant on Economic, Social and Cultural Rights, and the 1949 Geneva Conventions and the Additional Protocols.

Several international legal documents outline the rights of migrants, refugees, and internally displaced people. The 1951 United Nations Convention Relating to the Status of Refugees is the landmark legal instrument to protect and assist refugees. Additional documents supporting the human rights of migrants, refugees, and internally displaced people include the 1967 Protocol Relating to the Status of Refugees; the 1969 OAU Convention Governing the Specific Aspects of Refugee Problems in Africa; and the 1990 International Convention on Migrant Rights, which established that all migrant workers, whether they are documented or not, have fundamental human rights. Furthermore, the UN Pinheiro Principles detail the rights individuals have regarding returning home after a violent conflict. According to this document, individuals not only have the right to return home, but they also have the right to return to the same property. The aim of this principle is to ensure that no one profits from the violence and to reduce the amount of victimization that may occur after being forcibly displaced.

Status of Forcible Displacement: Refugees

Refugees

Accurately counting the number of refugees is difficult. According to the UNHCR, refugees totaled approximately 10.4 million refugee in 2009 and 10.55 million in 2010. The UNHCR's count of refugees is problematic because it does not include the large number of individuals displaced in urban cities around the world. Furthermore, the number does not include the more than 25 million individuals that are internally displaced.

Refugees are located throughout the world. The largest numbers are located in the Middle East and North Africa. There are approximately 2.7 million refugees in African, and 2.5 million refugees are in South and Central Asia. Refugees number nearly 650,000 in America and the Caribbean and nearly half a million in Europe. Pakistan hosted the highest number of refugees in 2010. By the end of 2010, the UNHCR estimates that the largest country of origin of refugees was

Afghanistan (3.05 million), followed by Iraq (1.7 million), Somalia (770,000), the Democratic Republic of the Congo (477,000), and Myanmar (416,000).

Approximately one-third of refugees currently live in a camp. Following larger population trends, since the 1950s, refugees are increasing settling in urban areas and mostly in developed countries. More than half of all refugees now reside in urban areas, and nearly half of refugees are women (47 %) and children (47 %).

IDP

In 2010, the number of people internally displaced by human rights violations, violence, and armed conflict totaled 27.5 million, the highest number in 10 years. Estimates are that 11.2–13.7 million children by the end of 2010 were internally displaced as a result of human rights violations, violence, and armed conflict. Approximately 80 % of all internally displaced individuals are women and children. Like refugees, internally displaced persons (IDPs) reside in countries throughout the world. The largest numbers are located in Columbia, Democratic Republic of Congo (DRC), Iraq, Somalia, and Sudan. In each of these countries, the IDP population was over one million. In 1 year alone, 2010, it is estimated that at least 2.9 million people in 20 countries were newly displaced. At least 200,000 IDPs in 2010 were displaced in the countries of Columbia, DRC, Kyrgyzstan, Pakistan, Somalia, and Sudan (IDMC 2010).

Current Issues and Controversies

1. Lack of Protection for Internally Displaced Individuals

   The UNHCR is responsible for protecting and assisting refugees; however, there is no comparable organization within the United Nations for internally displaced persons. With little to no international legal protection, internally displaced individuals often suffer greatly at the hands of their government. In 2010, attacks or threats against humanitarian workers occurred in Darfur, Afghanistan, Yemen, Somalia, and Columbia (IDMC 2010). In Darfur, the Sudanese government has prevented delivery of medical care and humanitarian aid to IDP camps (see ICC 2007; Totten 2006).

2. Refugees in Urban Areas

   More than half of all refugees currently reside in urban areas. Rather than be displaced in a refugee camp, many individuals select to be displaced in a city. UN High Commissioner for Refugees Antonio Guterres argues that their complex and unique challenges requires a radically new approach to providing protection and assistance. The primary concern is that internally displaced people receive fewer benefits if they live in urban areas than if they live in camps. Authorities often do not recognize them as displaced people and therefore do not provide them with services they are legally entitled to.

3. Protracted Displacement

   Returning home for a refugee is uncertain and typically involves a lengthy stay in a refugee camp. Displaced people may be displaced for years of even for decades. Nearly two-thirds of all refugees are in a protracted refugee situation, which is defined by the UNHCR as being in exile for more than 5 years. Like refugees, IDPs suffer from lengthy displacement. The Internal Displacement Monitoring Center (IDMC) found that at least 40 countries in 2010 contained IDPs living in protracted displacement. Protracted displacement violates numerous human rights contained in the 1951 Convention. Displacement affects all of nearly all aspects of life. Consequences of prolonged displacement includes poverty, loss of material possessions, kinship and village structure altered, and potential lack of ability to practice the culture and livelihood as they had in their homeland.

4. Loss of power and culture?

   Is culture lost when one is displaced? Should it be presumed that with loss of homeland come loss of cultural identity? To what extent is culture tie to homeland? Is culture portable or is it tied to homeland in such a way that it is lost when forcibly displaced?

The effect of displacement on culture and identity is a divisive topic. Our most nuanced theories of the relationship between displacement and culture comes from anthropological studies. Some anthropologists contend that while there is a strong tendency to equate displacement with loss of culture, this is an essentialist conception of place and emphasize that identity and place should be separated to show that when refugees are displaced, they do not necessarily lose their culture, identity, and power (Malkki 1995).

5. Crime, Perceptions of Crime, and Victimization

After being persecuted in one's homeland for reasons of race, religion, nationality, membership in a particular social group, or political opinion, refugees frequently continue to be discriminated against and victimized in the country that offers them asylum. In other words, refugees are forced to cope with discrimination, marginalization, and persecution in both their home and host country (see Pickering 2005). Refugees displaced due to genocide may continue to be victimized in much the same way as they were in their home country, and they may suffer from new forms of victimization such as ostracism, stigmatization, family disruption, domestic violence, and poverty.

Women in refugee camps from around the world report victimization that stems from gendered division of labor among some refugees. For example, collecting wood and water is often the delegated responsibility of women, and these activities make refugees more vulnerable to attacks because it requires travel to the edges and outskirts of the camps (see Hyndman 2004; Rymond-Richmond and Hagan 2012). In addition, raped women may continue to be victimized via physical trauma, sexually transmitted diseases, ostracism, and reduced likelihood of marriage.

One of the debilitating forms of discrimination is widespread negative stereotypes of refugees that render the refugee as undeserving, different, and marginalized. Of the stereotypes, perhaps none is more pervasive, damming, and incorrect than the perceptions of refugees as criminals. In fact, the perception of crime often extends beyond refugees to include all migrants. In the United States, the connection between immigration and crime has recently been in the spotlight, and it is here that members of the discipline of criminology have made valuable contributions. According to a poll conducted by the National Opinion Research Center in 2000, 73 % of Americans said they believed that immigrants are either "somewhat" or "very" likely to increase crime. Research by sociologists and criminologists find this perception is not only unsupported by data, but evidence demonstrates the opposite. Sampson and his colleagues examined more than 3,000 violent acts committed in Chicago from 1995 to 2003, census data, police reports, and a survey of more than 8,000 residents. They found that immigrants have lower rates of criminal involvement than nonimmigrants. In fact, first-generation Mexican immigrants were 45 % less likely to engage in violence than third-generation Americans. This pattern also extended to neighborhoods. Neighborhoods with large shares of immigrants tend to have lower levels of violence than similarly situated neighborhoods with few immigrants (Sampson 2008).

Coupled with the perception of migrants being criminal is a sentiment that all migration is illegal and undesired. In the USA, one of the results of this negative perception of immigrants is the passing of Arizona Senate Bill 1070. This controversial legislative act has received national and international attention and is considered the broadest and strictest anti-illegal immigration in US history. The result is discriminatory practices of police harassment and arrests including the right of police to demand immigration documents from any individual perceived as being undocumented. While other states are considering adopting similar legislation, some police departments discourage this practice because it could discourage immigrants from reporting crimes and cooperating with law enforcement. Further, a victimized group will likely be discouraged from reporting crimes committed against them, thereby leading to increased victimization of an already vulnerable population. Secretary of State Hillary Clinton reported to the United Nations Human Rights Council that SB1070 was evidence of human rights violations in the United States.

6. Human Rights of Migrants

   While the focus of this entry is human rights violations associated with forced migration, human rights violations are not limited to this particular type of migrant. In fact, "Evidence demonstrates that violations of migrants' human rights are so widespread and commonplace that they are a defining feature of international migration today" (Taran 2002:1). Yet, research on human rights of migrants has been minimal. Currently, there are approximately 214 million international migrants worldwide. Migrants represent 3.1 % of the world's population, or one out of every 33 individuals. 7.6 % of migrants are refugees.

   A few notable advancements in protecting migrant's human rights include the appointment of a UN Special Rapporteur on Human Rights of Migrants and 1990 International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families. The convention aims to prevent and eliminate exploitation of migrant workers. Further, the convention extends fundamental human rights to all migrant workers whether they are documented or undocumented.

7. "Refugee Studies" versus "Forced Migration Studies"

   Refugee studies emerged as an interdisciplinary field in the early 1980s. In more recent times, there has been scholarly debate concerning a paradigm shift from "refugee studies" in favor of "forced migration studies." The shift is largely motivated by the recognition that internally displaced people share much in common with refugees, yet technically would fall outside the scope of "refugee studies." Forced migration studies, on the other hand, would include the study of both categories of displaced people. For some, broadening the field of study signifies inclusion of a marginalized and invisible group of people. Others object with a primary concern that doing so could weaken attention on refugee concerns and detract from the distinct legal status and protection of refugees under international law.

8. Mental health

   Chronic mental health problems, which include depression, anxiety, and posttraumatic stress disorder in the aftermath of genocide and ethnic violence, affect a significant portion of refugees (De Jong et al 2001; Fazel et al. 2005). A survey of Darfur refugees in Cairo described depressive symptoms that include "hopelessness, tearfulness, apathy, decreased concentration, decreased or increased sleep, low appetite, weight loss, low mood, decreased energy, and guilt" (Meffert and Marmar 2009, 1841). Trauma for some forcibly displaced people may include witnessing extremely brutal killings and tortures. Darfurian refugees who survived the genocide provide a glimpse of the extreme brutality they witnessed and experienced. Several Darfurians interviewed as part of the ADS data reported perpetrators targeted pregnant women, male babies or fetuses, and children for torture and death (Rymond-Richmond and Hagan 2012). One female refugee witnessed extreme torture of young boys in the village, which included slitting their throat, cutting the foot open from the big toe to the ankle, cutting off hands and sexual organs, removal of the brain, and removal of skin. Another refugee from a small village in Darfur witnessed the death of seven men who were "dismembered alive. They cut off their penises and put them in their mouths. Cut off their tongues and cut them into pieces."

Future Directions and Suggestions

1. The discipline of criminology should expand beyond focusing on individual criminal actions to include crimes committed by the state.

Studying refugees requires this shift as the state is implicated as either the perpetrator of the crime, incapable of protecting its citizens from persecution or approving of the persecution.

2. Internally displaced persons are without a single agency clearly mandated to assist and protect IDPs. Assistance and protection of forcibly displaced people must include this marginalized population. The appointment of a representative on internally displaced persons (Walter Kälin as of 2004) by the United Nations Secretary-General is a step in the right direction, and significant progress will hopefully be made towards granting this group aid and protection.
3. The rights and protection of children in refugee camps and internally displaced camps must be upheld and prioritized. Children continue to be victimized and targeted for exploitation after being forcibly displaced from their homelands. In addition, their international human right to education is inhumanely comprised.

Forecasting of Shootings Using Risk Terrain Modeling

Joel M. Caplan and Leslie W. Kennedy
School of Criminal Justice, Rutgers University, Newark, NJ, USA

Synonyms

Risk terrain modeling (RTM); Spatial influence

Overview

This entry summarizes approaches that have been used to study patterns of shootings and empirically examines the environmental conditions that contribute to the emergence of these events. Geographic information systems (GIS) allow for the mapping of spatial influence which refers to the way in which correlates of crime, as features of a landscape, affect places throughout the landscape. Rather than just a feature's presence, its influence on space is important because context affects criminal behavior. Operationalizing the spatial influence of crime correlates allows analysts to move beyond just creating maps of points that coexist with crime to creating visual narratives of how settings become conducive to crime. This entry presents ways in which to operationalize criminogenic features of gun shootings to a geographic map. Then it presents the utility of this mapping technique for crime analysis through the use of risk terrain modeling (RTM) to produce a map of compounded criminogenic contexts for shootings in Irvington, NJ. RTM builds upon underlying principles of environmental criminology and problem-oriented policing to articulate and communicate criminogenic and vulnerable areas at the micro-level. By using theoretically grounded operationalizations of spatial influence from many correlates of gun shootings, the entry demonstrates how place-based risk analysis can be achieved by the application of some intuitively simple principles within the analytical reach of crime analysts using basic GIS software.

Introduction

At a time when overall crime rates have dropped, gun shootings continue to plague inner city areas tied to the illegal activity around gangs and drugs. Shootings are often seen as a sign of extreme disorder, occurring when offenders are at their most brazen and law enforcement at its least effective. Shootings are often used as indicators of crime sprees or uncontrollable gangs, and each event attracts special attention from the media. Shootings attract a lot of attention at the political level as well, prompting calls for special policing interventions to stop the violence. A well-known example of this is the multicity program "Operation Ceasefire" that has concentrated on reducing gun violence through a variety of initiatives, including arrest, assistance to offenders from criminal justice agencies, and active involvement in crime reduction by the affected community (for a complete review of these initiatives, see Koflas et al. 2011). Despite all of this attention, or perhaps because of the singular ferocity of the crime event, shootings are often considered in ways that focus more on the specific incident and not as much on the situational factors that might support and contribute to this violent outcome at certain locations. Academic research is beginning to turn more attention to these contextual affects. This entry summarizes approaches that have been used to study patterns of shootings and examines the environmental conditions that contribute to the emergence or disappearance of these events. The entry begins with an overview of the literature on place and crime and then turns to a discussion of spatial influence of place-based features on criminal outcomes, particularly gun shootings. It concludes with an example of a cartographic method for operationalizing spatial influence and then presents a composite model of place-based risk of shootings in Irvington, New Jersey.

State of the Art: Current Knowledge on the Concentration of Shootings

When considering gun shootings, questions have been raised about the extent to which this crime is, in fact, situational and nonrandom. Ratcliffe and Rengert (2008) make the case for the importance that previous shootings play in leading to near repeats – crimes that happen close to and soon after a previous similar incident: This research is modeled after similar studies on burglary. Ratcliffe and Rengert report that there is an elevated risk of about 30 % that a shooting will occur within 2 weeks and within one block of a previous incident. They suggest that these findings show shootings to be influenced by coercion, retaliation, and escalation of violence. So, the characteristics of the interaction between offender and victim will lead to an elevation in the likelihood of shootings in the vicinity of past events. But, why do the initial incidents happen where they do and are there similarities in the types of places that incidents occur? That is, are there environmental (i.e., contextual) factors that bring these crimes together at similar places?

Criminological research about the concentration of crime primarily focuses on spatial clusters or hot spots of crime – where there is a relatively high frequency of similar criminal behaviors at specific places. Foremost research by Sherman et al. (1989) studied the locations of requests for police assistance in the city of Minneapolis over a 1-year period. Spelman and Eck (1989) found that while 10 % of victims in the United States were involved in 40 % of victimization, 10 % of offenders were involved in 50 % of crime, and 10 % of places were involved in 60 % of crimes. More recently, Eck and Weisburd (1995), Johnson (2010), Johnson et al. (2008), Bowers et al. (2004), Braga and Weisburd (2010), and others reported similar clustering effects. Caplan (2011), for instance, reported that less than 1 % of the area of Irvington, New Jersey, accounted for more than 53 % of all shooting incident locations. In Houston, Texas, Wells et al. (2011) found gun assaults to cluster both temporally and spatially.

These findings related to hot spots and near repeats are important and address key situational aspects of violent crime. They provide evidence that these crimes connect to one another by being close to one another. However, they do not address the question of how these crimes, especially the initial instigator events, are influenced by the underlying conditions of the environment. Can one establish that there are spatial patterns that appear in these behaviors that are not just a function of individual decisions to be violent but are a function of underlying environmental factors that concentrate violent acts at specific locations? More simply, why do shootings happen in some places and not in others? This question leads one to consider how to use spatial analysis techniques to connect violent behavior to what Patricia and Paul Brantingham referred to as an environmental backcloth: a combination of qualities or characteristics of places that raises the risk of crime occurrence (Brantingham & Brantingham 1995). According to the Brantinghams, crime generators create settings that are conducive to particular types of criminal acts by creating particular times and places that provide appropriate concentrations of people and other targets. Their combined effects can heighten the risk of crime. The Brantinghams suggest that offenders find targets at these locations that are unlikely to be adequately protected through surveillance or policing. The high levels of crime that occur at certain places, then, come from people at these locations taking advantage of opportunities afforded them through placement of targets. The Brantinghams' conceptualization of crime generators was recently studied in detail by Bernasco and Block (2010) looking at robberies in Chicago. They indicate that certain features of the environment have a great influence on where crime locates. As a result, robberies, for instance, are not evenly distributed across the urban landscape but concentrate around generators. Similarly, Moreto et al. (2011) found that residential burglaries occur at micro-level places with risky environmental features and that near repeat burglary incidents were even more likely to occur at higher risk places than their instigator events. Studies such as these provide evidence that analyzing the risk heterogeneity of an area is especially useful for developing more complete understandings of crime problems. They also stress the reality that underlying (risky) environmental contexts are often present before either instigator or near repeat incidents.

It is clear from existing research that certain environments have characteristics that encourage or discourage the occurrence of shootings and, therefore, raise or lower criminogenic risk. Shootings tend to be spatially distributed according to the distributions of underlying generators, such as drug markets, or certain features of a landscape, such as bars, clubs, fast-food restaurants, or liquor stores; gang members; bus stops; schools; or public housing. Assigning risk levels to places with certain features of environments, such as these, requires an understanding (i.e., through past empirical research) of their relative importance in supporting shootings. The risk posed by each criminogenic feature throughout a landscape, as well as their confluence at the same place, contributes to a risk value that, when raised a set amount, increases the likelihood of shooting incidents. This risk value – a measure of the clustering of criminogenic factors – can be used to anticipate where shootings will occur and (possibly) cluster over a period of time. Stated another way, risk values are a measure of a place's vulnerability to crime.

People can live in vulnerable areas defined by an agreed-upon set of criminogenic features, but in the absence of motivated offenders, the existent risk of crime may be relatively low. Crime risks are both place-based and situational – affected by exposure to individual events that appear from location to location and by exposure to places where events cluster over time. It is important to build models of the environmental backcloth that consider different features of the landscape for different crime types because factors that influence the occurrence of one type of crime are likely to differ from those that are associated with other crime types. Cartographically modeling vulnerability as the clustering of risk factors, and then interpreting vulnerability in the context of exposure, permits a research strategy to identify, monitor, and control these environments.

Spatial Influence: The Future of Mapping Risk Factors

Opportunities for crime are not equally distributed across places, or "small micro-units of analysis" (Weisburd 2008, p. 2), and so the analytical approach to studying criminogenic places plays a critical role in the reliability and validity of efforts to assess vulnerabilities and future crime hot spots. Crime control and prevention activities must consider not only who is involved in the criminal events "but also the nature of the environments in which these activities take place" (Kennedy and Van Brunschot 2009, p. 129) because opportunity for crime is an attribute of all places. Risk assessment, defined by Kennedy and Van Brunschot (2009, p. 4) as "a consideration of the probabilities of particular outcomes," provides an efficient way to analyze crime opportunities. However, challenges appear in the operationalization of risk in a GIS. The way that criminogenic features have been modeled in a GIS is often contrary to how people experience and conceptualize their environments (Couclelis 1992; Frank and Mark 1991).

When assessing the risk of crime to occur at conceivably any location throughout a landscape, the use of finite points, lines, and polygons in a GIS is a poor representation of criminogenic features on a map because they bear no particular relationship to the dynamic environments of which they are a part (Couclelis 1992). "Points, lines, and polygons that define vector objects do not have naturally occurring counterparts in the real world," explained Couclelis (1992, p. 66). They are approximations of environmental features, but without any theoretical or empirical link to their geographies (Freundschuh and Egenhofer 1997). The way people conceptualize and operate in space is an important consideration for the mapping of crime risk throughout landscapes. Cartographically modeling these conceptualizations and the spatial influence of criminogenic features in a GIS in a way that reflects the actors' views is an important part of what Freundschuh and Egenhofer (1997) describe as "Naïve Geography, a set of theories of how people intuitively or spontaneously conceptualize geographic space and time" (Egenhofer and Mark 1995), and can yield more meaningful and actionable spatial intelligence for use by public safety professionals (Frank 1993; Mark 1993; Freundschuh and Egenhofer 1997).

The best way to map crime factors for the articulation of criminogenic backcloths (Brantingham and Brantingham 1981) is to operationalize the spatial influence of each factor throughout a common landscape rather than a-theoretically map the factors as points, lines, or polygons in a manner that keeps them disconnected from their broader social and environmental contexts. The concept of spatial influence refers to the way in which features of a landscape affect places throughout the landscape. The connection between criminogenic features and shooting incidents depends on one's ability to operationalize risk emanating from such features to all places throughout a landscape. Defining vulnerable places for shootings, then, is a function of the combined spatial influence of criminogenic features throughout a landscape that contribute to crime by attracting and concentrating on illegal behavior. Spatial influence can be cartographically modeled with a GIS to produce risk map layers for each criminogenic feature. So, while all places might carry some risk of shootings, some places are riskier than others because of the spatial influences of certain criminogenic features known to correlate with shooting incidents. Fortunately, decades of criminological research have identified a variety of independent variables to be significantly correlated with a range of crime outcomes that can be used to inform such expectations and to cartographically model them in a GIS, accordingly.

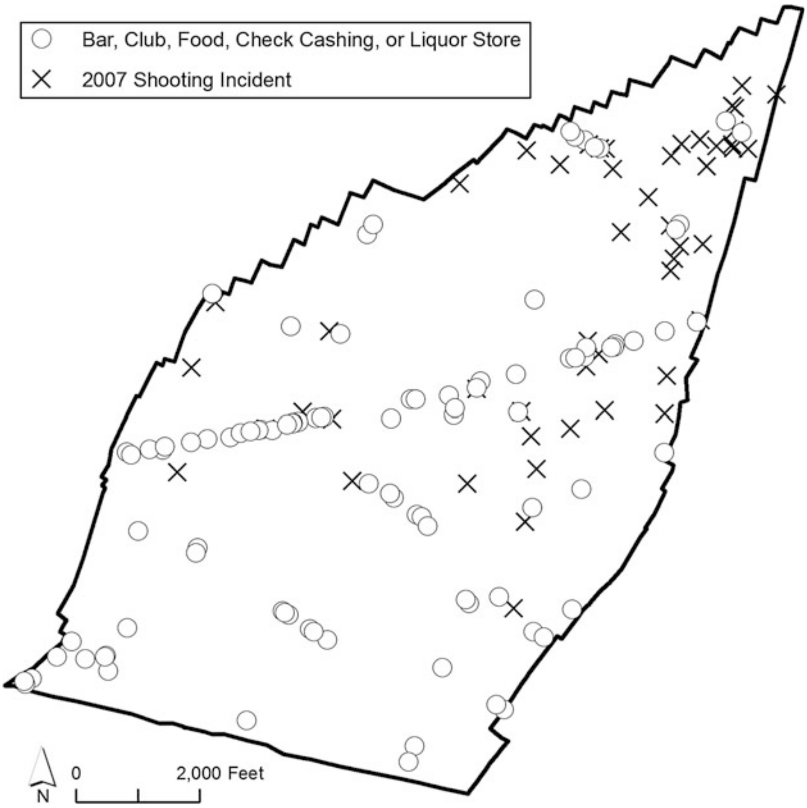
Operationalizing the spatial influence of crime risk factors addresses various theoretical and methodological issues concerning the use of GIS for crime forecasting and cluster analysis (Freundschuh and Egenhofer 1997). Though, crime analysis can yield different results when the same crime correlate is modeled in a GIS according to a variety of empirically justified spatial influences. To illustrate the issues at hand, presented in the next section is an illustration of the primary methods of operationalizing spatial influence of risk factors for shootings in one city.

Demonstrating Methods of Investigating the Concentration of Shootings

Figure 1 shows point symbols representing the locations of shooting incidents (the crime) and bars, clubs, fast-food restaurants, check-cashing outlets, and liquor stores (the crime generators) in Irvington, NJ. These crime generators, or criminogenic features of the landscape, are correlated with shooting incidents in several empirical research studies, both in Irvington and other settings (e.g., Caplan et al. 2011; Kennedy et al. 2011). There are 102 features and 60 shooting incidents from 2007 represented on the map in Fig. 1. Visual inspection of the map suggests that shooting incidents are distributed in a similar way as criminogenic features. However, only one shooting incident was at the exact same address as a fast-food restaurant.

Bars, clubs, fast-food restaurants, check-cashing outlets, and liquor stores are often not the exact locations where associated crimes happen. Rather, shootings occur at places that are in some way defined or influenced by them. As illustrated in Fig. 2, the spatial influence of these features on shooting incidents is related to their concentration at places throughout the

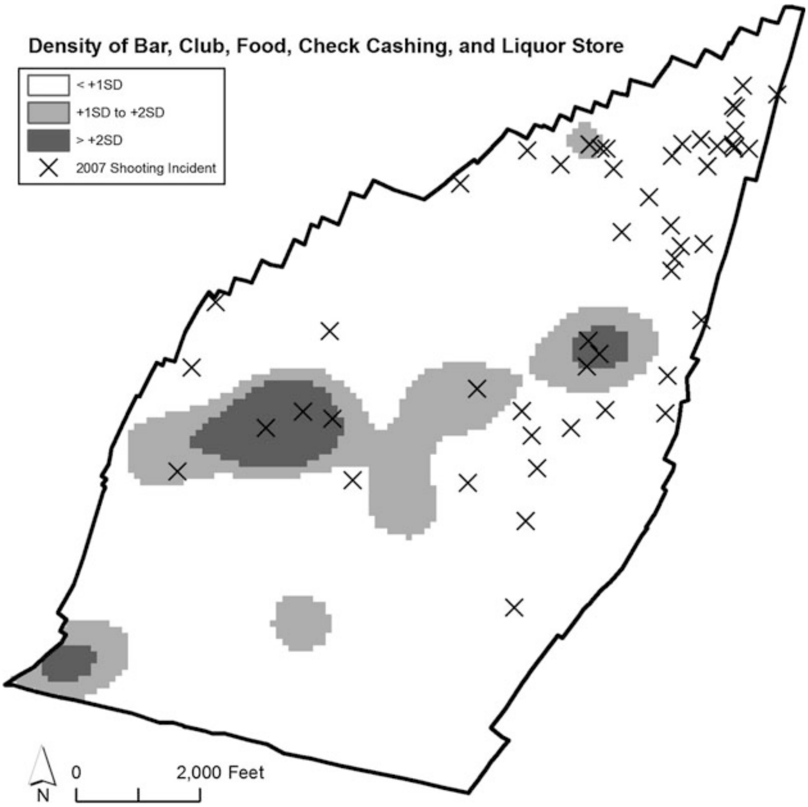
Forecasting of Shootings Using Risk Terrain Modeling, Fig. 1 Irvington, NJ: crime risk factors represented as points



municipality and was operationalized as a raster density map. Shooting incidents are cartographically modeled as more likely to happen at places where bars, clubs, fast-food restaurants, check-cashing outlets, and/or liquor stores are most concentrated. That is, the area over which these features may have an influence on the occurrence of shootings is not modeled as limited to the precise location of the feature itself but is likely to diffuse to nearby places. "Places" are defined in the raster map as cells sized 100 ft by 100 ft, and the distal limits of nearby features (i.e., the bandwidth or search radius) used to define the density of each place were set at 1,480 ft (i.e., approximately four blocks; a meaningful sphere of influence for these criminogenic features as attributes of places within the radius). The density map is symbolized according to standard deviational breaks, with all places colored in darker gray having density values greater than +2 standard deviations from the mean density value – which statistically puts these places in the top 5 % of the most densely populated with criminogenic features. As shown on the map, places with greater concentrations of criminogenic features appear to be more frequented by shootings than the bars, clubs, fast-food restaurants, check-cashing outlets, or liquor stores themselves (compared to Fig. 1). In fact, 13 out of 60 (22 %) shootings during 2007 occurred at places with density values above +1 standard deviations.

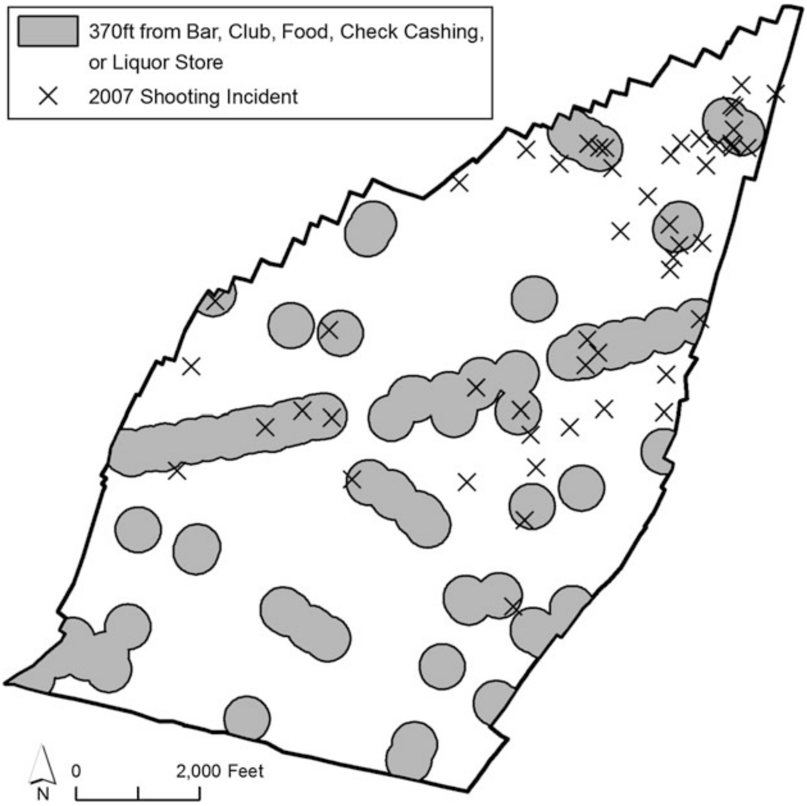
Perhaps bars, clubs, fast-food restaurants, check-cashing outlets, and liquor stores are the venues where most suitable victims hang out or where the most likely and motivated offenders visit, become intoxicated, or lose self-control. However, due to increased police presence or other capable guardians such as bouncers, witnesses, or CCTV cameras, offenders do not shoot their victims inside or directly outside of such facilities. Rather, shootings are more likely to occur at certain distances away. Thought of in this way, the spatial influence of bars, clubs,

Forecasting of Shootings Using Risk Terrain Modeling, Fig. 2 Irvington, NJ: crime risk factors represented as density



fast-food restaurants, check-cashing outlets, and liquor stores on shootings is more a function of distance from the closest feature rather than the presence or absence of the feature at the shooting incident location. Figure 3 presents a map that operationalizes this distal spatial influence with a 370 ft buffer (about 1 block) around all features. Thirty-one shootings occurred within one block from a bar, club, fast-food restaurant, or liquor store. The operationalized spatial influence of the highest risk created by these features to be all places within 370 ft – a definition that was grounded in theory and empirical research – identified places with more than half (52 %) of all shooting incident locations. These results are arguably due to identifying a larger catchment area to which shootings are aggregated. Compared to feature points themselves, this is true. However, the coverage area of places with density values above +1 standard deviations is 0.806 mile^2, and the coverage area of places within one block of a criminogenic feature is 0.725 mile^2. So, more shootings occurred in a smaller area that was deemed affected by nearby criminogenic features in a conceptually meaningful way.

The most meaningful cartographic model of places in Irvington that are at the greatest risk of shootings is one that operationalizes the spatial influence of bars, clubs, fast-food restaurants, check-cashing outlets, and liquor stores to be up to a certain distance away. This might not be the case in other jurisdictions or for other crime types, but it is corroborated by existing research, and it reinforces the importance of modeling these criminogenic features in commensurate ways on a map. This reinforces the notion that the study of crime concentration and approaches to crime analysis and forecasting cannot be a-theoretical and must be evidence based. They must be grounded in ways that account for the dynamic interaction of all criminogenic features throughout a landscape.

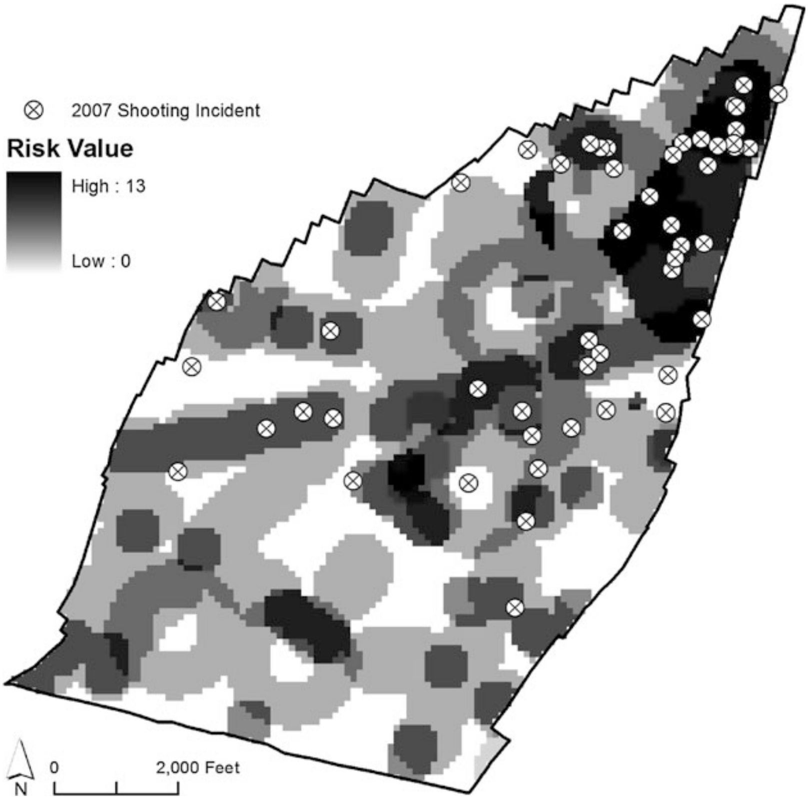


Forecasting of Shootings Using Risk Terrain Modeling, Fig. 3 Irvington, NJ: crime risk factors represented as distance

Combined Spatial Influences of Criminogenic Features: Risk Terrain Modeling

The inclusion of multiple risk factors for the place-based study of shootings allows one to consider the interaction between the offender and the environment. Particularly, the potential for crime occurrence as a function of the illegal behavior that one could expect from motivated offenders at these locations. For example, risk from gang membership could be measured as the addresses of all known gang members' residences and operationalized as a density map if the spatial influence of these features is understood as "areas with greater concentrations of gang members residing will increase the risk of those places having shootings." Risk from bus stops could be operationalized as a distance map up to 555 ft away if the spatial influence of these features is understood as "up to one and a half blocks away from bus stops are at greater risk for shootings because targeted victims are most vulnerable when they arrive at or leave these destinations." A school risk factor could be operationalized using evidence that "distances between one and three blocks (between 370 ft and 1,110 ft) are at the greatest risk for shootings"; public housing risk could be operationalized using knowledge that "distances up to one block (up to 370 ft) are at greatest risk for shootings."

Once shooting risk factors are identified and operationalized to maps according to their spatial influences, they can be combined in a geographic information system (GIS) to show their compounded presence, absence, or intensity at every location throughout the landscape. In such a composite map, crime explanations are accounted for by different factors that tie different components of risk together, rather than on their own, to explain environmental influences and impacts on shooting events. Clustering of illegal shootings at particular areas, then, is explained by the unique



Forecasting of Shootings Using Risk Terrain Modeling,
Fig. 4 Irvington, NJ: weighted risk terrain of gun shootings

combination of factors that make these areas opportune locations for such crime.

Risk terrain modeling (RTM) is a method of spatial risk assessment that utilizes a GIS to attribute multiple qualities of the real world to places on a digitized map. RTM builds upon underlying principles of environmental criminology and problem-oriented policing and offers a statistically valid way to articulate and communicate criminogenic and vulnerable areas at the micro-level. It "paints a picture" of place-based environmental context for criminogenesis.

Figure 4 is a risk terrain for shootings that includes all of the aforementioned risk factors and that was produced in accordance with the steps described by Caplan and Kennedy's (2010) *Risk Terrain Modeling Manual*. Essentially, it is the product of the summed risk map layers of operationalized spatial influences of bars, clubs, fast-food restaurants, check-cashing outlets, and liquor stores; gang members' residences; bus stops; schools; and public housing, respectively. The co-location of the spatial influence of these risk factors at a place increases the place's risk value accordingly. It may be expected that higher risk places in Irvington were the most conducive for shootings to occur and, therefore, would be most likely to host shooting incidents in 2007, unless one or more risk factors were mitigated at these places. Logistic regression results for this risk terrain suggest that for every unit increase of a place's (i.e., 100 ft × 100 ft cell's; n = 3,975) risk value, the likelihood of a shooting occurring there in 2007 increased by 35 % (B = 0.30; S.E. = 0.045; Wald = 43.67; df = 1; Exp (B) = 1.35; $p < 0.001$). For places with one or more risk factors, we can be 95 % confident that if shootings happened in 2007 the likelihood of them happening at these places was between 23 % and 48 % greater than other places in Irvington ($p < 0.001$). According to results of a chi-squared test, more than 53 % of all shootings that happened in 2007 occurred at places which comprised about 15 % of the area (where shootings could have been geocoded) of Irvington (Pearson chi-square = 88.37, df = 12, p < 0.001, n = 3,975). That is, 15 % of the highest-risk places in Irvington accounted for more than 50 % of shooting incidents.

Open Questions for Further Research

Although shootings may occur at different places from one incident to the next, they are most likely to occur at places where features of the landscape better enable such illegal activity to happen. The risk terrain model presented above does not include many (if any) dynamic risk factors. That is, the locations of school, bars, etc., do not change drastically from year to year. Therefore, this "time-stable" risk terrain model, created with data current for the year 2007, is also likely to predict micro-level shooting locations during 2008. This spatial forecasting strategy for shooting incidents, based solely on environmental context and not on prior shooting event locations, should be valid even if shooting locations change over time. Results of a logistic regression suggest that for every unit increase of a place's risk value, the likelihood of a shooting occurring there in 2008 increased by 28 % (n = 3,975; B = 0.24; S.E. = 0.045; Wald = 29.37; df = 1; Exp(B) = 1.28; p < 0.001). So, the likelihood of a shooting happening at particular 100 ft-by-100 ft places in Irvington during 2008 significantly increases as each additional risk factor influences that place. Fifteen percent of the highest-risk places in Irvington in 2007 accounted for more than 43 % of future shooting incidents in 2008 (Pearson chi-square = 51.63, df = 12, p < 0.001, n = 3975).

Although practically meaningful and statistically significant, the predictive validity of the 2007 risk terrain model for 2008 shooting incidents is not as strong as that for 2007 shootings. This is likely because changes that occurred to the Irvington environment throughout 2007 as a result of other crime events, police activities, or social interventions are not accounted for in the risk terrain model and subsequent year-long risk assessment of place-based criminogenesis. These activities and characteristics of the environment could be added to the model to make it more representative of the criminogenic environment during 2008 and to improve its predictive validity. Even as is, the risk terrain model successfully demonstrates the substantial influence that environmental context has on illegal behavior and crime occurrence. Such information can help police commanders and other community stakeholders stay ahead of crime problems by assessing the risk for serious crime hot spots to emerge.

Discussion and Conclusion

This entry reviewed ways of using criminogenic features to explain the emergence and concentration of shooting incident locations. Risk terrain modeling is one method for modeling place-based risks in a GIS. The risk terrain model produced with thoughtfully operationalized criminogenic features, selected according to findings from previous empirical research, yielded a valid and reliable place-based forecasting model. Operationalizing the spatial influence of criminogenic features to maps was an important task for maximizing the construct validity of the impact these features had on crimes. Combining these maps in a GIS articulated environmental contexts of places that were most likely to attract, enable, and/or generate criminal shooting incidents as a function of the combined influences of criminogenic features in Irvington. Resulting maps can be used to efficiently allocate resources and target interventions.

Police officers are often well aware of the factors associated with shooting incidents in their jurisdictions, and their intuitions about such relationships tend to enjoy support from empirical literature. Gun shootings can occur at similar places to other types of illegal behavior, such as open-air drug markets, gang membership/territories, or armed robberies. There is also specialization in terms of where shootings occur – both as a function of the underlying conditions most suitable for related or precursor crimes and as a function of where certain opportunities exist (e.g., where victims are located). Take out eateries, for instance, are characterized by high foot traffic and late hours of operation, making it difficult to distinguish legitimate customers from those loitering for unlawful purposes. Due to the relative lack of guardianship and concentration of potential offenders and victims, such eateries can create ideal environments for shooting incidents (Cohen and Felson 1979). Including measures of environmental risks for shootings yields a better model of where future shooting incidents are likely to occur compared to predictions made with past violent shooting incidents alone. Risk heterogeneity of environments, as articulated by risk terrain maps, exists prior to the initial victimization and can be enduring without proper intervention efforts. Certain environments may also enable a contagion effect that promotes (re)victimizations in close proximity and soon after an original shooting occurs.

Crime mapping has become a standard function of law enforcement agencies throughout the United States. Mapping innovations directly contribute to the police function and have moved the field towards a place-based approach. This is because offenders occupy space and bring to certain locations characteristics that might threaten others and disrupt social interaction at these locations. They may also engage in illegal activities (such as gangs or drugs) that themselves change the risk character of these locations (and also attract attention from law enforcement). Most often a crime analyst's measure of the presence of offenders is designated as the number of crime incidents reported or arrests that are made and tabulated by police in crime reports. But, there are other types of measures to use that are more enduring than the crime event. This point alludes to human ecologists' interests in studying urban processes in which "the whole is greater than the sum of its parts" – where the focus is on the potential for, or risk of, crime in areas that comes as a result of the characteristics found in these areas. As Abbott (1997) states, "the Chicago School thought that no social fact makes any sense abstracted from its context in social (and often geographic) space and social time. . . .Every social fact is situated, surrounded by other contextual facts and brought into being by a process relating it to past contexts" (1152).

Contextual forecasting models are repeatedly found to be more accurate in predicting future crime locations than are models based only on previous crime occurrences (e.g., Johnson et al. 2008; Caplan and Kennedy's 2010; Kennedy et al. 2011; Groff and La Vigne 2002). Tying predictions of shootings and other crimes to geographic locations provides the basis for connecting attributes of space to actual behavior that occurs at these places. It also takes the police beyond a tactical reaction to crime occurrence to one that is more strategic – anticipating where resources will be needed and to prevent newly emerging crime problems using contemporary evidence-based and interdisciplinary practices.

Forensic Anthropology

Roxana Ferllini
Institute of Archaeology, University College London, London, UK

Overview

Forensic anthropology, a subdiscipline of physical anthropology, is dedicated to the biological identification of human remains discovered within a legal context in advanced stages of decomposition, or in situations where the integrity of the body has been compromised, thereby thwarting a positive identification through conventional means. Since its inception during the late nineteenth century (Stewart 1979), forensic anthropology has matured as a science, and professionals in this field have become actively involved in domestic or international police investigations, human rights investigations, and disaster victim identification (DVI), forming an integral element of body handling within the mortuary and in some instances in the field during the search and location of victims.

The advent of global participation and communication among forensic anthropologists has led to the development of new methodologies, such as state-of-the-art 3D imaging technology, which assist with the biological identification of human remains within a variety of contexts and circumstances.

This entry aims to present the historical process from which the discipline has evolved, and sheds light upon the application and methods utilized when a biological identification is required during a legal investigation. Current challenges are expanded upon; the future of the discipline is discussed and also potential avenues for future research.

Fundamentals of Forensic Anthropology

Developmental Background

The origins of forensic anthropology commenced within the United States during the late nineteenth century, in connection with studies conducted by the anatomist T. Dwight (1843–1911), concerning among many elements, the determination of sex, age, stature, and variability in relation to the human skeleton; his contribution led to the title of *Father of American Forensic Anthropology* to be conferred upon him (Stewart 1979). Dwight's research constituted a catalyst for this discipline, and also served to inspire those who followed. When viewed in relation to modern standards, his studies may appear rather basic, but they provided the initial impetus for the promotion of a discipline that has aided law enforcement organizations with the identification of human remains through many decades and, within a more recent context, involvement in trauma identification and description related to cause and manner of death. Dwight's studies were continued by the American anthropologist G. Dorsey (1868–1931) into the early part of the twentieth century, at which time the latter offered a significant contribution to the development and refinement of techniques applied for human identification based on bone analysis; in addition, his intervention as an expert witness gave the discipline an initial profile within the crimninal justice system (Klepinger 2006; Stewart 1979).

The twentieth century can be seen as the era in which engagements with law enforcement agencies and the necessity to identify war casualties constituted decisive junctures which led to forensic anthropology becoming a valid discipline in its own right. During the last century, a particularly important figure which stands out is A. Hrdlička (1869–1943). Hrdlička, who was formally trained in medicine, was director of the Anthropology Department at the Smithsonian Institution, where he amassed an impressive collection of human remains, and conducted active research in the field of physical anthropology. Additionally, Hrdlička was the founder of the American Journal of Physical Anthropology (1918) and also the American Association of Physical Anthropologists (1930), of which both elements aided in providing a formal grounding to this discipline; within the area of forensic intervention, Hrdlička received skeletal cases from the Federal Bureau of Investigation (FBI) (Ubelaker 1999). Parallel to the work of Hrdlička was that of W. Krogman (1903–1987), who in 1939 published "Guide to the Identification of Human Skeletal Material" in the FBI Law Enforcement Bulletin, considered by some as the publication that formally recognized the specific importance of forensic anthropology (Tersigni-Tarrant and Shirley 2013; Stewart 1979; Ubelaker 1999). With the advent of Krogman's publication, a guide was available that provided a point of reference for further research, in addition to constituting a valuable reference guide for use in the field.

Upon Hrdlička's death, T. Dale Stewart (1901–1997) took over the post at the Smithsonian Institution; not only were investigative cases emanating from the FBI continued, but the valuable contributions that Stewart made to academic teaching and research improved and promoted new developments in bone analysis within forensic cases (Kennedy 2000).

In 1972 the physical anthropologist E. Kerley (1924–1998) founded the Physical Anthropology Section in the American Academy of Forensic Sciences (AAFS), and it is here where those involved in the analysis of human remains within the legal context were recognized formally within a prestigious association. This advance was followed by the possibility of members being formally certified through the American Board of Forensic Anthropology (ABFA), an organization created to foster and maintain standards within the profession and to confer professional weight and credentials to those practicing members (Tersigni-Tarrant and Shirley 2013).

These important events led to more in-depth research and initiatives, which were further strengthened when the US armed forces recognized the requirement for the identification of human remains of those who perished in combat. Such interventions occurred in World War II (1939–1945) and the Korean War (1950–1953) and during the Vietnam War (1965–1975) (Stewart 1979; Klepinger 2006), a challenge that has increased exponentially in relation to advancements in weapons technology. As a result of such interventions, the US Army Central Identification Laboratory, Hawaii (CILHI), was established in 1976; today it is called Joint POWMIA Accounting Command (Joint Prisoners of War Missing in Action Accounting Command) (JPAC 2013), with the mission of locating all of the Americans who are still missing from past wars. This is achieved by locating, recovering, and identifying the remains, a process whereby forensic anthropology is a key component for a successful outcome (JPAC 2013; Tersigni-Tarrant and Shirley 2013).

As a result of its evolution with respect to these major events, forensic anthropology became established as a specialized forensic field in its own right.

Definition and Functions

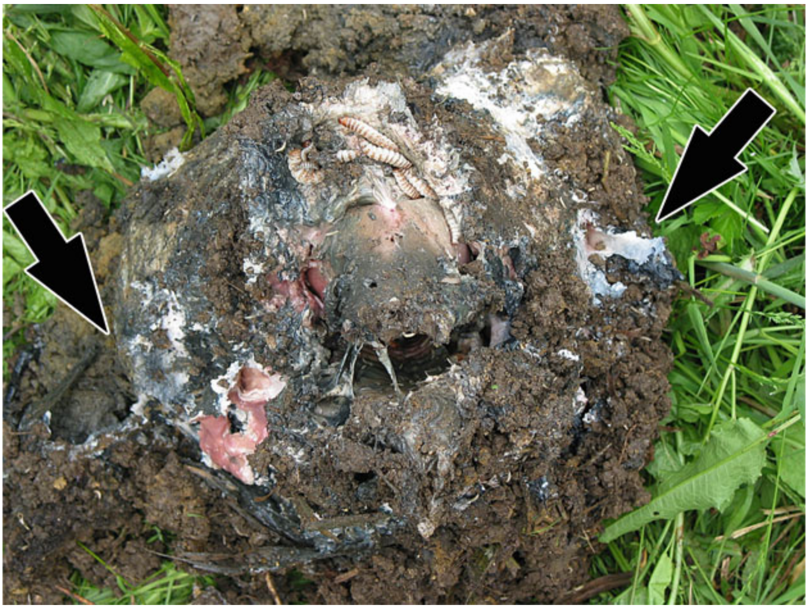
Forensic anthropology can be defined as a subdiscipline of physical anthropology (also referred to as biological anthropology), which conducts biological identifications on human remains within a legal context and in circumstances when they are in a poor state of preservation including advanced stages of decomposition, dismemberment, fragmented or possibly incomplete, burnt, skeletonized, saponified, or a combination of such factors (Nafte 2000; Klepinger 2006) (see Figs. 1 and 2). Within such scenarios, saponification occurs when the body, whole or in part, is covered with adipocere, a grayish waxlike substance formed by the hydrolysis of body fats when exposed to an environment which is moist and low in oxygen, such as the case with bodies held underwater; however, saponification may also occur in desertlike environments when the water content in the fat cells compensates for the lack of moisture within the environment (Gill-King 1997).

The process of identification is accomplished via biological profiling of the body in order to determine sex, age, stature, biological affinity (ancestry), and individual characteristics through bone analysis. In some individual cases, the forensic anthropologist will also be involved with trauma identification on bone in instances such as sharp (see Fig. 3) and blunt force trauma, gunshot wounds (see Fig. 4), strangulation and in circumstances in which a possible interpretation of events is required, such as cases where there is a requirement to determine if the event was peri-mortem (around the time of death) or postmortem (Byers 2008; Klepinger 2006; White and Folkens 2005). If the remains in question retain soft tissue of any kind, the forensic anthropologist will, as a matter of course, macerate the remains in order to access the bone tissue. However, in relation to the latter scenario, new and less invasive approaches through 3D imaging techniques are currently being developed (see Current Challenges and Future Directions section).

The profiling process is based on applying metric and nonmetric (morphological characteristics) assessment when appropriate, as both approaches are normally utilized in a complementary fashion. Ideally, all of the potential methodologies that can be applied should be used, as this will increase the possibility of a positive outcome.

- *Sex determination* is normally the first step taken when producing a biological profile of

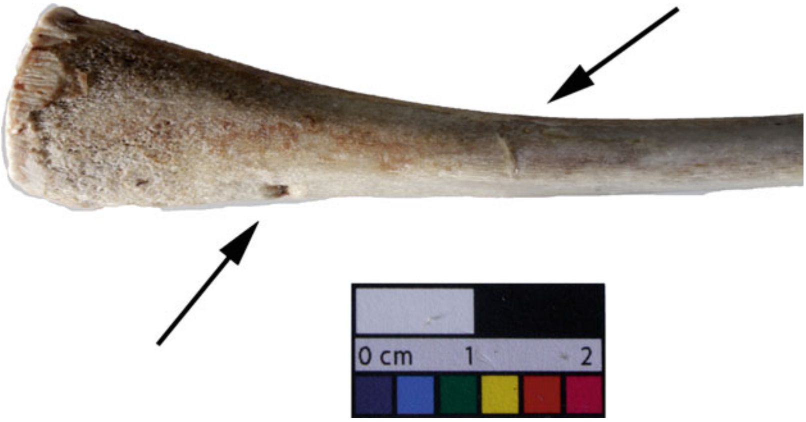
Forensic Anthropology, Fig. 1 Skeletonized and fragmented human remains (work conducted in Syria through the Freie Universitat Berlin) (Photo by author)



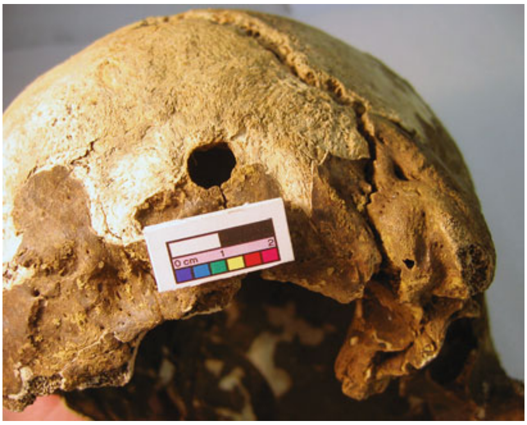
Forensic Anthropology, Fig. 2 Soft tissue in a state of decomposition with areas exhibiting adipocere formation, appearing as white/gray patches (experimental case using buried pig remains, *Sus scrofa*) (Photo by author)

human remains, as this element is also linked to the estimation of ancestry and the determination of stature (refer to appropriate sections below).

Determination of sex may be arrived at by morphological and metric analysis of adult skeletal remains (defined as those with finalized bone and dental development and which exhibit secondary sexual changes). Remains belonging to juveniles, also referred to as adolescents (characterized when secondary sexual changes are taking place) or younger individuals, are not normally sexed; in such cases, the skeleton is still going through a process of development, and sexually dimorphic characteristics (sexual dimorphism being the



Forensic Anthropology, Fig. 3 Sharp force trauma caused by a straight edge knife wound to the thorax region (experimentation conducted on pig remains, *Sus scrofa*) (Photo by author)



Forensic Anthropology, Fig. 4 Body within mass grave exhibiting a gunshot wound to the occipital region of the head (Courtesy of the Association for the Recuperation of Historical Memory, ARMH, Spain)

difference in size and shape between males and females) have not fully developed (Scheuer and Black 2000; Nafte 2000); when attempts at the determination of sex in adolescents are made, the results generally tend to be weak. Another consideration within the determination process is that traits may vary somewhat from one population to another, with some being more dimorphic than others; it is through accumulated experience that a forensic anthropologist gains insight into the specifics evident within any given group.

Various individual bones have been recently studied with the aim of developing new techniques pertaining to sex determination, with some approaches producing better results than others; however, the pelvis and the skull are still considered as the two areas of the body which are most reliable in this respect. In the case of the pelvis, composed of a sacrum and a right and left os coxa (hip bone), analysis through the Phenice's method, a morphological assessment of the pelvis, is reported to be as accurate as 96–100 % (Silva Braz 2009; Mays 2010), as this structure possesses well-defined sexually dimorphic traits associated with the ability of childbearing in females.

With reference to the skull, the major attributable differences are due to males being larger and with more robusticity, translating into noticeable muscle insertions upon bone, with competent analysis producing a rate of 92 % accuracy (Mays 2010).

Conversely, the metric approach uses a series of measurements on specified landmarks on bone. When using discriminant functions, the results are fed into a set formula that provides an ending score, which is subsequently compared against the sectioning point (determining the sex based upon the score obtained). A problem that is frequently encountered with available formulas is that they are population based, and as such, the results can be skewed if the remains do not belong to the relevant database. Moreover, the metric analysis can also be inputted into the computerized program Fordisc 3 (FD3), based on contemporary data gathered from the Forensic Data Bank at the University of Tennessee in Knoxville, USA

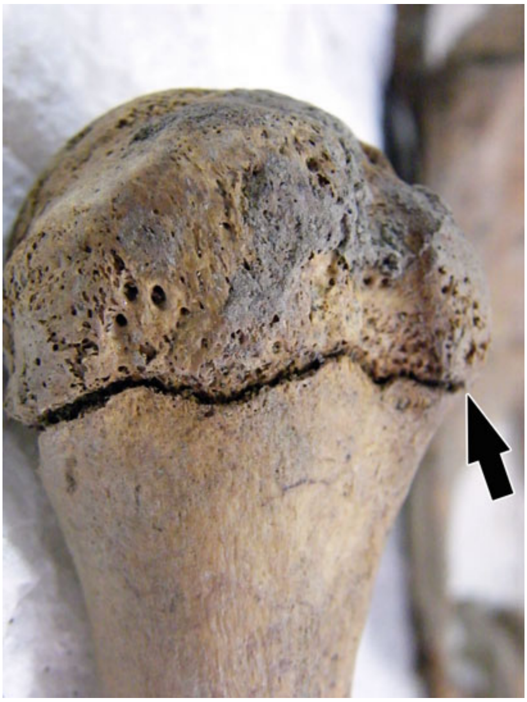
(Sauer and Wankmiller 2009; Tersigni-Tarrant and Shirley 2013). The negative side of using FD3 is that the said database is also population specific, with the possibility of the same problems arising as mentioned above.

- *Age determination* is a step that is applied to subadult and adult remains alike, in order to arrive at the age of death through morphological observations and metric analysis applied to dental and bone remains.
  - Subadults – subadult remains offer a wealth of information as the growth development follows a set sequence of events at the bone and dental level. These parameters have been cross-referenced with age and have been converted into what are referred to as growth standards, which are used by the forensic anthropologist in comparison with observations made on the final growth stage evident upon the remains being examined (Nafte 2000; Klepinger 2006). Because these processes of development tend to be standard in nature across populations, the overall results are highly accurate.

    Dental development may be appreciated through tooth mineralization and eruption and constitutes the most accurate method for aging as it is a constant and continuous process which has been well documented. Dental remains may be examined individually if found dislodged from the alveolar process (the socket which holds each dental piece in the upper and lower mandibles); furthermore, in cases when teeth have not erupted, they may be analyzed through x-rays or extracted and examined microscopically (Klepinger 2006). In the latter case, it is possible to determine if an infant was stillborn or a live birth as evidenced by the neonatal line, located upon the enamel surface on all deciduous dentition and first permanent molars, formed at birth or soon afterwards (Scheuer and Black 2000).

    Bone development can be assessed in subadults, and in the case of fetal remains, the bones can be measured from prescribed landmarks and compared with established growth standards that indicate the gestational age with relatively good confidence levels (Scheuer and Black 2000; Fazekas and Kósa 1978). It is after birth, however, that intrinsic and extrinsic factors play a strong role in skeletal development, creating variations in developmental rates at individual and population levels. As indicated by Byers (2008), age assessment in relation to the length of long bones may be applied up until the age of 10, at which time the correlation between age and length starts to widen, producing inaccurate age estimations.

    Another method utilized to establish age at death is through the identification of primary ossification centers (areas where bone is deposited), as well as their union with other primary centers or with secondary ossification centers (see Fig. 5). Because of their small size, the



Forensic Anthropology, Fig. 5 Immature arm bone (humerus) with the epiphysis in process of ossification (Courtesy of the Association for the Recuperation of Historical Memory, ARMH, Spain) identification of primary centers may prove difficult to recognize and recover at a scene when dealing with skeletonized remains or bodies in which integrity has been compromised; this method is best employed in connection with examination of the skull, mandible, upper cervical vertebrae, and ribs. On the other hand, the union between the primary and secondary centers is frequently more productive within forensic anthropology, as they unite at a scheduled rate (as indicated earlier with individual variations and population trends) extending into early adulthood; such is the case of the clavicle, in which final fusion ends at approximately 29 years of age (Scheuer and Black 2000; White and Folkens 2005).

– Adults – in the case of adult remains, age is determined by morphological changes visible through the naked eye, which in some instances may be degenerative in nature, and by remodeling processes at the microscopic level. The main areas within the skeleton that aid in age determination through morphological changes are the pubic symphysis, the auricular surface of the ilium upon the os coxa, the sternal end of the fourth right rib, and the cranial sutures (White and Folkens 2005; Byers 2008; Klepinger 2006). Additionally, it is also possible to obtain an estimate of chronological age through dental analysis of the incisors, canines, and premolars as specified by the Lamendin's technique.

In the case of the first three skeletal areas, these are widely used, as a process of "metamorphosis" or changes in the bone morphology occurs progressively as a person ages, associated with sex, and also to a degree with respect to population affiliation; these changes possess set characteristics which are compared against a set of representative age stages. In the case of the pubic symphysis, various methods are available including the Suchey-Brooks model (White and Folkens 2005), which is widely utilized as it constitutes a multiracial database, but is, however, not wide enough to encompass all populations; as such, problems have been reported in the past in connection with skewed results in relation to populations that are not represented within its database.

With regard to cranial sutures, the skull is examined at specific points in order to assess the degree of closure, whereby a prescribed value is scored for each area examined; these values are then compared against an existing table to obtain an age range. Because closure is not a linear occurrence associated with age, the results may indicate wide age ranges making this method somewhat unreliable, such as within cases in which only the skull is recovered without dental remains, or present in poor condition and not suitable for ageing.

Dental remains are normally utilized with relation to subadults in order to obtain a chronological age at death in association with the developmental stage in evidence; however, the Lamendin's dental aging technique was designed to more accurately determine the age of adult dental remains. The latter technique consists of examining single rooted teeth based upon their degree of root translucency and the degree of periodontosis (recession of the gum line). Research indicates that results are linked to sex and, to a lesser degree, to ancestry; however, this method may not be desirable if applied to young adults. Results may also be influenced by additional variables such as dental hygiene and dental treatment intervention (Prince and Ubelaker 2002).

Finally, the histological method consists of examining changes in bones and the teeth at a microscopic level; however, this method is time consuming and requires the use of specialized equipment and specific training (Byers 2008), and as such it is not always a viable option in some cases.

- *Biological affinity* or ancestry is the most difficult task that a forensic anthropologist attempts to evaluate when biologically profiling human remains, producing results which may be somewhat tenuous; however, the estimation of ancestry within an investigation is a necessary element, as it provides an avenue of inquiry for the authorities. Additionally, this information is also required when calculating stature (see section on Stature).

More specifically, the challenge arises from the element of phenotypic traits (expression of the genetic makeup) reflected at the skeletal level in one given population being small in number, but which may also be shared in part by other populations with added variation, thereby creating the possibility of a continuum wherein boundaries are blurred, not to mention the inherent variability that exists at the interpopulation level. Furthermore, sex-determining traits can influence the traits associated with estimating ancestry (Klepinger 2006). Additionally, individuals within any given population may describe or view themselves not in biological terms but by device of ethnic/social classification. For example, many Latin Americans would describe themselves as white or Hispanic; however, their morphological traits would not necessarily be categorized as white, and Hispanic is a term stemming from an ethnic category, something that cannot be verified biologically. To further confound this issue, the high level of migrant influx and intermarriages within any given geographical zone will intensify the challenges with respect to identifying any given question of biological affinity.

At present, global populations are divided into different groups, deriving from genetic or skeletal research, whether referring to the global population as a whole or to a specific population within a particular country. At the skeletal level, four main ancestry categories have been created: Caucasoid (white American/European) (white American/European), Mongoloid (East Asian), Negroid (African black), and Native American (Byers 2008; Klepinger 2006; Tersigni-Tarrant and Shirley 2013). As it may be appreciated, this categorization does not embrace all of the global geographical regions.

Attempts to assess ancestry through traits present on bone are accomplished primarily through morphological or metric analysis of the craniofacial region, as this is where traits are most effectively expressed, mainly with reference to the shape of the head and nasal region and additionally the upper mandible. Within a given morphological analysis, a sum of characteristics is sought and subsequently compared to known samples to arrive at a determination (Byers 2008; Klepinger 2006), a task best accomplished by an experienced anthropologist. Because the estimation is based upon morphological observations, and not all traits may be strongly reflected within one particular individual, the results obtained may be argued over due to the element of subjectivity. Conversely, a metric analysis compiled between specific landmarks can be perceived as a more accurate, objective approach.

Metric analysis can also be fed into the FD3 software, which contains data for this purpose drawn from contemporary remains from the USA, in addition to world samples, and representative of various archaeological populations (Tersigni-Tarrant and Shirley 2013); as well, another computer programme available to forensic anthropologists is CRANID, with a data base comprised of 74 samples (3.163 skulls) from various regions of the world (Sauer and Wankmiller 2009; Wright 2012). However, the application may not provide adequate results when the affinity of the specimen in question has not been represented within the available databases.

Postcranial bones may be used, with the femur (leg bone) being considered as being the best choice as it possesses various traits and has been comprehensively studied (Byers 2008; Sauer and Wankmiller 2009). However, in general terms, the postcranial bones retain fewer traits which are not as clearly expressed as in the craniofacial region, thereby reducing confidence levels with respect to accuracy.

Research has been attempted upon dental material, but this particular avenue of inquiry has not been as comprehensive as that completed with respect to bone; additionally, dental traits are fluid, varying in degree, and not strictly present within any given population.

For the reasons stated herein, it is always recommended to collate results from all available methods and to be actively aware that a definite determination of ancestry from the remains is not always possible, but predominantly an educated estimation.

- *Stature* – calculating the stature at the time of death is accomplished by measuring a selected long bone from the upper or lower extremities, with the result computed into a regression formula that has been designed by bone type, sex, and biological affinity; a proportional correlation may then be compared between the bone used and the height of the unknown individual. The result obtained will constitute the mean height with a standard deviation. The femur and tibia are the most widely utilized reference points, as the results obtained from these bones provide more accurate outcomes (Byers 2008).

In cases in which the body is highly incomplete or fragmented, such as when dealing with dismemberment, air crashes, or the victims of terrorist acts, there are a series of methods available that allow estimation of the stature of any given individual through the use of small segments from the long bones (Byers 2008). Because of the nature of these measurements, the results are not as accurate, but are still helpful in cases where an approximation of height is required. When skeletal remains are dry, due to time lapse, shrinkage can occur, and adjustments can be necessary in order to compensate for such factors through preestablished data; the same approach may be taken with remains that are determined to be over 45 years of age, as stature starts to diminish beyond this period (Byers 2008). It should also be clearly stressed that all populations are not represented within all available formulas, and as such, adjustments must be made and considered when confronted with each particular case.

The results obtained from such calculations often prove difficult to verify, as accurate reference to stature is information that is not often available through family members and friends or via official records.

- *Individual characteristics* – individual traits can aid in an investigation for two reasons: when there are no indications of who it may be or when the authorities have a suspicion of who the person may be. Such traits may include evidence of a fracture or amputation that the person may have suffered in life, with time to heal through bone remodeling, including misalignment of segments which produce evidence of the event (Byers 2008).

Other traits include pathologies left on bone that can indicate past conditions, diseases, or habits, as in the case of osteoporosis upon the skull, associated with malnutrition and drug addiction (Klepinger 2006); an infected tooth may cause an abscess which produces a small opening on the jaw bone. Diseases may also affect bone, such as tuberculosis, a chronic infection caused by a bacteria which can leave marks in the vertebral column, and in other bones such the os coxae (hip bones). Furthermore, congenital anomalies due to improper formation can aid in the identification of a person and may be present in various parts of the body, such as the vertebral column, hands, and feet (Otner 2003; Klepinger 2006; White and Folkens 2005).

The human skeleton also possesses traits which can assist in the individualization process, as is the case of improper non-fusion of segments conforming a bone, missing bone sections, or characteristics within a particular bone which are not pathological in nature, but which can be identified and compared against an antemortem x-ray or computer tomography image (CT).

All of the above conditions may be used to guide investigations, and with cross-referencing the information gathered in tandem with medical records, which can aid in the identification process.

Facial reconstruction is a method which can aid in the identification process by applying a variety of methods from sculpting in clay to the use of sophisticated computer graphic programs (Wilkinson 2008); such avenues are attempted by individuals from a variety of disciplines, including those from purely artistic backgrounds to forensic anthropologists who specialize within this specific field.

The described steps that a forensic anthropologist takes in order to compile a biological identification can lead to a positive identification through DNA, odontological, and/or medical analysis, once the investigating personnel have a description with which to guide them.

Trauma Analysis

The determination of the cause and manner of death legally rests with the forensic pathologist; however, forensic anthropologists do participate within cases in which bone reconstruction is required due to fragmentation caused by high-velocity projectiles or in connection with blunt force trauma; in both instances, an interpretation and sequence of events can be indicated when possible, as in cases when more than one impact has been inflicted upon the skull. Interpretations concerning the circumstances in which the trauma was caused can be assessed; an example would be when, there is a need to determine whether an individual fell or jumped intentionally or to determine the angle of force in which a chest cavity was crushed, as would be evidenced in cases of severe stamping. Additionally, in the case of sharp force trauma, the type of weapon used, such as a knife (see Fig. 3), axe, hatchet, or machete, may be accurately identified, in addition to the angle with which the implement was used. In the case of dismemberment through sawing, the type of striations deposited upon the cut site can aid in a more specific identification of the tool which was utilized (Byers 2008; Galloway 1999; Nafte 2000).

In cases where strangulation was the cause of death, a close examination of the hyoid bone (located in the anterior side of the neck) may show signs of subtle breakage which can be interpreted by an experienced anthropologist. With reference to children, this bone is very resilient as it has not ossified; hence breakage may not occur (Byers 2008; Klepinger 2006).

Depending upon the condition in which a body is discovered, including burnt remains, there may be a requirement for the anthropologist to determine if a given alteration on bone is peri-mortem or postmortem, a detail which may produce ramifications within a legal investigation; in some cases this element may be difficult to assess, necessitating specialized analysis.

Investigations into Human Rights Violations

Investigations of human rights violations have given way to interventions in countries such as Guatemala, El Salvador, Colombia, Chile, Argentina, Democratic Republic of Congo, Rwanda, East Timor, Bosnia-Herzegovina, and Spain, where forensic anthropology has played an important part within multidisciplinary forensic teams. Among the many challenges encountered prior to deployment, one aspect that concerns work within forensic anthropology is to select the appropriate methods to be used as references for determining the biological profile of the victims, keeping in mind the genetic makeup of the population to be examined (as indicated above) (Ferllini 2007; EAAF 2013); as previously highlighted, inherent variations exist within populations and all references utilized should be directed at the required analysis in order to avoid the production of skewed results.

Within this arena, work is accomplished both within the field and at the mortuary. In the field, a comprehensive knowledge of bone anatomy is crucial during the search for human remains which may have been left on the surface and thereby exposed to environmental elements. It is also advantageous to be able to recognize small remains and distinguish them from animal bones within an outdoor setting. In situations when bodies are comingled and dispersed, an attempt is made to determine the number of individuals that are present while in situ, aiding in the implementation of proper lifting and bagging procedures prior to sending the remains to the assigned mortuary, which in some instances may be a temporary installation in close proximity to the area being surveyed.

In the case of buried remains, the forensic anthropologist is also directly involved with the exhumation process, whether dealing with the contexts of single or mass graves. With reference to the latter scenario, hundreds of bodies may be present, resulting from a single event, as was the case after the Rwandan genocide (1994), and where the remains may be comingled and skeletonized. In such cases the forensic anthropologist determines which bones pertain to any given individual by applying analysis of bone morphology and determining a general sex and age identity, elements which are verified at the mortuary (Ferllini 1999; Koff 2004). However, this is only possible in cases where the bodies have been interred with small amounts of clothing or have subsequently degraded, with the bones becoming free.

During mortuary work, it is customary that the bodies are subjected to fluoroscopy imaging in order not only to detect metal objects, including evidence of gunshot wounds, but also to determine whether the remains may have been booby-trapped by the perpetrators with the aim of dissuading others from recovering the remains, or to directly harm those attempting such work. The descriptors produced from work in the field are subsequently verified and a final biological profile is produced. With reference to cases in which discrepancies of any type arise, an open communication is maintained with the lead forensic archaeologist of the rescue operation (Ferllini 1999). As with police cases, identifying traits are also sought, and DNA testing is applied when possible. The ultimate objective is to be able to not only return the remains to the surviving relatives but also produce documented scientific proof of the atrocities committed against a given civilian population, to be used in future judicial proceedings, which may be held at the local or international level (Ferllini 2007).

Investigations into Disaster Victim Identification (DVI)

Disaster victim identification (DVI) is at present a serious concern, as mass disaster events are more severe in nature and in consequence, the numbers of victims may be in the thousands, including foreign nationals as with the World Trade Center disaster in 2001, and the Asian Tsunami of 2004. For the forensic anthropologist, their participation within such scenarios is mainly at the mortuary, involving the sorting of comingled remains and including the identification of small bone fragments, sometimes in a burnt state; determination of the number of individuals at hand, followed by a biological profile on each case when possible, and identifying any bone trauma constitute the eventual objectives (Blau and Briggs 2011; Byers 2008).

However, the anthropologist does not operate within a vacuum, but within a multidisciplinary team, in which each set of remains is sent to one or more stations to be examined by other forensic specialists who can also contribute to the identification process, in areas such as odontology and DNA analysis. The results are subsequently cross-checked with personal belongings associated within the context of each individual, with the aim of arriving at a positive identification of each of the victims (Byers 2008). The challenge increases within situations in which a floating population is present, meaning that the true number of victims may be difficult to determine, and unlike the scenario of an aircraft accident, there is often no list of victims available as a reference.

The techniques applied during the biological profiling process must be verified against standards from varied population databases due to the potential nature of the victim population. Furthermore, in many instances the remains may present soft tissue, and the resulting de-fleshing process may be extremely time consuming. Recently, new techniques with reference to digital imaging have been proposed for the purpose of the latter activity (Rutty et al 2009) (see section on Conclusions and Future Research).

Current Challenges and Future Directions

At present, due to the elevated level of influx of immigrants throughout the globe, whether via illegal clandestine means, in addition to localized increases in murder rates, potential legal investigations are often hindered by the lack of proper identification papers and antemortem medical and dental records and the possibility that no missing person's reports exist. This situation dictates that every forensic anthropologist must possess a working knowledge of the available morphological and metric data for various ancestry groups, as it is no longer tenable for a professional within this field to focus solely upon a specific population which relates only to his or her "normal" casework; additionally, all populations are highly influenced by secular, biological, and cultural trends.

Furthermore, constant warfare, the utilization of weapons with high destructive capabilities, the ever constant violations of human rights with associated mass graves, and increasing levels of mass fatality incidents dictate that the discipline further develops more efficient methods of processing high numbers of potential casualties, which in many cases may be fleshed. This is reflected in the approaches now taken within the present millennium with respect to the utilization of digital imaging technologies in order to examine and profile human remains; the examination of skeletal elements by such means can be performed within a shorter time frame, as images may be obtained from bodies contained in bags of various kinds, both clothed and fleshed. Therefore, time is not wasted in de-fleshing the remains (Rutty et al 2009; Blau et al 2008; Dedouit et al 2007), and the possibility of damaging bone and adding a pseudo trauma indicator is avoided. Furthermore, this technology is mobile and creates the opportunity of sending information on a global scale directly from the field via a remote basis (Rutty et al 2009).

Such digital imaging techniques originated from within clinical settings and are now being applied to forensic postmortem examinations. Postmortem computer tomography (PMCT) is rapidly gaining acceptance and is being used more on a global scale, thereby replacing the traditional use of x-rays, as the former technique is more interactive, allowing the images to be manipulated in response to the needs of the examiner; in turn, the profiling can be accomplished with a good degree of success and is comparable to that obtained through conventional methods (Verhoff et al 2008).

The use of a multi-slice computed tomography (MSCT), also known as multidetector computed tomography (MDCT), allows the body to be viewed without the requirement for maceration and to view any bone element within the skeleton in 2D and 3D for the purposes of profiling, including the taking of measurements which apply to traditional parameters, and the assessment of trauma analysis (Rutty et al 2009). Ante- and postmortem image correlation can also be gained in order to arrive at a positive identification; finally, facial reconstruction may also be achieved from 3D images (Verhoff et al 2008).

While such new technologies constitute positive additions to postmortem examinations, such types of infrastructure will not be readily available within every area of the globe when required; such methods are often costly and will not normally be obtained in many developing nations unless intervening countries aid with adequate equipment.

Conclusions and Future Research

Forensic anthropology has come a long way since the days when isolated bone cases were passed on to the physical anthropologist for analysis. At present, the discipline forms part of a wide range of scenarios, whether pertaining to the remains of one or more individuals within a variety of situations and conditions, and by applying techniques which have evolved from the traditional setting to the use of sophisticated modern imaging technology.

This is not to say that as a discipline forensic anthropology has reached its zenith and that it does not require constant refinement with respect to the techniques it utilizes. As with any science, improvements upon widely used techniques and the creation of innovative new approaches are always required to drive the process within a dynamic context, as in the case pertaining to population levels with diverse secular changes and the factor of immigration, in addition to the intense scrutiny that any forensic scientist now faces within a court of law.

Due to present global challenges, research is required pertaining to quantitative methods of determining human variation, encompassing the areas of sex, age, ancestry, and stature estimation, all of which are essential in producing biological identifications, not only to improve existing applications but to develop new methodologies (Ross and Kimmerle 2009), and encompassing work with fragmented and incomplete remains.

Additionally, the development and refinement of new and existing imaging techniques is desirable, as such elements not only speed up the profiling process and shield the participating investigators from potential contaminants, but also take into account religious and cultural beliefs in which body handling and avoidance of autopsy procedures are an issue.

The combination of quantitative methodologies with the additional use of CT technology can be of advantage for the reasons already stated here, but also to obtain knowledge of contemporary populations (as long as this complies with local legislation), in order to study nonmetric and metric traits within populations, as modern skeletal collections have become a thing of the past. Populations within Latin America, the Middle East, and Africa need to be addressed by developing their own standards, which will subsequently provide more accurate results.

Forensic Environmental Evidence

Ruth M. Morgan[1] and Peter A. Bull[2]
[1]Security and Crime Science, University College London, London, UK
[2]Oxford University Centre for the Environment, University of Oxford, Oxford, UK

Overview

Forensic geoscience investigates the characteristics of sediments and soils and uses them to compare exemplar and specimen samples. They derive ultimately from both naturally occurring igneous, metamorphic, and/or sedimentary rocks, which maintain the characteristics of those parent materials, and also as admixtures of man-made constituents which in the main make up much smaller quantities within that sediment body. Some of these sediments are found in bulk form on beaches, outwash plains, etc., whereas others are found as trace particulates in both the natural and anthropogenic environments as dust, soil, and detritus. Soils represent sediments with organic additions, both floral and faunal, and so acquire not only the geological characteristics of the sediment but also incorporate materials such as palynomorphs, diatoms, mycological spores and fungi, and other micro- and macrofaunal and floral debris.

At a larger scale, an appreciation of the geomorphological and geological history of a region is pertinent for forensic characterization as is an understanding not only of the microscale characteristics of the forensic material but of the macroscale environment in which those materials exist (Ruffell and McKinley 2008). The macroscale landscape does not only have natural origins but also has anthropogenic modifications which are so important in forensic investigation. Macroscale landscapes can involve rural and urban environments, and indeed, investigations set purely within a building or dwelling can utilize geological evidence as well as anthropogenic additions incorporated within samples (Pringle et al. in press; Morgan et al. 2009).

Soils and Sediments

The dynamic nature of the natural world leads to the mixing of materials from very many provenances in discrete ways, and the addition of anthropogenic materials can characterize a particular forensic site to such an extent that it becomes highly distinctive and very useful when compared with samples derived from other pertinent locations. Thus, natural and anthropogenic soils and sediments are not mixtures of a myriad of provenances but are discrete and ordered micro-terrains and facies, worthy of the increased attention being given to these materials in the published literature (Morgan and Bull 2007a).

The concept of facies and sedimentary units is a keystone to the analysis of soils and sediments in forensic inquiry. A sedimentary facies has long been understood to be any spatially restricted part of a designated stratigraphic unit which exhibits discrete characteristics that are distinguishable from the other parts of the unit. The most important application of this is that sediments (both natural and anthropogenic) are not found to be in a melange of indiscrete units but rather the interrelationships of sedimentary environments, and hence, facies are not chaotic or random (Bull and Morgan 2006), but subject to controls such as climate, tectonics, and geological setting giving rise to discrete and ordered micro-terrains in both areal and profile contexts so that soils and sediments have great spatial variability at different scales of reference (Thomas 2001). As no two environments, however similar, are exactly identical, this characteristic of soils and sediments enables the use of comparison methods in the analysis of trace physical evidence to be used to great effect, and it is such comparison methods that are generally agreed to be central to forensic inquiry (Lane 1992). Due to the nature of the spatial, and indeed vertical, distribution and variation of discrete facies, soils and sediments have the ability to be compared with other samples and thus have the potential to be used as a predictive tool in forensic investigation. However, as the concept of the individualization of soils and sediments is problematic in the forensic context, we can only exclude and therefore state that a soil sample did not originate from the crime scene or indicate an inability to exclude samples taken from two discrete locations (i.e., the analysis results indicate that the two samples are consistent with having the same source).

In recent years, the importance of soils and sediments as physical evidence in forensic investigations has been more widely recognized. The writing of “Forensic Geology” by Murray and Tedrow (1975) brought the potential of soil and geology in forensic investigations to a wide audience. Textbooks on forensic science now increasingly make reference to soil evidence. However, it is very rare that more than a few pages are dedicated to the topic, and comparatively little is included about the analytical techniques that may be applied to such samples. It is a relatively new part of forensic science which has developed by means of resourceful geoscientists applying traditional geology in the forensic arena. While there are many examples of geologists and geomorphologists successfully aiding forensic investigations (at the microscale Murray and Tedrow 1975, and at the macroscale Ruffell and McKinley 2008), the use of soils and sediments has developed comparatively rapidly, and only recently has a specifically geoforensic philosophical framework been articulated and incorporated into the discipline (Morgan and Bull 2007b, c). The main problems encountered during the development of chemical analyses of forensic soil samples have been the complexity of the chemical nature of soils (which include complex organic acids and other additions). This issue has been compounded also by the use of automated chemical analysis techniques (e.g., ICP-MS) where false-positive or false-negative results can occur without recognition and therefore without correction, as a result of the necessary homogenization of the sample in preparation for the analysis.

Forensic Geoscience

Forensic geoscience utilizes the spatial and temporal variations found in soils and sediments to aid crime reconstructions. The distinctiveness of terrains at a variety of spatial scales reflecting the specific environmental and geological influences operating in particular places results in site-specific soils and sediment characteristics. Soil evidence has potential value in forensic investigations because of its prevalence at scenes of crime and also its propensity for transfer between crime scenes, victims, and perpetrators. A sample of soil from clothing, a vehicle, or a scene of crime can therefore be analyzed to identify its physical, chemical, and biological components, thereby enabling the indication of provenance within the forensic context.

Some common standard analyses can be seen in the published literature which distinguishes between soil and sediments derived from different source locations. These are outlined in Table 1.

The examination protocol for soil evidence will be dependent on the quantity of the sample available, the questions asked of the sample, and

the detection limits required. The general Palenik's sequence (outlined in Fig. 1) is often presented in the literature as a guideline for analysis that can be adapted for each separate case.

While such sequences are of great value in the geosciences, in forensic investigations, the quantity of the sample will often be a limiting factor, precluding the use of many steps included in such analytical sequences, and therefore, the forensic geoscientist needs to choose the relevant parts of the Palenik sequence that are appropriate for the samples being examined.

From a forensic (as opposed to a geological) perspective, the temporal scales involved are relatively short, even when the investigation of cold cases is considered. It is possible in some cases to return to a crime scene many years or decades after the crime took place and characterize the soils and sediments present and compare them with the original crime scene samples and indeed the relevant samples derived from the suspect. It has been demonstrated that certain aspects of soils and sediments may be subject to changes over these relatively short-time frames (such as the microbial communities present within soils (Meyers and Foran 2008)), but other biological components are often not subject to such significant changes over these time frames, such as the palynomorph and flora and fauna assemblages, and indeed similarly, the physical components such as mineral assemblages and characteristics.

Much of the early key literature in this field was based on case-based examples where forensic geoscience provides useful and pertinent intelligence for an investigation or ultimately evidence for a court hearing (Wiltshire and Black 2006;

Forensic Environmental Evidence, Fig. 1 The Palenik examination sequence (Diagram adapted from Murray and Solebello 2002)

Bull et al. 2006). There has also been significant debate within the literature as to the best methods for soil and sediment analysis within a forensic context, from sampling protocols (McKinley and Ruffell 2007) to the various advantages and limitations of particular analytical techniques (Bull et al. 2008; Morgan and Bull 2007c). It is only comparatively recently that a philosophical framework for forensic geoscience has been incorporated into the methods and practices of this discipline (Morgan and Bull 2007b).

Essentially, four key principles exist, those of:

- Exclusion/uniqueness
- Independence of analytical techniques
- Issues of homogenization of samples of mixed provenance
- Exotic/ubiquitous components of soils/sediments

These fundamental tenets are fully outlined in Morgan and Bull (2007b), but perhaps the most important of these tenets is that of the principle of exclusion. Forensic geoscience adheres to the philosophy of falsification (Walls 1968) and is considered to be a probabilistic science. There can be no philosophically correct way to state or strongly infer a match between two soil samples. The characteristics of particular samples may be indistinguishable, but the strongest assertion that can be made is that it is not possible to exclude sample A from having derived from a similar provenance to sample B. The assumption of uniqueness has been widely discussed in a number of forensic contexts such as fingerprint analysis and DNA interpretation and has broadly been demonstrated to be a blind alley to be avoided (Saks 2010). Ironically, both the methodology of fingerprints and DNA forensic analysis were introduced as exclusionary techniques. Subsequently, they are often used to infer a “match” between exemplar and specimen samples.

In order to test the assertion that two samples have derived from different provenances, it is imperative that a number of analytical techniques are employed on the samples and that those analytical techniques are themselves independent of one another. The one-step indicator can be very problematic, particularly in the case of an appeal to higher courts. A full chemical assay of a sample utilizing elemental data, a mineralogical analysis of the same sample, and its color, pH, and conductivity may at the outset appear to be extensive independent techniques of analysis. However, they are all dependent upon the same characteristics of the sediment sample and therefore cannot be considered to be independent techniques. Such comparisons have much less weight than corroborative findings from a number of independent techniques.

In the majority of forensic contexts, mixing of soil/sediment material is likely to have occurred due to use over time of footwear, vehicles, clothing, etc. The forms of analysis undertaken, therefore, must be able to discern when difference between two samples is identified because the soil/sediment is genuinely derived from different provenances and when a difference is identified because either one or both of the samples are of mixed provenance which can thereby illicit a false discrimination (positive or negative). For example, soil/sediment recovered from vehicle footwells has been demonstrated to contain materials from multiple provenances that have been collected over time. If a sample from that footwell were compared with a sample from a crime scene by means of an analytical technique that requires the homogenization of both samples, it would be highly likely that given the multiple sources of material in the footwell, a sample from that footwell would be demonstrated to be different to the crime scene (even if one of the contributing sources of material to the footwell was in fact the crime scene in question) (Morgan et al. 2006). It is therefore vital that collection practices and the analysis that is undertaken on forensic samples can account for sample mixing so that false exclusions are avoided. A compounding problem is that false-positive or false-negative exclusions may not even be recognized after analysis, thus impacting on the interpretations made from the results:

> . . .this is evidence that does not forget. It is not confused by the excitement of the moment. It is not absent because human witnesses are. It is factual evidence. Physical evidence can not be wrong; it can not perjure itself; it cannot be wholly absent. Only in its interpretation can there be error. (Kirk 1974: 2)

The exotic or rare components of soil/sediment samples can be highly indicative of the provenance of that sample particularly when samples are compared to one another. The presence of a rare component in the soil at the crime scene can provide strong diagnostic evidence that two samples cannot be excluded from having derived from a similar source. Examples include rare palynomorphs or suites of palynomorphs, distinctive diatoms, or mineral assemblages (Cameron 2004). However, during such comparative analysis, it is very important that like is compared with like. Often crucial exhibits will only have very small trace amounts of soil/sediment that can be recovered, and this may preclude the inclusion of the exotic/rare component from the crime scene even if a direct contact and transfer has taken place simply due to the trace amounts of sample being analyzed. Most common (or ubiquitous) materials lack diagnostic capabilities in forensic analysis, but there are techniques which can utilize their abundance while presenting distinctive characteristics which aid provenance sourcing, such as environmental profiling and quartz grain surface texture analysis. For example, quartz is one of the most ubiquitous minerals within soils and sediments and is regularly recovered during forensic analysis of exhibits. However, while its presence is ubiquitous, the morphology of the individual grains and the surface features that can be identified on the surfaces of the grains has been demonstrated to be highly distinctive, and the combination of quartz grain types at particular locations is generally considered to be able to provide highly discriminatory conclusions (Bull and Morgan 2006). Thus, the balance must be reached between the value of exotic components and diagnostic capabilities of certain types of more ubiquitous trace components of soil/sediment samples.

Other Issues

Two further issues cut through all forms of soil/sediment forensic analysis, namely, the issues of interpretation and the necessity of empirical experimental studies to establish theoretical frameworks for the practice of forensic science.

The issue of interpreting the analysis of forensic soils and sediments is becoming widely acknowledged, particularly given the high-profile controversies surrounding the interpretation of other forms of forensic evidence such as fingerprints and DNA profiles. While some have called for the avoidance of statistics in the presentation of forensic geoscience evidence in court altogether, more recently there has been a resurgence in interest in assessing the best means of presenting forensic evidence to a court (Law Commission report 2011; Fenton 2011). The desire to be able to provide a measure of the weight of a particular form of evidence within a case can be argued to be part of the bigger question that relates to the philosophical approach to forensic science, and the nature of its position at the intersection of science and the law. Both the law and science are in the business of producing knowledge, but given their very different settings, the production of knowledge in each context necessarily serves different purposes (Jasanoff 2006). Table 2 outlines the different contexts within which the law and science operate. Science primarily concerns itself with testing hypotheses in order to identify general theories. Scientific findings therefore have the aim of advancing our knowledge in a particular field and enabling the future development of the discipline. In contrast the law is generally concerned with legally relevant facts which are by their nature specific to particular cases. It is thus most often observed in the practice of the law that facts relate to specific cases; previous cases are looked to in order to provide knowledge pertinent to the particular case at hand (Jasanoff 2006). *When science enters the courtroom, it should do so as an adjunct to the law's need for credible and meaningful story-telling. In a court of law, science cannot hold itself out as simply science, the source of transcendental truths; more modestly, and with appropriate caveats, it can be the source of just evidence* (Jasanoff 2006: 339). Furthermore, Jasonoff argues that the philosophical approach of science that has been carried out to serve the law should be distinct from the approach of science undertaken purely to advance the frontiers of science.

Forensic Environmental Evidence, Table 2 Contrasts between the law and the sciences

Law	Science
Specific to particular cases	General validity
Backward looking	Forward looking
Requires evidence	Acceptability through peer review
Short timescales	Long timescales

Other key areas of debate have concerned the way that science is presented in court: the measures of certainty employed and the statistical analysis carried out and the methods of its presentation to that court (Lynch 1998; Morgan and Bull 2006). There is significant interest currently in the Bayesian approach to interpret and present forensic evidence in general, and it is highly likely that as the methods and practices are established for other forms of evidence, it will become increasingly possible to apply those methods to forensic geoscience.

Finally, there is the issue concerning the need for experimental studies that are able to provide the foundation of forensic geoscience theory and thus inform its practice. Such a foundation is required so that the dynamics of trace geoforensic evidence can be more fully understood which in turn has great significance for enabling more accurate interpretations of such evidence. There is clearly the need for general-level empirical experimental work to be carried out in order to establish and affirm the general theories that underpin forensic geoscience. However, it is also important to acknowledge that there is the need for secondary-level experimental studies that pertain to particular cases in order for the evidence in that case to be collected, analyzed, interpreted, and presented in the most accurate and philosophically appropriate manner (Morgan et al. 2009).

International Perspectives

To date, this discussion has centered largely upon the discipline as it operates within the UK.

The primary tenets of forensic geoscience philosophy remain true outside of the UK, and much the same can be said for the collection, analysis, and interpretation of the results. There is some variation between the presentations of evidence in some countries; however, a primary distinction which can be mentioned herein involves the principle of the admissibility of geoforensic evidence. Frye and Daubert rulings within the USA influence some (but not all) US state courtrooms, a trend which is mooted more frequently in the UK and European arena now.

The UK has the advantage for the geoforensic investigator of having so many different geological/soil types on such a small series of islands, whereas in the United States, although there may be up to 3,000 different soil types (in comparison to approximately 300 in the UK), its area is so vast that there are large sedimentological terrains and facies of similar sediments and soils that spatial discrimination of the physical characteristics of those materials becomes problematic unless there are biological or anthropogenic additions which may provide higher resolution provenance indicators. Elsewhere specific areas of large global sand seas (sand deserts), for example, will have sediments comprised almost entirely of quartz with very little biological (floral/faunal) additions, with those sand grains exhibiting near identical transportational provenance origins. It is perhaps fortuitous that anthropogenic additions to even the most extensive sediment terrain or facies are so prevalent that discrimination is possible in very many if not all locations. There are after all many thousands of variations of biological, chemical, physical, and anthropogenic components of soils that discrimination will often be viable. Even at the largest spatial scale of investigation, microscale analysis can still enable discrimination.

Future Directions

It is widely acknowledged that the future of forensic geoscience lies in the growth of the empirical research base of the discipline. It will also be crucial that the discipline develops within the specifically forensic geoscience philosophical framework outlined above. Research in the forensic geosciences should incorporate as much as possible good scientific methods and experimental design but also acknowledge and develop research questions in a manner that incorporates the practice of forensic geoscience.

A number of areas are currently being developed that may give an indication of the future in forensic geoscience: firstly, the development of automation processes for evidence analysis. New capacity in this area would enable far more evidence to be analyzed and screened on an exclusionary basis, and this would reduce the amount of operator time required and ultimately lower the cost of such analysis making it more widely available. Recent examples of "proof of concept" work in this area would include the work of Newell et al. (2012) who demonstrate the capacity of computer recognition programs to be able to distinguish between quartz grain types that have been classified visually based on their surface textures. Secondly, the area of independent verification of particular forms of geoforensic analysis is being increasingly pursued in an effort to ensure that the analysis is admissible in court. While the interpretation of geoforensic evidence operates within the realm of probability, and thereby can only offer exclusionary intelligence and evidence, its weight can be enhanced by presenting the corroborative findings from two or more truly independent techniques. To take the example of quartz grain surface texture analysis, there has been preliminary work undertaken using PIXE and PIGE analysis using Ion Beam Analysis that identifies the potential for elemental screening of both the matrix and inclusions of the grain to offer independent verification of the quartz grain types identified morphologically using SEM (Bailey et al. 2012).

Forensic Evidence

► Scientific Evidence in Criminal Prosecutions

Forensic Facial Analysis

Martin Paul Evison
Northumbria University Centre for Forensic Science, Northumbria University, Newcastle upon Tyne, UK

Overview

Closed-circuit television (CCTV) systems, digital cameras, webcams, and mobile devices are the source of a burgeoning number of facial images used in criminal investigations and prosecutions. Given the significance of facial identification to the courts – as well as to cases involving questioned identity documents and border control and immigration disputes – it is important that the strengths and weaknesses of methods used are properly understood.

Identification of an alleged offender is fundamental to the judicial process. Courts rely heavily on eyewitness evidence of identification, and they continue to do so where facial images are concerned. Evidence of identification, however, is widely acknowledged to be problematic. Procedures and processes intended to make identification more reliable – whether for use in investigation or in court – are perennial challenges.

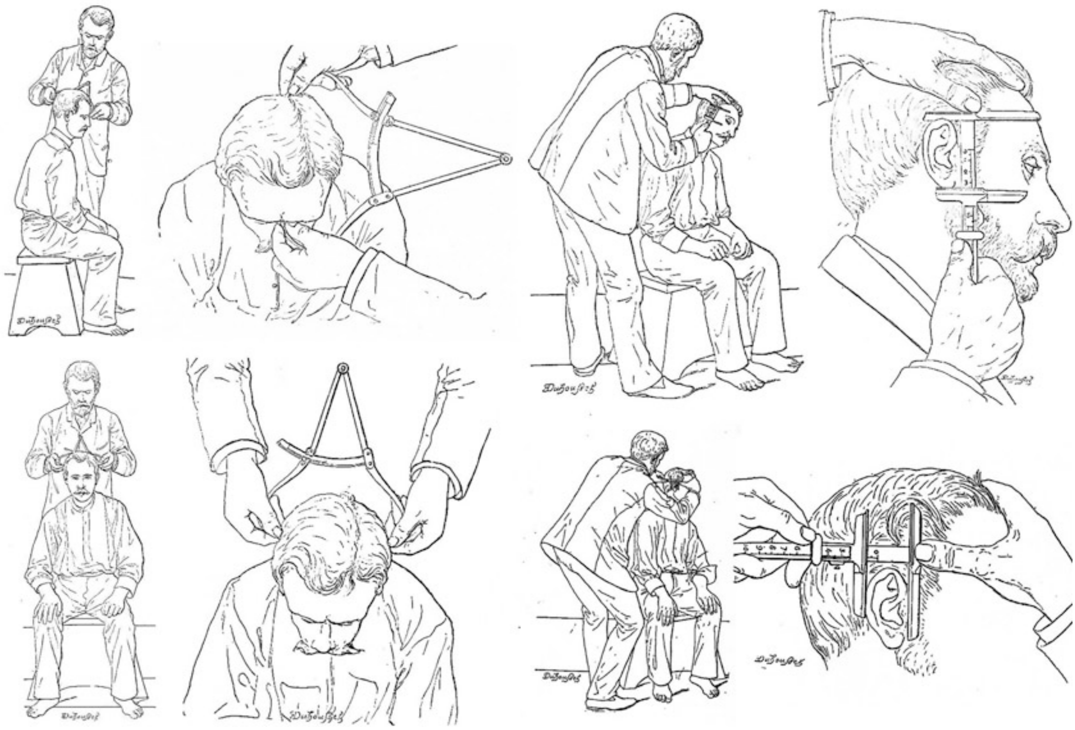
Where facial image evidence is in issue, eyewitness evidence of investigators or other witnesses familiar with the suspect may be given. Alternatively, expert opinion of facial image analysis may be adduced. As well as being susceptible to the general weaknesses of eyewitness identification, the methods of facial image analysis are susceptible to biases known to affect other opinion evidence. The methods of facial image analysis are scientifically rudimentary and are as distinct from computational biometrics as they are from the other ideals of human identification: fingerprints and DNA.

Identification of Offenders

It is almost self-evident that for a criminal prosecution to take place, an accusation must be made against a particular individual. The prosecution must prove beyond reasonable doubt that the offense was committed and the accused committed it. Identification of the offender becomes a fact in issue when the accused denies they were the individual concerned. The onus is on the prosecution to prove it was.

Identification of Repeat Offenders

It is easy to suppose that before the advent of fingerprinting and forensic DNA profiling,



Forensic Facial Analysis, Fig. 1 Standard measurements of the head and ear adopted by Bertillon (1885)

the only evidence available to establish identity from physical appearance was eyewitness evidence, but this is not the case. In the late nineteenth century, Alphonse Bertillon (1853–1914) pioneered measurement of body shape – anthropometry – for the purposes of forensic human identification (Bertillon 1885). Bertillon was a pivotal figure in the development of forensic science, and facial comparison was a substantial component of his technique. The method – coined *Bertillonage* – involved measurement of a set of bodily dimensions, including those of the head and ear (Fig. 1). The method also incorporated classification of facial features, including the color of the iris (Fig. 2); the shape of the forehead, chin, and nose (Fig. 3); shape of the ear (Fig. 4); and style of hair and beard (Fig. 5). The nature and position of distinctive marks on the face were meticulously documented (Fig. 6) as part of a recording system which also established early standards for forensic photography.

Despite its widespread adoption, *Bertillonage* was abandoned in the early twentieth century in favor of dermatoglyphic fingerprinting. This method of human identification was faster, less error prone, required less equipment and training, and could be applied to marks left at a crime scene (Cole 2001).

Eyewitness Identification

If anthropometric measurement and systematic classification were discarded in favor of fingerprinting, then how are people identified from facial images and appearance in the criminal justice system?

Not surprisingly, individuals depicted in images are very often identified via eyewitness evidence of some kind. In the London Riots of 2011, for instance, many of suspects were recognized from CCTV footage. In these investigations, most suspects were identified by members of the public. Some police officers, however, are regarded by the Metropolitan Police

as "super recognizers" on the basis of their ability to identify persons already known to them in CCTV footage using facial appearance and other cues. These apparent talents have been widely reported in the press (Grimston 2011; Jon 2009).

Forensic Facial Image Analysis

If eyewitness evidence is unavailable or inadequate, the methods of forensic facial image analysis may be applied. Three methods of facial image comparison are typically used in forensic investigation. They are photogrammetry or "facial mapping" (Fig. 7), image superimposition (Fig. 8), and anthroscopic or morphological analysis (Fig. 9).

Each of these methods requires an image of the offender – the questioned image – and a suspect image with the faces captured from the same or a very similar angle. The offender image may be obtained directly from digital closed-circuit television (CCTV), video or still cameras, cell phones, and similar devices. Offender images also continue to be extracted from legacy analogue videotape systems or scanned from photographs.

The offender image should ideally be the original. Alternatively, an unaltered copy can be used. There are a number of processes that have the potential to affect the fidelity of the copy, most notably digital image compression. Image compression may alter the image and may be "lossy," leading to a forfeiture of information that cannot be restored. Lowering the resolution of images leads to pixilation of points and features rendering them difficult to identify, classify, and measure. Digital capture or scanning of analogue images also has the potential to alter them. For these reasons, uncompressed copies at the highest possible resolution are desirable.

Since the pose angle of the offender in the questioned image cannot be altered, some effort

Forensic Facial Analysis, Fig. 3 Standardized references for the shape of the nose (Bertillon 1885)

can be made to capture an image of the suspect at the same pose angle – sometimes using the original imaging system in situ at the scene. Precision is very difficult to achieve, however, and pose angles of offender and suspect rarely match exactly.

The systems used to capture offender and suspect images may also affect the precision that can be achieved in a comparative analysis. The processes of digital and analogue recording are different, and in either case lens distortion, focus, and lighting may affect offender and suspect images differently.

Working from a presumption of innocence, if inexplicable differences between offender and suspect images are identified, then the

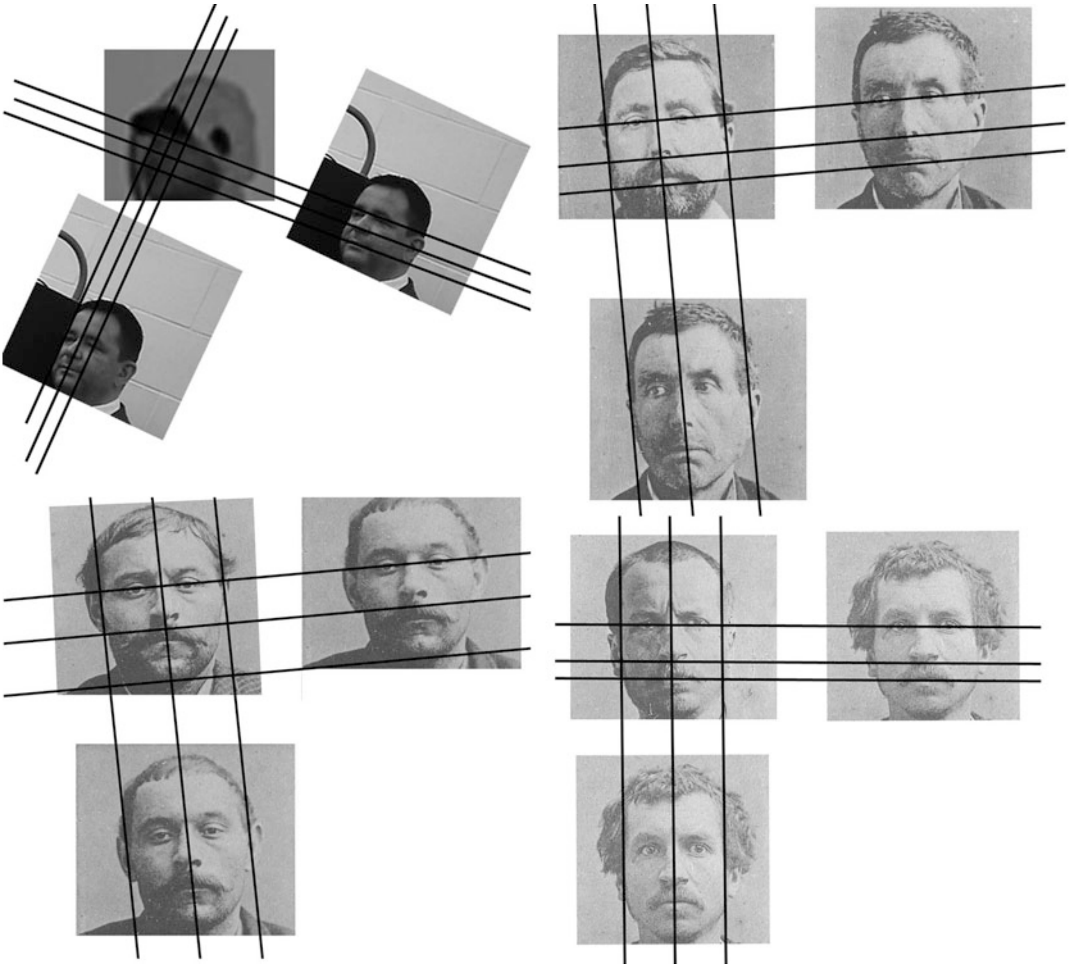
Forensic Facial Analysis, Fig. 6 Standard classification of distinguishing facial marks (Bertillon 1885)

facial images are assumed to originate from two different individuals, and an “exclusion” can be made. Explicable differences may be attributed to factors such as pose angle, lighting, lens distortion, focus, image resolution, and compression discussed above or due to other factors such as facial expression, aging, trauma or surgery, hair style, and clothing and jewelry. These are sometimes referred to as the “confounding factors” of forensic facial comparison.

If no explicable differences can be found, further comparisons using one or more of the methods of forensic facial image analysis may be undertaken.

Facial mapping and image superimposition require that the images be rotated into alignment and adjusted to the same scale. Good practice dictates that it is the suspect image that is adjusted in order that the offender image is unaltered. Changing the proportions of the image invalidates the process of comparison, however, as one of its aims is to assess

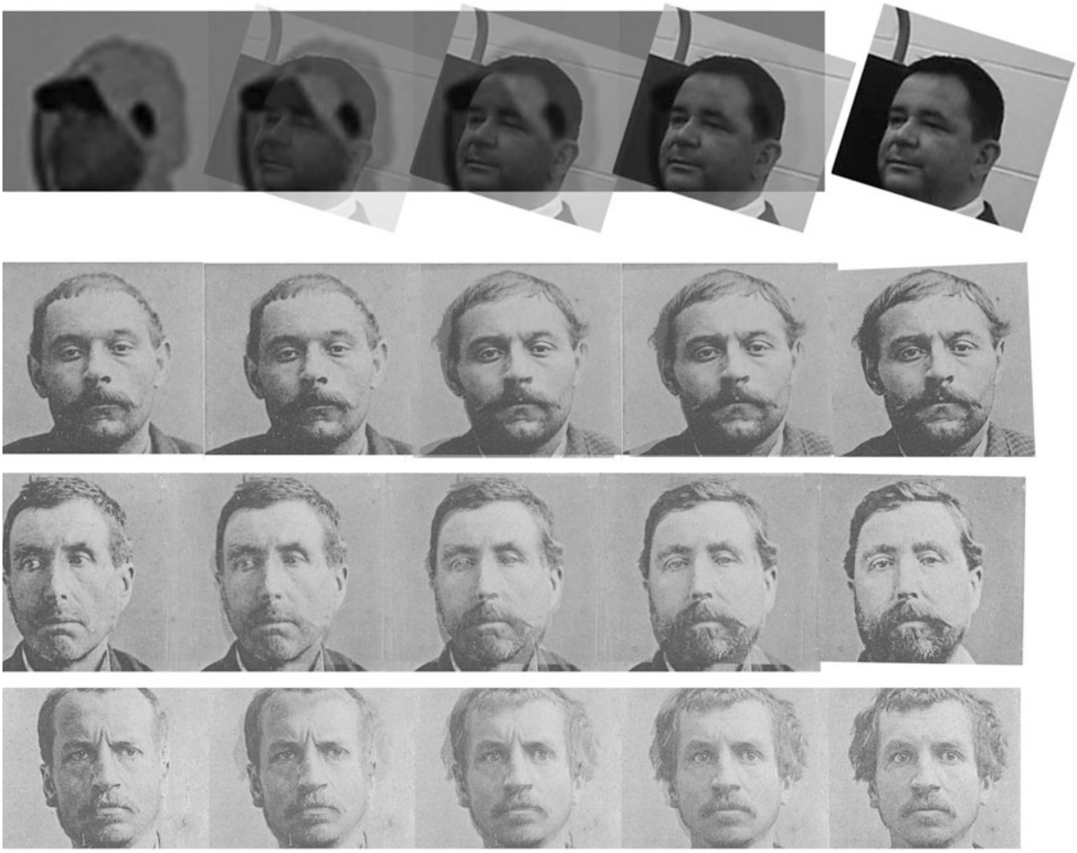


Forensic Facial Analysis, Fig. 7 Illustrative example of facial comparison by photogrammetry. Typically, a series of parallel lines are drawn between common features in offender and suspect images, such as the pupils, the commissure of the mouth, and the facial midline. If the lines are congruent and no explicable differences between the facial images can be identified, the expert may conclude the images come from the same individual or – more circumspectly – another individual of similar appearance

whether or not the two facial images share the same proportions. By implication, the scaling process would obscure any real difference in size between the heads of offender and suspect, should it occur.

Although "facial mapping" is known technically as photogrammetry, the implication that it involves detailed or complex mathematical analysis is misleading. The method simply consists of drawing parallel lines through points on features in the offender and suspect images, in order to compare their positions and the proportions of the face (Fig. 7).

Image superimposition involves the overlaying of offender and suspect images in order to perform a subjective assessment of similarity. The most common approach involves altering the visibility of the overlying image, gradually revealing the underlying one (Fig. 8). An alternative used in analogue systems is a "wipe," in which the overlying image is sequentially cropped from one side to gradually reveal



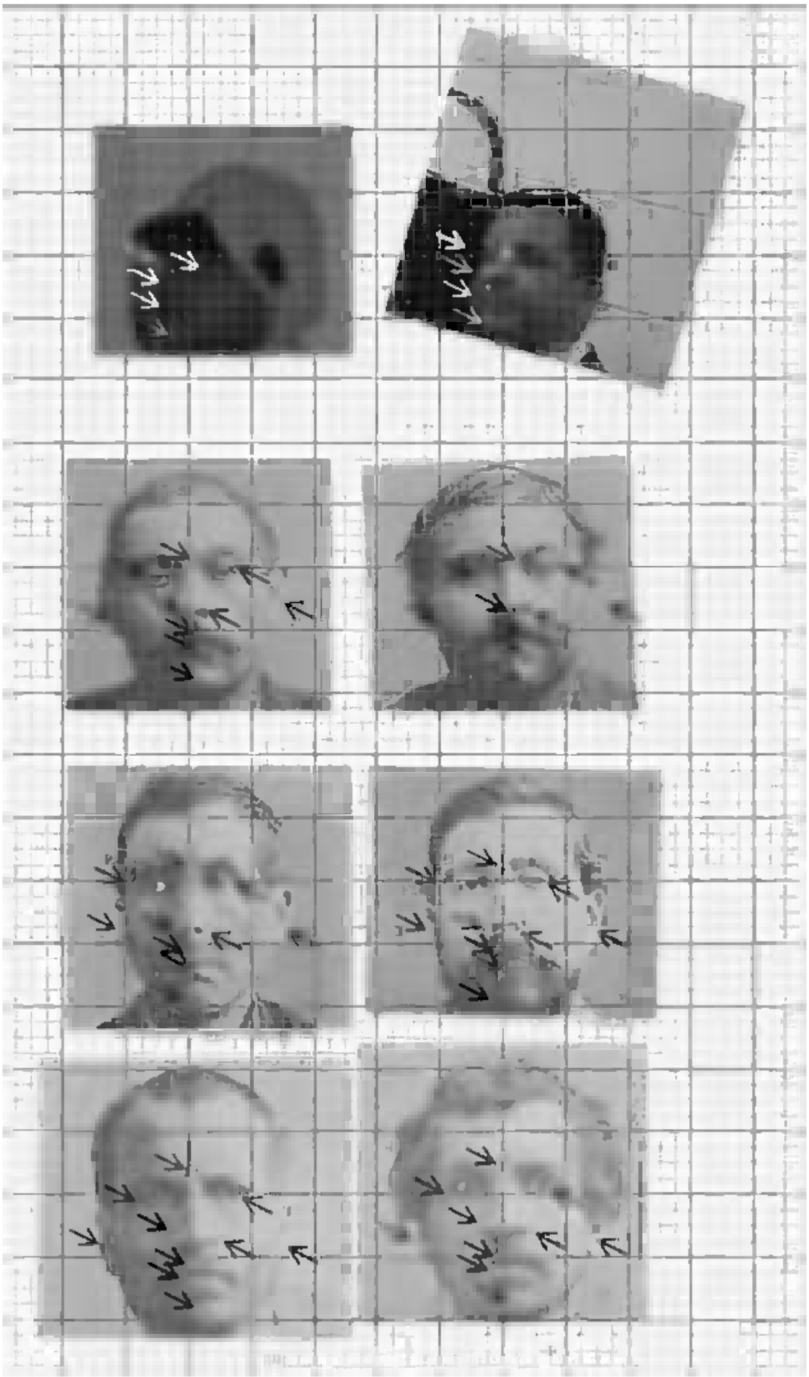
Forensic Facial Analysis, Fig. 8 Illustrative example of facial comparison by video superimposition. Images have been superimposed using Adobe® Photoshop® with the opacity of the superimposed image gradually reduced to reveal the underlying one. Again, if no explicable differences between the facial images can be identified, the expert may conclude the images come from the same individual. Video superimposition involves no explicit measurement, and its subjective nature is compounded by potential neurological (persistence of vision) and psychological (bias) influences on the examiner

the underlying one. A further alternative is a "blink," achieved by rapidly switching the overlying and underlying images. In each case, it is anticipated that the eye will detect subtle differences between the two images.

Morphological analysis or anthroscopy (Fig. 9) involves making a systematic assessment of the shape of the head, face, and facial features. Photographs or digital images can be used. A grid may be used to guide comparison.

If – after facial image analysis – no explicable differences can be found, the images may be said to "match." Normally, a further assessment is required to judge the extent to which the "match" supports the proposition that the faces in the offender and suspect images are from one and the same person.

The UK Forensic Imagery Analysis Group (FIAG) advocates a sliding scale of support (Bromby and Plews 2006), with criteria for assignment to each level on the scale (Table 1). The court is usually provided with a statement describing the analysis and the expert's view as to the strength of support it affords for the assertion that the facial images depicted are from the same individual. Recently, experts have qualified their opinion by stating matching evidence may arise from the defendant or *someone of similar appearance*.



Forensic Facial Analysis, Fig. 9 Illustrative example of facial comparison by anthroscopy. Anthroscopy or morphological analysis involves the systematic comparison of the shape of the facial features and other distinguishing marks. Although subjective, anthroscopy can rely on the use of classical anatomical classification and descriptive terminology that is open to confirmation or dispute. Descriptive classifications may include, for example, the shape and position of the inner and outer canthi (commissures of the eyelids), chelions (commissures of the lips), alares (nostrils), attachment and shape of the ear lobes, and shape and prominence of the chin

Bertillon (1885) appears to have perceived this issue. Distinguishing dissimilar faces is frequently trivial. Distinguishing similar faces is the real problem. Other than the author's own image, the faces given in the examples in Figs. 7, 8 and 9 are those Bertillon chose to illustrate the problem of distinguishing similar faces. In two of the three examples, the images originate from the same individual, in one exceptional example they do not.

Forensic Facial Analysis, Table 1 Sliding scale of support (Bromby and Plews 2006)

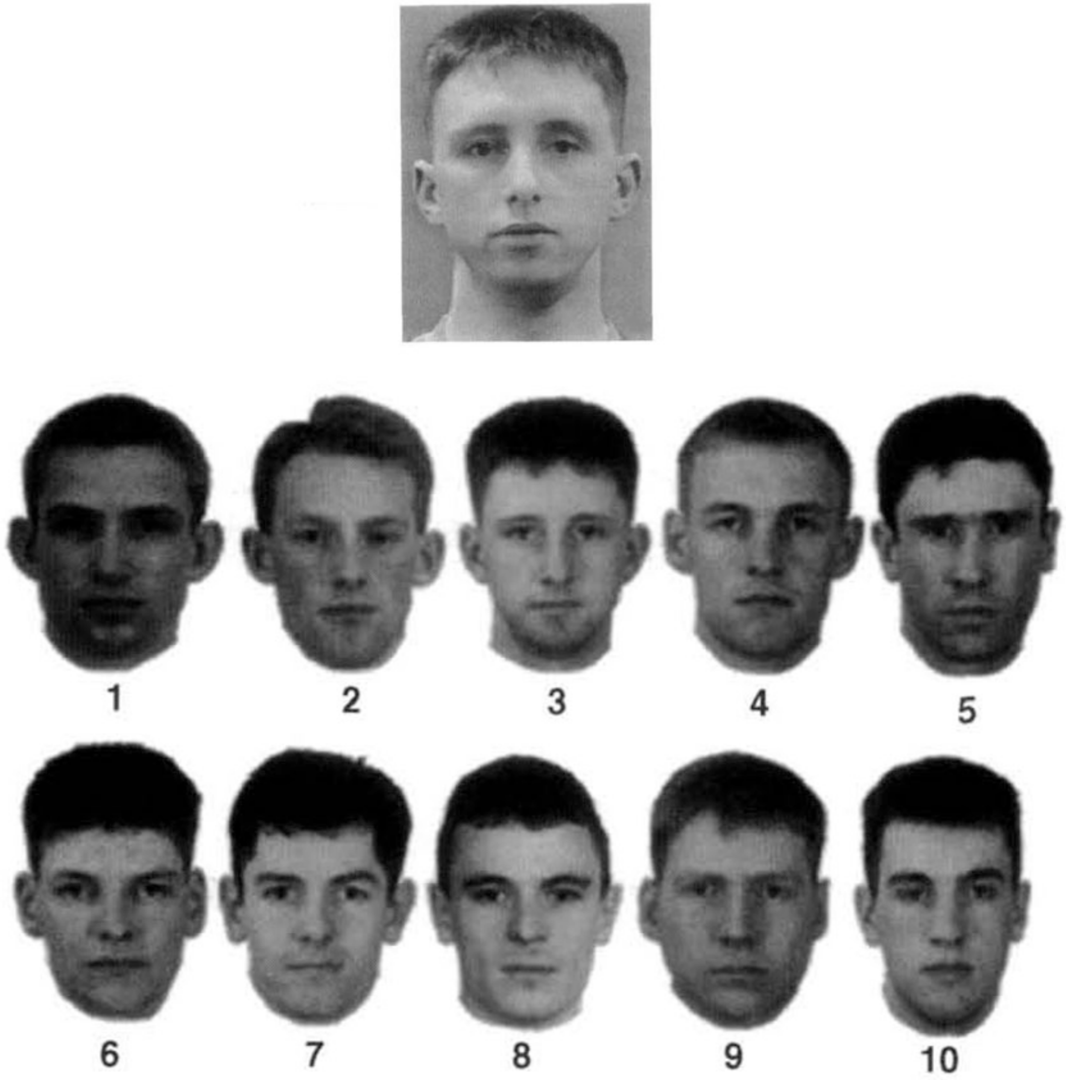
No support	There are no significant differences observable, from which to eliminate, and there may be a number of similarities. The imagery evidence is too poor to permit observation in either direction
	There may be very general characteristics observable (i.e., race, gender, hair color), but these do not offer enough support towards specific identity
Limited support	There are a few general characteristics observable. In combination, these provide a low level of facial uniqueness
	The image quality does not permit observation of individual facial feature detail (or only very limited detail)
	The facial geometry may or may not be matching, but observation of identifiable landmarks is restricted by the image quality
Moderate support	There are a few general characteristics observable
	The image quality permits observation of a moderate amount of facial feature detail, that is, for each visible feature, one to a few descriptives can be provided. For example, the nose could be classified as having a narrow bridge and a straight ridge
	In combination, a moderate level of uniqueness is available for the facial features
	The facial geometry may be matching, but observable detail is moderate (observation of identifiable landmarks is somewhat restricted)
Support	The image quality permits observation of individual facial feature detail to some extent
	There are a few facial features observable
	There may or may not be matching geometry, but this is limited to one or two instances
	In combination (or alone), the facial features have an average amount of uniqueness; they are shared by an average number of people
	The facial similarities can be observed a few times. This may be in combination
	The face is observable from only a few differing viewpoints
Strong support	The image quality permits a good level of individual facial feature detail to be observed
	A high number of facial features are observable
	In combination (or alone), the features provide a reasonably high level of uniqueness
	The facial geometry may be matching, and multiple landmarks are observable from which to align
	The similarities can be observed a reasonably good number of times
	The face is observable from multiple differing viewpoints
Powerful support	A very high number of facial features are observable
	The image quality permits a very good level of facial feature detail to be observed
	In combination (or alone), the features provide a high level of facial uniqueness. In the case of the ear, multiple points can be observed to be matching
	The facial geometry is matching on several occasions
	The facial similarities can be observed alone or in combination a high number of times
	The face is observable from multiple viewpoints allowing for a pseudo-three-dimensional impression of the face

Current Issues and Controversies

Facial image analysis remains a subjective process sometimes supported by a technical method and then only in part. Psychological studies have raised issues concerning the reliability of face recognition and of cognitive bias in comparative forensic analyses. Reviews of the effectiveness of forensic science have questioned the scientific basis of many forensic science subdisciplines as well as the subjective paradigm from which the forensic identification sciences operate.

The Psychology of Face Recognition

While face perception and face recognition remain exciting subjects of academic inquiry, certain features of our ability to perceive and recognize faces are clear. People are very good at recognizing familiar faces and very bad at

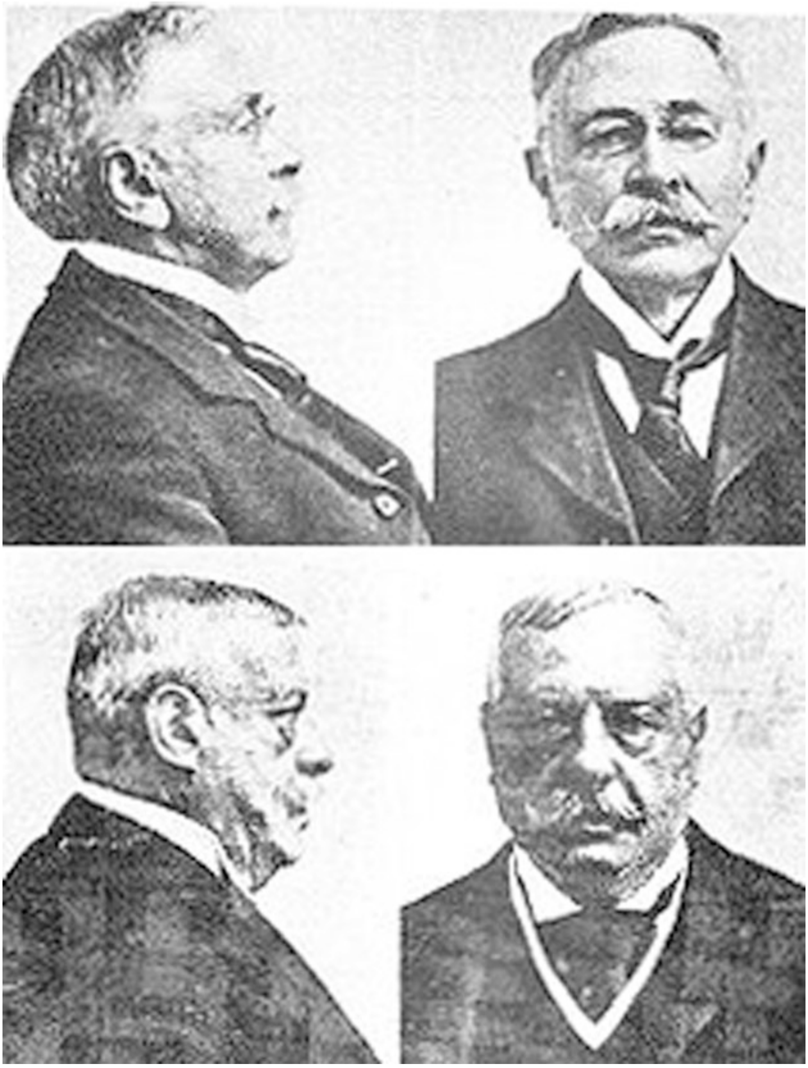


Forensic Facial Analysis, Fig. 10 Example of an experiment in facial recognition (Bruce et al. 1999 with permission) using a face pool. The subject is invited to establish whether or not the target face (*upper image*) is present in the array and, if so, which one it is

recognizing unfamiliar ones. Using standardized sets of photographic images called face pools (Fig. 10), researchers in psychology (Bruce et al. 1999) demonstrated the highly error-prone nature of recognition of unfamiliar faces. Kemp et al. (1997), for example, attached small photographs of shoppers to credit cards and asked cashiers to confirm that they belonged to the bearer. The subjects were able to detect fraudulent cards in only 36 % of trails when the photograph bore some resemblance to the bearer and in 66 % of trails when the photograph bore no resemblance.

Familiar faces are, in contrast, reliably recognized from face pools.

The same pattern is evident when reliability is assessed using CCTV footage of familiar and unfamiliar subjects. Burton et al. (1999) showed familiar individuals can be recognized quite reliably even from poor quality CCTV footage,



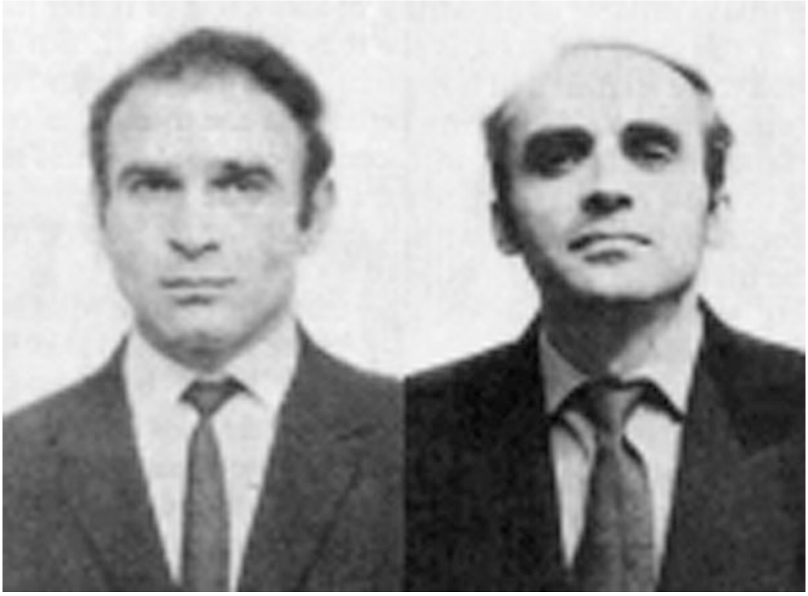
Forensic Facial Analysis, Fig. 11 Images of Adolph Beck (*upper*) and Wilhelm Meyer (*lower*). The Adolph Beck case was contributory to the development of the Court of Appeal in England and Wales

but unfamiliar subjects are frequently misidentified. The performance of students and police officers was similarly poor. Bruce et al. (1999, 2001) also demonstrated the highly error-prone nature of recognition of unfamiliar faces from CCTV images and video stream.

Error in Eyewitness Identification

The findings of Bruce and other psychologists of face perception offer scientific confirmation of the potential danger of eyewitness identification long recognized by the courts. Cases of mistaken identity – particularly of individuals unfamiliar to the witness – have become seminal in reforms of judicial procedure. In England and Wales, the *Turnbull* guidelines – arising from *R v. Turnbull* 1977 (QB224 CA) – govern the circumstances and nature of warnings to the jury of the risks inherent in eyewitness identification. Similar procedures are followed in US courts – see *Watkins v. Soders* 1981 (449 US 341; 101 SCt 654).

Both psychologists and the courts accept that eyewitness identification can be dangerous when unfamiliar faces are involved. Psychological evidence indicates that recognition of familiar faces is quite reliable, but it certainly is not perfect. A celebrated English case from the



Forensic Facial Analysis, Fig. 12 Images of Laszlo Virag (*left*) and Roman Ohorodnyckyi or Georges Payen (*right*). The Virag case ultimately led to the adoption of the *Turnbull* guidelines in England and Wales

nineteenth century involves that of Adolf Beck (Anon 1999), a man who had the misfortune to resemble fraudster Wilhelm Meyer, who presented himself to his victims as Lord Willoughby. One of Meyer's victims mistook Beck for Meyer. Beck's misfortune was compounded when ten or 11 of Meyer's other victims also did so. Two police officers familiar with Meyer also identified Beck as Meyer. One, Ellis Spurrell, stated "There is no doubt whatever he is the man. I know what's at stake on my answer, and I say without doubt he's the man." Having been found guilty not once, but twice of crimes committed by Meyer, Beck was awaiting sentencing when Meyer himself was arrested. The mistaken identity – and the passing resemblance of the two protagonists (Fig. 11) – finally came to light, and Beck was pardoned.

A further case arose in England in the twentieth century, which involved the mistaken identity of Laszlo Virag as armed thief Roman Ohorodnyckyi – also known as Georges Payen (Fig. 12). In the Virag case (Devlin 1976), a - number of witnesses including police officers again mistook Virag for Payen and confidently so. One officer, Police Constable Smith, stated "his face is imprinted on my brain." Virag was convicted, but items subsequently found in Payen's possession, including the relevant firearm, led to Virag's exoneration, the Devlin Report (1976) on identification in criminal cases, and the adoption of the *Turnbulls guidelines*.

Cognitive Bias

The findings of Bruce and other psychologists of face perception offer scientific corroboration for the premise that humans are good at recognizing familiar faces but poor at recognizing unfamiliar ones. Other psychological studies support the proposition that some individuals are exceptionally good at face recognition (Russell et al. 2009). Humans are, unfortunately, susceptible to other cognitive biases that can lead witnesses, including police officers, to mistakenly – if honestly – make highly confident, but erroneous identifications from facial appearance.

The wrongful convictions of Adolph Beck and Laszlo Virag each led to changes in the English court system and – in order to prevent errors and preempt courtroom challenges – to changes in police procedures relating to identification from arrest photographs and identification parades.

The risks of context and confirmation bias in forensic comparisons have been well rehearsed by Dror (Dror et al. 2006) in relation to fingerprints, and similar dangers apply to identifications from CCTV and forensic facial images. Video superimposition is a particularly subjective technique, with the capacity to obscure differences rather than reveal them.

Scientific Basis of Forensic Facial Image Analysis

Forensic facial image analysis is scientifically rudimentary. There is a small literature (Porter and Doran 2000; Vanezis and Brierley 1996; Vanezis et al. 1996; Yoshino et al. 2000) supported by guidelines published in the USA (SWGIT 2012) and UK (ACPO 2009). Validation studies are almost unknown. There is no reported error rate for forensic facial image comparison, whether conducted by police "super recognizers" or "facial mapping experts."

There is no scientific basis for assigning the weight of a comparison against a sliding scale of support. This is a matter of subjective opinion. Two experts could disagree, and both be "right" – see Mallett and Evison (2013). This is a position that is hardly tenable in science. The limited scientific basis of forensic facial image analysis is discussed in further detail by Edmond (Edmond 2011) in relation to courtroom admissibility of facial comparison evidence. The UK Court of Appeal held in *R v. T* (ECWA Crim 2439; 2010) with regard to footwear impressions that the expert should not use the word "scientific" where it gives an impression to the jury of a degree of precision and objectivity that is not present. This caution is equally warranted with regard to facial image comparison and is all the more important giving the compelling nature of facial image evidence.

Conclusions and Future Research

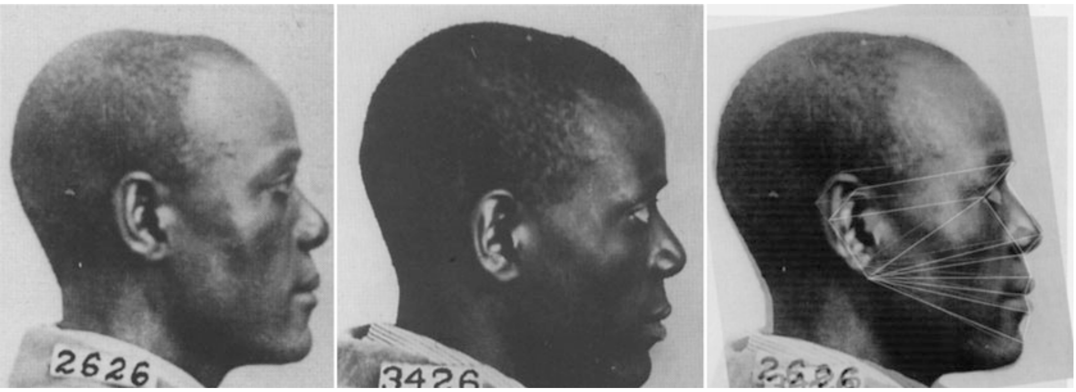
Despite the ubiquity of the face as the primary mode of recognition in humans and the increasing prevalence of facial images, most forensic identifications are based on eyewitness evidence of some form. Forensic facial comparison is not scientific, and the scientific claims of facial mapping and image superimposition are tenuous. There are presently two significant drivers of potential change, however, that may lead to the development of a forensic science of facial image analysis. These are the systematic investigation of images from CCTV footage and the expectation for increasing scientific rigor in the forensic sciences.

Systematic Use of Images in Criminal Investigation

The investigation of the London Riots of 2011 is notable for the extensive implementation of a thorough and systematic approach to the investigation of images from CCTV and other sources – digital cameras and other mobile devices. This approach was based on preexisting Visual Images Identification and Detection Office (VIIDO) units introduced by Michael Neville of London's Metropolitan Police Service (Grimston 2011). Not only do these units control collection and analysis of image evidence, they ensure that it is supervised and actioned (Jon 2009). Online and mobile (APCO 2012) apps are offered to support dissemination of images captured from CCTV and other sources.

The Paradigm Shift in Forensic Science

The unparalleled success and reliability of forensic DNA profiling has led to a postulated "paradigm shift" in forensic science (Saks and Koehler 2005), which predicts that more of the forensic science subdisciplines will need to follow the model offered by DNA. Both the United States National Research Council (2009) and the UK Forensic Science Regulator (Rennison 2008) call for forensic science to be based on sound scientific methodology, logical and statistically supported interpretation methods, and known error rates. Biometric technology may offer some value to forensic facial comparison, but at present the value of automated systems is investigative and not probative (Dessimoz and Champod 2007; Evison 2011). Reliance on automated biometric systems may also lead to a new kind of



Forensic Facial Analysis, Fig. 13 Images of Will and William West, inmates of Leavenworth Penitentiary in the United States who shared the same name, had similar facial appearances, and could not be distinguished by the Bertillon system. Will and William West were distinguished using fingerprints, however. Note also that their facial proportions (see superimposition, *right*) and ear shapes are also different

complacency that promotes context bias (Dror and Mnookin 2010).

Some research, such as that of Mardia et al. (1996), Yoshino et al. (2000), and Evison et al. (Evison et al. 2010; Evison and Vorder Bruegge 2010), has explored the potential for measurement-based and probabilistic methods of facial comparison using features demonstrable to a lay person. This approach is provisionally able to distinguish the famously similar appearances of Will and William West (Fig. 13), an early case of persons distinguished and identified from their fingerprints by the FBI.

Presently, however, investigation relies on recognition from CCTV images and prosecution on the admissibility of eyewitness identification as evidence in court. Although some investigators coin CCTV image analysis the third forensic discipline (Jon 2009) after dermatoglyphic fingerprinting and DNA analysis, the allusion is somewhat misleading as there is no definitive forensic science of facial image comparison.

Forensic Linguistics

Lorna Fadden[1] and Sandra Ferrari Disner[2]
[1]Department of Linguistics, Simon Fraser University, Burnaby, BC, Canada
[2]Department of Linguistics, University of Southern California, Los Angeles, CA, USA

Overview

Forensic Linguistics is a branch of Applied Linguistics involving the examination of language evidence in a criminal or civil matter and it can be carried out for two broad purposes. First, language analysis can be applied during investigations to assist in the identification of suspects or witnesses, or in determining the significance of utterances or writing to a case. Second, spoken or written language samples may be submitted as evidence in court, along with the testimony of a linguistic expert. Language evidence may bear heavily on the case itself, where the language in question constitutes a language crime: threats, coercion, bribery, hate speech, and hate literature, or language evidence might be more peripherally related to a case and it may necessitate a linguist to clarify the meaning of what is spoken or written, the manner in which it is delivered, and the role of context in the interpretation of the message.

This entry begins with some historical background, highlighting the first case to which a forensic linguistic analysis was applied. Four areas of practice are exemplified through case reports and the linguistic principles that underpin them: forensic discourse analysis, sociolinguistic profiling, authorship analysis, and forensic phonetics. A discussion of forensic linguists' roles in investigative and legal processes and the ethics surrounding practitioners' work concludes the entry.

Origins of Forensic Linguistics

The term "Forensic Linguistics" is said to have originated with Swedish professor of English, Jan Svartvik, who had examined a set of statements presumed to be a verbatim record of what was said by convicted murderer Timothy Evans during the 1949 investigation into the murders of his wife and infant daughter (Olsson 2004). Svartvik (1968) carefully scrutinized the language contained in four statements collected by police and demonstrated that a significant portion of Evans' words, particularly those drawn from the confession portions of the statements, were not likely to have been produced by Evans himself. Instead, Svartvik asserted, the investigators had likely added particularly damning information into his statements, which were then submitted as evidence. Svartvik highlights the compelling contrasts between the language likely to have originated with Evans, an illiterate, uneducated man with a low IQ, and language that would be consistent with someone versed in the discourse of law enforcement. The side-by-side comparison below illustrates the disparity.

Evans' words	Words falsely attributed to Evans
She **never** said **no** more about it.	She was **incurring debt**.
I **didn't** want **nothing** to do with it. . .	I **proceeded to**. . .
I **done** the usual thing.	I **made my way** to 93 Mount Pleasant
She asked me where Beryl and the baby **was**	I **then** fed the baby
My Guvnor used to pay her £50 **what** she used to sign for.	**In a fit of temper** I grabbed a rope.
	He handed me the money **which** I counted **in his presence**

Focusing on a few of the qualitative features that Svartvik uncovered, Evans' language samples contain several features consistent with nonstandard English, including double negatives: "she **never** said **no** more about it"; past tense verbs inconsistent with a more standard, educated variety: "I **done** the usual thing;" and relative clauses headed by relative pronoun "**what**," as opposed to "**that**" or "**which**." The words falsely attributed to Evans contained examples of vocabulary and phrasing likely out the range of someone like Evans, for example, "**incurring debt**," "**proceeded to**," "**made my way to**" and "**in his presence**"; and sentence structure containing hallmarks of a more educated speaking or writing style, including adverbs immediately after subjects, relative pronoun "**which**," rather than "**what**." The differences in sentence structure (syntax) and lexicon (vocabulary) comprised a significant portion of Svartvik's analysis that would demonstrate how Evans likely did not produce a confession, contradicting the police assertion that they had obtained from him a full confession.

Evans was executed for the murders of his wife and daughter, and would be posthumously pardoned after an inquiry showed that his neighbor, John Christie, had killed the mother and child, along with several others. The case today represents a milestone for the relevance of language evidence.

Forensic Discourse Analysis

The field of discourse analysis is vast, owing to the limitless purposes and contexts for human communication. Forensic Discourse Analysis is applied in cases where the meaning or mode of an utterance has some investigative or legal relevance to a case. Was something someone said a genuine threat? Does a racially tinged utterance constitute hate speech? Was the suicide note found beside a lifeless body written by the deceased or did his murderer write it? At what point in a series of written communications to a target (emails, letters, text messages) does the author exhibit language consistent with stalking? These and numerous other situations have called for linguistic expertise to shed light on language evidence, the meaning of which may be open to interpretation. The types of analyses in FDA touch on speech acts (Austin 1962; Searle 1969); speakers' cooperation (Grice 1975); turn-taking (Sacks et al. 1974); coherence and cohesion (Halliday and Hassan 1976); and institutional discourse (Drew and Heritage 1992). Two cases are shown below.

Hate Speech and Hate Literature

In many jurisdictions, the law prohibits people from making hateful statements toward a person or people on the basis of race, ethnicity, sexual orientation, religion, gender, or other demographic feature. It is not always certain, however, whether the spoken or written word meets the legal definition of hate speech or hate literature, at which point a linguist might examine the language in question and the context in which it occurs to assist in making that determination.

In Canada, hate speech and hate literature, including Holocaust denial, are illegal. In the 1990s, a case was brought before the Canadian Human Rights Commission, accusing Ernst Zündel of denying the Holocaust. Zündel, a German national who was living in Canada, disseminated anti-Semitic literature with language that was allegedly consistent with what the Canadian Charter of Rights and Freedoms deems hate language. Gary Prideaux, then a Professor of Linguistics at the University of Alberta, was consulted by the Commission and testified on the linguistic features that qualified Zundel's prolific work as anti-Semitic and holocaust denying (Prideaux 2011). A small sampling of his analysis is shown on the following passage, taken from Zündelsite (http://www.zundelsite.org/chrc/intervenors.html):

> To claim that World War II was fought by the Germans, as the Holocaust Lobby incessantly claims, to kill off the Jews as a group, is a deliberately planned, systematic deception amounting to financial, political, emotional and spiritual extortion. The "Holocaust," first sold as a tragedy, has over time deteriorated into a racket cloaked in the tenets of a new temporal religion - replete with martyrs to the Faith, holy shrines, high priests like Wiesel and Goldhagen, and theologians of the Faith such as Raul Hilberg, Deborah Lipstadt, et al.

Prideaux's analysis starts with the claim that WWII was fought "by the Germans. . .just to kill off the Jews as a group." The claimants here, the "Holocaust Lobby," and the presence of "just" suggests this group holds the simplistic belief that killing Jews was the Germans' only purpose in the war. Even the verb "claim" entails that the thing claimed is contentious, Prideaux indicates. "Holocaust Lobby" itself is a troubling label suggesting that there exists an organized, centralized group of Jews and Jewish sympathizers "advocating the reality of the holocaust" (p. 42) the reality of which is of course, what Zündel tenaciously rejects. That the Holocaust be "sold as a tragedy" suggests deception on the part of the "holocaust lobby" which then became an even more malicious movement in the form of a "racket." Rightfully, Prideaux asserts that "racket" entails a host of negative connotations: "shady, illicit, and negative commercialism, invoking hucksterism and racketeerting" (p. 43), all while cloaked in the accoutrements of religion, again pointing to deceptive, underhanded practices of the target group.

While there is no legislation in Canada equivalent to the United States' First Amendment guaranteeing freedom of expression, if the spoken or written word targets groups and individuals hatefully, then it is a criminal act, and the speaker or author can be prosecuted. As the passage above shows, the hostility that is apparent on the surface of Zündel's writing requires the precision of a linguistic analysis to demonstrate what, in the overall tenor, delivers the hatefulness, in this case Holocaust denial and anti-Semitism, that are both prohibited by law.

Undercover Recordings

Undercover recording is a tool used by law enforcement to aid investigation by capturing key evidence that arises in conversation. Assuming that such recordings are of adequate quality to hear any suspect and cooperating witness or undercover officer, it would seem that this sort of evidence would be very reliable. However, Georgetown linguist Roger Shuy illustrates how what is heard is not necessarily what was said or meant, nor is it necessarily even relevant to the purported criminal action (Shuy 2005).

In Texas v. T. Cullen Davis, the prosecution had relied upon covert recordings of Davis and a cooperating witness, David MCrory, whom Davis had allegedly hired to kill his wife and the judge presiding over their divorce. He also stood trial for the murders of his wife's lover, and her daughter, and the attempted murder of her as well. McCrory had been an employee in Davis' company, and he alleged that Davis confessed to the shootings, and that Davis wanted McCrory to kill his wife and the judge. McCrory cooperated with police, and during several interactions with Davis, he wore a hidden recording device. A portion of one conversation is shown below. Bracketed portions represent overlapping speech; italicized portions represent physical movements of the conversants as seen on video surveillance.

Davis	McCrory
I told him that, uh, to treat you like any other employee and, uh, so don't give me too much pressure in that regard. I can't uh, say you're gonna be gone a day or two every week or so.	
(*Davis gets out of the car and walks to the trunk*)	
	Well look, this fuckin' murder business—
You better—	
	—is a tough son of a bitch
alright	
	Now you got me into this
[give me]	[into this goddamn deal]
[give me]	[right?]
a little	
[noti-, advance notice]	[Now I got j-]
	I got Judge Edison dead for you
Good [inaudible]	
	I'll get the rest of them dead for you.
	You want a bunch of people dead, right?
alright but I	
[uh, you know]	[di-, di-]
	Help me too
[inaudible]	[okay?]
I got to have an alibi ready for Art when the-	
	Okay?
When the subject comes	
[up]	[alright]
(*Davis comes back to the front door of the car.*)	
So give me some advance notice	
	I will
warning	
	I gotta go
(*McCrory gets out of the car and leaves.*)	

Shuy (2005, pp. 46–47)

Using this side-by-side presentation, Shuy was able to demonstrate how Davis and

McCrory were speaking about two unrelated topics. Davis was talking about McCrory's having to account for his absences at work while McCrory was talking about the alleged murder-for-hire. That the two were not addressing the same topic is atypical of natural conversation, because speakers generally adhere to the topic at hand, and the turns are cohesive with one another, meaning that each turn bears some relevance to the turn before it (Halliday and Hassan 1976). The speakers here depart markedly from this principle, evidenced by each maintained his own topic. Davis himself does not in fact utter anything in relation to the killings, nor does he acknowledge what McCrory says about murder. Instead, he remains on the topic of McCrorys' work absences. He utters "good" and "alright" on the transcript, suggesting concurrence with McCrory's explicit reference to "getting people dead"; however, "neither was uttered in a response intonation, but rather as low-pitch discourse markers related to his own topic" (Shuy 2005, p. 48). It is not possible to be certain that Davis even heard McCrory, who was inside the vehicle by the time he was uttering what might have been the most damning words about the contract murder. Shuy refers to this as a "hit and run" in covert recordings, where the cooperating witness produces incriminating information while the suspect is either unaware or unable to respond to it. For language to be incriminating, it must be both cohesive with surrounding discourse, and if not from the mouth of the suspect, it must be evident that the suspect is in unambiguous agreement with what is said.

In both of the examples shown above, the linguists used linguistic principles to provide clarity in cases where language evidence was less straightforward than it appeared, and the importance of a thorough understanding of language samples cannot be overstated when the spoken or written word has some bearing in a legal matter. For a more thorough overview of Forensic Discourse Analysis, see Fadden (2012).

Authorship Analysis

In cases where the authorship of a document or set of documents is contentious, a linguist may be asked to opine on the authorship of the disputed writing. This typically entails comparing the disputed sample with samples known to have been written by a particular individual. There are two broad approaches to authorship analysis: linguistic and computational. Each is considered in this section.

Linguistic Approaches to Authorship

First, the linguistic approach, a more traditional approach to language evidence, typically involves a principled selection of qualitative and quantitative analyses comparing one piece of writing with another to rule in or rule out common authorship (see McMenamin 2002 for one systematic approach of this type). Underlying the linguistic approach is the notion of the *idiolect* (Bloch 1948, p. 7), meaning that "every native speaker has their own distinct and individual version of the language they speak and write" Coulthard (2004, p. 431) While the idea of a linguistic fingerprint unique to each language user is too strong, Coulthard assumes that individuals, with unique vocabularies and preferences for particular combinations and structures, typify the user's style. McMenamin puts it succinctly: "Unique markers are extremely rare, so authorship [attribution] requires the identification of an aggregate of markers, each of which may be found in other writers." (McMenamin 2002, p. 172) In other words, while we all have access to the same units and constructs of language, we as speakers have preferences for patterns and they cluster differently from one writer to the next.

Olsson (2004) walks the reader through several worked examples of authorship comparisons. Among his many techniques, Olsson applies the concept of markedness to his analyses. Markedness dates back to the 1930s commencing with Jakobson (see Henning 1989 for historical introduction), who described pairs of linguistic units as having an asymmetrical relationship to one another. The unmarked form is the most frequently occurring, or normal, ordinary form, and the unmarked form is the less frequently occurring, or unusual, irregular form. In the pair happy/unhappy, happy is unmarked, unhappy, with the derivational prefix un- is marked. Similarly, in the pair "He had often been seen with her" and "He often had been seen with her," the former is unmarked, with the adverb *often* being most commonly positioned between the two auxiliary verbs; the latter is marked, with the adverb *often* occurring in its less frequently found position before the first auxiliary verb.

In one of Olsson's authorship cases, anonymous, menacing letters were received by witnesses who were about to testify against the accused in a rape trail. A set of writings known to have originated with the accused were compared to the letters the witnesses turned over to police.

> Known Authorship 1: "…I was arrested and charged with the rape of Mary. I could not believe this as I am and was impotent."
>
> Known Authorship 2: "…when I was arrested, I was firstly charged with raping Mary, I stated to the Police that I could not rape anyone, as I was impotent, and had been since 1996."
>
> Unknown Authorship 1: "The good fortune is Joe was able through his solicitors, police forensics and medical reports to prove 100 % that he could not and did not rape or have unlawful sex, through his being Impotent and is and has been for five years or more."
>
> Unknown Authorship 2: "Neither would have known that Joe, was to enter hospital to have tests to Proving that he is and was impotent." (Olsson 2004, p. 49)

Given the ordering of the verb pairs on the basis of temporality, i.e., present + past (am/was; is/has been) or past + further past

am and was	(KA1)
was and had been	(KA2)
is and has been	(UK1)
is and was	(UK2)

Olsson concludes the known and unknown texts are likely to have been written by the same author owing to the fact that these verbs appearing in this temporal order represent marked structures, i.e., they occur much less frequently than past + present orderings. Olsson based his conclusion on a number of features in addition to the one described; however, these verb patterns provide a straightforward grammatical example of the type of elements that can be used to match writing samples.

Computational Approaches to Authorship

In recent years, those working at the interface of linguistics and computing science have begun to explore computational means for attributing authorship. Typically, their research focuses on the attribution of authorship in classic works in the humanities and in journalism, but it is not difficult to see the forensic application of computational approaches, in cases where the authorship of a piece of writing is contentious and of legal importance.

Whereas the traditional approaches to authorship involve manual, line-by-line analysis of linguistic features as shown in Olsson's example above, computing approaches involve mathematical and statistical treatments of the language data, making little or no use of linguistic elements (Juola et al. 2006). The leading approaches in the last decade reduce the documents to unpunctuated strings of letters that are then subject to linear discriminant analysis (Baayen et al. 2002; van Halteren et al. 2005), orthographic cross-entropy (Joula and Baayen 2005); common byte n-grams (Keselj and Cercone 2004), among others (see Juola et al. 2006 for more).

These methods have determined authorship accurately at rates much better than chance. In order to determine the most accurate and effective approaches to authorship attribution, contests are held where teams of researchers are given a set of documents (for example, sets of novels, sets of undergraduate terms papers, a set of letters, or other such corpora for which authorship is already known) and they compete to develop the most accurate system to attribute authorship. One such contest took place at a joint 2004 conference held by the

Association for Literary and Linguistic Computing and the Association for Computing in the Humanities, where the most successful team scored an average of 71 % across all of the sample types (see Juola et al. 2006 for an overview of the results and methods, including their own.) While these results are not yet high enough to satisfy the court for forensic determination of authorship, the trends and improvements are encouraging.

Linguistic or Computational?

The two approaches differ tremendously in that the first is wholly linguistic, where lexical features, syntactic constructions, and even rhetorical devices are examined and compared and the expert renders a conclusion regarding a match in the authorship of compared documents, a non-match, or inconclusive results. The second makes no use of linguistic features; rather letters or words are reduced to strings that are compared for similarity on the basis statistical measures.

Members of the International Association of Forensic Linguists, the professional association for linguists and law scholars concerned with language and law, have begun to address the merits of each approach (Solan 2011). Whereas traditional authorship attribution methods have been admitted in UK and US courts, Solan points out that at least for US jurisdictions, they do not meet the strict criteria set out by Daubert and Frye standards, specifically that the error rates of such methods are not known. Computational methods lend themselves well to meeting such criteria; however, current technology has not reached a satisfactory level for forensic identification.

Sociolinguistic Profiling

In the 1960s, William Labov introduced the linguistic variable, which accounts for why we have accents and why social factors like gender and cultural affiliation can contribute to our using language slightly differently from one another. As speakers, we belong to speech communities, meaning within a geographic area, we share many linguistic similarities, i.e., we share an accent. West coast English in the USA, for example, differs from East coast, northern varieties differ from southern varieties, and differences are found between rural and urban communities. The variation is not limited to geographic bounds. Ethnic and racial communities exhibit their own varieties: The English spoken by blacks and whites in the USA varies (Labov 1966; Shuy 1967). Aboriginal varieties of English are noted in Canada, the USA, and Australia (Fadden and LaFrance 2010; Scollon and Scollon 1979; Butcher 2008, etc.) There are differences found between young and old, male and female, and variation is distributed across socioeconomic lines, as well as linguistic variation noted between occupations, where specific vocabulary and phrasing serves the group in the commission of their jobs (see Wardhaugh 1986 for a comprehensive introduction in sociolinguistics). All of these noted variations can be useful clues to narrow down the suspect pool.

In a 2010 “poison pen letter” case, the board of directors and the executive team of a large Canadian company received a disturbing letter from someone claiming to be a staff member in the company. In the letter, the individual listed numerous complaints about the company, including nepotism, favoritism, and poor management. The company’s legal team asked one of the present authors to determine who, within the organization, could have written the letter.

While it is not possible to identify the precise individual on the basis of linguistic features, it was possible to assert that the author was positioned at the upper end of the company hierarchy rather than at the lower, service end.

The following excerpts show how the author had portrayed himself as part of a group of lower management and service staff addressing a variety of issues that would pertain to that portion of the company's workforce.

Claims to be low level management/staff	"Please accept this as a letter to the board on behalf of CompanyName managers and staff expressing our displeasure with the new extended hours."
Concerned with hours and scheduling	"…displeasure with the new extended hours"
	"These new hours have and will turn center manager's jobs into a full-time scheduling function."
Concern with morale	"…create poor morale"
"Us vs. them" stance	"They (executives) will all be home having supper with their families while we are dealing with the traffic that walked in the door at two minutes to six."
	"CEO's speeches about balancing home and work must only apply to him and his group."
No regard for service side staff	"The departments for each VP grow and grow and they care less and less about the front line staff."

The examples above might well have originated with a staff member who deals directly with customers. However, other features strongly suggest that the letter was written by someone who does not work at the service side of the business, but rather someone on the executive side. The following examples address concerns that would not fall within the domain of a service side employee.

Concern with company finances	"Determine how much Company has spent on the bank. How much has Company put into the bank accounts of other organizations and consultants during this project? What have been the returns? How much has been taken out of the wealth that was built by the traditional parts of Company?"
	"Why are they (one arm of the business) getting all their money for the constant spending without any regard to controlling expenses."
	"CEO makes sure the flow of cash…will eliminate accountability."
	"How much have their projects cost the other parts of the company with nothing to show for it but drained capital and resentment?"
Concern with business leadership	"[VPs] show unquestioning support to CEO's decisions and misguided image of himself as a business leader."
	"Like their leader, they (the VPs) are a group of people that are focused on their own self-promotion and have zero business acumen."

(*continued*)

It is unlikely that a low ranking staff member or even a low-level manger would have cause to comment on matters concerning the funding of projects, company cash flow, and capital. Nor does it seem likely that the same individual would make pointed criticism of the company executive because there would not likely be occasion for him to meet, much less work with VPs and the CEO to form opinions about their character.

The author further casts suspicion on his purported low-level position in the company in the following passage:

> Our managers are unwilling to deal with the worst of the staff knowing **they** will get little support form [sic] head office and will likely end up defending **themselves** from whatever accusation is thrown at **them.**

Personal pronouns (they, them) and reflexive pronoun (themselves) used in this sentence strongly suggest his exclusion from the group, and betray the author's claimed identity. The author of the letter was in fact a former vice president who had been forced to resign, and he had written anonymously to the board of directors and the executives to harass and embarrass the CEO.

Sociolinguistic profiling is carried out on language evidence and the linguist constructs an informed opinion on the basis of observable linguistic features. As with other types of profiling, it is an inexact science, because no subject will exhibit all features of their type, and subjects may exhibit features inconsistent with their type. The writer may also attempt to mask features, as the corporate letter case above demonstrates. However, the features to be found in our speaking or writing can in fact provide clues to our demographics. Alone or in combination with psych profiling, sociolinguistic profiling can be very useful when identifying suspects or witnesses at the outset of an investigation.

Phonetics in Criminal Cases

Where language evidence is spoken, phoneticians – that is, linguists specializing in the acoustics and articulation of the spoken word – may lend their expertise.

But forensic interest in the spoken word long predates the science of phonetics. Voice identification by earwitnesses has been admitted at trials dating back at least to the seventeenth century, when William Hulet was accused of having served as the executioner of King Charles I of England. Though masked on the scaffold, Hulet had been recognized by a witness solely "by his speech." This evidence – along with little else, mostly hearsay – resulted in Hulet being found guilty of high treason.

Another high-profile case involving voice identification, the Crime of its own Century, centered on the 1932 kidnapping of the young son of aviator Charles Lindbergh. Lindbergh, who had only heard six words uttered by his son's abductor, initially told a grand jury that "[i]t would be very difficult to sit here and say that I could pick a man by that voice". But at trial, nearly 3 years after hearing the voice of the abductor, Lindbergh went on to identify it as that of suspect Bruno Hauptmann. A year after Hauptmann was executed for this crime, the results of a voice-identification experiment shed light on some of the issues raised during the trial (McGehee 1937). Subjects were asked to pick out a previously heard target voice from a lineup of five similar voices. After an interval of 1 day, and even 1 week, subjects were able to identify the target voice with more than 80 % accuracy, but by 2 weeks that figure had dropped to 69 %, and by 3 weeks to 51 %. By 5 months, recognition had descended to chance level. This suggests some limitations to voice identification, unless a suspect is apprehended in short order, or the unknown voice is captured on a recording.

In 1962, an article in the journal *Nature* described a new and objective procedure for identifying voices with reportedly astonishing accuracy (Kersta 1962). The technology was not new, having been developed (under the name "sound spectrography") as part of the World War II effort to track German troop movements. The methodology – essentially pattern-matching among printouts of vocal energy – was based on a "theory of invariant speech," which claimed that each person's voice pattern is unique. (Little scientific support was ever offered for this theory, and it was soon undermined by studies involving vocal disguise.) Notably, the author of that article discarded the old name for the physical record of sound spectrography ("sound spectrograms"), and instead coined the word "voiceprints," which implied a level of reliability similar to that of fingerprints.

However, phoneticians (notably Professors Peter Ladefoged of UCLA and Harry Hollien of the University of Florida) argued strenuously that "voiceprints" of the highly mutable and continually shifting human voice are not nearly as reliable as fingerprints. The former are graphic representations of the energy produced by fluid articulatory gestures (such as the rounding of the lips and the raising of the tongue) which can occur simultaneously, sequentially, or not at all; the latter are direct physical impressions of digital topography, and are immutable.

Not long after the publication of the *Nature* article, the "voiceprint" technique began to be used by prosecutors in criminal cases. It was immediately challenged on the basis of not having gained general acceptance in the scientific community. Different jurisdictions reached different conclusions in this regard. However, within a few decades, Kersta's original methodology – mere pattern-matching, without even the need to listen – had been all but abandoned.

But a growing body of research has demonstrated that the acoustic information present in sound spectrograms, when interpreted in the light of phonetic principles, can indeed enhance the auditory identification of voices. Some robust results have been reported for lengthy voice samples. And even voice samples of moderate size can derive benefit from phonetic analysis.

Additionally, if two speech samples are lengthy enough to be compared in considerable detail, one may be able to evaluate the strength of the evidence in the form of a "likelihood ratio."

Numeric ratios of this sort can be assigned verbal values, such as "very strong evidence [to support the hypothesis of speaker identity]," "strong evidence," "moderately strong evidence," etc., and presented to the trier of fact.

Some of the phoneticians who had initially been most critical of the forensic use of sound spectrograms came to moderate their views, once those spectrograms were no longer associated with a superficial pattern-matching technique and no longer bore the unduly suggestive name "voiceprints." Ladefoged, for one, did so while advocating procedural safeguards such as sufficient length (far exceeding the FBI standard), clarity (a signal-to-noise ratio where the signal is higher by 20 dB), and frequency range (at least 3,000 Hz). Under good conditions, he later wrote, "virtually all phoneticians would agree that acoustic phonetic analyses have *some* evidential value" (Ladefoged 1982).

One example of a phonetic analysis that was considered to have evidential value was that presented at the trial of Paul Prinzivalli, who was accused of phoning in 25 separate bomb threats to Pan American World Airways in 1984. Prinzivalli, a disgruntled Pan Am employee, had been identified as the suspect by two senior supervisors – though his immediate supervisor disagreed, pointing to differences in the "inflection, accent, tone, depth, pronunciation, timbre" of his voice. The police nevertheless charged Prinzivalli with having made the bomb threats, and he faced a possible 6–8 years in prison.

Sound spectrograms of the would-be bomber's words and of Prinzivalli's exemplar of those same words displayed numerous differences. The lower vocal resonances, which mainly indicate which words are spoken, differed in a way that suggested the presence of two different accents. The upper vocal resonances, which can provide evidence of speaker identity, were attenuated, but still suggested the presence of two different individuals. In particular, the fourth resonance, where visible, did not match across conditions. And the third resonance closely tracked the rises and falls of the second resonance in the voice of the suspect, but remained high and steady in the voice of the would-be bomber.

These differences, presented in court by Ladefoged and by one of the present authors, were corroborated by a dialect study conducted by William Labov of the University of Pennsylvania, the author of numerous books on this topic, including the authoritative *Atlas of North American English*. Labov concluded that the unknown voice was a Bostonian, whereas the suspect was a lifelong New Yorker.

The judge found Prinzivalli not guilty, calling the linguistic evidence "objective" and "powerful."

Automatic Analyses

When an abundant amount of speech is available for analysis, the "auditory-acoustic" method described above may be supplanted by a computerized system that does not examine individual phonetic parameters at all. Instead, such "automatic" systems treat the speech sample as a single, continuously varying complex vibration, which can be modeled mathematically and then compared to another speech sample. "Automatic" methods of analysis are usually quite accurate, but they typically have a high rejection rate (otherwise associated with short samples, or with noisy samples of moderate length). In general, the optimal methodology will be dictated by the length and the quality of the speech signal.

Phonetics in Trademark Disputes

The phonetic methodology described above can also be employed in the resolution of trademark disputes. According to US law, trademark infringement may occur when two marks denoting similar products or services are sufficiently similar to cause confusion (or potential confusion) among consumers. When infringement is determined to have occurred, the newer ("junior") mark must give way to the senior mark. But there is often controversy over what constitutes "sufficient" similarity. What may seem misleadingly similar to one party may seem quite distinct to another.

The situation is difficult enough to resolve when it is limited to orthography and to related issues of trade dress such as the color and font of the mark. It becomes even more difficult for experts when sounds are taken into consideration.

A manufacturer may specify the intended pronunciation of a newly coined trademark directly on the package, or in a source such as the *Physician's Desk Reference*, or through advertising in broadcast media. But it is by no means clear whether the public will accept (or even notice) such specification, or instead fall back on the familiar rules of spelling. Such a dispute was, for example, at the heart of trademark litigation between the manufacturers of competing birth-control pills, OVRAL and B-OVal (Shuy 2002). The manufacturers of OVRAL maintained that their trademark name was to be pronounced with final stress (o-VRAL, to rhyme with go-ALL). However, final stress is not very common in English words. A reverse-order (or "rhyming") dictionary shows that, of almost 2,000 multisyllabic English words ending in –al, only about a dozen bear final stress.

A growing body of evidence shows that knowledge about such preferences, along with other spelling-to-sound relationships of the English language, is represented in the mind of the reader and is called upon when necessary, such as when words are encountered for the first time (Treiman et al. 2002). This can even help us to read nonce words, such as those in Lewis Carroll's poem *Jabberwocky*. But such rules can be a powerful counterweight to the trademark holder's intentions, and may indeed result in consumer confusion.

Litigants often commission consumer surveys to determine the likelihood of consumer confusion, but such surveys must be carefully crafted to avoid suggestiveness, and to adequately sample the marketplace.

As an alternative, or a supplement, to such surveys, litigants have called upon linguists to present any phonetic facts that might give rise to, or else rule out, the likelihood of consumer confusion. A linguist trained in phonetics can call attention to any articulatory or acoustic similarities that might exist between the sounds of two trademark names. The use of the International Phonetic Alphabet can override the vagaries of English spelling (such as orthographic "qu," which, despite appearances, is not a consonant-vowel sequence). And a table of documented misperceptions, a staple of the psycholinguistic literature, can suggest which of all possible pairs of sounds are most likely to be confused by the consumer.

All of the above arguments were made by one of the present authors in trademark litigation between two competing mortgage companies, Ameriquest and Americrest. Evidence from phonetics (articulatory lip rounding, acoustic overtone patterns, and the International Phonetic Alphabet) and from psycholinguistics (listeners' documented tendency to confuse the distinguishing letters of these trademarks under laboratory conditions – in this case a 28 % confusion rate, even without advertising jingles playing in the background) were offered as arguments for the potential confusability of these two marks. The case was promptly settled.

Forensic Linguistics and Ethics in the Legal System

As more linguists find themselves consulted by law enforcement and legal counsel on cases involving language evidence, the Linguistic Society of America compiled a four-part statement of ethics to which linguists are expected to adhere. First, a consulting linguist must act with professional integrity: He or she is to provide an objective analysis and compensation cannot be dependent on the outcome of any findings. Second, there must be transparency regarding the methodology used, as well as a clear account of any data, equipment, statistical tests, and software used. The linguist must also make clear any known limitations of the aforementioned and his or her own abilities. Third, the linguist must not disclose any confidential information relating to his or her casework without the consent of affected parties. Any research arising from casework should be anonymized such that there is no identifiable information appearing in presentations or publications. Furthermore, the linguist must not take on casework that can result in a conflict of interest, nor should she or he communicate informally or unofficially with an opposing party's linguist or legal counsel.

Fourth, linguists are strongly encouraged to communicate that they abide by the Code of Ethics passed by the Linguistic Society of America if practicing within the USA, although others are free to subscribe to this code as well. Furthermore, linguists are encouraged to abide by the codes agreed upon by any other professional organizations such as the International Association of Forensic Linguists and the International Association of Forensic Phoneticians.

Linguistics, like most other social sciences, is a wide field with a variety of subfields, and, as a discipline, is taught in many university campuses. Many research universities offer doctoral in linguistics. In American and UK courts, it is largely the decision of the trial judge to admit (or not) a linguist and his or her testimony, and it appears to be happening with greater frequency as the usefulness of linguistic analysis is understood.

Forensic palynology (the study of pollen grains)

Overview

Forensic palynology is an underutilized, but important tool for obtaining trace evidence from suspects, items thought to be associated with a crime scene, or for determining the geolocation of a sample. First used more than 50 years ago in Austria, it is now often used in the United Kingdom, New Zealand, and more recently, in other countries of Europe and Asia, but is still underused in the United States. Forensic palynology has gained importance for its ability to provide information about pollen and spores trapped in clothing or other items of interest needed to help resolve criminal and civil cases, including instances of homicide, terrorism, genocide, bombings, forgery, theft, rape, arson, counterfeiting, manufacturing and distribution of illegal drugs, assault, cases of hit and run, poaching, and identity theft. The foundation for using pollen in forensic applications comes from the discipline of pollen analysis, which began a century ago as a way to search for clues about past environmental changes. A few examples demonstrating the utility of using pollen and spores in forensic applications during the last half century are discussed. Finally, some of the recent analytical techniques that are being used to try to increase the precision of pollen identifications related to a variety of criminal and civil cases are examined.

Introduction

Palynology (the study of pollen and spores) has historically been widely underutilized in forensic science. Traditionally, forensic palynology focuses on legal evidence obtained from the study of pollen and spores that are associated with a crime scene or other aspects related to situations involving the law. As a discipline, the first recorded use was a little more than one-half century ago, but even today the use of this technique is relatively unknown or underutilized in many regions of the world. Even in those areas where forensic palynology is routinely used as a forensic tool, such as the United Kingdom and New Zealand, its utility for forensic science is often questioned.

One of the earliest recorded and successful cases involving the use of forensic palynology occurred in Austria in 1959, where pollen was used to link a suspect with a murder and to the crime scene where a shallow grave contained the murdered victim's body (Erdtman 1969). A decade later, pollen from the suspected holy relic called the Shroud of Turin was recovered and then analyzed by Max Frei in the 1970s. Using pollen trapped on tapes that had been lightly pressed against the Shroud, Frei claimed the relic could be linked to its purported origin and thus suggested authenticity (Frei 1982). Over the next decade, there were a few additional attempts to use pollen as trace evidence in both civil and criminal cases, but the next use that gained widespread attention occurred in New Zealand (Mildenhall 1990). Dallas Mildenhall, a palynologist trained in geology was asked to help solve a case involving the suspected poaching of deer to obtain the velvet from their newly formed antlers. The recovery of pollen from the seized deer velvet did prove the deer had been killed illegally and thus led to a conviction of the poacher. Finally, forensic palynology in the United Kingdom began when Patricia Wiltshire (1993) first used pollen in helping to solve criminal cases in the United Kingdom. Since the early 1990s, the United Kingdom has led the world in the routine application and use of forensic palynology as part of many criminal investigations.

In the United States, there appeared to be little interest in following the examples set forth in the United Kingdom and New Zealand in using forensic palynology until after the destruction of the Twin Towers of the World Trade Center in New York City on September 11, 2001. Terrorists, using commercial airplanes flown into the two skyscrapers, claimed the lives of over 3,500 innocent victims and created an immediate need to learn more about the terrorists who committed that crime. In a search of information, authorities focused on using every known forensic technique, including the use of pollen as a forensic tool. Although the recovered pollen evidence associated with the terrorists did not produce any immediate useful clues, the addition and use of recovered pollen as a new forensic trace evidence tool was finally accepted as being potentially important for future uses in the United States.

Foundations of Palynology

To use forensic palynology effectively and to explain its potentials to others, one needs to understand factors that control the type and amounts of pollen and spore production and how those pollen and spores are dispersed. Among the cryptograms, spores are dispersed into either air or water and use those mediums as a transportation vector. Among the gymnosperms, all species produce wind-dispersed pollen. In angiosperms, the vast majority of species now rely on insects, birds, or mammals to vector the pollen from one plant to another. A limited number of angiosperms still rely on wind dispersion for its pollen.

All of the spore and pollen species that rely on wind dispersion generally produce large numbers of spores or pollen because of the inefficiency of wind dispersion. Conifers and some of the angiosperm species are capable of producing hundreds of millions of pollen grains per plant, and some spore-producing species, such as *Ganoderma* (Kadowaki et al. 2010), reportedly produce and disperse several billion spores during one annual dispersal period of about 6 months. The large number of produced pollen and spores cast into the air, and the inefficiency of that technique provides large numbers of essential clues that are captured as part of the pollen rain at each location. That unique mixture of airborne pollen and a few insect-pollinated pollen and spores at each location is what forensic palynologists primarily rely upon for clues related to a specific crime scene or to assign geolocation to some object of unknown origin (Fig 1). Some pollen grains are tiny, are lightweight, and are aerodynamically designed to travel easily in air currents, while other wind-pollinated types, which are larger and heavier, do not usually get dispersed far from their source. Some pollen grains have been recovered more than 1,000 km from their nearest known source, but as a general rule, the vast majority of airborne pollen and spores do not travel too far from their dispersal source, which in many cases means that much of the pollen falls to the surface within a radius of about 100 m (Tauber 1965) (Fig. 1).

Although the large number (about 75 %) of angiosperms that rely on some type of insect or animal vector to transport their pollen grains usually produces miniscule amounts of pollen, which often range in number from as few as 10

up to about 1,000 pollen grains per anther, their pollen is often a key component in any forensic sample. By design, the non-wind-borne plant species produce pollen grains that are often highly ornamented, are thick walled, have a heavy mass, and are covered with sticky lipids and waxes. Those are all factors that make for the ideal transport of pollen by some animal or insect vector. The ornate surface ornamentation of these pollen types is designed to hold sticky lipids that will keep the pollen grains firmly stuck to the hairs or bodies of pollinators until those pollinators land on another flower. At that point, the sticky surfaces of the attached pollen grains adhere to the surface of the stigma of a new flower, and if a pollen grain falls in the right location, fertilization will occur. The thick pollen walls and heavy mass of these insect- and animal-pollinated types ensure that the fragile contents of the pollen grains remain protected from abrasion and sudden changes in humidity during the flight time from one flower to another. From the above reasons, only rarely do pollen grains from these types of plants become part of the normal pollen rain of a location. Nevertheless, it is that characteristic that becomes especially useful in many types of forensic situations.

When people or objects come in contact with insect-pollinated plants, especially ones that might be in flower, some of the sticky pollen can often be transferred from the plant's leaves or flowers to the person or object. Because most of these types of pollen become associated with people or other objects "only through direct contact with the plants," that type of evidence, when linked to similar plants at a crime scene, can infer evidence of direct association. The highly unlikely argument that such pollen grains were deposited on a person or object by accident from airborne sources as part of the normal pollen rain makes these types of pollen grains an ideal evidence for direct association. Another advantage of many of these insect- and animal-pollinated types is that their sticky surface, durable pollen walls, and ornate surface morphology enable them to adhere firmly to objects they touch. Even after persistent attempts to remove all such pollen traces from objects associated with a crime scene, some of these pollen types often remain and can help to place a suspect at the scene of the crime (Milne 2005).

Utility of Forensic Palynology

The analysis of pollen and spores (collectively called palynology) is recognized as an effective forensic tool for a number of reasons. First, many types of pollen-producing plants (angiosperms and gymnosperms) and spore-producing cryptograms (algae, fungi, ferns, mosses, liverworts, etc.) disperse vast quantities of pollen or spores as part of their reproductive process. For most of these, they rely upon wind currents to carry these single-celled pollen or spores from the dispersal source to another location where they can carry out part of the reproductive cycle. Because this process is haphazard, the vast majority of these dispersed cells eventually fall to the ground in a thin coating called the "pollen rain." In some regions, the amount of dispersed pollen and spores is so great that once deposited, they can coat exposed surfaces with a thin yellow layer or form a yellow scum on water surfaces (Faegri and Iversen 1989). Although not a precise measurement of the surrounding vegetation, the pollen rain at each location provides a snapshot of that area's vegetation. Even though there is not a one-to-one correlation between the percentages of each plant type in an environment with the precise percentages of each pollen type in the pollen rain, the resulting "pollen print" for each area becomes an effective way to identify each particular region of the world. The precision required to recognize a specific region, based on the pollen print from some forensic sample, often depends on the experience and knowledge of the pollen analyst and that person's awareness of how the presence and various percentages of each pollen type in a sample can often relate to the presence of certain types and quantities of plants.

A second reason why pollen and spores can become effective forensic clues pertains to their tiny, invisible size. All are microscopic in size and the sizes can range from only 1 or 2 μ (1,000 μm is equal to 1 mm) for some spores and up to over 200 μm in size for large pollen grains. Because of their tiny size, many are airborne and can then be deposited or become trapped on almost any type of surface. This means that at any geographical location, pollen or spores from local and even some regional vegetation, or in specific cases, the pollen and spores associated with a crime scene can become effective markers for those locations and can often link a suspect or some object with a precise geographical region or a specific crime scene.

Third, there are over 330,000 different pollen-producing plants and thousands more when adding the cryptogram species that produce spores. However, differences in the pollen and spores of closely related species, or in some instances related genera, may appear so similar that precise identification using only the resolution capacity of light microscopy (LM) is tenuous and sometimes unreliable. In those cases, when needed, greater precision of pollen and spore identification can often be achieved through detailed studies using the higher resolution capabilities of a scanning electron microscope (SEM) and/or the resolutions available with a transmission electron microscope (TEM). Nevertheless, obtaining these greater degrees of precision can be costly and time-consuming because they must rely upon comprehensive SEM and TEM pollen and spore reference micrographs for making direct comparisons. Because of the time and cost of using SEM and TEM, other analytical techniques are now being considered to speed the identification of both pollen and spores, which will be discussed later in this entry.

A fourth reason why most pollen and spores are useful as forensic tools is that the majority of them are highly resistant to destruction or decay. This is why the oldest geological evidence of organic material, related to plants, comes from what is believed to be very ancient spores (Faegri and Iversen 1989). This ability to remain preserved for hundreds or even millions of years means that pollen and spore evidence, if collected and stored properly, can still be used effectively many years after some event has occurred. In one such case, pollen and spore evidence collected more than 30 years ago from the clothing of a murdered victim was examined and then used to help identify where that person may have lived prior to being killed.

It should be noted that even though pollen and spores are resistant to decay, in certain types of oxidizing environments, they can degrade very rapidly and disappear completely in only a few months or years. In addition, studies reveal that in certain types of depositional environments, such as alkaline soils, certain fragile types of both pollen and spores can degrade almost immediately, while other types remain in pristine or recognizable conditions for many decades or hundreds of years (Traverse 2007).

In some regions, and in some countries, law enforcement personnel continue to expand the types of collected evidence they hope can reveal pertinent information based on the trapped pollen and spores. The list of items that can trap pollen and spores, and thus are being collected and examined, has become almost limitless (Mildenhall et al. 2006). During the past decade, a partial list of items that forensic palynologists have been asked to examine for pollen and spore evidence includes the vacuum contents trapped on the pages of books or on various documents, material trapped on the surface of weapons or inside homemade bombs, pollen and spores collected in air conditioning filters or in air filters from different types of vehicles, pollen and spores trapped on or in all sorts of transportation ranging from boats and airplanes to trucks and bicycles, briefcases, illegal and counterfeit drugs, laptops and cell phones, all sorts of clothing and the contents in suitcases, pollen and spores from victims that were buried, and even the pollen trapped on pieces of wire and shoelaces. Pollen and spore evidence examined by other forensic scientists has also been used to resolve situations involving forged documents, fake antiques, authentication of paintings by master artists, removal of artifacts from historic or archaeological sites, illegal poaching of animals or fish, and cases involving the illegal pollution of the environment (Mildenhall et al. 2006).

Although forensic palynology has been accepted as a proven tool by some, it does need to be pointed out that the reliability of using pollen and spore data as forensic trace evidence is often called into question by courts and law enforcement officials, particularly in the United States. Because forensic palynologists often present their results as relative percentages of various pollen types within the total pollen and spore composition of a sample, some question the uniqueness of such data, especially when a forensic palynologist attributed a sample to a single location or to an actual crime scene. Questions often arise about the precision of the overall pollen data and the precision of identification of individual pollen taxa.

Forensic pollen specialists generally present their conclusions in terms of probability of association and often cite the importance provided by the combination of many pollen and spore taxa in a single sample. Often when challenged to produce "statistical data" that could be used to support or negate the importance or relevance of a pollen sample, or the potential link of a pollen sample to either a suspect or to a crime scene, the palynologist cannot effectively do so. This inability to provide statistical confirmation results from an almost endless list of variables that influence the deposition of pollen types and their ratios within a single sample deposited on some surface or person. Even though some scientists have championed the limited use of statistical techniques, most types of statistical analyses cannot be adequately adapted in ways that will test the multiple unknowns or conclusions based on forensic pollen assemblages (Mildenhall et al. 2006).

One question that is frequently raised during investigations or in court focuses on whether or not two different locations will signal identical pollen spectra. The chance of that occurring is virtually impossible and thus far, an identical match in the pollen spectra at two different locations has yet to be proven. The unlikeliness that this possibility would occur depends to a great extent on how precise the attempt might be. Experience has shown. Minimal pollen counts of only a few 100 pollen grains from comparative samples collected at two separate locations might suggest that both locations appear nearly identical in terms of their pollen signatures. However, as the pollen signature of each sample is refined by counting larger numbers of pollen grains and spores from each sample, the potential of both samples providing nearly identical pollen spectra disappears. The list of variables at any given location is numerous, and each one contributes in some way to the formation of a pollen spectrum for that location, which in turn produces a pollen spectrum unlike those from similar locations.

Instead, the focus should be on the knowledge, skill, and research experience of the pollen analyst and on the discussion of which variables may have been a factor in producing the pollen assemblage in question. The reputation, previous work, and the acceptance of the person's skills by courts and by other forensic palynologists should serve as a guide to support the conclusions of competent scientists and also prevent evidence and testimony being accepted from less-skilled or under-qualified individuals.

Types of Forensic Palynologists

There are essentially two types of forensic palynologists, based upon the types of information or investigations that are being usually undertaken. Although some forensic palynologists are called upon to work in both areas, often each group tends to specialize and focus mostly on one type of needed information. The primary type of forensic pollen specialist becomes directly involved in the investigation of crimes as they pertain to situations involving victims, suspects, actual crime scenes, and items suspected of being associated with one of the previous situations. These individuals generally work directly with local, state, and national law enforcement agents, they usually work within a law enforcement agency or established forensic lab, and they are generally included as part of the forensic teams that are the first to reach crime scenes. This type of forensic palynologist relies on his/her botanical knowledge, previous experience, and an ability to evaluate a crime scene and/or other places of forensic interest. He/she should determine what types of comparative pollenreference samples need to be collected to properly reflect the pollen print of the crime scene and can also be used later for comparisons between the crime scene and evidence recovered from potential suspects and other items. These forensic palynologists need to have training in palynology, plant ecology, and plant taxonomy and should also understand the relationships of those botanical areas to other crime scene features such as, soils, past vegetational changes, and the topographic features of the landscape in and around the general region.

The other type of forensic palynologist worked mostly with questions related to geolocation. In other words, this type of individual is often called upon to examine items related to crimes, items of unknown origin, or items associated with threats to national security or terrorist activities. The goal in each of those types of studies is to determine the geographical location where such items originated or were used. For scientists working in this second area of forensic palynology, their background and training should include all of the areas and aspects needed to conduct the first type of forensic work, but in addition, they also need other related types of expertise. These individuals should have a comprehensive understanding of pollen and spore dispersal patterns, pollen productivity as it pertains to different taxa, knowledge about how topography and climatic conditions can affect the potential pollen rain in a region, pollen sinking speeds and potentials of key types of both pollen and spores being recycled, and access to an extensive pollen database covering many potential pollen and spore types found in different geographical regions from the Arctic to the equatorial tropics in all of the major continents.

One of the problems that also affect potential geographical interpretations, based on recovered pollen and spore data, is the never-ending process of expanded and new plant distributional ranges related to the introduction of agricultural or ornamental plant species into new regions of the world, the natural catastrophes such as volcanic eruptions and fires, or the widespread changes in landscapes created by human modifications. Before the Age of Discovery and the worldwide expansion by European nations, if pollen from key types of plants, such as maize (*Zea mays*) and chili peppers (*Capsicum*) (native to the New World), *Melaleuca* (native to Australia and some areas of Southeast Asia), and tamarind (*Tamarindus indica*) (native to Africa), were found in a forensic sample, it could be linked quickly to some specific geographical location. Today, however, those plants, and hundreds of other ones, have become almost pandemic and their pollen is now found in many regions far beyond where those plants were once restricted. Therefore, a major problem confronting these types of forensic analysts is an understanding of the potentials in each world region for the introduction of foreign ornamentals that are not native to those areas.

Collecting Forensic Samples

For those forensic palynologists, who work closely with law enforcement personnel, an early arrival at a crime scene is often essential. Pollen and spores at a crime scene are easily disturbed, removed, or contaminated with unassociated pollen and spores that arrive on the clothing of law enforcement personnel and forensic teams investigating the crime scene. Ideally, the forensic palynologist should be given early access to a crime scene so that careful studies of the plants and pollen sources can be collected, noted, and photographed. Normally, the forensic palynologist will need to collect undisturbed comparative samples of surface soils of various locations in and around the actual crime scene, which, when analyzed, form the basis for comparisons with future pollen evidence thought to be related with the crime scene. Unfortunately, potential comparative samples collected improperly or gathered by untrained personnel can often endanger the reliability of the pollen evidence or render samples useless as evidence. Such problems can also provide a basis for the dismissal of evidence in court.

One should collect many reference or comparative samples from a crime scene. Sometimes control samples need to be collected from both sides of a path or walkway or from a series of closely spaced areas in and around a crime scene. Without this type of precise knowledge, it becomes difficult to argue either for or against the confirmed association of a pollen assemblage found on a suspect's shoes, or car, or clothing, with the pollen types found at the actual crime scene. Therefore, even though a large number of comparative samples might be collected from a crime scene, not all of them may need to be examined. However, because the pollen spectrum in each comparative sample may vary slightly in reference to the pollen types and percentages of each taxon, the combined pollen spectra from a variety of comparative samples provide a potential range of pollen variation that can be expected in and around the actual crime scene. Once a crime scene has been trampled upon by law enforcement personnel, teams of forensic specialists, and eventually by others who might be curious about the events that took place, the value of collected pollen evidence is reduced and those samples become subject to suspect from post crime pollen contamination or removal.

An example that illustrates the importance of collecting adequate numbers of control samples focuses on samples collected from the ground where a sexual attack occurred. A woman was kidnapped at knifepoint while jogging in a New Zealand city park. She was then sexually assaulted and killed in a nearby wooded area. A man who lived near the park had been seen near the jogging trail in the park just before the woman disappeared. Later, when questioned by the police, the man admitted being in the park, but denied he had seen the victim and said he had never been in the nearby wooded area. A search warrant was granted and items of clothing were gathered from the suspect's apartment. Of particular interest were a dark woolen sweater and a pair of soiled pants, which might have been worn during the kidnapping and assault. Pollen studies of the sweater and pants revealed that each garment contained a rich combination of pollen and spores from pines and ferns. Comparison samples collected from the crime scene revealed a dominance of both pine pollen and fern spores. Likewise, the jogging shorts worn by the murdered woman also contained pine pollen and fern spores.

The pollen spectra from all three groups of samples (suspect's clothing, comparison samples, jogging shorts from the murdered woman) were consistent and revealed that the only way so much pine pollen and fern spores could have become trapped in the clothing was that both the victim and suspect must have struggled on the ground in the wooded pine forest where there was only one local area an understory covering of fern plants. Because pine trees are not native to New Zealand and are used as ornamentals in parks and grown for its timber, there was only one local area near the park where both pine trees and ferns grow together. Thus, the pollen evidence did not prove the suspect was guilty, but it did show he had been in the same wooded area where the crime scene occurred; an area he denied he had ever visited (Mildenhall 1992). As with all types of forensic trace evidence, it is essential to keep accurate records and photographs of how and where each comparison sample was collected, ensure that complete records of the chain of custody are maintained, and provide detailed information related to the method of analysis and the steps taken to provide for security of the samples when not being directly examined. When doubt can be raised about the possible contamination of a forensic pollen sample at any point between the time of collection and the time of final analysis, then that sample is compromised as evidence, even if it might clearly establish a link between a suspect and a crime.

Once all control samples have been collected, they should be stored in airtight, contamination proof containers that are clearly marked. Because comparative reference samples might contain moisture, which could encourage the growth of microbes, a microbe-killing solution, such as alcohol, needs to be added to each sample. Another alternative, which is effective, is to place samples in cold storage at or below 0° C, which will retard the growth of most microbes and will not damage the pollen or spores in the sample (Holloway 1989).

There are three potential areas where forensic pollen samples could be ruined or compromised. The first area is during the collection phase, the second area is during the extraction of pollen from the matrix material of collected samples, and the third area is in the identification and analysis of the collected sample.

Forensic palynologists often only have very small amounts of evidence material available for analysis; the exception is the collected comparative samples at a crime scene where ample amounts of soil can be collected for each sample. There is almost no limit to what types of pollen and spore samples one can collect as potential evidence because their tiny size enables them to become trapped on or in many different types of surfaces (Mildenhall et al. 2006). For instance, items sampled for pollen evidence include a tissue wipe of a tabletop, leather shoes and sandals, a shoelace from a boot, a piece of crumpled electrical wire from an explosive device, the vacuumed contents from pages in a book, dust vacuumed from the keyboard of a laptop computer, pollen trapped on tape used to wrap a package of illegal drugs, the lint trapped in the pockets of a pair of pants, and pollen and spores vacuumed from all sorts of clothing, backpacks, suitcases, rugs, and vehicles.

Samples used for forensic pollen evidence offer several major challenges during the extraction process. First, often there is very little material sample and thus the extraction procedures selected must be the right ones for the sample. Although some samples do not present much of a challenge, others do. Samples containing microscopic charcoal flecks or soot and samples collected from various types of oils and grease can present problems when trying to remove the pollen from those matrix materials. Other types of difficulties arise when examining samples vacuumed from polyester clothing or other synthetic materials, which contain many fibers and fiber fragments that resist most forms of chemical digestion or turn into partly digested globs that stick to pollen trapped in the sample. Second, because most samples cannot be replaced, great care must be taken not only to prevent contamination but also to prevent the loss of the pollen sample during the extraction process. Lab accidents must be avoided such as the accidental spilling or breaking of beakers or test tubes containing a sample, mixing of samples, using incorrect chemical reagents, or not keeping samples tightly sealed throughout each stage of processing. The primary objective in most cases is to remove as much debris in the samples as possible, thereby freeing the pollen grains for analysis and preventing remaining debris from obscuring part or all of the individual pollen grains during analysis. This means a forensic sample's matrix material will not be available later for other types of forensic testing. If planned studies of the DNA, isotopes, trace elements, hairs and fibers, or other sample contents are planned, they should be completed before pollen extraction occurs. In those types of situations, however, great care should be taken to avoid any pollen or spore contamination of the sample. There are a number of reliable extraction procedures that can be used to prepare forensic pollen samples for both light microscopy and for scanning electron microscopy analysis (Faegri and Iversen 1989). The choice on which procedures to use will be dictated by the type of sample and by the type of matrix materials in the sample.

Microscopy and Other Analytical Techniques

The primary analytical techniques used in forensic palynology is light microscopy because it is easy to use, and most of the identification keys and atlases (printed and on web sites) rely on LM images as guides to the identification of pollen and spore types. LM is also a fairly fast technique that, in most cases, is adequate for determining the ratio of each pollen or spore type in the total pollen and spore spectrum of a sample. Thus, it is often the combined identification of both the pollen and spore taxa and the abundance of each type that provides the critical data needed for analytical precision. The primary problem with LM is that the resolution capability is limited to about 0.3 μm even using the best optimal microscopic lenses available (Jones and Bryant 2007). That resolution ability typically limits the identification of pollen and spore in some groups to the family level (i.e., Cupressaceae, Poaceae, and Chenopodiaceae) and others to the generic level (i.e., *Pinus, Quercus, Artemisia, and Eucalyptus*). Unfortunately, when using LM analysis, it is rarely precise enough to identify most pollen types confidently to the species level. Therefore, when added precision is needed, the forensic palynologist must rely upon some other technique, such as the higher resolution ability provided by both SEM and TEM (Milne et al. 2005).

Some analysts have been asked to examine entire forensic pollen samples using only SEM in an effort to gain the added precision of pollen and spore identification to the species level. Analyzing samples using only SEM is time-cosuming, costly, requires access to expensive equipment, and assumes that the forensic palynologist has the expertise and familiarity with SEM usage to ensure accurate results. An added problem of conducting SEM analyses of forensic samples is that one must have access to a large databank of SEM images of all the potential species in a genus in order to ensure the correct identification, to the species level, of pollen grains found in samples. Although this can be done, and has been done (Jones and Bryant 2007), these techniques are rarely feasible based on the funding constraints facing most investigative agencies.

The search for new techniques that could increase the accuracy and identification of pollen and spores in forensic samples has focused on a number of analytical techniques often used with other types of forensic samples. One of these is the use of Raman spectroscopy.

Raman spectroscopy has gained praise for its use in forensics as a successful analytical tool. This praise is based on a number of advantages of Raman spectroscopy, which makes it ideal for applications in the field of forensics. First, the techniques used in Raman spectroscopy are rapidly changing as improvements broaden its potential uses. Second, Raman spectroscopy is a nondestructive technique meaning that samples do not have to be destroyed or changed in order to enable analysis. Third, Raman spectroscopy is quick because it does not require any special type of sample preparation prior to examination.

This means that forensic pollen samples can often be examined first using Raman spectroscopy rather than having to wait until other types of analyses have been completed, each of which might alter or contaminate the original sample. Fourth, only minimal amounts of material are required for a complete analysis, which means that tiny amounts of a sample, containing pollen and spore evidence, can be effectively examined. Fifth, Raman spectroscopy is highly sensitive to slight differences in the molecular and chemical composition of materials, which enables it to detect very small differences in samples. That type of high-resolution potential is important where minor differences are essential to distinguish one type of pollen or spore from all others (Ivleva et al. 2005).

A significant drawback of Raman spectroscopy for use in forensic pollen studies, however, is that the identification of pollen and spores down to the species level requires the construction of high-resolution spectral maps for each taxon. To construct such spectral maps for just 1 pollen or spore species requires an estimated 360–720 h of time gathering and storing the needed data. Therefore, the amount of time and cost expenditures required doing this type of analysis on samples containing a variety of pollen and spore species is usually considered unreasonable. An additional problem is that conducting and interpreting the signatures of Raman spectroscopy require a special expertise, which most palynologists may not have.

Although a few studies have shown that successful spectral signatures can be used to identify specific types of pollen using Raman spectroscopy (Manoharan et al. 1991), the use of this technology in forensic palynology is hindered by a number of problems. First, very few pollen species have spectral signatures that could be used for comparative purposes. Even if more pollen spectral signatures were desired, the very large investment of time and effort to obtain these signatures for each new species would be impractical. Second, a major problem with Raman spectroscopy is that for any given forensic sample, it might provide identification for some of the pollen and spores, but it could only offer statistical ubiquity rather than quantitative percentages of each taxon in the entire forensic sample. Finally, in some cases, it appears that Raman spectroscopy cannot identify some pollen types with certainty. After mounting fresh *Celtis* (hackberry) and fresh *Cannabis* (hemp, marijuana) pollen, it was noticed that some of the pollen grains in each group were folded, deflated, broken, and overlapped with other grains or were partly covered by pieces of debris. When setting the laser beam on specific targets within each group, the resulting Raman data for each group and between both pollen types was not conclusive enough to provide the certainty of identity that would be needed for accurate identification of those pollen types to the genus level.

Another technology that can aid in the identification of pollen grains in forensic applications is Fourier transform infrared spectroscopy (FTIR). This technique uses infrared rays (IR) to stimulate different chemical bonds in pollen grains that vibrate at certain known frequencies when excited. When the surface of a pollen grain is bombarded with an IR beam, the transmittance and reflectance of the IR beam occurs at different frequencies, which is measured and translated into an IR absorption plot. By matching the IR plot of an unknown pollen grain with IR signatures of known pollen taxa, the identity of the unknown type can be confirmed. The advantage of using FTIR technology is that it does not require complex sample preparations.

When targeting the surface of a pollen grain, an average depth of 2–3 μm is excited by the IR beam. Experiments using FTIR technology for pollen identifications note that individual pollen grains within a single genus and species will produce similar, yet sometimes slightly different, IR absorption plots depending on various factors such as slight chemical variations in the composition of the pollen wall, and the level of maturity of the pollen grain. These variations within a single pollen or spore taxon can be recognized by developing a FTIR database from multigrain spectra for each known pollen and spore species. Similar to Raman spectroscopy, there are several drawbacks associated with using FTIR technology for pollen identifications in forensics. The number of IR absorption plots for known pollen taxa in the current FTIR databases is limited, thereby decreasing the chance of successfully identifying individual pollen grains. Also, it has yet to be determined if pollen grains in various stages of degradation continue to send the same, or different IF absorption signatures, meaning it is unknown if degraded pollen grains will give the same signature as that of a pristine grain of the same species. Finally, there remains the problem of quantification of pollen and spore taxa in terms of the ratios of each type in a forensic sample to all others types present. Similar to Raman, FTIR can determine the "presence/absence" of individual taxa, but it cannot determine how many individual grains are present in a sample (Gottardina et al. 2007).

DNA analysis, a common technique used by many forensic laboratories, could potentially aid in pollen and spore identification. Recent evidence has demonstrated that a DNA signature can be recovered from a single pollen grain. DNA in pollen grains, however, can only be found in the cytoplasm inside the walls of a pollen grain. Once the cytoplasm degrades or is lost through rapid decay, the DNA signature is lost. Since this technique, as related to individual pollen grains, is still fairly new, the recovery methods, techniques to isolate individual pollen grains from the surrounding matrix materials, and adequate polymerase chain reaction (PCR) replication and identification database constructed from existing pollen DNA are still in the testing phase. Another problem concerns the type of pollen evidence that is used for forensic interpretations. Since DNA can only be recovered from viable pollen, using DNA signatures one could not identify nonviable pollen or degraded pollen in a sample (Zhou et al. 2007). Therefore, this type of data recovery would provide only limited results in terms of the total pollen present in a forensic sample. Another potential problem with using the DNA of individual pollen grains is that even with an adequate databank of information, it still may not be possible to identify individual pollen grains in a sample. That potential exists because certain species of plants can easily hybridize with other species of the same genus producing an F1 generation. Studies of the DNA signatures from other types of plant material, such as leaves and wood, reveal that the DNA of F1 plants is not identical to either of the parent plant sources (Schaal et al. 1998).

Unfortunately, DNA, Raman spectrometry, and FTIR analysis methods will provide only ubiquity types of data related to the pollen types in a sample. Instead, what are essential elements in forensic pollen studies are quantitative counts of the relative frequency of each pollen taxon. Finally, aside from the other already mentioned limitations created by the data obtained from the DNA of individual pollen grains, the ultimate cost and time needed for this type of study make it unsuitable for forensic pollen analyses.

Similar to DNA analysis, stable isotope analysis is another important analytical technique that is gaining added use in forensic science. The advantage of this principle is that isotope ratios in organic and inorganic materials retain a record, in their molecules, of conditions that existed when that material was created (West et al. 2006). Using that principle, studies reveal that pollen grains contain recoverable isotopic signatures that can be recovered and mapped. During the last decade, scientists have attempted to recover the isotope signatures recovered from individual fossil pollen grains and then use those data to provide information about the environmental and climatic variations that existed where the pollen grain was generated. Further studies have revealed that stable isotopes of individual pollen grains from different plant families and different genera, and in some cases even individual plant species, generate unique isotope signatures. However, the major problem those scientists have encountered when trying to do isotope studies of individual pollen grains is how to isolate and concentrate the pollen grains in a forensic sample and remove them from the various types of surrounding matrix material. Thus far, the various chemical treatments designed to concentrate pollen and remove non-pollen debris in forensic samples alter the molecular composition of the pollen wall (Loader and Hemming 2000, 2001).

Similar to Raman spectroscopy, DNA, and FTIR, this type of study using isotopes would provide only ubiquity data. Finally, isotope studies of individual pollen grains would be very costly, time-consuming, and extremely complicated, thereby limiting its effectiveness as an analytical technique in forensic palynology (Loader and Hemming 2004).

Case Studies

Forensic palynology has been used to assist in the solving of a variety of criminal cases. In one instance, a suspect with a large quantity of cannabis resin was arrested at a port in New Zealand. Authorities believed that the cannabis was grown outside of New Zealand and they wanted to test their hypothesis. Several subsamples of the cannabis were tested for pollen and spores, which were then analyzed to determine whether or not the cannabis came from New Zealand. All subsamples yielded a similar pollen and spore spectra that included plant sources that are not indigenous to New Zealand. Based on the pollen and spore evidence, authorities were able to confirm that the cannabis was imported from Asia and was not from a locally grown crop (Mildenhall 1990).

Forensic palynology can also help to resolve murder cases. In 1999, the body of a man was discovered in a mountainous region north of Wellington, New Zealand. An eyewitness claimed to have seen another person with the victim in the area where the murder took place. Based on evidence, a suspect was arrested and a search revealed that the suspect had the distinctive type of clothing, which has been described by the eyewitness. To verify the eyewitness' claim, the suspect's clothing, camping gear, and other accessories were analyzed for their pollen and spore content. The recovered pollen and spore assemblage from the suspect's clothing and backpack gear closely matched that of a mountainous region where the victim had been found. Although the pollen and spore evidence did not confirm the guilt of the suspect, it did show that the suspect had been in the immediate area where the crime had occurred and where he had been seen by the eyewitness (Mildenhall 2004).

In another case, a murder victim was found in an excavated depression wrapped in a bedcover in West Yorkshire, England. To determine whether or not the victim was murdered where the body was discovered, investigators sampled the bedcover and the victim's hair for pollen. Upon analysis, the recovered pollen from the bedcover and victim suggested that the murder had taken place in a household garden and not where the body was discovered. Wood ash was also recovered from the victim's hair, suggesting that the victim had been near a fire at the time of death. About a year later, a suspect was identified, and the recovered pollen spectra that had been recovered from the murdered victim and from the bedcover were compared with comparison soil samples collected from the suspect's garden. Multiple samples were taken from different locations around the suspect's garden and property. Not only did the pollen recovered from the bedcover and victim's clothing match that of the suspect's garden, but it also contained wood ash that matched an area next to a bonfire that had been constructed by the suspect. The pollen evidence did not confirm the suspect was the murderer, but it was important because it linked the victim and the bedcover to the suspect's garden and property (Wiltshire 2006b).

Summary

Forensic palynology is a predominantly underutilized field. Only recently have some governments and law enforcement agencies around the world begun to explore and appreciate the utility of pollen and spores in forensic cases. Among these, the United Kingdom and New Zealand still lead in terms of the number of cases and applications they have explored using pollen and spore evidence. The potential uses of forensic palynology are many and have already been used effectively in instances involving homicide, terrorism, genocide, bombings, forgery, theft, rape, arson, counterfeiting, manufacturing and distribution of illegal drugs, assault, cases of hit and run, poaching, and identity theft. Pollen and spores are microscopic in size and are often produced in large numbers. They can be found in almost any environment and can become attached to almost any type of surface; these are reasons why they have become useful as trace evidence of places where items originated or were used. Although forensic palynology has played an important role in helping to convict criminals and in some cases support the innocence of some suspect, most countries have been slow in adopting this technique. This hesitation often comes from the discipline's lack of notoriety and often an unfamiliarity with how the use of pollen and spores can contribute to as forensic evidence.

More law enforcement agencies should consider using pollen and spores in forensic cases and come to understand the importance of how to collect samples without contaminating them and whom to depend upon for help with the analyses. Pollen evidence has a bright future as one of the types of materials that can be useful in determining the geolocation of some person or object. Currently, there are limited numbers of scientists trained in the field of forensic palynology, mainly because there has not been a demand for their services. This, however, could change if the need to conduct these types of analyses was to broaden. Unfortunately, the training of these individuals cannot be accomplished overnight and thus when the time comes for new forensic palynologists, they will need to be able to meet the needs of law enforcement and others requiring their services.

Forensic Science and Criminal Inquiry

Overview

Often narrowly depicted as the contribution of science to the production of evidence for courts, forensic science fundamentally relies on the extraction of information from physical traces that are remnants of a past action. By searching, scrutinizing, and testing physical traces, forensic scientists gain pieces of information that can bring significant contribution to different dimensions or phases of criminal inquiry.

The practice of this discipline alone does not really make any sense, as it is intimately dependent of the context and the expectations of the criminal inquiry. The decision to attend a scene as well as the process of physical traces detection and collection do not solely respond to technical considerations. They are influenced by different dimensions of knowledge available (such as the physical, immediate, and criminal environments) as well as by policing issues. Considering the distinct phases of a criminal inquiry reveals the manifold functions of the use of physical traces. The exploitation of physical traces provides intelligence or leads that support police investigation, participating for instance to the search for the perpetrator. It plays a crucial role in the reconstruction of the sequence of actions and the clarification of events by putting the information gained from the traces to context. Ultimately, the structuring and thorough interpretation of this information may also lead to the constitution of evidence to be presented and evaluated in court.

Beyond its use within the investigation of a specific case, physical traces hold a potential, still underexploited, to reveal or reinforce connections between offenses, unveiling the extent of a criminal activity or phenomenon. Moreover, the value of physical traces as vectors of information continuously bursts the context of criminal inquiry, expanding its contribution to issues related to security or criminology.

This perspective changes the traditional view on what is expected from forensic science. Requirements and needs are intelligence-led or the result of a trade-off between many parameters imposed by the actual inquiry, rather than based on the routine use of specialized techniques and methods essentially dedicated to the production of evidence for court. This dramatically impacts the way quality is perceived as forensic operations at the different stages of the judicial inquiry achieve different objectives following intelligence, investigative or evaluative processes.

As an event occurs and is recognized as a potential dispute or even an offense, legal systems, whatever their differences and specificities, usually converge to a response in the form of an inquiry. The formal terms as well as the scope of this inquiry may be defined differently according to legal systems, but it generally remains the duty of police forces proceeding under the responsibility or supervision of judicial authorities. The inquiry will have many aspects and examine the event from several angles. One of them whose importance has been growing in the last decades is the use of natural and computer sciences in order to gain information, sometimes also evidence, from physical traces produced during the course of the event. This aspect of the inquiry falls under the prerogative of forensic police units that use the principles and methods belonging to criminalistics in order to detect, recover, record, collect, decipher, analyze, evaluate, and present relevant physical traces (see entry *Forensic science culture*). For several years, this discipline of the police activity has been attracting lots of attention by the media. Movies, reports, and TV shows provide a very compelling, yet skewed, aspect of the use of forensic science, strengthening the illusion of the primacy of science and technology on crime solving and having deleterious effects on several levels of the judicial system (Durnal 2010; Brodeur 2010). On another hand, the utility and efficiency of forensic science in terms of its impact on judicial outcomes or crime solving is questioned (Baskin and Sommers 2010; Brodeur 2010). For instance, the effectiveness of DNA testing, often depicted as the most powerful and reliable physical evidence, has turned to be undisputable for high-volume crimes such as burglary, but much lower for more serious crimes, often violent crimes (Wilson et al. 2010). Besides these two antinomic views of the utility of forensic science to the judicial inquiry, its true contribution is not straightforward and unique, but may occur on different dimensions or levels in the context of the judicial response following an event as well as for other law enforcement activities.

Physical Trace as Fundamental Object of Forensic Science

Forensic science focuses its attention on physical traces that are produced during the course of an event, generally a litigious action. As first emphasized in the first half of the twentieth century by Edmond Locard, a French pioneer of criminalistics (see entry *Forensic science culture*), any criminal activity, considering the intensity it encompasses, implies the exchange of material and thus generates marks or what we call traces. The perpetrator of the action, more often unconsciously, leaves traces on the scene of the action (on the physical environment as on the victims), and he/she takes traces from the scene of the action. The intensity of the action influences the generation of physical traces as more violent or more severe events are prone to end up in massive exchange of traces. Traces then constitute the remnants of this action, its subsisting physical symptoms. By applying the scientific principles and methods of criminalistics, the forensic scientist aims at detecting physical traces, discriminating traces that are consecutive of the action from traces that are not relevant, and exploiting traces to gain information on the source – a person or an object – and/or the sequence of events that produced them. This approach is extremely challenging as the relevant traces may be dispersed on several, also often not known, locations and confused with "background" and/or "contamination" traces, i.e., traces produced by events anterior, respectively posterior, to the relevant action.

Physical traces are the vectors of information about a past action and, therefore, the fundamental element of forensic science scrutiny. But the information on the past carried by physical traces is more often than not fragmentary and does not enable to perfectly depict the sequence of events. Moreover, this information is not directly decipherable. Traces are symptoms of a specific event whose causes are not known and cannot be repeated, but has to be inferred from these symptoms. The detection and examination of physical traces lead to the construction of hypotheses about their causes (reasoning called "abduction" in Peirce's semiotic). With the information that is thus gained, physical traces become signs that provide indications, with variable degrees of reliability and certainty, that serve to the process of reconstruction of the relevant events. These clues provide information that feeds different processes of the criminal justice system and even beyond, e.g., gathering intelligence for the police inquiry, supporting the structuring of evidence for court decisions, or revealing the structure of repetitive criminal activities. Forensic scientists exploit physical traces to gain pieces of information in an approach of systematic questioning, trying to contribute to the fundamental questions the justice faces: who, what, where, when, why, and how. It is obvious that physical traces alone cannot answer comprehensively these questions. The part of the story that scientific clues help to tell is completed by the use of "traditional" human-based information gathered during the police inquiry. Physical traces may corroborate or invalidate hypotheses generated by police investigation; they are also able to bring out new hypotheses leading to unsuspected investigative paths. In the very first steps of the judicial inquiry, generally devoted to police forces, physical traces are used in combination with other clues, such as testimonies for instance, to generate intelligence about an action under investigation (Barclay 2009). A key aspect of the investigation is to implement a collaborative approach between scientists and investigators in order to keep a global view on the case and to develop, as comprehensively as possible, realistic alternative hypotheses, devise an experimental approach to test hypotheses, and search for the most relevant use of specialists and instruments. This is why the forensic generalist, as opposed to the forensic specialist, has a pivotal role during the investigation. It avoids favoring or ruling out premature conjectures. However tempting is the tendency to follow a lead that is favored, such approach must be banned as it encompasses the major risk of neglecting some traces and wrongly reinforcing the confidence in the selected hypothesis (confirmation or contextual bias) (see entry *Cognitive Forensics: Human Cognition, Contextual Information and Bias*).

Physical Traces Search and Collection: Crime Scene Investigation

The existence of physical traces is linked to the remaining presence of substrates or traits in the location and at the time of their search. As noted previously, traces are unconsciously exchanged during litigious actions and constitute remnants of these actions after their completion. But the use of physical traces in a judicial inquiry entails first that they are searched, seen, recognized, documented, and perhaps, collected. These different steps are undertaken during a so-called crime scene investigation that is not only performed when a crime is committed, but whenever a confirmed or presumed litigious action has occurred. The scope of the investigation encompasses then every location where traces relevant to the action under consideration are expected to remain: on the geographic sites where the action took place, at the place of a suspect's residence, in a vehicle used by a suspect, etc. While it is often essentially presented in technical terms in books and manuals, the problematic of the search and collection of traces on a crime scene calls for much wider competencies than solely technical skills (Ribaux et al. 2010a).

Different factors have an influence both on the decision to attend a scene, or not, once a potential litigious action is known (crime scene attendance) and on the manner the scene is processed and searched for physical traces (crime scene processing). First of all, the strategic policies of a law enforcement organization frame the decision-making process to attend a crime scene. Generally, the importance of a case, in reference to its criminal law qualification, and the priority given by organizations for specific security or policing issues rule the strategies and the attribution of resources. For example, cases assessed as important, such as homicides, will often result in a massive deployment of human, time, and material resources to the crime scene investigation, whereas less serious offenses, volume crimes, for instance, will rarely involve systematic crime scene attendance or intensive investigation. Beyond these strategic policies, which mainly rely on legal, managerial, and organizational issues, several knowledge dimensions contribute to the decision to attend a crime scene and to shape the investigative approach. A general knowledge of physical traces' taxonomy as well as of their potential exploitation in the different information processes of a judicial inquiry is a prerequisite to suitable crime scene investigation. The detection of physical traces on a crime scene represents a difficult yet decisive task that requires a solid knowledge of the multiple forms that traces can have. Crime scene investigation is never a passive process. Traces with blurred morphology, such as shoemarks or earmarks, or latent traces, such as certain fingerprints or DNA deposits, cannot be detected by someone who does not know what they look like or is not prepared to anticipate their presence. As emphasized by an aphorism well known to every forensic scientist, generally associated to Alphonse Bertillon who had this maxim displayed in his teaching room, "the eye only sees what it's looking at and it looks only at what is already in the mind." This quote also warns crime scene examiners to go beyond strict procedures and routine by keeping their mind open when processing each specific case. Thus, more than an awareness about physical traces, the process of searching and detecting traces relies on a structured education and training and based on the purchase of a forensic culture (Margot 2011). The preservation, recording, and collection of traces require then technical skills as well as knowledge of the persistence and recovery possibilities of the different types of traces in the given physical environment that is investigated. This specific knowledge is also often a significant parameter that is considered in the decision-making process of crime scene attendance: for instance, for burglary cases, if the chance of recovering relevant physical traces is weak on the basis of the available information, the decision not to investigate the scene will often be made.

Analysis of the immediate environment where the action occurred provides another kind of knowledge that influences the processing of crime scene. Sometimes epitomized as a determination of the modus operandi of the criminals, this analytical process relies on the attempt to reconstruct the sequence of activities in order to orientate the search for traces. As a starting point, the analysis of the immediate situation requires the integration of information about the environment and circumstances of the action. Taking into account this context, the processing of the crime scene can start progressing in the search for traces following an iterative hypothetico-deductive approach. Every piece of information or recovered trace leads to the generation of hypotheses regarding the events. These hypotheses then orientate the search and collection of new traces that contribute to invalidate, reinforce, or discriminate the hypotheses, maybe also suggesting new alternatives. Finally, the decision to undertake a crime scene investigation and the reasoning applied to detect and collect traces are definitely influenced by the knowledge of the general criminal environment. An analysis of the criminal activities informs about the current structure of the criminality and active criminal phenomena. Some litigious actions may belong to the general activity of a same perpetrator or a group of perpetrators, especially considering volume crime offenses that are highly repetitive. Therefore, knowledge about this activity and a priori detection that a given event may belong to a current criminal phenomenon provide valuable intelligence feeding both the decision to attend the scene and the management of scene search. As such, the practice of forensic science through crime scene investigation becomes a decisive instrument of intelligence-led policing (Ribaux et al. 2010b).

From Clue to Evidence: The Manifold Dimensions of Forensic Science' Contribution to the Criminal Inquiry

As an introductory overview, the tension between the omnipotent picture of forensic science constructed with science and technology and the dispute of its efficiency by empirical research was emphasized ► Forensic Science Effectiveness. A similar tension appears when considering the use of forensic science and its utility in the frame of the judicial inquiry. In the first stages of the judicial process, essentially conducted by police investigative units, the use of physical traces is continuously expanding. The types of traces that are searched, collected, and exploited increase, and the range of situations for the investigation of which traces are used extends. Some knowledge indicates that the major contribution of physical traces relies in refinement, checking, and preparation for the trial (Kind 1994), while other researches attribute them little value in influencing decisions during the later stage of the process (Baskin and Sommers 2010). In some aspects, the current contribution of forensic science can lead to harmful and counterproductive consequences as it is presented as a source of miscarriage of justice (National Research Council 2009). Beyond this apparent antagonism, the valuable benefit of forensic science appears in its potential to bring decisive contribution to the multiple dimensions of the judicial process. The criminal inquiry is not a continuous process but a succession of phases, or *times*, that are characterized by distinct aims, distinct reasoning, and distinct ways of using information. Being inspired by the decomposition of the criminal investigation in chapters suggested by Kind (1994) and by the taxonomy proposed by Brodeur (2010), it is possible to assess the multidimensional contribution of forensic science.

Physical Traces Serving the Investigations

The first phase of the criminal investigation is speculative and consists of searching. An action occurred which entails the starting of an investigation handled by police forces. Its main purpose is to clarify the events regarding possible further criminal prosecution (is this a crime?) and to identify the persons involved. In this perspective, the early investigation looks like a quest for information that serves as raw material to support initial generation of hypotheses about the events and the perpetrator. What is expected from forensic science at this time is thus dramatically different from services provided by traditional laboratories driven by court-oriented quality processes: rapid indications about the nature of a trace, even very uncertain, may orient decisively investigations.

The attendance of crime scene enables the detection of physical traces that, as vectors of information about past events, are exploited to gain intelligence. If the traces detected are relevant to explain the activity that is considered, they become clues that can assist in the clarification of the events. In this first phase of the investigation, the detection and collection of physical traces tend to be directed by the concern of the inquiry. The main, if not exclusive, issue to be answered at that time is often the question of "who?" with its two main subdivisions: the identification of the victim (e.g., when a dead body is discovered or when the victim is not known) and the search for the perpetrator. In certain cases, besides the question of "who?" the determination of the nature of the action ("what?") is also a main concern. For instance, the very first stages of the investigation of a dead person focus essentially on the issue of the cause of death (e.g., can the action of a third party be excluded?), the identity of the deceased, and the circumstances of the action.

As instruments serving the police inquiry, the detection and collection of physical traces are largely influenced by its concern. The approach of crime scene processing tends to favor the search for traces that could provide indications on the perpetrator or another participant of the action. This is why the detection of fingerprints and traces containing DNA is often promoted. Indeed, there is a direct association between those physical traces and the individual at the source of the trace. Thus, fingerprints and traces containing DNA are likely to provide information on the searched identity of a person. But the trace does not self-reveal its sources. Let's take the example of a trace left by the finger of an individual. The detection of this trace by applying the suitable enhancement technique and its identification as being produced by a finger (or a portion of friction skin showing papillary ridges) are not sufficient to provide the identity of the individual at the source of the trace. In order to gain this information, it must be compared with reference marks (e.g., ten print cards produced by a known person), and the results of this comparison must be evaluated. This mechanism operates thanks to the availability of databases holding ever-increasing amounts of reference fingerprints and DNA profiles. Obviously, the efficiency of this process relies firmly on how this reference material has been selected. This explains why major efforts are made to collate reference materials within databases and to increase exchanges between existing databases. In parallel, research activities and publications tend to focus on the potential for individualization of such traces, aiming at quantifying the output of the comparison process between a trace and a reference material. This does not however mean that without reference material, such traces are worthless.

Beyond their potential for identification or individualization traces provide above all elimination criteria. In a criminal inquiry process led by the progressive size reduction of a suspect population, the elimination potency of physical traces is a precious contribution (Barclay 2009; Kind 1994). Besides, it is worth to mention that the very first use of DNA in a criminal case in 1986 resulted in the exclusion of a suspect that the inquiry designated as guilty, the confirmation that the case was linked with a previous crime, and then a DNA-based manhunt founded on a progressive reduction of the population of potential suspects (Wong et al. 1987). Technically, the existence of DNA database opens also the perspective for alternative investigative possibilities, maybe more speculative and risky than the conservative quest for individualization. Partial profiles could thus be further exploited, giving a list of potential suspects than would then be reduced by traditional investigation. Familial searches in DNA databases are another example of investigative strategy that already proved to be decisive in some major inquiries, but which however can raise ethical issues that still need to be clarified.

Obviously, information obtained from physical traces detected and collected can also be misleading. As traces are remnants of the past history, the locations subject to scene investigation encompass traces related to the action of interest as well as nonrelevant traces produced either before or after the action. If rapid discovery of the action and efficient scene preservation may significantly limit the addition of "contamination" traces, there is no possible control or influence on vestiges from the history of the environment preceding the action of interest. Thus, on all physical traces that are detected and collected from the crime scene, some of them will inevitably convey pieces of information unrelated with the inquiry. Considered solely, these pieces of information materialize a risk of orientating on misleading paths or even lead to false exclusion. But considered with all other information gathered in the inquiry and after verification, the hypotheses they suggest can be disregarded. This typically occurs when characteristics of a trace do not match with a reference. In this situation, the general attitude would be to exclude the person of being involved in the case. However, this entirely depends on the circumstances of the case and how another origin of the trace is possible.

In the early times of the inquiry, the search and use of physical traces provide information that is neither perfect nor complete but which can be incorporated into the corpus of other pieces of information gathered from "traditional" inquiry. How the investigation integrates these *mute witnesses*, is able to generate relevant hypotheses as completely as possible, and devises experimental tests are central issues to properly use the whole information. Forensic scientists cannot be excluded from this process because they know the informational potential of physical traces and how to identify specialized fields of expertise needed. While this key dimension of the role of forensic science, as a corpus of scientific methods employed to gather intelligence from physical traces, is widely applied by forensic staff and crime scene units in police forces, it is often misjudged by scientific laboratories and the research community that are framed by a paradigm oriented to court concerns. Conversely, they create distance with the investigation in order to keep independence that is supposed to promote their impartiality in the perspective of the trial process.

Reconstruction of the Events: The Structuring of Evidence

As previously emphasized, the criminal investigation process encompasses multiple dimensions. A second phase that usually follows the searching consists in structuring the evidence against a suspect in order to form the decision to prosecute or not (Kind 1994; Brodeur 2010). At that time of the investigation, which begins with a fuzzy delimitation being the belief that an identified individual is the perpetrator of the action, this individual becomes the main focus of the inquiry and the reasoning scheme is significantly altered. All pieces of information accumulated during the first phase of the investigation are scrutinized under the assumption that the identified individual is the perpetrator, revealing elements that corroborate this assumption as well as those that invalidate it. There is a conspicuous risk, associated to this reasoning scheme, to fall in a cyclic argumentation consolidating the assumption of implication of the identified individual (Kind 1994).

This second phase of the investigation corresponds also to a shift of the main concerns of the investigation. As the inquiry tends to be focused on the identification of the perpetrator (and/or his accomplices) in the first phase, all the other issues of the systematic questioning (where, when, why, how, and what, if not already carefully examined) are considered in a process of reconstruction of the action. All pieces of information of the inquiry are sorted and integrated together reconstructing as precisely as possible the sequence of events and their degree of certainty.

This approach is often favorable to unfold new locations where physical traces can be looked for, extending the concept of "crime scene." Materializing the idea of exchange of materials and signs emphasized by Locard, forensic investigation is undertaken in the direct environment of the individual believed to be the perpetrator taking into account the context of the case: at his home, in his vehicles, on his clothes, his shoes, his tools, under his fingernails, etc. In practice, this search is generally not as speculative and open as the one undertaken during the first time of the inquiry. More often than not, it is directed towards the detection of physical traces related to the action or removed by the perpetrator. Such focussed investigation can be very successful if the individual suspected turns to really be the offender. However, it tends to neglect traces that could invalidate the putative link of the individual with the action or to underestimate the value of the absence of traces. Yet the fine reconstruction of the event or the extension of the concept of "crime scene" to new locations can reveal new hypotheses, new paths to investigate. The investigating process is not – or at least should not be – as directed as it seems but remains an iterative hypothetico-deductive process, open to hypotheses' generation and assessment.

The fine reconstruction of the action implies to consider all the available information within the context and situation of the case. It requires also to distinguish different dimensions of information that physical traces can convey (Cook et al. 1998). While the analytical process of the traces often aims at identifying and determining (if possible) their *source*, the reconstruction of the events entails the combination of the different traces as well as the study of their position. The information relating to the source of the traces is then considered within the context of the specific case, enabling to gain hypotheses or clues on the *activity*, i.e., the sequence of events that lead to the production of the set of traces.

The Provision of Evidence to Court

Once the whole inquiry conducts the investigators (or the judicial authority supervising them) to consider they have sufficient information to demonstrate that the perpetrator is identified and the sequence of the events can be reconstructed, they have to prepare a corpus of proofs from the collection of information. Physical traces can also significantly contribute to this third phase of the inquiry, the preparation of evidence to the court. Since they are remnants of the past whose availability in the present is not contingent upon the memory nor the interpretation of an individual, unlike testimonies for instance, physical traces hold a good potential to have the results of their analysis presented as evidence to a court. This requires interpreting the value of the results measured from the traces, assessing their level of uncertainty, and evaluating what this information brings to support the decision-making process of the judicial dispute. In this third time of the inquiry, only a small amount of traces are retained and presented as evidence, assuming they are informative and considering a specified and finite set of propositions. Under its simplest expression, the evaluation of the evidence takes the form of a balance between the probabilities to observe the evidence given two alternative propositions (usually referred as the proposition of the prosecution and the proposition of the defense). This "likelihood ratio" for the evaluation of forensic evidence (issued from the exploitation of traces) is expressed through a Bayesian framework that models how a new information (the physical trace) logically changes a priori beliefs on propositions (see entry *Probabilistic inference in forensic science*). This ratio indicates thus the strength of the evidence.

The use of traces as pieces of intelligence was presented as a collaborative process where some forensic scientists fully participate to the development of hypotheses. This contrasts with the evaluation scheme of evidence oriented to court, which restricts the forensic scientist to provide an opinion only by using absolutely necessary circumstantial information. While forensic scientists assess the strength of the evidence strictly in the eyes of the proposed assumptions, it is left to the judge's duty to integrate this assessment within the context of the case. Due to this fundamental difference, the practice of forensic science has been sometimes depicted as a confrontation of models: the first one promoting the use of traces to gather intelligence for the inquiry and the second centered on the preparation of evidence for the court. In fact, both of these paradigms adopt a narrow, and thus incomplete, view on the dimensions of information that can be generated by the exploitation of traces.

The Unifying Paradigm

But considering physical traces in a semiotic perspective reveals their intrinsic potential and allows to recognize their contribution to the production of information in a unifying paradigm embracing the two models that tend to confront each other. Instead of focussing on the finality of the use of information that can be extracted from traces (intelligence vs. evidence), it is much more relevant to place physical traces in the center of the model, recognizing them as vector of information about an action that belongs to the past. This also brings us to acknowledge the large scope of information traces can convey and to accept that they can be used for different purposes, feeding different reasoning processes: sometimes sustaining speculative and profuse argumentation and sometimes being the object of rigorous assessment based on strict interpretation and evaluation of uncertainties.

From the crime scene to the court, the role of the forensic scientist becomes thus progressively restricted. At the scene, he/she develops hypotheses and elaborates an experimental approach; he/she makes the essential of the decisions to investigate some places, engage technologies, and detect, record, and collect traces. During the inquiry, he/she shares the approach with experts and investigators in a more collective decision-making process. At the court, the decision is entirely the prerogative of the judge and the jury; the forensic scientist limits his role to show how the specific piece of evidence may change a priori beliefs on the propositions coming from prosecutor and the defense.

A Path Forward: Forensic Intelligence

This conception of traces, rather than representing a revolution, refers to the origin of forensic science, when traces were neither entrapped in predefined reasoning schemes nor confined to be used restrictively within the context of a specific case. Moreover, as pioneers of the discipline already identified it, physical traces can also be used beyond the frame of a given case. This additional dimension, referred as forensic intelligence, relies on physical traces to forge or corroborate connections between discrete actions perpetrated by the same offender, to draw an overall view of criminal phenomena, or to follow the evolution of certain types of crime (Ribaux and Margot 2007). The constitution of databases collecting massive amount of traces and information related to them increases the potential to find links between traces resulting from the same source. A systematic use of physical traces as indicators to establish potential links between actions, events, or crimes materializes an extension of the contribution of forensic science beyond the sphere of judicial inquiry, for security issues. While still underexploited, the potential of physical traces to act as semiotic marker of connections between crimes will indisputably gain more and more attention (Rossy et al. 2012). As it does not entail the transfer or divulgation of personal information, the exchange of traces escapes ethical or legal restrictions. Therefore, it will certainly become a major tool for the prevention and the repression of illegal activities occurring beyond administrative, structural, or political borders. Forensic intelligence may extend its scope of application to transregional or transnational volume crimes, to the comprehension of several forms of organized crime (such as to contribute to the fight against drug of abuse trafficking for instance), and to the identification of repeated offenses perpetrated in different jurisdictions.

Far away from the picture depicted in TV shows or in the media, the current needs expressed by law enforcement authorities, judicial authorities and other beneficiaries of the information conveyed by physical traces, lead to reconsider the role and the scope of contributions of forensic science. Forensic scientists must emancipate from the models and reasoning schemes they've applied so far to bring into focus the multiple and nonexclusive dimensions of information that can benefit from the detection, collection, and exploitation of physical traces.

Considering traces in criminal inquiry and intelligence necessitates a shift from the traditional court-oriented laboratory to a better integration in policing. Rather than focusing on the validity of specific techniques used mostly in routine processes, forensic science should much more engage in the resolution of criminal problems. The variety of the contribution and the logical processes, more offensive and risky by nature, have dramatic consequences in terms of the flexibility of standards, harmonized processes, attitudes, and globally on the way to envisage quality management for forensic operations. It necessitates combining quality of services for a court, with integrating to intelligence-led and investigative processes.

Criminalistics; Wrongful convictions

Overview

The relationship between forensic science and miscarriages of justice is complex and paradoxical. Miscarriages of justice are, in a sense, fundamentally unknowable. Forensic science, in the form of postconviction DNA testing, is the data source of much of the little we do know – and much of what we feel we know most securely – about miscarriages of justice. At the same time, forensic science has emerged from those very data as a significant contributor to miscarriages of justice.

Conceptual Framework

"Forensic science" is a broad term encompassing a variety of different techniques for using physical evidence in the investigation of crime. Forensic techniques include document examination, toxicology, pathology, drug analysis, print analysis, impression evidence, hair, fibers, paint, glass, soil, entomology, arson and explosives, gunshot residue, materials analysis, "jigsaw" physical fit matching, ballistics, blood spatter, crime scene reconstruction, computer forensics, serology, and DNA profiling.

"Miscarriages of justice" is an ambiguous term, more commonly used in the UK than elsewhere, that "can be defined in many different ways and nearly in whatever way one wishes" (Nobles and Schiff 2000). For scholars who construe the term broadly, a miscarriage of justice is any legal outcome in which the result is not just. Thus it may include both the conviction of factually (or "actually") innocent persons ("wrongful conviction") and the acquittal of factually guilty persons ("wrongful acquittals"). It may also include the conviction of legally, though not factually, innocent persons, those whom the state was not able to prove guilty to the appropriate legal standard. Arguably, it may also include much broader categories of injustice, such as excessive or insufficient punishments, unfair procedures, or unjust outcomes of nontrial procedures: pretrial detentions, plea bargains, failures to prosecute, dropped charges, closed investigations, and so on. In this sense, "miscarriage of justice" is a broader category than "wrongful convictions," a term with which it is often used almost interchangeably (Huff and Killias 2008). These ambiguities have inspired some commentators to propose alternative conceptual terminology such as "errors of justice," "false convictions," "actual innocence convictions," "unlawful convictions," and "truly innocent persons," none of which has really caught on. This entry primarily employs the generic term "miscarriages of justice," while occasionally referring to "wrongful conviction" or "wrongful acquittal" to designate particular types of miscarriage.

"Wrongful convictions" include at least three categories of cases: the conviction of the factually innocent, the conviction of the factually guilty but legally innocent, and the conviction of the factually guilty through procedures tainted by judicial error (Risinger 2007). Factual innocence (one did not commit the crime) is not the same as legal innocence (the state has not proved one guilty by the appropriate legal standard), though they are often conflated by the public (Nobles and Schiff 2000). The legal terms "convicted" and "acquitted" are not necessarily coterminous with the commonsense terms "guilty" and "innocent," and a trial, strictly speaking, is not concerned with determining "innocence," though its determinations do often come to be equated with innocence, or the lack of it, socially. For scholars with a narrower, legalistic definition of "miscarriages of justice," the procedurally tainted conviction of a factually guilty person would be a miscarriage of justice, but not a "wrongful conviction" (Naughton 2007). Most miscarriages of justice scholars, however, are primarily concerned with the conviction of the factually innocent.

A further complication is how to define "factual innocence." One approach is to rely on the courts, possibly supplemented by the findings of official inquiries or commissions, leading to the rather unsatisfying position that "miscarriages of justice are whatever appellate courts say they are" (Edmond 2002). The position is unsatisfying because courts are stingy about bestowing legal exoneration upon appellants, and many individuals claiming factual innocence are released from prison under procedural rulings, diversion from formal prosecution, or even guilty pleas – thus, without official findings of innocence. Another approach, then, is for external observers to try to make objective determinations of factual innocence. Inevitably, however, such determinations will be open to dispute by other observers. On very rare occasions, extra-legal events may provide strong epistemic authority for labeling something a "wrongful conviction," the classic example being the unexpected reappearance, alive and well, of a supposed homicide victim.

If we focus on the conviction of the factually innocent, a miscarriage of justice is the worst possible outcome of a legal procedure, producing the exact opposite of what it was intended and expected to yield: the awesome power of the state to punish has been deployed against a person undeserving of that punishment. In cases in which a crime undoubtedly occurred, the wrongful conviction is often accompanied by a collateral miscarriage of justice: the failure to punish the true perpetrator. Further adverse side-effects may include damage to the legitimacy of the courts and other criminal justice institutions. Because such outcomes are so manifestly unjust, they have often captured public attention. Such attention always operates on both a personal and a systemic level. In other words, miscarriages of justice are perceived as personal tragedies, but they are also generally perceived as symbolic of justice system failures (Nobles and Schiff 2000).

As an empirical topic, miscarriages of justice are notoriously difficult to investigate. Scholars, criminal justice system actors, and policymakers would especially like answers to two empirical questions about miscarriages of justice: (1) Prevalence: How frequent are they? (2) Causation: What proportion of blame for their occurrence should be assigned to what causes? Unfortunately, satisfying answers to these questions have been impeded by methodological stumbling blocks, of which two are paramount. First, miscarriages of justice are in a fundamental sense unknowable events since, by definition, they are events in which our primary determinant of truth, the criminal justice system, has produced falsehood and labeled it truth (Simon quoted in Gould and Leo 2010). As Gross (2008) notes, "We can't study an event if we can't tell when it happens. This is a severe problem for false convictions since, by definition, we don't know when they occur." What we can study, instead, is a small number of miscarriages of justice that have been *exposed* – been made known to the public. However, everything we know about exposure suggests that exposure is a fortuitous, rather than a systematic, process. Therefore, we do not know the proportional relationship between exposed and actual miscarriages of justice. A second major methodological headache is that the mechanisms typically exposing miscarriages apply to actual cases in a skewed, rather than a representative, fashion. Known miscarriages are skewed toward those serious crimes which attract the greatest legal, media, and public attention. Serious crimes, carrying longer prison sentences, present more time, as well as greater incentives, for the parties to pursue every avenue of redress. The most powerful exposure mechanism of all, post-conviction DNA profiling, is skewed toward a specific set of convictions, primarily rape-murders, that occurred during a specific historical period, disproportionately based on specific types of evidence (Gross 2008; Schiffer 2009; Simon quoted in Gould and Leo 2010; Natapoff 2012). It may be possible to make empirical generalizations about that set of cases, but whether and how to extrapolate from that data set to all relevant cases remains a contentious matter of judgment (Risinger 2007).

What, then, might these two phenomena, "forensic science" and "miscarriages of justice," have to do with one another? Forensic science is used as evidence in criminal prosecutions, and, as such, it may contribute to wrongful convictions. It may do so by erroneously implicating an innocent suspect, for a variety of reasons. Or, it may do so by failing to exculpate an innocent suspect. At the same time, forensic science may also be responsible for averting wrongful convictions by exculpating, or failing to implicate, innocent suspects when they fall under suspicion. Likewise forensic science might contribute to wrongful acquittals by failing to implicate, or even exculpating, a guilty suspect. Or, it may avert wrongful acquittals by implicating guilty suspects. Figure 1 summarizes these possibilities schematically by conceptualizing forensic science as an "independent check" on police investigators' theory of the crime. Of course, as noted above, "forensic science" is a general term encompassing a variety of techniques; the performance of different techniques in this scheme may well vary greatly.

Historical Relationship Between Forensic Science and Miscarriages of Justice

Historically, forensic science and miscarriages of justice were rarely discussed in concert. Certainly forensic science has been cited as a contributor to miscarriages of justice since as long ago as the Dreyfus case. But, until recently forensic science has tended to take a back seat in discussions of miscarriages of justice, compared to other issues like eyewitness identification, perjury, official misconduct, and interrogation practices (Roberts and Willmore 1993). Although the earliest US study of miscarriages of justice mentioned "[t]he unreliability of so-called 'expert' evidence" as

a contributor to wrongful convictions (Borchard 1942), most of the early American studies which attempted to systematically identify causes of wrongful conviction discussed eyewitness identification, false confessions, police and prosecutorial misconduct, bad lawyering, race, failures of the discovery process, and public pressure for a conviction, but made scant mention of forensic science. Radelet et al. (1992) was a notable exception, discussing the use of misrepresented serology and hair evidence to leverage false confessions and misleading medical examiner testimony. As Schiffer and Champod (2008) observed, "forensic science (to convict and to exonerate) is underrepresented and often wrongly understood in research concerning wrongful convictions."

This disjunction between forensic science and miscarriages of justice made intuitive sense because the characteristics popularly associated with "science" would seem to be the antitheses of the characteristics of miscarriages of justice. Miscarriages of justice were thought to be caused by unclear, misguided, or fallacious reasoning, but science is supposed to embody clear, logical reasoning from valid, empirically demonstrable premises. Miscarriages of justice were thought to be caused by unjustified biases against people of certain races or classes, against persons with prior criminal records, or even simply against the police's preferred suspect, but science is supposed to be objective and free of bias. Miscarriages of justice were supposed to be caused by deceitful and otherwise unreliable information from witnesses, informants, co-conspirators, and the like, but science, goes the truism, "never lies." Miscarriages of justice were supposed to be caused by evidence that was less reliable than it appeared, like eyewitness identification evidence, but the very notion of science is associated, in the popular imagination, with high reliability, indeed often with certainty. For these reasons the notion that forensic science might contribute to miscarriages of justice is often treated as ironic because of the popular association of science with notions of "truth" and "certainty." Of course, any sober assessment should clearly understand that forensic techniques, like any other detection system, should be expected to yield errors – both "type I" and "type II" – at some rate (see Fig. 1). And yet, much discourse surrounding forensic science invokes popular stereotypes of science as "certain" in a way that other evidence is not.

The Rise of Forensic Miscarriages of Justice

The discourse on forensic science and miscarriages of justice changed dramatically during the 1990s. In large part this was due to the development of forensic DNA profiling in the mid-1980s, as will be discussed further below. However, even without DNA profiling, enough dramatic miscarriages of justice were exposed during the 1990s to generate a sense of a miscarriage of justice “crisis” (Nobles and Schiff 2000). In the UK, for example, this “crisis” was prompted by alleged miscarriages of justice in a series of Irish Republic Army (IRA) bombing cases, including the 1970s convictions of the “Guildford Four,” “Birmingham Six,” and “Maguire Seven,” some of which involved explosive residue evidence (Nobles and Schiff 2000). Two official inquiries prompted by these cases highlighted the role of forensic science in miscarriages of justice. The 1993 Runciman Report of the Royal Commission on Criminal Justice discussed a number of issues concerning forensic science, including failure to adhere to objectivity and impartiality, problems with interpretation of evidence, failure to communicate findings clearly, inequalities between defense and prosecution resources, defense access to samples, proprosecution bias, expert shopping, quality control issues, and the low accuracy of the residue detection techniques themselves (Edmond 2002). In 1994, the “May Inquiry” discussed the role of forensic science in the Guildford Four and Maguire Seven cases. The May Inquiry primarily blamed individual forensic scientists for the failings of forensic science (Edmond 2002). It has been observed that these cases could only be construed as miscarriages of justice by placing the same sort of faith in the *exonerating* scientific analyses that was – now, supposedly erroneously – initially placed in the *incriminating* forensic analyses (Edmond 2002). While these cases forged a connection between forensic science and miscarriages of justice, the most dramatic role in drawing attention to miscarriages of justice, especially in the US, came to be played by forensic DNA profiling.

Forensic DNA Profiling

The earliest use of forensic DNA profiling, in the investigation of two rape-murders in the English village of Narborough for which Colin Pitchfork was eventually convicted, arguably helped avert a miscarriage of justice in that the DNA evidence exonerated an individual who had emerged as the prime suspect and falsely confessed. Post-conviction DNA testing has exposed hundreds of miscarriages of justice in the US, beginning with the cases of David Vasquez, and then Gary Dotson, in 1989. These were both rape-murder cases in which physical evidence (hair and semen, respectively) presumed to derive from the assailants was recovered and implicated the defendants. However, post-conviction forensic DNA profiling on biological samples presumed to derive from the assailants excluded the convicted individuals. Because the prosecution theories of the crimes required that the defendants be the source of the samples, the two convicts were exonerated and released. Realizing the potential of post-conviction DNA testing to expose miscarriages of justice, the American attorneys Peter Neufeld and Barry Scheck founded the Innocence Project at Cardozo Law School in 1992 as a legal clinic dedicated to such testing. Over the next two decades, the Innocence Project and other independent efforts exposed more than 300 wrongful convictions in the US through post-conviction DNA testing. This set of wrongful convictions has taken on a significance beyond the parties involved in the cases themselves. These high-profile exonerations have drawn attention to the issue of miscarriages of justice, to flaws in the American justice system, and to capital punishment. In part, their significance derives from their ability to be packaged and conceptualized as a “data set,” and disseminated through reports, books, and the Innocence Project’s website. In addition, however, their significance derives from their ability to achieve supposed “scientific certainty” or “epistemological closure” (Aronson and Cole 2009). Alleged miscarriages of justice exposed through post-conviction DNA testing were less vulnerable to the sort of definitional disputes over whether alleged miscarriages of justice should be characterized as miscarriages of justice at all that had dogged previous scholarly analyses of miscarriages of justice. While some post-conviction DNA exonerations may be challenged, even the most determined innocence skeptics concede that the vast majority of post-conviction exonerations constitute genuine miscarriages of justice.

Post-conviction DNA exoneration has largely been an American phenomenon; other countries have not reported a proportionate spate of post-conviction DNA exonerations. Exposure of miscarriages in general seems to occur most frequently in the US and more often in the common law countries than in continental Europe (Schiffer 2009). However, it is unclear whether this difference represents a less frequent *occurrence* of miscarriages of justice because of different procedural safeguards and legal cultures or a less frequent *exposure* of miscarriages of justice perhaps because of less favorable policies on the retention of evidence or post conviction review (Huff and Killias 2008).

Forensic Science as Cause of Miscarriages of Justice

Post-conviction DNA exonerations emerged as a principal, and privileged, source of data about miscarriages of justice. A series of analyses of the post-conviction DNA exonerations were performed which treated the development of forensic DNA profiling as a sort of natural experiment that offered a window into flaws in the justice system. Each subsequent analysis treated a larger number of exoneration cases and was increasingly detailed (Connors et al. 1996; Scheck et al. 2000; Saks and Koehler 2005; Garrett 2008, 2011; Garrett and Neufeld 2009). These analyses were primarily concerned with identifying the major causes of wrongful convictions and roughly weighing their relative contributions. Among the most prominent causes identified were eyewitness identification, false confessions, perjury, police and prosecutorial misconduct, and ineffective counsel. Analyses of the post-conviction DNA exonerations, however, also revealed a paradox. Forensic science was not merely the engine for exposing miscarriages of justice: analyses of post-conviction DNA exonerations revealed that forensic science itself was ranked among the most prominent contributors to miscarriages of justice (Saks and Koehler 2005). Seemingly paradoxically, forensic science was little discussed as a cause of miscarriages of justice until its role was exposed by . . . forensic science.

Some analyses of exonerations have attempted to construct rank-ordered lists of contributory factors. The position of forensic science on such lists has varied. Saks and Koehler (2005) rated forensic science second only to eyewitness identification as a cause of miscarriages of justice, whereas Gross et al. (2005) hardly mentioned forensic science at all. A larger study by Gross and Shaffer (2012), however, lists forensic science fourth among the five leading causes of exposed wrongful convictions. Such measurements must be regarded as crude at best, and they have been challenged by defenders of forensic science (Collins and Jarvis 2009). Among the methodological problems that beset drawing inferences from post-conviction DNA exoneration data are: How should categories of causes be constructed? Should causes be coded for cases whenever present or only when contributing to the miscarriage of justice. If the latter, how would that be determined? How can we quantify the relative contribution of multiple causes to any individual miscarriage of justice when we do not know how much different items of evidence contributed toward the jury’s verdict? Finally, as noted above, post-conviction DNA exonerations are a manifestly unrepresentative data set. They can tell us something about the causes of the subset of miscarriages of justice susceptible to exposure through post-conviction DNA testing, but can tell us much less about the entire universe of all miscarriages of justice. While it seems reasonable to use such analyses as rough indicators of where in a criminal justice system the principal causes of miscarriages of justice might lie, the common practice of characterizing each cause as a proportion of the total number of exonerations risks media reporting that may fuel popular misconceptions. For example, the research finding that 60 % of miscarriages of justice exposed by post-conviction DNA testing were caused in part by eyewitness identification may be misinterpreted to imply that misidentification by eyewitnesses is responsible for 60 % of *all* miscarriages of justice; or even – far worse – that 60 % of eyewitness identifications result in miscarriages of justice.

Bearing these caveats in mind, analysis of post-conviction DNA exonerations clearly shows that forensic science contributed to exposed miscarriages of justice in two primary ways. First, serological evidence which ought to have been interpreted as either excluding the defendant or as having nothing useful to contribute to the fact finder's perception of the defendant's guilt was instead presented to the fact finder as inculpatory. This occurred in 67 of the first 250 post-conviction DNA exoneration cases. Second, microscopic hair comparison evidence that ought, if used at all, to have been conveyed to the fact finder only as failing to exclude the defendant, or perhaps as including the defendant among a very large population that could have contributed the hair, was instead presented to the fact finder as highly incriminating. This occurred in 29 cases. In Canada, meanwhile, the 1998 Kaufman Commission report discussed the role of microscopic hair comparison in contributing to the wrongful conviction of Guy Paul Morin for murder, a miscarriage of justice that was only exposed through post-conviction DNA testing (Kaufman Commission 1998; Roach 2009). Among other things, the report emphasized overstatement of the probative value of scientific findings and failure to disclose possible sources of contamination.

To be sure, these were not the only ways in which forensic science contributed to miscarriages of justice exposed through post-conviction DNA testing. Bitemark evidence, fingerprint evidence, shoe print comparison, voice analysis, and even DNA profiling all contributed to some miscarriages of justice. However, the frequency of such cases was small compared to those involving serology or hair comparisons (Garrett 2011).

Some have suggested that post-conviction DNA exoneration data point only to the failings of specific forensic techniques (serology and hair comparison), rather than to a problem with the larger institution of "forensic science" (Collins and Jarvis 2009). However, transcript analysis reveals that the issue was not merely these techniques' lack of discriminating power, but also repeated exaggeration of the probative value of the evidence by forensic expert witnesses (Garrett 2011). This suggests a general tendency among forensic scientists to exaggerate the probative value of evidence and a general failure of courts to control it. But to what extent is it valid to extrapolate from documented problems with serology and hair comparison to "forensic science" in general?

While serology is relatively undiscriminating and hair comparison may be a forensic technique with limited accuracy, at least part of the explanation for the prevalence of serology and hair cases in the post-conviction DNA exoneration data has to do with the skewed nature of the data set (Gross 2008; Schiffer 2009). Only a small subset of all miscarriages of justice is eligible to be exposed through post-conviction DNA testing. These are typically cases deriving from a specific historical period, in which preconviction DNA profiling was not performed, but biological evidence was preserved; in which biological evidence is recovered; and in which charges are serious enough for convicts and attorneys to make strenuous efforts to obtain post-conviction DNA testing. These cases will be skewed toward sexual assaults and rape-murder cases and away from crimes with lesser penalties (Risinger 2007; Gross 2008; Natapoff 2012). Such cases are quite likely to have relied upon serology – and to a lesser extent hair comparison – at the time of the original conviction. We may thus expect post-conviction DNA testing to be better at exposing miscarriages of justice associated with serology or hair comparison than miscarriages of justice precipitated by, say, fingerprint identification. Even further at the extreme, consider, for example, arson and medical evidence of unexpected infant death which are now suspected of being major contributors to miscarriages of justice (Science and Technology Committee 2005; Findley 2011; Plummer and Syed 2012). Miscarriages of justice involving these forms of medical and scientific evidence are rarely, if ever, susceptible to post-conviction DNA testing. Indeed, in most cases they are not susceptible to dispositive exonerating evidence in any form, in part because the material issue is not the identity of the perpetrator but whether a crime was committed at all (the alternative hypothesis being that the death was accidental) (Naughton 2007; Findley 2011). Usually, the best the convict can hope for is a finding that the court relied upon scientific evidence that is now in doubt and that the conviction, therefore, should be quashed.

Some commentators argue that the post-conviction DNA exonerations offer a window into more systemic flaws within forensic science as an enterprise (Thompson 2008; Garrett 2011). These flaws include biased interpretation of evidence; poor regulation of forensic laboratories (Giannelli 2007); vague, nonstandardized, and misleading reporting of scientific conclusions; and failure to validate forensic techniques. Overlaid upon these problems is the courts' extremely permissive stance in admitting forensic science evidence at trial, despite these documented problems (National Research Council 2009; Garrett 2011).

The exposed cases run the gamut from alleged forensic vigilantism to what appears to have been "honest error" (Schiffer 2009). These are obviously quite different problems which invite different remedies. Vigilantism suggests a sort of generic personnel problem that could affect any industry, whereas "honest errors" seems to indicate flaws in forensic procedures themselves. Assigning exposed miscarriages of justice to specific causes, however, is problematic. Often, it is difficult to determine through post hoc analysis whether a forensic analysis that contributed to a miscarriage of justice derived from malicious intent or honestly held belief. While thorough and transparent documentation of the reasoning behind a forensic conclusion may permit answering this question, many forensic techniques historically have required only the kind of rudimentary documentation of conclusions that would be of little help in determining the cause of an error. In addition, once a miscarriage of justice has been exposed, the forensic analysts involved will usually have retained their own lawyers and have little incentive to speak candidly with auditors.

In sum, while post-conviction DNA exoneration data may be helpful in drawing attention to systemic problems in forensic science and the courts' treatment of it, the two key issues, concerning (1) the prevalence of forensic miscarriages of justice and (2) the relative magnitude of forensic science as a contributing factor, remain matters of speculation and – sometimes heated – debate.

Broader Policy Impact

Despite these methodological limitations, analyses of exposed miscarriages of justice have exerted considerable influence on US public policy, notably in relation to the death penalty. Abolitionists have cited miscarriages of justice exposed – often fortuitously – through post-conviction DNA testing as clear evidence that the risk of executing an innocent person in the American capital punishment system was too great. One federal court even adopted this view before it was overturned by a higher court (United States v. Quinones 2002). Post-conviction DNA exoneration provided an appealing rhetoric in which "science" was seen exposing the unreliability of American capital punishment. However, this rhetoric proved to be a double-edged sword in that some politicians adopted the view that convictions that rested upon forensic science might be viewed as "certain," and thus impervious to the risk of being labeled miscarriages of justice. Forensic science, then, might render capital punishment certain and safe (Aronson and Cole 2009). Such claims obviously belie the understanding of forensic science as a detection system that should be expected to produce a certain number of errors, as a statistical truism (see Fig. 1).

Another area in which these analyses have had an impact is on the movement to reform forensic science itself. Although it may be argued that there are plenty of good reasons to reform forensic science independent of miscarriages of justice – lack of validation of techniques; lack of accreditation, certification, and regulation; lack of basic research; lack of standards; vague reporting practices; insufficient funding; insufficient education and training; insufficient independence from law enforcement; insufficient ties with mainstream science, and so on – high-profile miscarriages of justice have been important in supplying tangible causes célèbres and a *raison d'être* to propel forensic science reform. If it cannot be shown that acknowledged problems in forensic science actually result in miscarriages of justice, policymakers may wonder why forensic reform is necessary when apparently just results continue to be achieved despite acknowledged weaknesses. Such claims are sensitive to what might be called the "base rate of guilt" – if the police present forensic analysts with an extremely high proportion of factually guilty suspects, even very poor forensic analyses may yield very high rates of factual accuracy. Nevertheless, it seems that it is difficult to generate public and political momentum to improve forensic science as an end in itself, so that miscarriages of justice are invariably invoked in official reports urging reform of the forensic sciences. In this essentially presentational and rhetorical sense, recent miscarriages of justice have played an important role in giving forensic science reform more traction than it has been able to secure in the past (e.g., Kaufman Commission 1998; Science and Technology Committee 2005; National Research Council 2009).

Other Sources of Data about Forensic Science and Miscarriages of Justice

In view of the well-known methodological limitations of relying on post-conviction DNA exonerations as a measure of miscarriages of justice, an alternative approach attempts to preempt objections regarding representativeness by studying all relevant cases in which particular forensic techniques have been utilized (Cooley 2004; Giannelli 2007). Yet this alternative research methodology still suffers from the principal problem afflicting all miscarriages of justice research: the fortuity of exposure of miscarriages of justice. It is clearly statistically inadequate to estimate the rate at which a particular technique produces miscarriages of justice simply by treating exposed errors attributable to that technique as the numerator and all cases in which it figured as the denominator of a fraction (Gross et al. 2005; Naughton 2007; Gross 2008).

Another approach is to try to use experimental psychology to model the processes and "human factors" which might cause forensic science to contribute to a miscarriage of justice. There have been several studies of contextual bias in forensic science, developing the argument that biased scientific evaluations or expert opinions may be responsible for some miscarriages of justice (e.g., Schiffer 2009). Schiffer (2009) endeavored to study the relationship between forensic science and miscarriages of justice by interviewing forensic laboratory managers. Contradicting much received wisdom on what causes forensic science to go awry, Schiffer's interviewees suggested that the locus of error might be the crime scene as much as the crime laboratory. They also maintained that more coordination between forensic scientists and law enforcement might reduce forensic errors. This finding is in tension with the contextual bias literature, which tends to imply that forensic scientists should be shielded from "distorting" contextual information about the case provided by investigators and prosecutors.

Conclusion

The relationship between forensic science and miscarriages of justice has received greater attention over the last two decades, but that relationship remains complex. Forensic science, primarily in the form of post-conviction DNA profiling, has emerged as among the most powerful and persuasive exposers of miscarriages of justice. However, in the very process of exposing miscarriages of justice, post-conviction DNA profiling has implicated forensic science – including DNA profiling – as a contributor to acknowledged cases of wrongful conviction. Increasing awareness of miscarriages of justice has lent impetus to the growing clamor advocating reform of forensic science.

Generating empirical knowledge about the role of forensic science in miscarriages of justice poses methodological difficulties that render it difficult to draw firm conclusions. The evidence amassed thus far, however, does indicate that two particular forensic sciences, serology and microscopic hair comparison, played a major contributory role in generating that restricted and unrepresentative set of miscarriages of justice that were susceptible to exposure through post-conviction DNA testing.

The extent to which it is safe to extrapolate that finding to those unexposed miscarriages of justice that may have occurred in other cases or to other forensic science disciplines remain matters of ongoing debate.

Overview

Due to various contexts and processes, forensic science communities may have different approaches, largely influenced by their criminal justice systems. However, forensic science practices share some common characteristics. One is the assurance of a high (scientific) quality within processes and practices.

For most crime laboratory directors and forensic science associations, this issue is conditioned by the triangle of quality, which represents the current paradigm of quality assurance in the field. It consists of the implementation of standardization, certification, accreditation, and an evaluation process. It constitutes a clear and sound way to exchange data between laboratories and enables databasing due to standardized methods ensuring reliable and valid results; but it is also a means of defining minimum requirements for practitioners' skills for specific forensic science activities.

The control of each of these aspects offers non-forensic science partners the assurance that the entire process has been mastered and is trustworthy. Most of the standards focus on the analysis stage and do not consider pre- and post-laboratory stages, namely, the work achieved at the investigation scene and the evaluation and interpretation of the results, intended for intelligence beneficiaries or for court. Such localized consideration prevents forensic practitioners from identifying where the problems really lie with regard to criminal justice systems.

According to a performance-management approach, scientific quality should not be restricted to standardized procedures and controls in forensic science practice. Ensuring high quality also strongly depends on the way a forensic science culture is assimilated (into specific education training and workplaces) and in the way practitioners understand forensic science as a whole.

(Scientific) Quality

Generally speaking, quality represents the attribute of an element that will make this element different from the others; but it also refers to the notion of grade as a *"degree of excellence."* The American Society for Quality (ASQ 2011) defines quality as *"[a] subjective term for which each person or sector has its own definition. In technical usage, quality can have two meanings: 1. the characteristics of a product or service that bear on its ability to* *satisfy stated or implied needs; 2. a product or service free of deficiencies*." Indeed, reaching the highest degree of excellence is relatively symptomatic of the modern society, for which being efficient and effective is mandatory to ensure customers' satisfaction in a commercial competition. Quality management appears to be a key aspect in monitoring performances and in reaching preestablished goals.

Historically, the quality movement finds its roots in the Middle Ages (thirteenth century), where craftsmen started to organize guilds. These professional unions were dedicated to enacting rules to ensure product quality but also to exercise commercial control over their specific activities. As a sign of positive inspection, craftsmen were asked to mark flawless goods. With time, they added a new mark as an indication of origin that turned to be a pledge of quality related to the craftsmen's reputation. During the Industrial Revolution and throughout the twentieth century, the original marking practice of the craftsmen changed through manufacturing sector evolution while conserving an inspection dimension with the quality control of processes. Then, the total quality approach emerged from Japan, where quality assurance was no longer only focused on the manufacturing process, but encompassed the whole organizational process. In the twenty-first century, people are developing new quality control systems that involve not only the manufacturing sector but also areas such as healthcare or education, for instance. These quality systems have been developed to become a widely used marketing tool that controls industrial production, without taking into consideration the individual needs of each area.

Quality management is specific to any sector that wants to be competitive while being effective and efficient. For that matter, striving for quality calls for quality assurance and quality control. Quality assurance is the establishment of a program ensuring that quality standards are met through monitoring and evaluating the different stages of a process. Quality control consists of an aggregate of operational activities set up to meet the quality requirements.

The use of the "scientific" epithet before "quality" appears to give a stronger dimension of objectivity and robustness to that notion. This is often cited whenever science comes into the equation. Paraphrasing Jean Ladrière (1995), science is a critical mode of knowledge (or *"mode de connaissance critique"* in French), being characterized by specific principles and methods used through a reflexive and prospective reasoning process, which enables an extension of its body of knowledge. A way to strengthen a science is to challenge its principles and reasoning using a critical approach; this is achieved by establishing validation criteria used to test and control processes and every aspect of this science. Within that context, it can be assumed that the notion of scientific quality is also part of a critical approach of a science. It involves defining sound criteria of quality that require practitioners' agreement within the scientific discipline in order to evaluate and improve the degree of excellence of methods and processes. The implemented criteria and tools are found in quality management systems to improve performances and to ensure scientists' competencies in applying scientific methodologies. However, setting up quality criteria for a science implies a serious study of its dimensional aspects. It not only pertains to the science's application – this is where a suitable quality management system is of importance – but also to its foundations and philosophy, or more simply to its epistemology. In other words, scientific quality is often considered from the management's perspective in terms of performance when it may be more relevant to consider it from a cultural perspective of the given science (see ▶ Forensic Science Culture).

Within forensic science practice, quality is currently driven by a quality management culture (largely influenced by legal and public funding aspects), whereas scientific quality viewed from a forensic science culture perspective is largely missing.

Quality in Forensic Science

Since quality is defined differently depending on persons or activity sectors, scientific quality in forensic science should be determined by forensic science practitioners and researchers. Willis (2010) introduced this specific notion of quality but further added the need for competencies. She highlighted the Japanese two-dimensional vision of quality, which implies that quality must be adapted to specific needs while taking into account customers' considerations. This position is currently widely shared by the forensic science management communities. Quality notions in forensic science are oriented according to the business relationships between customers (defense attorneys, prosecutors, etc.) and (forensic science) service providers. This approach is clearly dictated by the quality movement coming from the manufacturing sector and driven by public administrations.

This vision was first applied to the laboratory examination stage. This is likely because this stage could largely benefit from methods that were already standardized and because it is the easiest one to get into a quality management system, at least for routine analyses, such as with drug or toxicological samples. Now, international forensic organizations tend to expand that vision to the pre- and post-laboratory examination stages, thus including the investigation scene as well as the opinion and report transmission (see ► Forensic Science and Criminal Investigation). This is where the forensic science culture truly becomes important: Although it was relatively straightforward to define and implement a quality system with laboratory procedures, it is a whole other problem with scene examination or opinion development. The forensic science community struggles today with the comprehensive quality approach because it failed to develop its own approach, instead, mistakenly copying the work from the manufacturing sector.

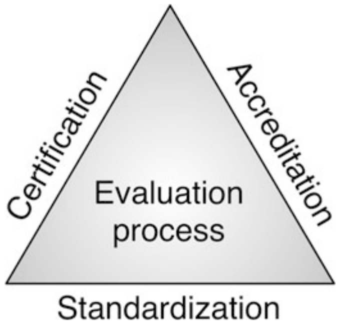
Quality System in Forensic Science Practice

Since the early 1990s, the quality triangle, presented by Lawrence Presley, a former quality assurance unit chief at the FBI laboratory, stands for the "paradigm of quality assurance" (Lentini 2006, 2009) for forensic science. Standardization, accreditation, and certification are the three sides of the quality triangle, which, when assembled together, represents the actual quality management system that should prevail. The evaluation process is used to test different aspects of the institution, such as its degree of expertise and the quality of the processes and results produced by it.

The forensic science quality movement traces its roots back to the mid-1970s when the Forensic Sciences Foundation (FSF), which was funded by the US National Institute of Law Enforcement Assistance Administration (LEAA), conducted a study about proficiency performances in American crime laboratories. The 3-year project had the following objective: "*to determine the feasibility of proficiency testing as a tool to uncover problem areas in laboratory performance*" (Peterson et al. 1978). Two hundred nineteen laboratories from the United States and Canada participated in the project and performed up to 21 controlled tests. Despite results showing a wide range of performances between laboratories, the authors found a positive outcome by stating that "*properly supported, laboratories [could] be extremely proficient*." Since then, crime laboratories and professional organizations, recognizing the heterogeneity of practices characterized by a lack of regulations and quality control aspects, had worked to implement a culture of quality in forensic science. Initially, the American Society of Crime Laboratory Directors (ASCLD) initiated the accreditation process through its ASCLD/LAB (Laboratory Accreditation Board) program. The four conditions shown in Fig. 1 are part of this culture that has expanded over the last 40 years.

Proficiency Tests

Proficiency tests appear to be the starting point of the forensic practitioners' interest for quality issue. Even though they are still performed today, they are no longer the focus point of current quality systems, which are rather based on accreditation programs and certifications. However, proficiency tests represent a valuable process that helps monitor the performances of the institution and, by extension, the robustness



Forensic Science and the Paradigm of Quality, Fig. 1 The quality triangle as paradigm of quality assurance in forensic science

of their quality system. As such, they are part of a whole revolving around the quality triangle and cannot be dissociated from the other quality processes.

Proficiency tests are meant to evaluate different aspects of the service producer's practice. There are different types of proficiency tests. Blind proficiency tests are sent to a laboratory like regular casework, thus rendering the analysts unaware of the presence of an evaluation process. These tests are the most optimal for evaluating the entire process (administrative and scientific) of a laboratory without any bias. On the other hand, failing to pass the test does not enable to accurately identify where the problem lies. Known proficiency tests are usually utilized to evaluate a given part of the examination process. Some proficiency tests are designed to evaluate solely the interpretation process (e.g., a fingermark identification), while some others focus on the examination process (e.g.,, enhancement of fingermarks on a sheet of paper). However, since the analysts know they are working on a proficiency test, different resources may be attributed to the test than when working on regular casework.

As a result, proficiency tests are not limited to the evaluation of inter- and intra-laboratory/practitioners' knowledge, skills, and abilities. They (may) also include the evaluation of laboratory procedures and administration. In any case, they represent a useful tool to ascertain that the requirements for the accreditation process are met. In general, proficiency tests lead to the interlaboratory comparison of the results. This is a way of placing participants *"on a scale of agreements given by the consensus conclusion of the participants' population"* (CTS website). Pointing out potential differences in their conclusions when compared with colleagues and expected results provides an opportunity for confronting the robustness and reliability of methods and constitutes an interesting tool for analyzing what could be practically improved. However, foundations of quality systems are not based on interlaboratory testing, but on standard methods and practices (Lentini 2009).

Standardization

The standardization process consists of a normalization of (scientifically validated) procedures, considered as a valuable attribute of the quality system by forensic science practitioners and their partners (police, magistrates, public). This contributes to enhance the confidence of forensic science partners, presented as customers. However, it is (mistakenly) perceived as an assertion of reliability and validity of measurements and analyses.

Established norms for output format combined with the use of standard methods allow for interlaboratory comparisons and are necessary in databasing. In this regard, the use of a common language is the question that must first be addressed when a quality system is implemented.

Specific sources produce references within the forensic science field such as the following:

Scientific Working Groups (SWG), where forensic practitioners of a specific discipline meet to update their knowledge and, as mentioned in the framework for expert working group of ENFSI (European Network of Forensic Science Institutes), to promote quality assurance, develop professional standards, and harmonize methods.

ASTM International. A significant list of standard practices, test methods, and guides for forensic applications has been developed by ASTM International Committee E30 on forensic sciences. These standards are based on specific criteria accepted in the forensic science community.

Accreditation

The accreditation is defined as *“a procedure by which an authoritative body gives formal recognition that a body or person is competent to carry out specific tasks”* (ASTM E1732 2009). While ASTM International mentions accreditation for persons, the authors reserve the term “certification” for persons and the term “accreditation” for institutions.

This recognition process highlights the competencies of the accredited body to produce results using reliable and valid methods. Perceived to be of public benefit and as a quality safeguard, many institutions emphasized the implementation of accreditation as vital. Two examples are the National Academy of Sciences (NAS), which declared the implementation of accreditation and certification programs to be mandatory (see ► Critical Report on Forensic Science; NAS 2009), and the ENFSI, which requires pre-member institutes to be accredited (or in the process) to become members of its forensic science experts' network. The accreditation process is influenced by the business-oriented approach to the quality process, which is mainly focused on guaranteeing a high degree of customer satisfaction within a given economical environment (see ► Organizing and Supplying Forensic Science Services).

Management and professional entities support this culture of quality focused on tools applied to solve forensic science problems and, most particularly, laboratory processes. A substantial list of standards and guidance has been adopted and published, with the objectives of strengthening analytical procedures and ensuring more transparent actions in order to limit (or even cancel out) error risks. Within the collective perception, this analysis stage appears to be the place where problems occur; for most legal and forensic science communities, the forensic science process starts in the laboratory, without consideration that the process should be largely adapted to handle imperfect, incomplete, dirty trace specimens whose relevancy may also be questioned. This has become particularly evident with the increased sensitivity of techniques (such as DNA) and the problem of managing contamination issues. Pre- and post-analysis steps have become subject to difficult accreditation issues, requiring adaptation and specific guidance for the application of the norms.

The main accreditation norms introduced within forensic science are the following:

- *For crime laboratories*: ISO (International Organization for Standardization) 17025-05 *(General requirements for the competence of testing and calibration laboratories)*, associated with the guidance ILAC-G-19 (2002), specifically concerns forensic laboratories. This standard leaves proficiency tests as a minor activity within the quality assurance.
- *For scene investigation*: ISO 17020-98 *(General criteria for the operation of various types of bodies performing inspection)* is perceived to be more flexible than the previous norm leaving some scopes of adaptation to practitioners. Two specific standards comply with this norm: IAF/ILAC A4 (2004), guidance on its application, and the European standard EA-5/03 (2008) (*Guidance for the implementation of ISO/IEC 17020 in the field of crime scene investigation*). Interestingly, Australia has chosen to follow the stricter standard ISO 17025 (Horswell 2004).
- *For data evaluation and interpretation*: There is no accreditation norm emanating from ISO for the evaluation stage. However, the AFSP (Association of Forensic Science Providers) has proposed standards for the formulation of evaluative forensic science expert opinion in the UK (AFSP 2009; Brown and Willis 2009), although they are not compatible with most European continental legal systems.

In order to become accredited, an institution must go through an accreditation body, i.e., another institution that can verify that the accreditation standards are met and officially recognize it. In this regard, many accreditation bodies for forensic science have flourished around the world, such as ASCLD/LAB;

Forensic Specialties Accreditation Board (FSAB); National Association of Testing Authorities, Australia (NATA); and European co-operation for accreditation (EA).

Certification

Most norms ensure that procedures are followed according to rules of quality; they do not evaluate competences of the scientists behind the procedures. Certification is carried out as an independent process, established to monitor a forensic science practitioner's expertise and proficiency. Mostly conducted on a voluntary basis, certification is defined as the process that will recognize a minimum or certain level of competences evaluating the knowledge, skills, and abilities (KSA) of a scientist in a given field. Forensic professional organizations have to define the expected KSA in relation to their discipline. Setting up these programs is not an easy undertaking. There are as many definitions of KSA and conceptions of their evaluation, as there are professional certification programs. This situation shows a relative lack of homogeneity in assessing forensic scientists' competences. Every program has its specificity and requirements regarding the expected level of education (with or without academic degrees), experience (number of years), and examination type (written, oral, practical). Ideally, a certification program should attest to a forensic scientist's competence to carry out his/her duty, thus contributing to ensure a scientific quality within his/her practice. Unfortunately, in practice, certification does not always equate to competency.

Nevertheless, the expected KSA, the evaluation process of these competencies, and the conditions for maintaining certification should be well defined and harmonized within the whole forensic science community. The certification purpose should be specified, whether it is to ensure that a forensic scientist has reached a minimum level of competencies or to recognize a certain degree of expertise and excellence acquired through the practice (Stauffer and Schiffer 2007): two different perspectives that require their own approaches. It also means that the way forensic science is taught through various existing learning processes (education curricula, in-house training, continuing education) has sound and accepted foundations. For example, in the USA, certification programs do not require academic degrees as a condition to sit for the crime scene investigator certification exams, whereas university degrees, such as a Bachelor of Art (BA) or Science (BS) in a natural science, are required for analytical positions in a crime laboratory. Despite the fact there are many educational means of entering forensic practice, such discrepancies can be explained by a difference in the consideration of some forensic disciplines by forensic practitioners. For example, crime scene investigation is often not considered as part of the forensic science process by many practitioners, particularly laboratory ones. And yet, this is where the whole process begins. Surprisingly, many forensic science disciplines that require a strong and sound scientific basis suffer from a lack of relevant formal scientific education programs. This is the case with firearms/toolmarks examination or fingerprint examination.

Forensic science is a science with specific rules and a specific methodology that cannot be improvised or mastered through apprenticeships, but needs to be taught as a whole through a suitable and specific education program. It cannot be sufficiently emphasized that one must acquire the forensic science culture and formal education should not be mishandled. The needed harmonization of certification programs cannot be achieved unless the approach to forensic science education is fully reconsidered.

The Customer-Provider Relationship Approach

The standard terminology for forensic science (ASTM E1732-09) emphasizes that *"In quality management, consideration is given to economic aspects."* In reality, this approach has been taken to the extreme in the UK, where economy, effectiveness, and efficiency (named the 3 E's, coming from the circular 114/83 that had a strong impact on policing policy in UK in the 1980s) are linked and are part of a performance quest. Eventually, such a vision led to the closing of the

Forensic Science Services (FSS) in 2012 (see ► Organizing and Supplying Forensic Science Services, Lawless 2011).

A customer-provider relationship focus could limit and bias forensic scientists' vision in view of providing the best scientific information for their customers, the prosecution or defense rather than for justice or the courts (see ► Cognitive Forensics: Human Cognition, Contextual Information, and Bias). Quality assurance is important, but the way it is perceived and applied, i.e., through an economical perspective rather than a scientific one, leads to restraining the vision of forensic science from a complete process to an easily usable and high-performance tool for the sake of a client within the criminal justice system. Although forensic scientists provide results, which are considered valuable products, criminal justice system stakeholders should not be considered customers to satisfy, but partners to work and interact with in an open and effective way. Approaching the forensic science process through an economical perspective leads to fragmentation and compartmentalization that is detrimental to scientific inquiry (see ► Forensic Science and Criminal Investigation). As Willis and Brown (2009) stated, it is a *"complicated end-to-end-process,"* and market forces cannot rule it.

To cite Willis (2009), *"Quality assurance is increasingly seen as one of the safeguards of good science. It is sometimes mistakenly considered that quality systems guarantee good science and though this is definitely not the case, a quality system is vital in an organizational setting."* It is vital because it helps to harmonize methods and practices throughout forensic science practice. Furthermore, it helps to focus on the necessary KSA that forensic science practitioners must have to be good forensic scientists. Also, it forces crime laboratories to show some transparency in how things are done, a definite paradigm shift from the secrecy that these laboratories benefited from for decades. However, this race for standardization and accreditation should not be the first that forensic scientists should run.

Standardization is reached through peer consensus within a discipline and leads to processes of varying rigidities. In general, a standard puts up a structured and rigid frame, meaning that the analyst must not deviate at all from it. It is ideal to perform routine analyses, such as drug of abuse or toxicology analysis, since they can be ensured by calibration and comparisons with standards and accredited according to international quality norms. Alternatively, a standard could also offer some flexibility in its application, allowing the analyst to utilize other ways of achieving the desired result. Any standard can specify whether it is intended as a rigid frame or to offer some flexibility. The use of the wording "may," "could," "should," and "shall/must" usually defines the level of rigidity of the described action. However, the approach to standardization can only apply to specific and repetitive tasks on similar samples. As such, it does not allow for a view of the overall process that the forensic science practitioner has to face on a daily basis. This is where harmonization comes into play.

Harmonization, similarly to standardization, is based on agreement reached among expert groups such as ENFSI guides. Nevertheless, it is not meant to be mandatory or rigid, contrary to standards. Harmonization leads to recommendations and guidelines for which the scientist is able to choose fit-for-purpose methods to apply when faced with peculiar or less than perfect specimens, as it is the case with the investigation of a scene. Best practice manuals (based on a harmonized approach), edited by professional organizations such as ENFSI, should provide solid and sound tools for tackling every non-standardized specimen based on a scientific and critical approach. This perspective reinforces that a forensic specimen, or physical trace, does not have to adapt to practice but that practice has to adapt to the specimen or trace.

This is why the focus of forensic science practitioners should be on the harmonization process that leads toward quality developments rather than the standardization and accreditation of specific tasks that do not offer an overall view of a case.

Finally, independently of his/her KSA, a forensic science practitioner must adhere to a professional code of ethics. In this regard, professional associations, such as AAFS, American Academy of Forensic Sciences; ABC, American Board of Criminalistics; ANZFSS, Australian and New Zealand Forensic Science Society; and ENFSI, promulgate codes of ethical practice to which members must adhere. Without the ethical behavior of the forensic science practitioner, all the quality assurance and quality control systems in the world cannot offer any guarantee as to the validity of the examinations performed at the scene or at the laboratory. This is also where the process should sometimes start.

Strengths and Weaknesses of the Existing Forensic Science Quality Assurance Paradigm (Table 1)

The focus on quality in forensic science should differentiate various steps and applications in the whole process.

Strict controls and standards are necessary for routine applications that need interoperability (between laboratories and authorities), strict limits, or possibility to share databases, allowing comparisons between results originating from different laboratories that can be trusted along calibrated ranges. This means that data are of a comparable instrumental analytical nature and sufficiently routine to be used, as in a manufacturing plant. This is the case for DNA, some narcotic drug analyses, vehicle paints, blood alcohol concentration, etc.

However, standards and controls are clearly not adapted to deciphering information about criminal phenomena or activity-level information in forensic intelligence, investigation, or interpretation of an inferential nature (see ▶ Forensic Science and Criminal Investigation and ▶ Probability and Inference in Forensic Science). Yet, this is where forensic science is often the most useful and a valuable asset for the criminal justice system and for society (Ribaux et al. 2010a, b). Harmonization of the detection process here is essential.

One further difficulty in the way quality is perceived is the fragmentation and compartmentalization of data that feed linkage blindness. This phenomenon has been identified as the single most important factor in failed criminal/terrorist investigation (Egger 1984). A sound quality system for operational tools and methods is essential, but this is not where most problems lie when faced with crime-solving difficulties.

Forensic Science and the Paradigm of Quality, Table 1 Overview of the main strengths and weaknesses of forensic science performance management, based on the quality assurance system

Plus	Minus
Definition of international standards accepted through peer reviews	Overload with documentation
Standard operative procedures (SOP): anyone can rely on the documentation useful for new employees	Not so convenient and fit for purpose for some forensic science stages (crime scene and interpretation areas, for instance)
Transfer of procedural knowledge	Time and cost consuming
Ensure transparent actions by following standardized methods	Rigid frame that prevents initiative
Facilitation of data interchange between laboratories with feasible comparisons	Mechanical application of SOPs, *"Lack of focus on the purpose of the examination"* (Willis 2011)
Adequate to biological-chemical analysis and routine procedures	Does not ensure quality in the application of the forensic science as a science
Documentation of what has to be and was processed	Does not ensure a comprehensible implementation of the process by the forensic scientist
Systematic approach	Lack of scientific skepticism, '*brains are left outside the door and strict adherence to protocols replaces judgment*' (Willis 2011)
Legal and public trust in the forensic science process: robustness, validity, reliability	Overreliance upon the system

Concluding Remarks

Mainly attributed to laboratory management matters, quality issues are the engines for standardization and accreditation programs. All is related to evaluation processes through controlled and monitored actions based on standard operative procedures or specific attributes (criteria) considered as representative of what quality is. The criteria that are used are numerical, useful for lay people who need tools to evaluate and consider what seems to fulfill their high-quality requirements, and avoid errors and a lack of validity and reliability. Indeed, risks of miscarriages of justice are a reason that explains this quest for absolute quality assurance. Interestingly, perspectives diverge in perceptions of error sources and advanced solutions within forensic science circles and their partners (Schiffer 2009).

Quality within the forensic science process is a difficult question to answer to and a priority. However, as long as it is considered through the legal and economic perspectives, it is not consistent with case-oriented, strategic, and operational needs. To ensure the overall quality of instrumental processes and competences is a good start, but it is clearly insufficient, as it does not focus on the right issues: understanding criminal activities, diminishing linkage blindness, and solving crimes (Ribaux et al. 2010a, b). Legal and economical systems, rather than science, condition the way forensic science is approached as a profession. Forensic scientists should become the driving force in defining who they are and what they are working for. Ensuring and improving quality does not only find solutions in quality assurance and controls, where criteria are associated with performances management and market forces (see ► Organizing and Supplying Forensic Science Services, Lawless 2011), but also in the overall definition of the profession. The scientific foundations of forensic science define its values and performance as well as its position within a criminal justice system as an independent discipline. It provides a challenging perspective in this matter by emphasizing the whole process and the interdependence of the different parts of forensic science.

Overview

Heretofore the issue of quality in forensic science is approached through a quality management policy whose tenets are ruled by market forces. Despite some obvious advantages of standardization of methods allowing interlaboratory comparisons and implementation of databases, this approach suffers from a serious lack of consideration for forensic science as a science. A critical study of its principles and foundations, which constitutes its culture, enables to consider the matter of scientific quality through a new dimension. A better understanding of what pertains to forensic science ensures a better application and improves elementary actions within the investigative and intelligence processes as well as the judicial process. This leads to focus the attention on the core of the subject matter: the physical remnants of the criminal activity, namely, the traces that produce information in understanding this activity. Adapting practices to the detection and recognition of relevant traces relies on the apprehension of the processes underlying forensic science tenets (Locard, Kirk, relevancy issue) and a structured management of circumstantial information (direct-indirect information). This is influenced by forensic science education and training. However, the lack of homogeneity with regard to the scientific nature and culture of the discipline within forensic science practitioners and partners represents a real challenge. A sound and critical reconsideration of the forensic science practitioner's roles (investigator, evaluator, intelligence provider) and objectives (prevention, strategies, evidence provider) within the criminal justice system is a means to strengthen the understanding and the application of forensic science. Indeed, the whole philosophy is aimed at ensuring a high degree of excellence, namely, a dedicated scientific quality.

Culture and Forensic Science

Culture is considered "in anthropology, [as] all knowledge that is acquired by human beings through their membership of a society. A culture incorporates all the shared knowledge, expectations and beliefs of a group." Besides, sociologists defined it as "human processes of meaning-making generating artefacts, categories, norms, values, practices, rituals, symbols, worldviews, ideas, ideologies and discourses" (Spillman 2007). If the first definition puts forward the acquisition of a specific knowledge within a limited group of persons, the second view specifies the nature of this extensive knowledge, which emanates from these meaning-making processes that have a signification or a reason to be only within a given society or community. Culture is not innate and is acquired through various cognitive processes including (continuing) education and (in-house) training.

Forensic science is characterized by heterogeneous conceptions regarding its position within criminal justice systems (CJS). It has its own culture, despite the fact that it is often perceived through the eyes of various specialized professional bodies and is hardly ever emphasized (Margot 2011a). The implementation of (accredited) standards and procedures according to the logic of market forces represents one of the meaning-making processes shared within the combined community; this does not stand for the core of the forensic science culture. Forensic science is neither chemistry nor biology or physics, but is in fact based upon a *historical* or *reverse engineering* reasoning surrounding *the physical residue of an event* (to paraphrase Kind (1987)), in the form of a physical or material trace.

This cultural background leads to investigate the meaning-making processes that generate the key characteristics of this science, like its fundamental principles or values. An epistemology of forensic science investigates its principles and information framework and the way this knowledge can be transmitted in the form of education, training, and research for a recognized profession. In this perspective, the notion of quality is not instrument or market based but rather positioned within a complex justice system, quality being the added value afforded by the extracted knowledge and its interpretation within the justice context.

The Physical Trace as a Primitive Source of Information

The Scientific Investigation of Crime

The need to introduce scientific foundations within the investigation of crime was understood and suggested by Gross in the 1880s (Gross 1899), followed by various authors in the twentieth century to the fundamental contribution of Kind. These authors emphasized this peculiar connection between forensic science and the investigation process—where police and magistrates are partners, who rely on a need for valuable information. Thus, various types of information, whether direct or indirect from human sources or investigative means, are traditionally considered in solving cases. These above authors introduced a further dimension with the physical information. It comes from the scientific study of the only physical remnants of the criminal activities, the physical traces. The latter are the essential components of evidence and intelligence-led policing due to the reliability of the information extracted from it, and it can turn into general policing knowledge.

In every science developing a critical relationship to time (such as history, archaeology), physical trace—improperly called evidence at the stage of its discovery—is considered the single most reliable record, seen as the relevant witness of past events, whereas forensic science still has the secondary role as far as understanding crime is concerned. It is mostly considered through its capacity as an evidential piece in case solving to support traditional law enforcement investigation. The quality of even fragmentary physical records is such that it often becomes evidence in desperately empty investigation due to its pure strength. It should take at least equal importance within the criminal justice framework since it is usually the only measurable resource. This task is complicated because current forensic scientists and partner communities do not give a great place to forensic science information other than the analytical end product for courts. There is little interest shown to determine the scientific quality outside the laboratory, because it is generally seen as a subaltern part of law enforcement or judicial administration with little or no control over any other processes but the laboratory process.

Nevertheless, physical records transmitted to crime laboratories are collected from scenes of investigation without, often, due consideration to the problem of detection, recognition, and diagnosis/interpretation that should be based on scientific and circumstantial observations. It is the starting point of the whole forensic science process. The quality of the information given to partners is mostly, not to say exclusively, conditioned by the work achieved at the scene of investigation: a sound reason to focus on this stage of the process whenever quality matters are discussed.

The scene of investigation is a complicated environment fraught with various uncertainties that constitute a risk forensic science practitioners have to confront, but also offers huge opportunities. Detecting and finding relevant physical records that will provide useful data is faced with the uncertainty of not knowing the causes that have created traces. The value of the ensuing analytical process may be highly controlled and calibrated; it remains useless when it comes to control the uncertainty pertaining to (criminal) causal events. The way forensic science practitioners deal with risk conditions decisions taken at this stage, which affect the whole process that follows the detection and collection of traces. From the collected observational data, a complex and continuous reasoning process starts at the scene through an abductive reasoning to determine/diagnose probable or possible causes/propositions of the resulting events that may be tested through a deductive phase, which should help question or strengthen those hypothetical explanations (Bonfantini and Proni 1988). Eventually, the selected hypotheses constitute a network that will lead to identify relevant information to be used for evidence-led inquiry and/or intelligence-led policing (Ribaux et al. 2010a, see ► Forensic Science and Criminal Investigation).

This management of uncertainties constitutes an interesting subject to study, approached by forensic science researchers through many ways: some focus on external/circumstantial bias effect advocating that information should be filtered to avoid contextual effect on decision making (see ► Cognitive Forensics: Human Cognition, Contextual Information, and Bias), others propose a Bayesian approach as an inference framework useful to consider objectively the whole spectrum of propositions within a given context (through the CAI (case assessment and interpretation) approach (Cook et al. 1999, see ► Probability and Inference in Forensic Science), or others carry out studies with sociological perception to determine the best conditions for improving process effectiveness (e.g., Julian et al. 2011, see ► Forensic Science Effectiveness). These approaches are not mutually exclusive but share a common perception that the most demanding step in the whole process occurs at the investigation scene and constitutes an essential quality issue, whereas the current debates are mostly focused on the end-product interpretation (after analyses) rather than the trace itself, the essential component of the forensic science discipline. The recognition of relevant information calls for a comprehensive vision and knowledge of what pertains to the apprehension of the trace, and a qualitative and quantitative appreciation of its information content (often incomplete) before any other issues.

The Physical Remnant of the Criminal Activity

Kind (1987) defined the trace as information whose origin was a material residue of the investigated event. More specifically, it is defined as a mark, a signal, or an object that is a visible sign (not always visible by naked eye) and a vestige indicating a former presence (source level information) and/or an action (activity level) of something where the latter happened. The physical trace is the common, elementary, and indispensable piece of the forensic puzzle. It is common since, to paraphrase Locard (1920), every action creates a trace on any kind of support as a consequence of interactions between the actors of the event and the support. It is elementary, because the trace represents the first essential entity onto which the reasoning process will be based at the scene. And it is indispensable by virtue of its potential content of information that feeds the investigative and intelligence processes. The trace can be viewed from three different angles via:

– The *genesis* (or creation): complex factors interact and lead to create relevant physical traces. The creation of the trace takes place in a specific context that is conditioned by the *activity* of the criminal (the *source*) who interacts with the *scene* according to basic forensic science *principles* (Locard, Kirk) within the *immediate environmental context* (according to the situational approach theory) in a certain period of *time*. The presence (or absence) of the physical element within such a framework allows inferences to be made about the criminal and his activity. Without its creation, there is little object of reasoning except the possible meaning of an absence of a trace.

- The *discovery*: this step corresponds to the intervention after the event when forensic science practitioners come into play. This implies successive reflections, decisions, and actions that will condition the latter stages of the forensic science process. The problem of finding, detecting, and recognizing relevant traces is not trivial; it requires a comprehensive study to understand the types and mechanisms of transfer. In any way, without the discovery of the trace (or a realization of an abnormal absence), there is also no object of analysis or reasoning.
- The *meaning-making process*: the information carried by the trace may be a strong indicator of source and/or activity. According to variable utilitarian dimensions and basic logical steps (such as trace-to-source, source-to-trace, trace-to-trace relationships), forensic science practitioners evaluate the potential information content of the trace. Among the various parameters used to decide its value, the utilitarian perception by the forensic science practitioner grossly influences the detection capability and the will to detect. Practitioners notoriously prefer highly discriminating traces or those presenting a direct relationship with their source, e.g., fingermarks and DNA, compared to those that offer an indirect relationship or considered as less discriminating, e.g., shoemarks and microtraces. This well-known preference for individualizing traces is due to the capacity to indicate the source, whereas indirect "evidence" indicates a probable source extended to a group or a specific activity, whose relevancy depends on the case's circumstances. This preference seems to be directly motivated by the strength it offers in the form of evidence in court, the main beneficiary of traditional forensic science. Practitioners may even decide to ignore some physical traces because of their expected complexity to be interpreted and/or used in court. In such situation, the selection at scenes is conditioned by an output concern "collected trace versus evidence easily interpreted in front of a Court" (Ribaux and Margot 2008). This view completely obliterates the rich information content (especially the activity dimension afforded by many traces) provided by physical data as shown in many studies. The multidimensional nature of relevant information for an extremely useful intelligence as well as evidence should be the norm and the cultural base of forensic science practice, because relevant physical traces provide information, whether in an intelligence process, in an investigative case solving perspective, or even to provide evidence for court.

The duality *criminal's activity–forensic science practitioner's activity* constitutes the elementary group conditioning the discovery and evaluation of relevant physical traces at scenes. If the former aspect is outside the control of the forensic scientist, the latter is entirely under her responsibility. Discussing scientific quality in this respect goes inevitably through a sound and introspective reflection of the role of forensic science and its activity as well as the perception of the profession.

The comprehensive vision and culture of the trace, as the essence of forensic science, emerges as a complex science whose principal role may not be the ultimate use by the courts, but the provider of essential data about crimes and their actors within the CJS that also helps public security strategies and measures. This leads to reflections about data collection and structured memories, and the necessity to implement sound and practical operating systems (e.g., relevant databases, data mining systems) to support and relay valuable and reliable information. This may strengthen the whole forensic science process only if it is part of a comprehensive model, such as the four-level model proposed by Ribaux et al. (2010a).

The Set of Inferences According to the Standpoint of "Clues" Paradigm

A culture of the physical trace exists in forensic science (Dulong 2004). It contributes to the representation of the discipline: a science ("a scientific approach and technical methods [based on] the study of physical traces" (Ribaux and Margot 2008)) fostering the ability to infer causes from observations. This model may be seen through the Ginzburg's *paradigma indiziario* or clues' paradigm (Ginzburg 1989), applied to the physical remnants of the criminal activity.

Ginzburg observed that society developed the view that knowledge about a whole could be obtained from physical details afforded by science and observations. He coined this *paradigma indiziario* as a model for a whole cultural movement in the nineteenth century. He traced the roots of this approach back into the cynegetics (i.e., the art to decipher traces and marks of animals decoded by hunters) back to Neolithic time when men were hunters and learned to use details through an elaborate, rapid, and complex thought mechanism to reconstruct events (Ginzburg 1989). The analogy between cynegetics and the forensic science process at the scene is astonishing: *the hunter* (*the forensic science practitioner*) *trails the animal* (*the criminal*) *using traces and marks* (*physical traces*) *left in the wood* (*at the investigation scene*) *by the animal* (*the author*) *following his passing* (*criminal activity*). The Ginzburg's paradigm has a distant origin and is found in various disciplines (e.g., divination, law, medicine) where the aim is to tell stories based on observations of traces, signs, and clues. This paradigm marked many detective novels in the nineteenth century. Writers, such as Voltaire, Poe, Gaboriau, and Doyle, turned their heroes into fine observers of traces who applied reasoning methods based on drawn inferences that can be linked to Peirce's pragmatic philosophy. More specifically, abductions are seen as a third fundamental form of logical inference, besides induction and deduction, that help devise logical explanatory hypotheses about observed results (traces/tracks), to go back to their potential probable causes.

Ginzburg draws a parallel between three specialists of importance: Morelli, doctor by training and art historian, who put in place an identification method relying on "negligible details" found on paintings in order to identify painters (method known today under the term "connoisseurship"); the second, Freud, who had an interpretative approach inspired from Morelli's method and used neglected details indicating the hidden presence of reality; and the third, Doyle, doctor and writer of the adventures of the famous detective gifted with an accurate sense of details. All three used traces within their reasoning processes, precisely symptoms for Freud, clues for Sherlock Holmes, and pictorial signs for Morelli. Besides their common medical training, they also shared the application of a reasoning model specific to medical semiotics, a medical discipline based upon sign study of the invisible disease in order to propose a diagnosis. The criminal activity is like the illness, leaving traces at scenes that can be visible or latent (like signs of illness); the trace is the indirect expression of this action that the forensic science practitioner investigates and tends to highlight by inferences drawn from discovered and collected traces (becoming clues), as the doctor who makes a diagnosis of a specific disease by listing and correlating the relevant symptoms. In the presence of an epidemic, the doctor may identify relevant signs just like forensic intelligence may help find hidden traces from serial crimes.

The trace may therefore be analyzed according to different viewpoints—which may also correspond to different specialized occupation from investigators and intelligence analysts, laboratory analysts to policy makers. The trace is considered through its information content to determine:

– Source/composition: it may be a pattern, a chemical composition, or a biological trait that will be identified (with the use of databases) and compared to establish potential common origin. Indeed, the instrumental analysis of the source is where current quality assurance is focused.
– Form/activity: it may be a distribution of the trace with a specific position—following a sequence, within a certain period of time, with a specific physical distribution—that provides information about the transfer and the persistence or the activity that took place.
– Frame: it may only be inferred from source and form that set up the limits within which

a reconstruction or understanding of the reasons for a current state is forming. This leads to hypothesize about the crime(s) and sets up a kind of window of opportunity.

– Aim/motive: considers the motive or a crime/event, which may influence both form and frame and may be seen as a result, which gives undue advantage to a party through fraudulent means.

Frame and motive may feed intelligence and need logical reasoning to integrate some form of reconstruction and linkage in organized memories. Form relies also on logical and transparent reasoning in the association of traces to the events. Determination of source/composition needs specific technical reasoning in relation to qualitative and quantitative analyses. In summary, everything is based on one basic object, the remnant of criminal activity in the form of a physical object: the trace, although it leads to a complex phase of reasoning and professional decisions.

Source/composition requires discrimination and sensitive analytical tools; but grouping in relevant classifications in order to have elements of a same class within the class and elements from different classes separated may often be more important than traditional analytical performances. For example, is it better to be able to discriminate each drug seizure or each counterfeit from each other, or is it better to determine that a whole market is dominated by a single mode of production that may be from one source? In most cases, the answer to the second question has much more strategic and operational dimensions needed in an inquiry than in the first option. This is a measure of intra- and inter-variability, which has a greater impact on the potential meaning of a trace than knowing the limit of detection (LOD) and limit of quantification (LOQ) of techniques that focus on analytical tools detailed in standard procedures.

Milestone #1. The trace is the primitive source of information available to forensic science. Found at the scene, it is the core of the forensic science practice. It finds an interesting parallel with Ginzburg's paradigm of "clues" viewed from an historian's perspective. The trace contributes to intelligence-led and evidence-led dimensions fundamental to resolving or understanding crime phenomena. Comprehension of the logical process information goes through—from the trace to the evidence/intelligence—should be an essential step toward scientific quality assurance. The cultural background of this process lies in its specific rules.

Fundamental Principles of Forensic Science

Locard's and Kirk's Exchange Principles

> There exists in the field of criminalistics a serious deficiency in basic theory and principles, as contrasted with the large assortment of effective technical procedures. (Kirk 1963)

Even in the days of undisputed DNA evidence, this quote finds its echo in the identified lack of sound scientific methodology in the application of DNA according to the latest Campbell systematic reviews (2011) and serious flaws detected in the way of reporting even within accredited laboratories. Improving procedures through standardization processes or pushing forward, selectivity, limits of detection, and quantification are the main focus of scientists. As long as the focus will remain on technical features, the scientific quality will suffer from deficient outcomes.

The well-known principles of Locard and Kirk constitute two fundamental and specific cornerstones of forensic science. Most inferences can be based on these fundamental principles using other established sciences such as chemistry (composition, structure), physics (dynamics, laws of nature), and biology (heredity, metabolism). Although attributed to Locard and Kirk, these are axiomatic dimensions of nature that a contact will in some way be the cause of some transfer of a physical nature that constitutes a kind of signature of this contact and that the shared uniqueness of the trace and its source may ultimately lead to the individualization of the trace to a specific source. There is a vital need to investigate the validity of Locard's and Kirk's principles, considered as forensic science's founding principles. Inseparable from its culture, they remain part of its foundations.

Interestingly, Crispino's recent contributions brought valuable scientific arguments to the critical investigation of those organizing principles (Crispino et al. 2011). He stated that:

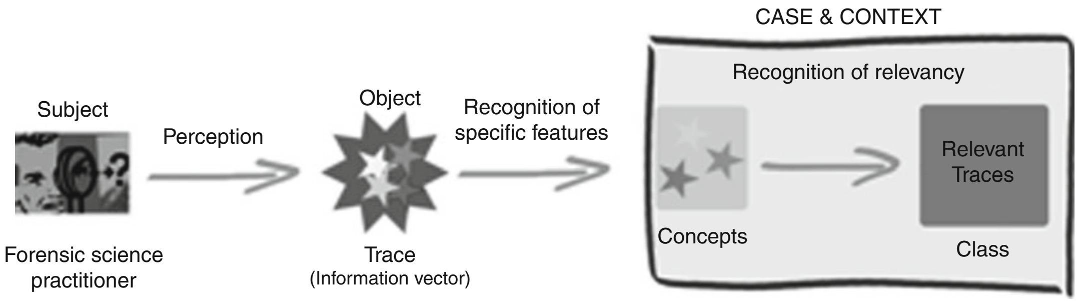
1. Kirks' principle of individuality (Kirk 1974) can be considered as being a scientific principle upon which forensic science practices lie everyday through the comparison of entities, since it fulfills Popper's falsifiability criterion. Briefly, the whole point of comparison in forensic science is to ascertain the degree of concordances or discordances of measurable properties that might be found between two entities coming from allegedly the same source. Such process can be seen as an attempt to falsify the philosophical principle (Kirk's) stating the uniqueness of every object, making this principle scientifically acceptable according to the Popperian logic.
2. Locard's principle of exchange (Locard 1920) is introduced as the basis of forensic science. It refers to the trace as representative of the identity of a source that is the object of transfer during the questioned activity and that will be submitted to the effect of time. The whole point within forensic science is to be able to trace back the source or the activity, but the process comes with all the uncertainties related to the fact that causes remain unknown. This is where reasoning through probabilistic inferences (abduction to deduction) comes into play. Methodological solutions, such as proposed by Cook et al. (1999), with the CAI model, help focus on interpretation difficulties and solutions for forensic science practitioners. Crispino demonstrates that Locard's exchange principle is scientific because it is at the basis of forensic science reasoning. It is also corroborated pragmatically over centuries through the experiences of man as a hunter (cynegetic), where the reasoning process lies upon inferences drawn from observations of traces resulting from exchanges between animals and their environment. Investigating the scientific nature of Locard's principle comes back to questioning the scientific nature of forensic science, an epistemological approach that may prove very effective to strengthen forensic science.

The two principles are part of the forensic science paradigm, "both have the ability to be accepted as scientific laws. They add knowledge that can be measured and used in logic for the sake of the law (if not justice)" (Crispino et al. 2011). However, another fundamental issue for forensic practitioners is whether a detected trace is relevant, and this constitutes the essence of the forensic quest.

Relevancy and the Use of a Proper Terminology

The forensic scientist is not a witness of the events under investigation and can never be certain to observe, detect, and see relevant traces for collection and analyses; however, this is the challenging goal. From crime scenes to laboratories, working with relevant physical traces is a leitmotiv and belongs to the thought processes fed by Locard's and Kirk's principles. Relevancy can be seen as a basic tenet describing the everyday life and doubts of forensic science practitioners. Currently it is mainly perceived according to criminal laws. The concept of relevancy is a key issue in a legal perspective and is understood as the "the adequacy between the fact that has to be proven and the brought evidence or between an allegation and the law rule to apply" (Le Grand Larousse Universel 1995). Though it is a requested condition for evidence to be admitted in court, the legal concept is not well defined (Twining 2006). Understood differently depending on the legal structure and proceedings, it should not stand for the forensic reference, since it does not cover the essential discovery step involved at the onset of an investigation that should be part of forensic science practice.

Although preliminary, the concept of relevancy is not clearly defined, but implicit within the reasoning process in forensic science. At the scene of investigation, there is a need to take decisions as to what to collect and then within the laboratory as to what sequences of methods have to be followed. When structuring databases and memories or preparing expert's reports for



Forensic Science Culture, Fig. 1 Semiotic approach of trace objects when forensic science practitioners process the investigation scene (Hazard©)

intelligence or evidence, further decisions have to be made, and this is based on a sound appreciation of relevancy. The reasoning process can only be sound if pieces of the arguments are relevant.

Focusing on the relevancy concept in forensic science goes far beyond a simple question of definition. Precisely, Inman and Rudin (2000) did formalize the current conundrum that criminalists have to deal with: the most difficult challenge is *the recognition of relevant physical evidence*, although it may be questionable whether the capacity to recognize objects as clues would not have limits. Those limits fundamentally rely on the case-by-case approach: crime scenes are consecutive but not alike, being peculiar to every criminal activity, where resources are always limited (whether material, time, etc.). This forces forensic science practitioners to adapt to places and cases in order to find what is relevant.

A relevant trace carries information in relation to the event at its source and may be studied through basic logical relations (trace to source, source to trace, trace to trace, source to source, geographical, temporal relationships, etc.). The focus on the trace and the relevancy of meaning in relation to events is a semiotic quest that has to be studied.

The Recognition of Relevant Traces

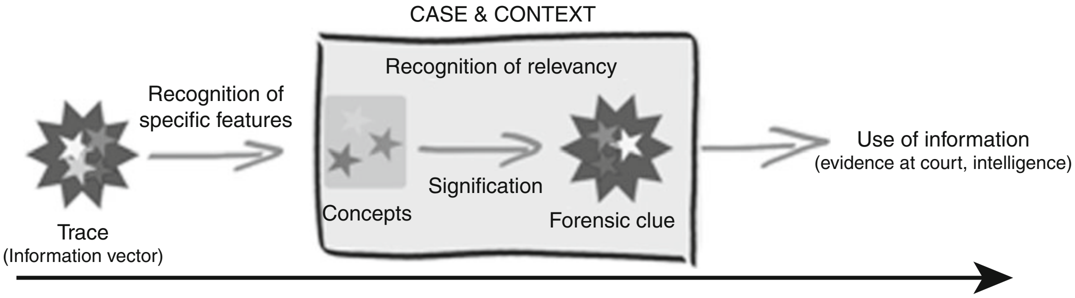
> "L'oeil ne voit dans les choses que ce qu'il y regarde. Et il ne regarde que ce qui est déjà dans l'esprit" (i.e., "The eye only sees in things what it looks at. And it only looks at what it has in mind"), famous quote used by Bertillon that is attributed to the French journalist L. Peisse

Semiotics is the science that studies the sign—the very first act of communication—and its various forms; it questions and describes the mechanism of signification. This is a complex domain of research and study in both linguistics and medical diagnosis but has a direct importance in forensic science practice, since giving a meaning to observations is part of the process: whenever a relevant trace/object is recognized and perceived as such, a signification is attributed.

The semiotic standpoint of relevancy sets forth the importance of the processes of perception and recognition, which are conditioned by the practice *in regard to which the subject considers the object* in a given context (Sebeok 1986). The concept of relevancy is not an intrinsic quality; it only exists in a specific context (Fig. 1).

The semiotic key terms used in the previous figure are defined as such:

– A *class* consists of a set of equivalent objects regarding a specific use, i.e., the *class* of interest is the *relevant traces* that consists of any kind of traces that might be relevant to the investigation and/or intelligence process.
– A *concept* is a set of features that is specific to a *class*; *these features have to be recognized in the object to classify it*. The forensic science practitioner may perceive explicit or implicit features (e.g., *type of traces*, *quality*, *spatio-temporal localization*, *kind of information given once the trace object is used*) and recognize the concept they belong to, namely, the concept of source and action that are linked to the criminal event in this situation.



Forensic Science Culture, Fig. 2 Trace, clue, and relevancy: the following process from the scene to the beneficiaries (Hazard©)

– If a *concept* is recognized in an object, the latter becomes a part of the *class*, i.e., a trace object that realizes the *criminal source/action concepts* of the *class relevant traces* belongs to this *class*.

In summary, according to the semiotic view, relevancy is defined as a perception of trace objects conditioned by the *context* and by what the *forensic science practitioner* decides to *recognize* at investigative scenes and to use as features from (*relevant*) traces (i.e., *potential for discrimination*, *for case linkage*) found at the scene of investigation. These signification processes are ruled by cultural conventions; the whole reasoning is based upon the practice and the context. Relevancy is a conventional dimension specific to the practice the forensic practitioner evolves in; such a fact shows how important it is to understand what forensic science culture is and what it is made of, since it conditions forensic science practitioners' work.

Trace, Clue, and Evidence

Interestingly, the discovered physical trace is often called physical "evidence," whether at scene, laboratory, or court, although there is a huge difference in reality between these three settings. It is not because a trace has been discovered that it can be automatically classed as evidence: an indication of direction may or may not be relevant information. This information may be useful in directing search and in providing indications about frame, but it is not evidence (in a legal sense) until it is recognized in court to be an element on which the decision on the issue is made (judgment). Thus, evidence is solely the province of the court.

A trace exists in itself and does not have a meaning initially (although it can be measured), except that it is perceived as a support with an unexploited potential of information that might explain issues in the investigated cases. Once this potential is recognized, it is considered as a sign that potentially pertains to the class of *relevant traces*. The metric associated to the meaning gives some strength in view of probable causes. This measure, which may be expressed as the likelihood ratio in Bayes' theorem (see **Probability and Inference in Forensic Science**), may be a strong indicator or clue of something insofar as it is interpreted in a specific context. The value of this clue in deciding on the issue by a judge is the evidential value (Fig. 2).

As illustrated, the belief in the information content is built up between the discovered trace and the final outcome through measurements and a reasoning process. Therefore, the distinction of a trace from a clue and evidence are as follows:

– Trace and clue are two distinct states of a same object whose distinctive parameter is the recognition that the information it carries is relevant.
– Clue is therefore a trace with recognized and measured information content.
– Clues are gathered and constitute structured information about the case in issue. This helps the decision process (i.e., evidential process). Evidence consists of pieces of information that have been accepted to be relevant and useful in the decision process by a judge.

The study of relevancy is a key point between these entities and the understanding of it is an essentially cultural cornerstone of forensic science practice. Questioning the issue of relevancy in the forensic science process might be considered as a safeguard: it involves a meaning-making process where decisions and actions depend strongly upon the assessment of the relevancy of the features expected to be recognized as such. Significations come from the dynamic process of inferences set up by practitioners with regard to their personal stock-in-trade (knowledge, education-training, experience, called KEE model). Understanding this concept may help selection, training, and education of forensic scientists.

Milestone #2. Sound reflections regarding forensic science foundations enable it to be properly defined: "[...] a science on its own, defined as the science of identifying and associating traces for investigative and security purposes, based on its fundamental principles and the case assessment and interpretation that follows with its specific and relevant mode of inference" (Crispino et al. 2011). The study of principles is aimed to strengthen forensic science foundations and culture. Mastering the concepts and principles pertaining to forensic science is a way to ensure scientific quality.

Sound Education and Training for a Professional Judgment of Quality

The Roles of a Forensic Scientist

A real culture of the physical trace exists and is at the core of forensic science with two principles (Locard, Kirk) and the relevancy. The search, detection, recognition, and collection of relevant traces call for specific abilities for forensic scientists. Kirk (1974) described features of the forensic science practitioner's work: "The investigator...must understand (a) what physical evidence is [sic]; (b) how to collect and preserve it; (c) how to obtain from it the information it carries; and (d) how to interpret the information so obtained." This statement assumes some corollaries:

1. To know and master the way a physical trace is created, which calls for a sound understanding of transfer, persistence, selectivity through teaching, and experimental research, using common sense and logic.
2. To recognize the relevant trace with its potential of information (whether at the scene, the laboratory, in any kind of information process), which calls for a sound culture about the trace and the environment (recognizing situations as defined in criminological studies).
3. To be able to evaluate the discovered trace (to read the signs), which calls for a comprehensive vision of the forensic science process and the part it may play within the CJS. It requires a sound scientific methodology of interpretation.

The whole approach is based on cognitive processes such as experience and culture of the trace acquired through education and training but is also based on the thoughtful use of available information related to the case and the current series identified as crime phenomena (e.g., through forensic intelligence). The work is therefore not limited to running methods and techniques; it goes far beyond. As simple as it seems, a doctor is not good because of the quality of her tests (even if this is important), but because of her cognitive abilities used through sound observations of signs or symptoms and the application of a logic that leads to an accurate diagnosis; this statement is also true to qualify a good forensic scientist.

Emphasis is mostly directed to technological progress and implementation in many forensic science laboratories rather than promoting forensic science culture and development through education and training. New technologies are important to master but remain tools, even useful to provide answers to preestablished questions according to the given problem (DeForest 1997). Education has to focus on means to foster relevant questioning when forensic scientists are faced with a (crime) problem.

Surprisingly, in most countries, people with a primary degree in forensic science are not the first choice for employers. Brown and

Willis (2009) describe the typical route followed to become a forensic scientist within laboratories in the UK and Ireland. The preference is given to scientists with qualifications in another discipline rather than forensic science, who receive in-house training once hired. Despite a substantial number of university programs offering forensic science degrees popping up throughout the UK, but also elsewhere, such a statement is worrying about the quality of the forensic science education. It is reasonable to think that some of the forensic science programs do not educate students in a fit for purpose way to the reality of the field and in agreement with a forensic science culture, but responding to marketing interests instead (Lawless 2011), trying to attract students and associated financial rewards. There is a need for a sound and serious reappraisal of the way education of forensic science is conceived, and academic programs should be implemented considering a complete process of reasoning that starts from the perception of the trace at scenes to its interpretation as evidence/intelligence, a stage that represents a serious issue (currently the most controversial one).

Interestingly, the observed deficiencies in giving reliable and quality results of significance in forensic science laboratories participating in collaborative testing, even in the perceived "gold standard of DNA," is proving deficient as far as interpretation of forensic data is concerned. If such a discrepancy within results emanates from a lack of solid (academic) interpretation bases, it also shows that hired scientists may master technical skills but are not educated and trained to handle forensic issues.

Addressing the education-training issue is not an easy matter and requires a definition of roles and functions. A forensic scientist may be an investigator (who infers from direct observations based on discovered physical traces assessed as being relevant), an evaluator (who helps partners to make inferences with regard to the case and provide answers) (Jackson et al. 2006), or an intelligence provider (who provides information that will reduce linkage blindness).

The forensic scientist may take the different roles or specialize depending on organizational decisions. All roles must be emphasized and integrated into the education's vision in order to provide a foundation and a vision about the complexity of the forensic science process. It is, in all its actual dimensions, a true problem-solving process applied by the same or different people with a view to solve a problem (not to follow a process).

The Role of Education Programs

> "First we need to note that the educational field that underpins forensic science is heterogeneous and confusing." (Willis 2009)

Forensic science communities have, in some way, started to undertake this reflection, though organizations and structures are just as heterogeneous and confusing, perhaps because of an historical evolution that contributed to the current fragmented vision. Three visions coexist nowadays and find their roots with pioneers:

1. Gross—a lawyer—introduced the use of scientific methods as the basic methodology for an investigative magistrate. He called "Kriminalistik" the single basic methodology of criminal investigation. This became the French "criminalistique" used by Locard or the North American "criminalistics." The influence of Gross is still felt throughout Central and Eastern Europe and has seen the development of forensic science laboratories within justice departments.
2. Bertillon, an administrative assistant, introduced structured databases to identify recidivists within police structures. The methodological approach was developed from the 1880s, and its investigative methods became technical and identification-oriented at the base of technical police and identification bureaus.
3. Finally, the third approach was more about expertise with a method developed to express experts' opinions within specialized laboratories, which was emphasized by Locard (Crispino et al. 2011). Locard was a trained forensic medical doctor who directed his vision outside and complementary to medicine. Although he created what is now considered the first "police forensic science laboratory" (founded in 1910) in Lyon,

he was adamant that this should be within the justice department, and his first laboratories were within the Lyon tribunal!

Such fragmented evolution is reflected in the current education and training programs. The logic according to which the clue development relies on trace detection is not currently leading the scientific methodology and technologies (Crispino et al. 2011). The current education and CJS emphasizes efforts on an incomplete role perceived through the eyes of government and justice policies. Focusing on the trace and the science itself to reconstruct the whole puzzle might be a sound thread to follow in developing education programs.

Education is meant for developing critical scientific reasoning relying on a sound scientific basis, while training represents the acquisition of the command for specific tasks. Barnett (2000) emphasized that education programs should achieve three main goals by developing:

- Forensic science professors, to teach the forensic science "philosophy" with the methodology and logical reasoning process standing behind the words "forensic science." The knowledge specific to the discipline has to be fostered and transmitted through a more holistic vision.
- Practitioners dedicated to research, to improve and strengthen the science by investigating foundations of the science as well as leading research with a more pragmatic concern for the field.
- The core of the forensic science profession with practitioners who apply the developed knowledge and are expected to undergo further in-house training and continuing education.

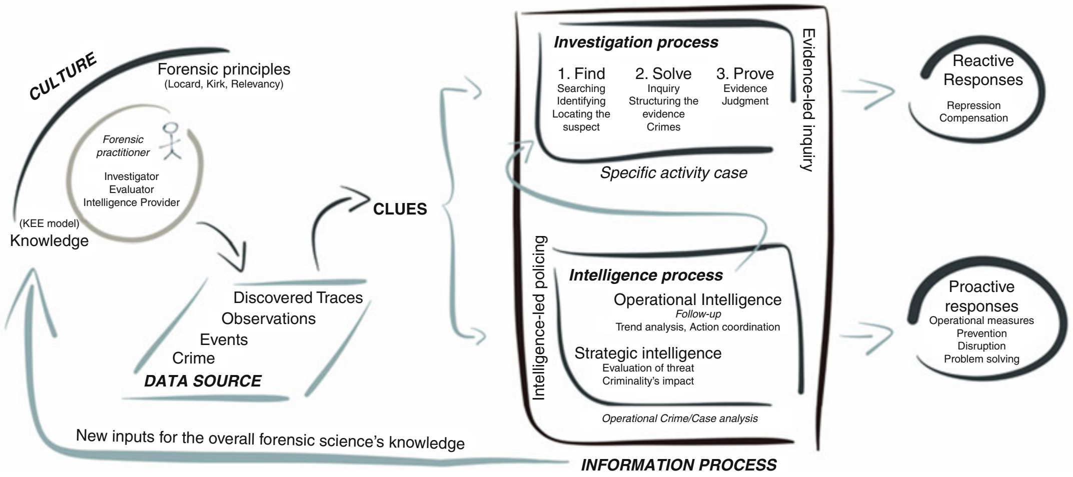
To succeed in such an enterprise, relations between academia and practice have to be strengthened in order to establish a valuable and effective flow of knowledge (Willis 2009) and develop sound professional judgment to assess whether a particular piece of data is relevant.

Milestone #3. Education and training frameworks have to foster a holistic vision of forensic science as a science based on the trace, convey the culture of the relevant questioning, and emphasize the multiple roles of the forensic scientist within the CJS.

Only education, training, and research may guarantee quality and relevancy consistently within a forensic science profession.

An End to Think About

As a meaning-making process that defines the culture of forensic science is the one transforming traces into information and then into (forensic science) knowledge (see Fig. 3).



CULTURE

Forensic Science Culture, Fig. 3 Forensic science as part of the overall security system (adapted from Ribaux and Margot 2008) (Hazard ©)

Think forensic consists of a thought methodology that lies on games of drawn inferences, which are based on critical observations of details (discovered traces), a sound scientific knowledge, a forensic science culture, and a capacity for adjustments. Details are made to "speak" and are used as clues for intelligence and/or evidence purposes. The latter are not mutually exclusive since the follow-up of information, part of the intelligence process, can provide support for the evidence-led inquiry or new inputs.

The forensic practitioner, who undertakes various roles, contributes to two processes, which diverge as to the effect of their outputs albeit they are part of the same system: the evidence-led inquiry provides reactive measures, like a response to a current case, while the intelligence-led policing allows proactive ones in terms of implementation of prevention, security, and operational matters.

Finally, ensuring scientific quality depends on the ability to recognize the impact and the limits of the forensic science knowledge and forensic scientists duty in the overall system, illustrated in this figure; by showing a comprehensive picture of their influence on the whole system, it enables to ask relevant questions that will improve the quality of the process. Such a conception of the forensic science culture fostered through an appropriate education and training will provide sound basis for forensic scientists, whose professional judgment would not be questioned as long as it relies on this basis, allowing the development of a sound trust in forensic scientists "expertise."

Overview

This entry reviews the state of the art in the area of effectiveness of forensic science and ultimately attempts to address the central question: What do we actually know about the impact of forensic science on the criminal justice system in general and on criminal investigations in particular? It is concluded that, although research to date has shown interesting trends, there is a need to better understand and explain the broader contribution of forensic science, as a precondition to accounting for its effectiveness. Otherwise, conclusions drawn from limited studies may have unintended effects for the whole system. Research outcomes to date probably reveal more about the need for methodological improvements in how to undertake such research than providing a clear answer with respect to the effectiveness of forensic science. More research is needed.

Introduction

Over the last decade, forensic science has been heavily present in popular culture through a number of TV shows, fiction or documentary. It has been argued that this situation led to increased public awareness of, and interest in, forensic science. There is a widespread belief that science and technology have become a "magic bullet" against crime, partly fuelled by the media continuously reporting forensic science successes, in particular those obtained through DNA analysis. Not only is such analysis often described as having "revolutionized" the ability of law enforcement to protect the innocent from wrongful prosecution (Innocence Project 2012), but it is also quoted as having enhanced the capability of police to identify, arrest, and prosecute offenders. For example, in a number of countries, "cold cases" have been revisited, taking advantage of modern technologies, primarily DNA profiling and novel fingermark detection methods. This situation has reinforced the perception of the infallibility of science in solving crime.

Contrary to this view, recent studies have questioned the effectiveness of forensic science on actual crime solving and justice outcomes (Baskin and Sommers 2010; Brodeur 2010).

For example, the effectiveness of DNA testing was found to be questionable when applied to serious or violent crimes (Wilson et al. 2010) unlike in volume crimes such as break and enters. It also appears that the perception of scientists about their own contribution is not uniform; and such questions do not even seem to be of major interest to laboratory scientists (Crispino 2008). In fact, current knowledge regarding the application of forensic science, particularly its effectiveness in criminal investigations and judicial outcomes, is limited. Further, as quoted by Julian et al. (2011), "*to a large extent, the policing and forensic services community has been 'flying blind' in terms of the true impact of its work.*"

These discrepancies may be symptomatic of the fact that the contribution of forensic science is not straightforward to assess because it occurs on a number of different dimensions or levels depending on the context of the judicial response or police activity. In addition, the judicial response itself is not linear nor continuous but can be seen as successive phases with different aims, distinct reasoning, and distinct ways of using information (Delémont et al. 2013). This entry reviews the state of the art in this area and ultimately attempts to address the central question: What do we actually know about the impact of forensic science on the criminal justice system in general and on criminal investigations in particular?

Efficiency or Effectiveness?

The terms "efficiency" and "effectiveness" are often used interchangeably in attempts to assess the value and/or impact of forensic science in the criminal justice system. However, the terms have distinct meanings and should be clarified if being applied for the purpose of impact assessment. A lack of clarity when using these terms creates confusion when undertaking research and leads to difficulties in identifying any trends in the value of forensic science in the criminal justice system. In their research, Kelty and Julian (2012a) found that stakeholders attached five different meanings to the terms "effectiveness of forensic science" and how it could be better achieved:

- Higher quality science
- Broadening the role of forensic science
- Reflection on, and improvements to, the current process
- Having an influence on justice outcomes
- Ensuring a "bang for your buck"

It is the latter, with its emphasis on cost-effectiveness, that is meant by the term "efficiency." The meaning of the term "effectiveness" is broader, can be operationalized in a number of ways, and may often encompass "efficiency." Since the studies we discuss below assess the value of forensic science in a variety of ways, we will adopt the term "effectiveness" throughout, unless the research specifically incorporates a financial component in its assessment.

This entry reviews current knowledge on the effectiveness of forensic science in the criminal justice system by focusing on the stages of the forensic process: crime scene, triage, laboratory processes, databases, and from identification to charges and to court. This is followed by a review of studies that examine the whole process from crime to court. This entry concludes with a brief discussion of future directions in research that is attempting to measure the value and/or impact of forensic science.

Crime Scene

It is often quoted that good forensic science starts at the crime scene. Many well-publicized miscarriage of justice cases find their root in poor crime scene work. In general, crime scene processing cannot be reproduced. It predetermines the quality and quantity of the information available to the investigation and ultimately presented in court. From this angle, it is impossible to discuss the topic of effectiveness in forensic science without a closer examination of what is happening at the crime scene (Julian et al. 2012).

Despite the paramount importance of this work, it is interesting to note that, from an organizational standpoint, crime scene models vary greatly depending on the type of crime and across jurisdictions. Laboratory scientists often attend specific scenes requiring specialized capabilities. Examples include disaster victim identification cases, mass murders, and fire scenes. However, in most countries, the vast majority of crime scenes are attended by police personnel. And in many jurisdictions, a further distinction is made between volume crime (e.g., break and enter) and serious crime (e.g., homicide). The personnel attending the latter have access to more resources, including the latest technology, compared to those attending volume crime. The status of crime scene personnel also varies greatly: sworn police officer with minimal training in forensic science, fully trained sworn police officer, civilian with a science degree, etc.

Beyond these very general trends, police models are variable, and it is difficult to identify what the dominant model is (Tilley and Ford 1996; Bradbury and Feist 2005; Adderley et al. 2007; Girod et al. 2008; Roman et al. 2008). Regional or local structures and customs usually dictate the most appropriate implementation model. The time spent at the crime scene, the types of crime attended, or even the type of trace that is collected may sometimes be imposed by the investigation process in practice within a specific police force. Other peculiarities such as the size of the police force and the local topography are also factors to be considered. The following observations can be considered as symptoms of an apparent lack of harmonization between organizations:

- The number of crime scenes attended by crime scene examiners per annum can vary greatly depending on the crime scene unit. For example, Tilley and Ford (1996) noted a variation between 400 and 1,350 in their English study.
- The quantity and quality of traces collected at the scene can also vary greatly depending on the region or crime scene unit. For example, Girod et al. (2008) showed that shoemarks are collected in 60 % of domestic break and enter cases in a region and in only 10 % of the cases in another region in Switzerland. This picture converges with results obtained by Rix (2004) in England.

More puzzling is the variation which may exist within one crime scene unit. In his study on shoemarks, Girod (2002) showed that the collection rate could double within the same unit, depending on the individual crime scene examiner. Further, Adderley et al. (2007) found that some crime scene examiners are more prone to collect some types of traces than other types and that high performers collected higher quality evidence, attended more scenes, and submitted evidence more quickly, and the evidence they collected was more likely to lead to positive identifications. It appears that, in addition to individual knowledge, experience, and motivation, the quantity and quality of traces collected at the scene also depends on the quality of the relationship between the crime scene examiner and the investigator (Bradbury and Feist 2005; Adderley et al. 2007; Crispino 2008; Girod et al. 2008; Kelty et al. 2012b).

The trend identified by these studies is that crime scene work appears to encompass a major "human factor," which makes any study on its effectiveness at the team or unit level difficult to interpret or generalize. To this end, in their Australian study, Kelty et al. (2012b) attempted to profile "top-performing" crime scene examiners. They found that such examiners shared a number of qualities within the following seven key skill set categories: knowledge base, experience, work orientation, approach to life, communication, professional demeanor, and cognitive abilities.

Overall, forensic science at the crime scene shows significant variations in terms of quality and quantity of the work undertaken. It appears that there is no universally accepted role for forensic science at this stage, and, in turn, this role depends on the historical development of the hosting organization. Further, these variations cannot solely be explained by differences of organizational setting and/or personnel status, and dimensions that are individual to the crime scene examiner have to be factored in. It is fair to conclude that, with regard to the paramount significance of the work undertaken at the crime scene, we only have limited empirical data to assess the true effectiveness of forensic science in this area and further research is strongly needed.

Triage

Once the crime scene is completed, specimens are generally sorted, and a decision is taken as to whether they must be considered further and forwarded to a forensic science laboratory. This step, called triage, is essential for financial reasons and also to focus the forensic examination on relevant traces, that is, those traces that are more likely to bring valuable information to the investigation and intelligence or are the more promising in terms of evidence. Efficient triage is therefore necessary to avoid flooding the laboratory with unnecessary items which contribute to laboratory backlogs.

Delays in providing laboratory results strongly diminish the relevance of potential links or "matches." In homicide cases, laboratory results are often provided once the case is solved (Schroeder and White 2009). In some cases, traces are not sent to the laboratory because the investigator has not identified a suspect or assumes that results will not be obtained in time for the investigation to progress satisfactorily (Strom and Hickman 2010).

Interestingly, despite its crucial role, triage has been rarely studied. Some trends however exist. According to Bradbury and Feist (2005), the selection is based on the case urgency, whether the specimen is degradable and how serious the case is (e.g., violent crimes vs. property crime). Specimens coming from cases where a suspect is known or in cases where there is a direct judicial request tend to be selected and analyzed as a priority. Scientific aspects are also considered, for example, the probability of extracting a usable DNA profile from a given substrate and/or from a degraded specimen (Raymond et al. 2009). It becomes evident therefore that the best model for an efficient triage should integrate police (investigation) and scientific (laboratory) considerations with a strong focus on the trace and its relevance. However, it appears that, in reality, the triage function largely remains reactive in response to judicial pressures and does not follow a proactive strategy aimed at solving a problem. It is believed that sound triage management would go a long way to addressing the challenge of laboratory backlog, as well as providing value-added information to the criminal justice system.

Laboratory Processes

Once traces have been sorted, a number of exhibits and/or specimens are generally forwarded to one or several well-equipped forensic science laboratory or laboratories or otherwise examined using scientific equipment. This stage of the process, compared to crime scene, appears more codified and more in line with the work undertaken by traditional (i.e., non-forensic) scientific laboratories. However, does it mean that the work is more effective? Or even that its effectiveness can be more easily and accurately assessed? The studies reported so far give a rather confusing picture. However, it seems relevant to distinguish the results obtained in serious crime vs. volume crime.

Serious Crime

In their studies based on homicide cases, Mucchielli (2006) and Brodeur (2010) provided a rather skeptical picture with respect to the effect of modern technology on case resolution:

- In two thirds of the cases going to court, the perpetrator was arrested because of his or her behavior, and the enquiry did not contain elements of identification or localization (Mucchielli 2006).
- The trace found at the scene was crucial in charging a suspect in only 7 % of the cases (Mucchielli 2006).
- 71 % of homicides were solved within 24 h without the need to exploit traces collected at the scene (Brodeur 2010).
- DNA enabled the perpetrator identification in only 1 % of the cases Brodeur (2010) studied.

These results are supported by other studies which showed the minor contribution of DNA in solving homicides (Schroeder and White 2009) and the fact that serial murderers were primarily identified by means other than forensic traces, for example, traditional eyewitness or victim statements and confessions. However, Bradbury and Feist 2005 showed that, in serious crimes (e.g., homicide), traces are mostly useful to solve difficult cases. In other words, the potential for a positive contribution would exist in only 10–20 % of homicides approximately. This could explain the limited apparent contribution of forensic science in the studies described above.

Volume Crime

There is only a small number of studies focusing on volume crime (e.g., break and enter, vehicle thefts). It is also difficult to make generalizations. However, the trend regarding the impact of forensic science appears to be more positive than the results obtained considering serious crime. In particular it appears that a systematic use of DNA in such cases has a significant effect on solving such cases (Roman et al. 2008; Wilson et al. 2010).

Roman and coworkers compared, between 2005 and 2007 and across five police forces, cases where a DNA specimen was sent to the laboratory for subsequent search in a DNA database with similar cases where no specimen was analyzed and only a traditional method of investigation was applied. Using DNA led to more than double the number of suspects being identified, twice the number of suspects being arrested, and twice the number of suspects being accused, compared to the control group where no DNA was used. Multirecidivists were also in higher number in the group using DNA than in the group using traditional methods. This indicates that these methods of investigations are complementary as DNA databases and traditional methods tend to identify different suspects.

Wilson and coworkers included the study by Roman et al. in their systematic review of field studies on the effectiveness of DNA testing. This review included:

- A study that had examined the impact of a DNA database on rates at which crimes are cleared and/or offenders prosecuted and convicted in the context of prison inmates in New South Wales, Australia
- Studies of the effect of DNA on case outcomes
- An evaluation of DNA use in burglary investigations

Wilson et al. concluded that their findings "*generally support the value of DNA testing for police investigations, particularly for high volume crimes such as burglary, although most of the empirical evidence is methodologically weak. Additional work is needed, not only with respect to DNA testing but other forensic methods as well.*"

Databases

If forensic databases have been in existence for a long time, in some cases for more than 100 years (e.g., fingerprints, identification systems), the scope and computing power of these databases only really took off in the late 1990s with the development of systematic collection and collation of DNA profiles. Not only did the development of these databases change the way investigations are carried out, but it also changed the perception of the judiciary toward forensic traces (Walsh 2009). Such databases usually contain information (1) derived from traces found at crime scenes and (2) obtained from people. The use and success of these databases are constantly reported in the news. Anecdotal evidence about the effectiveness of such databases in identifying people is compelling. However, the question ought to be asked: In regard to their cost as well as the legal and broader societal concerns associated with their use, are forensic databases (and in particular DNA databases) really effective? What is their actual impact on solving crime and on other aspects of policing and security?

Bradbury and Feist (2005) confirmed that DNA databases lead to impressive results. An interesting finding, based on the experience in England and Wales, is that such databases seem to change the way forensic traces are perceived and used: From being mostly corroborative evidence previously, they are now more systematically used to identify suspects.

It is, however, difficult to make general and global conclusions in this area because the management of these databases and the processes involved vary greatly across jurisdictions and police and forensic organizations. Factors having an effect on the content and uses of DNA databases, and hence impacting on their effectiveness, include:

- Number of cases attended
- Number of organizations involved in the collection of specimens and their analysis
- Anonymization protocols
- Profile removal policy
- Technology used
- Crime scene and triage policies
- Training and qualifications of the people involved
- Legislative compliance

The ideal database would contain the entire criminal population that is active at a given time. This is obviously impossible in practical terms.

DNA databases performance can be measured in different ways (Walsh 2009). A common model is to measure the ratio between the number of "matches" and the number of people profiles stored in the database. Recent European data based on 19 available databases (ENFSI DNA Working Group 2011) show this ratio varies between 0.03 (France) and 0.26 (Denmark and England and Wales). This variation reflects variation in practices and usages rather than intrinsic differences between databases. For example, if a jurisdiction submits fewer profiles from traces than others for a similar number of people profiles stored in the database, there will be fewer "matches" and the performance ratio will, in turn, be smaller. Differences in the policy applied with respect to profile removal will also have a major effect on the calculated performance.

Another point to emphasize is that the discovery of a database "match" will have an influence all through the criminal justice chain. It is, however, difficult to know the global effect of this "match" on operations including the effects of saving time and linking cases on court outcomes (see below).

In summary, it can be accepted that the development of forensic databases such as DNA databases leads to spectacular results, especially when the aim is to identify links between a trace found at the crime scene and a person. However, their effectiveness in terms of linking information obtained from traces remains unclear. Further, accurate database performance evaluation is difficult and may be misleading without a complete understanding of the overall information treatment processes involved (Bieber 2006). As stated by Bieber (2006), "*a lack of integration between the DNA laboratories and the other components of the justice system responsible for following up on results is perhaps the biggest weakness, in that desirable outcomes have not been clearly defined or carefully researched*." In this regard, the integration of forensic information in a crime intelligence database should be seen as a positive development (Rossy et al. 2012). This approach seems particularly effective when the system in place enables the exchange and comparison of marks and traces across several jurisdictions.

From Identification to Charges and to Court

If the identification of the offender is one of the major aims of an investigation, the forensic science work goes well beyond the discovery of a fingerprint or a DNA "match." Identifying an individual does not necessarily lead to an arrest, let alone to a guilty outcome in court. The effectiveness of forensic science is therefore closely related to the conversion rate between "identifying an individual (through forensic means)" and "arresting this individual." Do we have an idea of what this rate could be? Only a small number of studies have been undertaken in this area and the results appear sometimes inconsistent. However, the following trends have been identified:

- In England and Wales, out of ten fingerprint and DNA "matches," approximately seven could be translated into an arrest in high-volume crime cases (Bradbury and Feist 2005).
- In a 1-year study across seven divisions of two police forces in England, it was found that 81 % of links identified on the basis of shoe marks, toolmarks, and biological traces led to

an arrest. Further, investigators interviewed in this study estimated that forensic traces played an essential or secondary role in the arrest in 91 % of the cases (Burrows and Tarling 2004).

Overall, there seems to be an attrition rate of 20–30 % between the identification and arrest stages. There are many reasons to explain this attrition. For example, the suspect may admit a contact with the scene or surface under investigation but challenges the context that would lead to the charges; for example, he or she can claim a legitimate contact. Further, secondary transfer, contaminations, uncertainty in the identification, and laboratory or clerical errors are well-known phenomena and can also play a role in some cases. For these reasons, a forensic "match" has little value per se. The investigator in charge must integrate the results obtained from forensic examination into the remaining information available in the case. In other words, the exploitation of a forensic result is strongly related to the investigation. It is therefore not surprising to see that the likelihood of an arrest once an identification is made depends on the quality of the investigator in charge (Julian et al. 2012). To this end, the investigator's work appears scientific in nature, not only because material traces are considered, but also because hypotheses are identified and tested in a structured and logical manner. However, some cultural issues (i.e., investigator vs. scientist) often remain and explain why investigators usually tend to favor human aspects (e.g., eyewitnesses, informants, and psychological profilers) over material traces. Integrating investigators and scientists, sharing the same goal, in a common (or at least closely related) structure appears to deliver improved outcomes, although this is difficult to capture and measure (Barclay 2009).

It is also interesting to note that a "match" may be identified once an individual has already been arrested. The forensic result in this case is added to the file, and it becomes difficult to measure its impact on the defendant's behavior and on the defense or prosecution strategies through the court process. There seems to be a difference between serious crime and volume crime. For example, Briody and Penzler (2005) found that DNA evidence was a positive predictor that prosecutors would pursue cases in court and had a powerful influence on jury decisions to convict. Incriminating DNA evidence demonstrated no significant effect on inducing guilty pleas from defendants for serious crimes against the person. However, it did correlate significantly with cases reaching court and with guilty pleas being entered for property offence cases. In serial cases involving DNA, offenders have the tendency to confess their involvement in additional cases, in which no forensic traces exist and no suspects have been identified (Bradbury and Feist 2005).

"End-to-End" Process

It is clear that the accurate assessment of forensic science effectiveness requires a consideration of the overall process involved in the practice of this discipline, from the actual crime to court or other contributions to policing. Such studies are difficult to undertake because the process by which forensic traces are discovered at the scene and then moved through the criminal justice system to court is very convoluted. As a result, while end-to-end studies provide a more holistic view on how forensic science contributes to the criminal justice system, there are many difficulties in generalizing any statement about forensic science effectiveness as practices vary tremendously and are almost never explicitly integrated with clear policing strategies. Examples of such studies reported to date are briefly described below.

- ***United Kingdom Scientific Work Improvement Model (SWIM) and Derbyshire Constabulary Study***

The SWIM project (Home Office 2007) built upon some work undertaken during 2002 and 2003 in the Derbyshire Constabulary, in which a direct correlation between the time taken from crime occurrence to forensic-led detection (lead time) and crime levels had been identified. In other words, reducing the lead time could reduce the level of crime. The SWIM program ran over a 2-year period and involved 41 forces looking at the police and scientific functions in England and

Wales. Focusing on burglaries and vehicle thefts and on DNA and fingerprints, the study examined the main stages of the overall process (attendance, submission, identification, and detection) and evaluated the lag time between each of the phases and the success of the case as it moved through to the next stage. At each stage, the result was calculated as the proportion of transactions that were transferred to the next stage. The lead time was calculated for each crime report as the earliest activity date at each forensic process stage. The success rate was calculated as the percentage of cases that successfully moved to the next stage.

The SWIM report made a large number of general and police force specific recommendations for improvement at all stages of the forensic process. In particular, it demonstrated the need to identify significant leakage points in the process and that systems should be developed to capture and compare relevant data and learn from top performers.

- ***Denver Colorado Study***

This study (Ashikhmin et al. undated) aimed to evaluate the effectiveness and cost of DNA technology on high-volume crimes such as burglary, auto theft, and theft from motor vehicles in 2006. The study found that aggressive use of DNA in such investigations and subsequent prosecutions resulted in a significant decrease in property crimes compared to similar metropolitan areas in the United States. It also found that, in burglary cases with hits in the Combined DNA Index System (CODIS), much harsher sentences were given to high-volume, habitual offenders whose criminal activity had a higher impact on society. The study also conducted a cost benefit analysis and found that the return on investment for every dollar spent with this approach was estimated to be $90 with an actual 2-year savings to the citizens and the city of Denver of more than $5 million in police costs and $36.8 million in property loss. In conclusion, this study recommended an expansion of DNA science in high-volume crimes based on the high success rate for prosecution and the value for money return on investment.

- ***Waikato District and Environmental Science and Research: Forensic (ESR Forensic) DNA Project***

In mid-2010, the Waikato Police District in New Zealand (NZ) undertook a 3-month study in collaboration with ESR Forensic, the main government forensic science laboratory in New Zealand (Coley 2010). The aims of this trial were to monitor the implementation of quicker turnaround times by ESR Forensic and police for DNA submissions from volume crime scenes and to assess the value of the forensic submissions being made in terms of their likelihood to produce a profile and the value of those links to investigators. Return on the investment was also considered.

The trial led to a significant improvement in turnaround times by ESR Forensic which significantly increased the value of the forensic results to police. It was also found that the trial made a significant contribution to volume crime reduction through better prioritization of district volume crime DNA collection and submission and through the actioning of forensic identifications. For example, it was found that ESR Forensic Volume Crime Laboratory averaged 5.4 days turnaround time from receipt to result in the laboratory for 78 % of Waikato submissions over the 3-month trial period, improving significantly on the previous 4-week turnaround. By ensuring attendance within the same day as a crime is reported, Scenes of Crime Officers (SOCO) were able to see the added value of their forensic results and the effect of their timely response on the current crime environment. Further, investigators identified the benefits of working with rapid identifications: (1) It has the potential to recover property and to prevent future offending and (2) it assists in identifying current "hot" offenders, which in turn allows the police to apply a targeted approach disrupting and influencing the current crime patterns.

- ***ANZPAA-NIFS End-to-End Forensic Identification Process Project***

The Australia New Zealand Policing Advisory Agency National Institute of Forensic Science endorsed this project in 2010 to *"review end-to-end forensic processes and develop* *a national framework for efficient crime scene analysis*" (Brown and Ross 2012). End-to-end processing was defined in this project as the time from the report of a crime through to the arrest of an offender. The process was broken into five distinct stages: attendance, submission, analysis, identification, and investigation. The study aimed to benchmark performance for the use of fingerprints and DNA in burglary cases. It was carried out in 2011 in partnership with the eight Australian police agencies and a number of relevant DNA laboratories. In total, 17 sites across Australia were considered for more than 8,000 burglaries reported over a 5-month period.

The findings and recommendations are still being discussed and reported to the participants and stakeholders at the time of writing. It is hoped that this project will not only provide an appreciation of the forensic performance within Australia but will also identify some directions with respect to (1) the scope of evaluation that could be carried out and (2) the possibilities that exist to improve forensic science service delivery. Further, a second snapshot study is envisaged to determine if recommended changes have a positive impact on performance for the end-to-end forensic process.

Conclusions: Future Directions

This entry presents a critical review of the topic of effectiveness of forensic science. In particular, it attempts to address the central question: What do we actually know about the impact of forensic science on the criminal justice system in general and on criminal investigations in particular?

It is, however, impossible to discuss the topic of effectiveness without knowing what the contribution of forensic science is expected to be. Similarly, it is impossible to assess effectiveness without contrasting outcomes and impact against what the forensic science community itself claims to be able to achieve. This discussion is challenging because, in general, expectations are poorly defined. Further, the traditional contribution of forensic science is primarily oriented toward the court's needs and requirements. How can we account for this contribution? In this context, it is impossible to define what "successes" and "failures" are, because, in this dimension, forensic science's role is to provide impartial information to the trier of facts. Forensic scientists never celebrate the outcome of a court process. Why would they be assessed on this basis then?

Beyond the court process, assessing the effectiveness of forensic science is equally challenging. Effectiveness cannot only be measured in terms of crime resolution. The contribution of forensic science is actually much broader (Barclay 2009). To this end, there is an emerging shift from the traditional focus on forensic science in the laboratory toward a more significant contribution of forensic science in intelligence-led policing and investigation (Ribaux et al. 2006, 2010a, b; Roux et al. 2012). This contribution, which is not trivial, must be accounted for in the overall assessment of the effectiveness of forensic science.

Research to date has shown interesting trends, such as that the best use of forensic science is reached when the collection and processing of forensic case data is promoted through close cooperation between forensic scientists and investigators. There are however major discrepancies in forensic policies across institutions and even across individuals, and they are poorly integrated into policing strategies. Thus, inference of any general rules about the effectiveness of forensic science drawn from individual studies may be invalid. It is argued that there is a need to better understand and explain the broader contribution, as a precondition to accounting for effectiveness. Otherwise, managerial decisions taken on the basis of limited studies and misunderstandings about what forensic case data can bring may have unintended consequences for the whole system.

Research outcomes to date probably reveal more about the need for methodological improvements on how to undertake such research than providing a clearer answer with respect to the effectiveness of forensic science. In other words, more research is needed in this area.

Forensic Science Evidence

► Scientific Evidence in Criminal Prosecutions

Forensic Science in the Nineteenth and Twentieth Centuries

Douglas M. Lucas
The Centre of Forensic Sciences Ontario,
Burlington, ON, Canada

Overview

Medicine was the first science-based profession to be used for forensic purposes, and forensic medicine can be considered to be the mother of forensic science. In the sixth century, the Emperor Justinian recognized the special position of the expert witness when he declared that physicians were not ordinary witnesses but rather persons who gave judgments rather than testimony. In England, the Statute of Westminster in 1265 contained the first provision for the office of coroner, and, in 1507, the Bamberg Code in Germany required that medical evidence be presented in all cases of violent death. These provided a legal basis for the practice of forensic medicine and were the precursors of modern coroner and medical examiner legislation. In North America, the early English settlers brought the coroner system with them and inquests were held as early as 1635 in New England.

Prior to the nineteenth century, evidence of poisoning was purely clinical and circumstantial because there were very few chemical tests for poisons available. As knowledge of chemistry increased, it was applied to the detection of poisons, usually by university professors ensconced in traditional university departments. Other now commonly recognized forensic sciences – fingerprint identification, trace evidence examination, questioned document examination, firearms and toolmark examination, and serology were essentially unknown.

Toward the end of the eighteenth century, precursors of what would now be considered "Institutes of Forensic Medicine" began to appear as personal chairs in university departments. The first such was the *Chaire de médecine légale et de histoire de l'art de guérir* established in the University of Paris in 1794. Within a few years, similar chairs were established in the Universities of Strasbourg and Montpellier. Forensic science laboratories, however, were nonexistent.

Developments in the Nineteenth Century

Forensic Medicine

Although most of what we now refer to as the forensic sciences did not begin to develop until the latter half of this century, forensic medicine began to be recognized as a specialized branch of medicine, "legal medicine," early in the 1800s. In Austria, a Chair in Legal Medicine and Hygiene was established in the University of Vienna in 1804, while in France *l' Institut de médecine lé gale de Paris* was founded in 1868.

The first British Professor of Legal Medicine was Andrew Duncan Sr. in the University of Edinburgh. Duncan persuaded the University to establish the Regius (government-funded) Chair in Medical Jurisprudence in 1806; however, it was his son, Andrew Duncan Jr., who became the first incumbent in that Chair. This father/son succession pattern was repeated in the same Chair in 1906 when Henry Harvey Littlejohn succeeded his father Sir Henry Littlejohn. Similarly, at the University of Glasgow, John Glaister Sr. and Jr. combined to hold the Regius Chair of Medical Jurisprudence and Forensic Medicine, established in 1839, from 1898 to 1962. Edinburgh became the cradle of forensic medicine for the English-speaking world as graduates established forensic medical services in many other countries.

In England, the most prominent early name was Alfred Swaine Taylor who became Professor of Medical Jurisprudence at Guy's Hospital Medical School in London in 1834. Taylor was a prodigious author, and his "Principles and Practice of Medical Jurisprudence," first published in 1865 and continuously revised and updated by later authors, was long recognized as a standard work.

The first lectures on legal medicine in the USA were given in New York in 1804 by James S. Stringham, a graduate of the University of Edinburgh. A major development occurred in Massachusetts in 1877 with the abolition of elected coroners and the establishment of a medical examiner system which required that the medical examiner be a qualified pathologist.

Forensic Toxicology

As the science of chemistry developed, a few professors of forensic medicine began to use this new science for one of their more intractable problems, the detection of poisons. One of these was Mathieu Joseph Bonaventure Orfila, universally acknowledged to be the "Father of Toxicology" (Schuller 2003). Orfila studied at Valencia and Barcelona before graduating in medicine from the University of Paris in 1811. He soon became Professor of Legal Medicine and Chemistry at that University and, in 1814, published the first major work on toxicology "*Traité des poisons tirés des règnes minéral vé gétal et animal ou Toxicologie Générale*" which rapidly gained international recognition. Much of Orfila's research was devoted to the study of arsenic, and, in 1839, he was the first to extract it from human organs rather than from just stomach contents. Orfila used the results of this research in 1840 in his testimony at the trial of Marie Lafarge for the murder of her husband by means of an arsenic-laced cake. This trial focused worldwide attention on the new science of toxicology; *L'affaire Lafarge* was probably the first case in history in which convincing scientific testimony (other than medical) was presented.

The introduction of analytical methods for metallic poisons caused potential poisoners to turn their attention to the alkaloids that were beginning to be isolated from plants. These were considered to be undetectable in human organs; however, in 1850, this began to change with the development by Jean Servais Stas, a Professor of Chemistry at *L'École Royale Militaire* in Brussels and a former student of Orfila's, of a method for the extraction of nicotine from the organs of a murder victim. Stas' basic procedure (as modified by F.J. Otto in 1856) was based on the differing solubility of such drugs in acids and bases and is still in use. Identification of any extracted drugs was based on colors developed, and microscopic morphology of crystals formed, when the extract was reacted with other chemicals.

A trend toward specialization in toxicology began near the end of the nineteenth century with the emergence of, for example, the most prominent of the early American toxicologists, Rudolph August Witthaus who had studied chemistry at Columbia University and at the Sorbonne. He became a Professor of Chemistry and Physiology at New York University in 1876 and published one of the earliest American textbooks on chemistry and toxicology in 1879.

Fingerprints

In the late nineteenth century, the only accepted method for identifying habitual criminals was photography. While useful when the criminal's name was available, there was no way to file photographs other than by name. If the criminal changed his name, photograph files were of no assistance. In 1879, Louis Alphonse Bertillon, a junior records clerk in the headquarters of the *Sureté* in Paris, devised a detailed system of anthropometric measurements, such as the length and width of head and lengths of left middle finger, right foot, and left forearm, which would be unique and relatively constant for an individual. His system, which he called "anthropometry" and which the press dubbed "*Bertillonage*" was adopted by the *Sureté* in 1882. Bertillon went on to become the Director of the Police Identification Service in Paris.

Bertillonage was a cumbersome process with an unwieldy filing system and even Bertillon recognized that criminals do not leave their anthropometric measurements behind at a crime scene. The basis for a better technique had been established in a paper published in England in 1684 by Dr. Nehemiah Grew in which he referred to "innumerable little ridges" on the ends of the fingers. In 1686, these ridges were independently described by Marcello Malpighi, a Professor of Anatomy in the University of Bologna. Neither, however, suggested any potential of these for personal identification. It was not until 1823 that the patterns formed by these ridges were described by a Czech physiologist, Jan Evangelista Purkinje, of the University of Breslau. While Purkinje suggested a classification system based on nine major types, he too failed to recognize their potential for individualization.

In 1877, Thomas Taylor, a microscopist in the US Department of Agriculture, published an article in the "American Journal of Microscopy" in which he suggested that "markings on the palms of the hands and the tips of the fingers" could be used for identification in criminal cases. This suggestion was not pursued in the USA, and it was left to a Scottish physician working in Tokyo, Dr. Henry Faulds, to publish a letter in Nature in 1880 in which he suggested that they might be useful as a means of personal identification (Faulds 1880). His letter prompted publication of a second letter a month later in the same journal from William Herschel, a British officer working in the Indian Civil Service, reporting that he had been using thumb impressions to identify illiterate prisoners since 1856. Herschel, who later received a knighthood, also made the critical observation that the patterns of what he called "papillary lines" did not change with time.

Despite the fundamental importance of these observations, they were of limited practical value until Francis Galton, an English scientist and explorer, published a book titled "Fingerprints" in 1892 (Galton 1892). Galton corresponded with Herschel and they agreed that fingerprints were individual and permanent – a fundamental requirement for their value as a system for identification. Galton described a classification system, using the arches, loops, and whorls of fingerprint patterns, which came to be known as "dactyloscopy." Also in 1892, in Argentina a Croatian, Juan Vucetich, used the identification of a bloody fingerprint to solve the murder of two small children by their mother, the first use of fingerprint identification in a criminal case.

Edward Richard Henry, the Inspector General of Police in Bengal in the 1890s, became aware of Galton's work and, by 1897, had enhanced Galton's classification system into a more practical system that bears his name and is still used worldwide. Henry published "Classification and Use of Fingerprints" in 1900 (Henry 1900), and his system formally replaced anthropometry in England in 1901. Henry was by then Assistant Commissioner in charge of the Criminal Investigation Branch at Scotland Yard.

Trace Evidence

Two of the commonest requests made of a forensic science laboratory are "What is this material?" and "Could these two items have come from the same source?" The items can be almost anything but typically are paint, glass, soil, hairs, fibers, metals, gunshot residue, flammable liquids, or explosives. The science involved in trace evidence examination is principally chemistry and the early practitioners were usually professors of chemistry who accepted this type of request from local police investigators as a public service.

Remarkably, it was a lawyer, not a scientist, who first emphasized the assistance that police investigators could derive from the basic sciences. Hans Gustav Adolf Gross was a Professor of Law at the University of Linz in Austria. He also served as an examining magistrate which inspired him to spend 20 years studying science textbooks and developing principles of criminal investigation. Gross first published his classic book "*Handbuch für Untersuchungsrichter*" ("Handbook for Examining Magistrates") in 1893. It was later translated into English under the simple title "Criminal Investigation" and resulted in Gross becoming widely referred to as the "Father of Scientific Criminology."

Although chemistry was developing rapidly, it was microscopy which was the fundamental tool of the nineteenth-century forensic scientist and which piqued Gross's interest. Even today, the examination of trace evidence usually starts with a low-power stereo microscope, often just to find the evidence, and then may progress to higher power microscopes and, in the nineteenth century, to the basic "wet chemical" procedures such as color and crystal tests. One of the first types of trace evidence to be studied was human hair. In 1857, Jean Louis Lassaigne, a French chemist, published the results of his systematic microscopic studies of hair "*De l'examen physique des poils et des cheveux*" ("On the Physical Examination of Hair").

Firearms/Toolmarks

The marks left by a hard tool on a softer surface are known as "toolmarks" and their examination in an effort to, for example, associate a particular tool such as crowbar with a forced entry mark, is quite common. The striation marks made on a rifled firearm barrel by both the original rifling tool and subsequent use are impressed onto a bullet surface as it passes through the barrel and are a particular form of toolmark.

In 1835, Henry Goddard in London identified a lead ball which had killed a man as having been made in a mold belonging to a suspect on the basis of an unusual mold mark on the ball. During the Civil War in the USA, a number of shootings (including that of Confederate General Stonewall Jackson in 1863) were resolved by associating "class" characteristics of the bullets, for example, shape, caliber, number of lands and grooves, with the types of firearm suspected (but not with an individual weapon).

In 1889, Jean Alexandre Lacassagne, the founder of the Faculty of Legal Medicine at the University of Lyon in 1880, was probably the first to use a microscope to examine a bullet removed from a shooting victim. He observed seven longitudinal grooves on it and concluded that they must have been made by the rifling of the barrel. Further advances in firearms examination did not develop until the twentieth century.

Forensic Biology

Attempts to identify and individualize body fluids have been a major activity in forensic science since the early nineteenth century. In 1827, the above-mentioned Mathieu Orfila published his research on the microscopic identification of red blood cells based on their size and whether or not they were nucleated. This technique was quite impractical for dried blood in which the blood cells are no longer intact. In 1853, Ludwig Teichmann, a Polish Professor of Anatomy in Gottingen, Germany, described a microscopic crystal test for hemoglobin based on the formation of brownish crystals of hematin. A Dutch scientist, Izaac Van Deen, discovered in 1861 that when tincture of guaiacum and oil of turpentine were added to a bloodstain a blue color resulted. This "guaiac test" was the first of many color tests for hemoglobin; some such as luminol and phenolphthalein are still in use. These tests, although very sensitive, are not specific for blood and, therefore, are referred to as "presumptive tests."

Questioned Document Examination

Establishing the genuine or bogus nature of handwriting, and of documentary material in general, has been an issue in investigations for centuries. Early "handwriting experts" were teachers, bankers, etc., usually having little or no experience in forensic work. For example, Alphonse Bertillon, who had no qualifications in handwriting examination, testified in the infamous Dreyfus affair in 1894 in France and, incorrectly (as it later turned out), identified Captain Alfred Dreyfus' handwriting on the incriminating document.

By the end of the nineteenth century, although forensic medicine was frequently used in criminal investigations and trials, the other forensic sciences were just beginning to be recognized as having the potential to assist in such procedures. Some of the techniques (or at least the fundamental bases for them) had been established, but practitioners were relatively few. That was to change dramatically in the twentieth century.

Developments in the Twentieth Century

Forensic Science Institutes and Laboratories

Institutes of legal medicine began to increase in number in Europe in the early part of the century, but remained primarily based in universities. The Edinburgh influence continued to spread with the appointment of Sidney Smith, an Edinburgh graduate, as the Principal MedicoLegal Expert in Cairo, Egypt. There he persuaded a team of experts in other disciplines to devote some of their time to forensic science. One of these was Arthur Lucas of the Government Chemistry Laboratory who, in 1921, published "Forensic Chemistry" which was one of the first texts to cover forensic science topics other than medicine and toxicology. Smith himself developed expertise in the emerging field of firearms identification. He returned to Edinburgh to take up the Chair in the University in 1927 and received a knighthood in 1949.

In North America, there was minimal progress in forensic medicine until the establishment of the Office of the Chief Medical Examiner in New York City in 1918 under the leadership of Dr. Charles Norris. Norris' objective was to develop a medicolegal institute which would provide service and research equivalent to the leading institutes in Europe. The Office also became a leading teaching center after Milton S. Helpern became an integral member in 1931. "Alumni" of the Office went on to establish important institutes across the USA.

More broadly based forensic science laboratories gradually began to appear, the first being *L'Institut de police scientifique* in the University of Lausanne established in 1909 by Dr. Archibald Rodolphe Reiss. Within a year, it was followed by *Laboratoire de police technique* in Lyon under the leadership of Edmond Locard a native of Lyon who had studied under Lacassagne in the Faculty of Legal Medicine. Because he wanted to significantly expand the scope of Lacassagne's Institute, Locard persuaded the police of the *Rhône préfecture* to provide him with two rooms in an attic and two assistants to establish a police laboratory in Lyon, equipped initially with only a microscope and a simple spectrometer. This lab went on to become a major center for teaching and research, in addition to providing forensic science services to the police. Students came from around the world, many returning home to establish laboratories of their own. Over the ensuing 15 years, similar laboratories were established in Germany, Austria, Canada, Finland, Germany, Holland, and Sweden.

In Britain, it was not until 1935 that a forensic science laboratory was formally established by the Metropolitan London Police. The "Met Lab" went on to become one of the most respected such organizations in the world. In the rest of England, laboratories that had been started by local police forces gradually came under the wing of the Home Office Forensic Science Service (FSS) – as did the Met Lab in 1996. (Ironically, one of the reasons for these transfers was to enhance the appearance of impartiality and independence from the police. However, following the decision by the Home Office in 2010 to disband the FSS (see below), some police forces decided to again establish their own labs).

In 1966, the Home Office opened the Central Research Establishment (CRE) at Aldermaston. This laboratory had a major impact on forensic science not only within the FSS but worldwide. Most operational laboratories have neither the time nor the capability to perform systematic research on fundamental issues. This dearth was the subject of a classic essay by Paul Kirk of the University of California in 1963 (Kirk 1963). He wrote: "In short, there exists in the field of criminalistics a serious deficiency in basic theory and principles, as contrasted with the large assortment of effective technical procedures." CRE was staffed and funded to perform such studies and share the results internationally thus greatly enhancing the reliability and validity of scientific evidence. Unfortunately, CRE was closed in 1997.

All of the FSS Labs were funded from central and local government funds until 1991 when the FSS became an Executive Agency of the Home Office and changed to a fee for service basis. (This move toward "privatization" evolved into a full Government-Owned Contractor-Operated Company in 2005. The format was not successful financially in spite of the FSS's stellar scientific achievements and reputation and, in December 2010, the Home Office announced that the operation would be closed in March 2012. A fundamental issue is whether forensic science service delivery should be "commercialized" or should be recognized as an essential part of the justice system and thus a core public service funded by the state!).

In North America, the first government-funded forensic science laboratory was established by Dr. Wilfred Derôme in Canada in 1914. Derôme had gone to Paris in 1909 to study under Professor Victor Balthazard and, while there, became aware of the laboratory Locard was developing in Lyon. He determined to do the same in Canada and, on his return from Paris, Derôme persuaded the Attorney General of Quebec of the importance of this new type of service. As a result, in July 1914, the Premier of Quebec announced the establishment of *Laboratoire de recherches médico-légales* in Montreal (Côté 2003).

The first forensic science laboratory in the USA was established in the Los Angeles Police Department in 1923 by Chief August Vollmer, a great innovator in police work. After his brief term with LAPD, Vollmer returned to the Berkeley Police Department where he had established a School of Criminology in the University of California. Although located on the campus, the School had no official status until 1948 when the School of Criminology was formed and Professor Paul Kirk became the first Chair of the Criminalistics Department. Kirk became a legendary figure in forensic science in the USA and many of his students went on to establish forensic science laboratories across the state and the country. Unfortunately, the UC School, one of the few in the USA with a graduate program in forensic science, was closed in the 1970s.

Although the LAPD Laboratory was the first in the USA, its early days were overshadowed by the prominence of a laboratory established in Chicago in 1930. Following the St. Valentine's Day Massacre in 1929, a coroner's jury of prominent citizens was so impressed with the firearms evidence presented by Calvin Goddard (see below) that one of their members provided $125,000 to fund the creation of a full-service "crime laboratory" under Goddard's leadership. With the support of John Henry Wigmore, Dean of the Law School in Northwestern University, the "Scientific Crime Detection Laboratory of Chicago" was housed in the Law School building. At this lab, Goddard trained staff from many agencies around the USA. Following his retirement, the Laboratory was transferred to the Chicago Police Department in 1938 and then to the Illinois State Police in 1996.

What was to eventually become the largest and best known of the forensic science laboratories in the USA was not established until 1932 when J. Edgar Hoover created the FBI Laboratory in Washington, D.C., a modest facility with a staff of one who had studied firearms examination under Goddard in Chicago.

Beginning in the late 1960s, the number of forensic science laboratories in the USA virtually exploded, driven largely by "the war on drugs" and Federal Government funding through the Law Enforcement Assistance Administration (LEAA). The vast majority of these were established within law enforcement agencies, some staffed with police officers who had limited or no science backgrounds. As the century progressed, the trend was toward better qualified civilian scientific staff although sometimes still with police administrators.

Forensic Medicine

For much of the first half of the century, a giant in forensic medicine in England was Sir Bernard Spilsbury who was a Home Office Pathologist from1908 to 1948. It was he who convinced Scotland Yard Detectives of the importance of having the pathologist and other specialists at murder scenes. In the courtroom, he was able to exert a spell over judges and juries, sometimes with little more basis than confidence in his own vast experience of over 25,000 cases. His reputation was not based on his writings, however, since, unlike most of his predecessors and contemporaries, he published virtually nothing.

Following Spilsbury, forensic medicine in England was led by Keith Simpson at Guy's Hospital and Francis Camps at the London University Hospital. Camps set up the Department of Forensic Medicine in the London Hospital Medical College in 1945. By the time of his retirement in 1970, he had built this Department into one of the foremost of its kind in the world.

In the USA during much of the twentieth century, forensic medicine was dominated by a relatively small number of individuals. In addition to Charles Norris, there were Milton Helpern in New York, Alan Moritz in Cleveland, Theodore Curphey in Los Angeles, Russell Fisher in Baltimore, and Charles Petty in Dallas. Forensic pathology services in much of the rest of the country were provided by "part-timers" with varying degrees of qualifications and expertise. That began to change toward the end of the century with more and better training and with recognition of the need for research-based (as opposed to experience-based) testimony. Nevertheless, in large parts of the country, the quality of death investigation services remained variable – elected coroners (often funeral directors) presided and, for much of the century, autopsies had to be performed in makeshift facilities such as funeral homes.

Forensic Toxicology

It was not until Norris established a Toxicology Section led by Dr. Alexander Gettler in 1918 that improvements in toxicological service began to occur. Gettler had no model to follow so much of his early work was of a pioneering nature, and his laboratory became the birthplace of forensic toxicology in the USA.

Virtually all of the early analytical methodology was based on wet chemistry and microscopic procedures which required large samples – 500 g of liver was the typical starting point – as contrasted with the 1–2 μl of blood that is now the norm. In addition to his innovative analytical procedures, Gettler's principal contribution to modern forensic toxicology was a graduate course in toxicology at New York University which he started in 1935 and taught until his retirement in 1959. His graduates went on to become an outstanding "second generation" of forensic toxicologists who started laboratories across the country.

As the twentieth century proceeded, developments in the pharmaceutical industry made forensic toxicology much more complex. While the inorganic and vegetable poisons continued to be used, synthetic drugs which were much more potent became more common. Their detection required more sensitive analytical procedures. The traditional color and crystal tests began to be supplemented by ultraviolet spectrophotometry and paper chromatography in the late 1940s, gas chromatography in the late 1950s, thin layer chromatography in the mid-1960s, mass spectroscopy combined with gas chromatography (GC/MS) in the late 1960s, and by liquid chromatography and immunological techniques in the early 1970s. GC/MS became the predominant technique for identification; when it was introduced, the complexity of interpretation of the data was such that a Ph.D. was considered an essential qualification. Within a few years, interpretation of mass spectra became more a matter of "pattern matching" with databases which could be done by persons with lesser qualification. (A similar phenomenon later occurred with DNA analysis.)

Although not toxicology per se, identification of "street drugs" employs many of the same analytical techniques and this type of analysis, because of the "war on drugs" constitutes the largest volume of casework in most forensic labs in the USA.

Of all the drugs which forensic toxicologists deal with, by far the most significant in terms of its prevalence and impact on human behavior is ethyl alcohol. Dr. Erik Widmark, a Professor of Physiological Chemistry at the University of Lund in Sweden, was among the first to systematically study the absorption, distribution, and elimination of alcohol in the body (Widmark 1932). A prerequisite for such studies was a reliable microanalytical method for alcohol in blood. Widmark's method, published in 1922 (Widmark 1922), became the most commonly used procedure worldwide and continued to be used well into the 1960s and 1970s. His mathematical pharmacokinetic parameters are still in use.

Another major development with alcohol was the invention of breath alcohol testing devices. Rolla N. Harger, a Professor of Pharmacology and Toxicology in the Indiana University Medical School, perfected the first such device, the "Drunkometer," in 1937. Robert F. Borkenstein, of the Indiana State Police, improved substantially on this in 1954 with the "Breathalyzer®," an instrument which, although now superseded by more modern equipment, continued to be used in the USA and Canada for over 50 years.

Fingerprints

The first investigator to use fingerprints for criminal investigation in the USA was Detective Sergeant Joseph A. Faurot of the New York City Police Department in 1911. It was not until 1930 that the Director of the Federal Bureau of Investigation, J. Edgar Hoover, set up a national bureau for identification which became the largest repository of fingerprints in the world.

Inked fingerprint impressions compared with the known fingerprints of an individual are still considered to be the most positive form of personal identification, although other biometrics may be used for specialized applications. Latent fingerprints, on the other hand, present greater challenges. For much of the century, development of latents was primarily by dusting with fine powders which adhered to the moisture or sebaceous deposits retained in the impression. In the 1970s, it was recognized that the chemicals in perspiration, including amino acids and various salts, presented opportunities for chemical detection and some quite sophisticated chemistry and physics was applied to this challenge. These reactions, with other chemicals or induced by various forms of radiation including argon lasers (Dalrymple et al. 1977), can produce colored or fluorescent patterns distinguishing the ridges from the valleys. One interesting technique was discovered by accident in Japan in 1977. When a hair examiner in a crime lab was mounting hairs on a microscope slide using cyanoacrylate (Superglue), he noticed that his fingerprints were developing on the slides and brought this to the attention of a colleague who confirmed it to be a valuable latent fingerprint development process.

Latent prints left at the scene of a crime can be important investigative tools but only if they can be related to the known prints of a person. Until the late 1970s, finding the knowns for such comparisons was largely based on the memories for patterns of experienced latent print examiners. In 1977, the FBI introduced an automatic fingerprint recognition system for the computerized search of fingerprint databases. Commercial providers developed other systems over the next several years culminating in the introduction in 1999 by the FBI of the Integrated Automated Fingerprint Identification System (IAFIS) containing the fingerprints and criminal histories of millions of individuals. The ability of such systems to make "cold hits" has made fingerprints the important investigative tool that the pioneers in the field had originally envisaged.

Although the use of fingerprints for individual identification originated in the medical/scientific world, their widespread application became primarily a police function. In many areas in North America, the service is provided by police "identification bureaus" rather than by forensic labs. These bureaus are generally staffed by individuals with minimal scientific background. While there is now only slight dispute of the presumption that fingerprints (friction ridge patterns) are unique to an individual and persistent for life, there remains some valid criticism of the manner in which examinations are sometimes performed. Major efforts are being exerted in the twenty-first century to deal with this through enhanced training, research, and development of recognized standardized protocols.

Trace Evidence

The exchange principle that is the basis for trace evidence examinations – "every contact leaves a trace" – was first enunciated in 1920 by Edmond Locard in *L'enquete criminelle et les methodes scientifique*. When two objects, two persons, or an object and a person come into contact, dust, fibers, hair, paint, glass, soil, etc., may transfer between them and comparisons may establish the fact of the contact. Finding, identifying, and comparing such "trace evidence" introduced additional chemistry professors to the world of forensic applications of science during the first half of the twentieth century, and this type of examination later became a common part of the work of forensic science laboratories.

Although the microscope continues to be the basic tool of the trace evidence examiner, a variety of analytical instruments to supplement microscopy began to appear and these are now capable of providing almost unbelievable sensitivity. The first of these analytical instruments, introduced in the early 1940s, was the emission spectrograph which was ideally suited to trace evidence examination because it permitted the comparison of the trace element composition of a wide range of small samples. These results were often interpreted as indicating "batch" compositions of many types of materials, interpretations which are no longer considered feasible as a result of improvements in manufacturing processes. Later analytical techniques to appear include infrared (IR) spectrophotometry introduced in the early 1950s, gas chromatography (GC) in the late 1950s, atomic absorption spectrophotometry (AAS) in the early 1960s, gas chromatography linked with mass spectroscopy (GC/MS) in the late 1960s, scanning electron microscopy linked with X-ray spectrometry (SEM/XRS) in the early 1970s, and Fourier transform infrared spectrophotometry (FTIR) later in the 1970s. New developments such as the various forms of inductively coupled plasma spectroscopy (ICPS) in the 1980s/1990s continue to be adopted.

Ironically, the enhancements in analytical capability did not substantially change the answers that could be given to the typical question "Could these two items have had a common origin?" Because the evidence items are often common materials – either manufactured, for example, paint, glass, fibers, or natural, for example, soil, hair – the answers to the question were still typically limited to "Yes they could" or "No they could not." However, the answers were of much greater quality and reliability because of the significant increase in the amount and type of analytical data derived from the items. Toward the end of the century, with investigators and courts becoming used to the much more definitive answers provided by DNA analysis (although applicable to only about 10 % of cases received in a typical forensic lab), demands for this type of examination began to diminish despite the fact that the results can still often be of considerable value to an investigation.

Questioned Document Examination

In the early years of the twentieth century, Albert S. Osborne of New York City began to develop the examination of handwriting and questioned documents into a specialized forensic science discipline. Osborne, originally a teacher of penmanship, published several papers on document examination, including one on typewriting identification in 1901, but it was the first edition of his book "Questioned Documents" in 1910 that cemented his position as the leader of the profession (Osborne 1910). This work, with later revised versions, formed the cornerstone for much of what document examiners continue to do. Today, these types of examinations require knowledge about inks, paper, writing instruments, printers, copiers, and computers. Nevertheless, the majority of the work remains the comparison of handwriting.

In England, Wilson R. Harrison published his massive work "Suspect Documents, Their Scientific Examination" in 1958 and Locard in France published *Les Faux en Écriture et Leur Expertise* in 1959.

Following World War II, many new challenges began to develop as a result of advances in the technology of writing and printing instruments. In 1945, the ballpoint pen was introduced and by the mid-1950s had almost completely replaced the fountain pen. Around 1960, the fiber-tipped pen started to become popular and brought its own challenges to identification work. Typewriter technology also began to change with the introduction of the electric typewriter in the 1930s, proportional spacing typewriters in the early 1950s, the single element typeball machine in 1961, and the correcting "lift off" typewriter ribbon in 1973. The ability to easily change balls between machines and correct errors quickly presented another challenge to the examiner. The print-wheel typing unit which became common in word processing and computer systems was introduced in 1972 followed not long after by the dot matrix and laser printers that are so common today. All of these developments in "typewriting" reveal fewer of the individual anomalies which the document examiner relies on to identify the product of a particular machine.

As the office copier became common, it introduced a whole new set of challenges to the document examiner, including the identification of the machine on which a particular copy had been produced. The thermographic process, introduced in 1950, was quickly replaced by the electrostatic plain paper reproduction process in the late 1950s.

The tools available to the document examiner have also expanded. Electronic ultraviolet and infrared viewers for the differentiation of inks; electrostatic detection apparatus for revelation of pressure patterns and indented writing, specialized photographic procedures, and computerized digital imaging equipment have all been added to the examiner's arsenal. Improved training, enhanced quality assurance, and additional generally accepted protocols resulted in questioned document examinations becoming very reliable. (Although, as stated in the 2009 National Academy of Science Report (NRC 2009), "the scientific basis for handwriting comparison needs to be strengthened").

Firearms/Toolmarks

While interest in the identification of the firearm from which a bullet has been fired began before the nineteenth century, it was not until the beginning of the twentieth century that an important discovery was made – that microscopic marks ("striations") on bullets of the same caliber and type, fired through guns of different makes, varied in appearance. This critical observation was published in 1900 by Dr. Albert Llewellyn Hall in the Buffalo (New York) Medical Journal. One of the techniques for the examination of bullets used was to roll them on a plane surface of wax or lead foil to reproduce surface markings; however, only the gross markings could be reproduced.

The first use of striation matching did not involve bullets but rather knife marks in the wood of vandalized trees. R. Kockel, a Professor at the Institute of Legal Medicine in the University of Leipzig, published two papers in 1900 and 1903 describing a method for producing test marks with the knife and for using oblique lighting and photography for the comparisons.

The first case in the USA in which identifications of ammunition components were made occurred in what became known as the "Brownsville Affray" in which a civilian was killed in Brownsville, Texas, in 1906 by shots fired by several soldiers during a riot. In 1907, staff of the Frankford Arsenal in Pennsylvania were able to identify eleven of the fired cartridge cases to one of the soldiers' rifles, eight to a second, eleven to a third, and three more to a fourth. This pioneering work remained relatively unknown for many years because the only publication of it was in the Annual Report of the US Army Chief of Ordnance.

In 1912, Victor Balthazard, a Professor of Legal Medicine in the University of Paris, described the principles involved in linking a particular fired bullet to an individual firearm. His procedure involved making a detailed sequential series of photographs of the surface of the complete circumference of the bullets, enlarging the photographs and comparing the striations revealed in the process. In 1922, he published "*Identification des projectiles. Perfectionnement de la technique*" in *Annales de Médecine Légale*. Unfortunately, the system was too cumbersome to ever gain wide acceptance.

Between 1919 and 1923, Charles E. Waite, an investigator in the New York State Attorney General's Office, accumulated rifling data for almost all the firearms manufactured in the USA and Europe. In 1925, he persuaded John H. Fisher, a precision instrument designer, Phillip O. Gravelle, a microscopist at Columbia University, and Major (later Colonel) Calvin Goddard, to join him in establishing the "Bureau of Forensic Ballistics" in New York City. Goddard, a graduate in medicine from Johns Hopkins, had served in the Army Medical Corps but, following World War I, had transferred to the Ordnance Corps. Gravelle, who had used a comparison microscope in work with textiles, had the inspiration to suggest applying it to the comparison of fired bullets and cartridge cases. He therefore assembled a hybrid instrument suitable for examining ammunition components. Initial tests of the equipment by Goddard in April 1925 confirmed its value, and the comparison microscope subsequently became the universal tool of firearms/toolmark examiners worldwide. This technique continues to be used in much the same way that it was used by Goddard.

In 1925, Goddard published the first description of the use of the comparison microscope for firearms identification in the November/December issue of "Army Ordnance" under the unfortunate title "Forensic Ballistics" – "unfortunate" because, from then onward, "Ballistics" became the popular – yet incorrect – name for the work of the forensic firearms examiner. Over the next several years, Goddard was contacted by many experts, including Professor J. Howard Mathews of the Department of Chemistry in the University of Wisconsin, Sydney Smith (then still in Egypt), Derôme in Montreal, and Locard in France. Derôme published a book on the subject (Derôme 1929) and Professor Mathews produced a massive three-volume series "Firearms Identification," the first two volumes in 1962 and the third (posthumously) in1973.

Confirmation of Goddard's stature as the preeminent firearms expert in the USA came with the infamous "St. Valentine's Day Massacre" in Chicago in 1929. He was asked to examine the 70 fired .45 caliber cartridge cases and 14 bullets recovered from the scene. His conclusion was that 50 of the casings had been fired from one Thompson submachine gun and 20 from another. Later that year, two "Tommy" guns were located in a house owned by a member of the Al Capone gang and identified as having fired the bullets.

There has been little fundamental change in the examination of firearms and toolmarks since the early work of Goddard and others. Attempts to bring greater objectivity to identifications, such as that by Alfred Biasotti with his publication "A Statistical Study of the Individual Characteristics of Fired Bullets" (Biasotti 1959), were initially received coolly by practitioners. Toward the end of the century, however, Biasotti's concept of "Consecutive Matching Striations" began to receive greater acceptance by the discipline.

In 1991, Walsh Automation Inc. of Montreal developed the "Integrated Ballistics Identification System" (IBIS) for scanning the surface of bullets and cartridge cases using sophisticated laser and computerized digital imaging techniques. This system was adopted by the Alcohol, Tobacco, Firearms and Explosives (ATF) Bureau. In 1993, Mnemonic Systems, under contract to the FBI, developed a similar system "DRUGFIRE" for fired cartridge cases. The two systems were integrated in 1999 into the National Integrated Ballistics Information Network (NIBIN) operated by ATF. While highly valuable for developing and searching databases, final identifications continue to be made visually by examiners using the comparison microscope.

Similar to the situation with fingerprint identification, the delivery of firearms examination services developed in the latter half of the century, primarily within law enforcement agencies. Examiners frequently had little or no scientific background and were ineligible for membership in professional organizations such as the American Academy of Forensic Sciences (AAFS). They therefore established their own organization, the "Association of Firearm and Tool Mark Examiners" (AFTE), in 1969. AFTE has created valuable criteria for operational aspects such as training, examination protocols, and terminology. In 1972, the AFTE Journal was established and became the principal vehicle for publication of research results. Most of this research, however, relates to practical developments rather than the fundamental science of the process. Again, the NAS Report commented that "Individual patterns from manufacture or wear might, in some cases, be distinctive enough to suggest one particular source, but additional studies should be performed to make the process of individualization more precise and repeatable."

Forensic Biology

By the end of the nineteenth century, forensic scientists could determine that a stain was blood but could not answer the follow-up question – "Is it human blood?" That answer was not long in coming. In 1901, Paul Theodor Uhlenhuth, an Assistant Professor in the University of Greifswald in Germany, published "A Method of Investigation of Different Types of Blood, Especially the Differential Diagnosis of Human Blood" in the German journal *Deutsche Medizinishe Wochenschrift*. Uhlenhuth had observed that when chicken egg protein was injected into rabbits, the blood of the rabbit would subsequently react with the chicken protein, causing it to precipitate, but would not react with other types of bird protein, that is, it was specific for chicken. This reaction became the basis of the "precipitin test." Uhlenhuth soon expanded his research to develop antisera that would react with the protein of humans and other species. In his paper, Uhlenhuth modestly foresaw that his process "could prove to be of great importance in medical jurisprudence."

Although blood could now be identified as human, it might (theoretically) be from any human. Progress toward reducing the number of potential human sources began almost immediately. Later in 1901, Karl Landsteiner, an Assistant Professor at the Institute of Pathology and Anatomy in the University of Vienna, published a paper entitled "On Agglutination Phenomena of Normal Human Blood." It began with: "Some time ago I observed the fact that blood serum of normal persons can frequently agglutinate the red blood corpuscles of other healthy individuals." His eventual conclusion was that human blood was either Type A, B, O, or AB. The first step toward demonstrating the biological individuality of humans, as observable in blood, had been taken.

Landsteiner's test was based on antigens on the cells and, in 1915, Leon Lattes at the Institute of Forensic Medicine in the University of Turin in Italy, developed the first serum antibody test for the ABO blood groups. Lattes's procedure continued to be used by many forensic serologists for the remainder of the twentieth century.

Blood is not the only body fluid of importance in forensic science; semen and saliva are also common evidence materials. Identification of saliva is usually based on tests for its amylase activity. Semen can be identified by the microscopic detection of spermatozoa, a process first described by Henri-Louis Bayard in France in 1839. A presumptive color test for semen based on its high acid phosphatase content was developed in 1945 by Frank Lundquist in the University of Copenhagen. In 1925, a Japanese scientist, Saburo Sirai, discovered that the ABO system could also be detected in these other body fluids in about 80 % of the population who are referred to as "secretors."

Although the ABO system was widely used in forensic serology, its discriminating power (e.g., about 45 % of the population are group O) could establish exclusion of possible sources but was of only limited value for inclusion. Forensic serologists therefore continued to look for other "genetic markers" which could enhance their ability to discriminate between sources. This search led them in the 1950s and 1960s to a multitude of genetically controlled systems in blood including plasma proteins and variants of some of the enzyme systems. While the biological functions of these systems were important to medical researchers, genetic variants within any system were not. For this reason, identification and validation of these variants had to be performed almost exclusively by forensic scientists, primarily in the UK at the Metropolitan London Police Lab and the Home Office CRE.

The first of these polymorphic ("many forms") systems to be introduced was the phosphoglucomutase (PGM) system, discovered in 1964. Brian Culliford, of the Met Lab was able to apply it to bloodstains in 1967. PGM was particularly useful because it was subsequently shown to be present in semen, vaginal secretions, and hair roots while most of the later systems could only be applied to blood. Using Culliford's original procedure, three different PGM polymorphs could be identified. Later work in 1977 at CRE using a different process permitted the observation of ten different PGM types thereby vastly increasing its discriminating power. By the late 1970s, nine different polymorphic enzyme systems had been validated. In addition to the enzymes in red blood cells, some proteins in serum were also found to exhibit polymorphism. Not all of these systems became widely used, but they collectively provided a useful "toolbox" for the forensic serologist (Culliford 1971).

The incentive driving the development of additional blood group systems was the fact that each is inherited independently of the others. As independent variables, the population frequencies of each could be multiplied resulting in sometimes relatively low frequencies of occurrence for bloodstains. So, by the mid-1980s, forensic serologists had come a long way in their ability to exclude possible donors of a bloodstain.

As genetic variants, the blood group systems are manifestations of their genetic control by DNA. Why not, instead, look directly at the DNA? In forensic science, the ability to do so began in March 1985 when Alec J. Jeffreys (now Professor Sir Alec after being knighted in 1999) and two colleagues at the Department of Genetics in the University of Leicester in England published their seminal paper in Nature (Jeffreys et al. 1985). In that paper, they described regions along the length of the DNA molecule which were highly variable from one person to another. In the conclusion of that paper, Jeffreys wrote – in a massive understatement – "We anticipate that these DNA 'fingerprints' —— can be used in forensic applications ——" thereby coining a name which, although like "ballistics" before it was incorrect, became popular in the media.

The first forensic application of Jeffreys' process came in 1986 when a young man, accused of the rape/murder of two young girls near Jeffreys' laboratory in Leicester, was exonerated by his DNA and Jeffreys concluded that one other man, then unknown, was the source of the semen in both victims. After a massive investigation which came to be known as "The Blooding," Colin Pitchfork was eventually identified through his DNA and was convicted. As a result of this case, Peter Gill and David Werrett at the FSS became actively involved in the development of DNA profiling, and the FSS became a world leader in this field.

The analytical process Jeffreys used was "restriction fragment length polymorphism" (RFLP), which became the first technique used for "DNA profiling" in forensic laboratories in the late 1980s and 1990s.

In North America, the FBI quickly became interested in DNA and, through close cooperation with other forensic labs in the USA and Canada, developed standards of practice which became widely accepted. The first RFLP cases in North America were in 1987/1988.

The RFLP process, while highly discriminatory, was extremely labor intensive, very demanding in the size and condition of the sample, and required several weeks to carry out. In 1983, Kary Banks Mullis at the Cetus Corporation in California conceived the "polymerase chain reaction" (PCR) process which dramatically changed the face of molecular biology including forensic DNA profiling (Mullis et al. 1986). PCR uses small synthesized pieces of DNA (primers) to make a million or more copies of short but highly informative regions of the DNA molecule. As a result, much smaller samples in poorer condition can be profiled. Most forensic applications of DNA analysis are now based on PCR technology using "short tandem repeats" (STRs) of the molecule, introduced in1992 by Thomas Caskey of Baylor University in Texas.

DNA profiling represents what is unquestionably the most dramatic advance in forensic science of the twentieth century. In a period of only a few years, forensic science had gone from reporting frequencies of occurrence ranging from one in a few hundreds for blood, to frequencies of one in many millions or even billions – in effect individualization – for all body fluids. The dream of forensic serologists – individualization based on stains of body fluids – had become, virtually, a reality.

Other Developments

Until about the middle of the twentieth century, communication of developments in forensic science was primarily through publication in scientific journals, of which there were few devoted to forensic science. As a result, exchanges of information and discussion were limited and slow. In 1948, Dr. Rutherford B. Gradwohl, Director of the St. Louis Police Department Laboratory, invited 150 forensic scientists to attend a meeting in St. Louis which led to the formation of the American Academy of Forensic Sciences (AAFS). The Academy has since became the preeminent forensic science organization in the world and, in 2011, had over 6,000 members from 65 countries. The Academy's Journal of Forensic Sciences, established in 1956, has become a major peer review vehicle for the exchange of scientific data and research.

In the UK, Stuart Kind of the FSS led the creation of The Forensic Science Society in 1959. The Society's journal, now called "Science and Justice," is another important vehicle for communication among forensic scientists. Such organizations also facilitated communication by personal contact which was then dramatically enhanced with the development of the Internet.

When Dr. Briggs White became the Director of the FBI Lab in 1970, he recognized the need for closer cooperation with state and local labs. In 1973, he invited 30 US and Canadian lab directors to a meeting at the FBI Academy in Quantico, Virginia. This led in 1974 to the birth of the American Society of Crime Laboratory Directors (ASCLD) devoted to management and policy matters. ASCLD has gone on to play a leading role in the improvement of forensic labs in North America. In Europe, an organization with similar goals and objectives, the European Network of Forensic Science Institutes (ENFSI) was established in 1995.

ASCLD played a critical role in a major initiative which has contributed significantly to dramatic improvements in quality assurance in forensic science – laboratory accreditation. In the late 1970s, ASCLD recognized the need for objective standards for crime lab operations. A committee began studying the matter and drafting a series of objective criteria which lab directors could use to evaluate their laboratories. What emerged in 1981 was the American Society of Crime Laboratory Directors/Laboratory Accreditation Board (ASCLD/LAB). The first laboratories were accredited in 1982 and, in1988, ASCLD/LAB was incorporated as a totally separate entity from its parent. Recognition of the value of accreditation gradually expanded and there now are almost 400 forensic laboratories in the USA and around the world which have been accredited by ASCLD/LAB. Accreditation of forensic labs in other countries is done by national accrediting bodies such as UKAS in the UK, NATA in Australia, and the Standards Council of Canada.

Another major contributor to the enhancement of quality in forensic science is a "spin off" from the introduction of DNA profiling. The FBI recognized the enormous impact that this new process was likely to have and realized that strict standards of performance would be required to ensure acceptance of the evidence. This could best be accomplished through collaboration of many experts, and so it established the Technical Working Group on DNA Analysis Methods (TWGDAM) consisting of representatives from the fields of forensic, industrial, commercial, academic, and international communities. The name was subsequently changed to SWGDAM ("Technical" was changed to "Scientific"). The ongoing result of the development of these standards has led to much greater uniformity and consensus on the part of practitioners. SWGDAM was so successful that the concept was applied to other forensic science disciplines, and there now are about 20 "SWGs" developing recognized standards and protocols (Cormier et al. 2005).

Conclusion

Despite the many advances in forensic science in the past two centuries, there remain some fundamental limitations as described in the NAS Report. This, of course, does not mean that the procedures are invalid or unreliable but rather that there is a need to more adequately demonstrate their validity through conventional empirical data, peer review and publication. Much of the necessary data already exists because it is collected by every trainee during their training process to validate for themselves the reliability of the techniques and their ability to use them. Unfortunately, these data are scattered in thousands of widely distributed and uncoordinated laboratory training files and therefore not readily accessible; more systematized data collection is required to meet the required standards. This work is being done – in the twenty-first century!

Faculty of Education, Science, Engineering,
Technology and Maths, University of Canberra,
Canberra, ACT, Australia

Overview

The use of forensic science used in criminal investigation brings the occupations of forensic science and policing into an immediate and interactive relationship.

Regardless of the organizational home of forensic science within or outside of policing organizations, the success or failure of forensic science in support of investigations depends on how well this interaction is managed.

This entry proposes that the tensions which can sometimes be seen in the current relationship would be reduced if both "occupations" more ideally met the characteristics of a true profession. The paper argues that in the modern world we need to look forward in developing a professional project which recognizes the increased role of the state in the regulation of professions.

Key Issues and Future Directions

Introduction

> *"We trust our health to the physician; our fortune and sometimes our life and reputation to the lawyer and attorney. Such confidence could not safely be reposed in people of a very mean or low condition. Their reward must be such, therefore, as may give them the rank in society which so important trust requires."*
> (Adam Smith, Wealth of Nations, BK I p. 10. As quoted in Macdonald 1999)

To the above should we add, we trust our liberty, safety and just outcomes to our police and law enforcement services, and if so, what role or contribution is made or should be made, by forensic science? Do we have confidence in policing and/or forensic science and do we accord them the "rank" which such trust requires? Adam Smith would not have thought of policing when he wrote Wealth of Nations in 1766, some 63 years before Robert Peel established the Metropolitan Police Force in the United Kingdom. Dating the "formal" start of forensic science will no doubt be dealt with elsewhere in this series but practically it is an invention of the late nineteenth and early twentieth centuries, or the modern world.

The purpose of this entry is to explore the relationship between policing and forensic science, focusing on how these two "occupations" have developed and what implications this has for that working relationship. The paper will propose that although both occupations will lay some claim to being professions they fall well short in critical areas of full professional status. It will further propose that "confidence" and "trust" of both policing and forensic science would be enhanced if both met more ideally a professional model. Macdonalds' (1999) concept of a professional project will be used to discuss how the latter might be achieved.

What Differentiates a Profession from an Occupation?

Although there is no single agreed definition of what constitutes a profession all dictionary and encyclopedia definitions of the word "profession" stress key common criteria which invariably include:

- An occupation or vocation requiring, or founded upon, specialist training or education, and,
- The body of persons in such an occupation.

In this sense any occupation has the potential to become recognized as a profession provided there is a specialist body of knowledge which can in some way be defined, codified and persons educated and trained.

The journey from occupation to profession, or "professional project," typically involves milestones being achieved such as:

- It becoming a full time occupation
- The establishment of formal training and education

- Local and national associations being formed, and,
- A code of professional practice being established.

The national association would commonly develop professional rules and structures aimed at establishing a high degree of autonomy and self-regulation. This concept of professional autonomy is based on three claims that:

- The work of professionals entails such a high degree of skill and knowledge that only fellow professionals can make accurate assessments of professional performance
- Professionals are characterized by a high level of selflessness and responsibility such that they can be trusted to work conscientiously, and,
- In those rare instances in which individual professionals do not perform with sufficient skill or conscientiousness, their colleagues may be trusted to undertake proper regulatory action.

(Velayutham and Perera 1995)

Included in the regulatory role of many professional bodies will be some measure of control over qualifications as a pre-requisite for professional practice and a code of practice. It is now well recognized that another hallmark of a profession is the recognition of the need for continuing development and lifelong learning. Finally, professions would "profess" to provide their services in a disinterested way and with an ethic of service to others.

Individuals may purport to deliver their services in a professional way, or meet agreed standards, but this in itself is not sufficient for an occupation to be considered a profession.

Forensic science is delivered by persons with science qualifications but also includes important roles for technicians. The US Department of Labor (Anon 2010) describes technicians as follows.

> *Science technicians use the principles and theories of science and mathematics to assist in research and development and to keep, invent and improve products and processes. However, their jobs are more practically oriented than these of scientists.*

The US Department of Labor also stress that technicians *"work under the direction of scientists"* and that an appropriate level of qualification is a 2 year or associate degree, although of interest is that it states biological and forensic science technicians usually require a bachelor's degree.

Other definitions of technician draw out the key differences between a scientist and technician as being

- Level of entry qualification (although this is increasingly becoming blurred!)
- Technicians will usually have a vocational qualification
- Technicians have a more practical understanding which will usually include a more in depth understanding of specific techniques than a scientist
- Technicians may have their own work structure and hierarchy but generally will come under the supervision of a scientist.

Technicians will often have a formal representative body or association which may even offer formal certification but these groups would not normally be considered professional groups although meeting many of the tenets of a profession.

Forensic science is characterized by its multidisciplinary nature and many commentators would consider some aspects of forensic science are in fact more technical than scientific. For example, are crime scene examination and some aspects of fingerprint examination technician work or scientific work? In the context of this entry *all* aspects of forensic work will be considered capable of either meeting the requirements for professional status or evolving towards this status.

The study of professions has attracted considerable attention from social scientists. It is beyond the scope of this entry to explore in any detail the history of the sociological study of the professions but the reader is referred to two key books on this subject by Larson (1977) and Macdonald (1999). In the context of policing Rohl (1990) suggested that Australasian police should adopt Witham's (1985) "attribute" approach which defines a profession around eight characteristics. These are,

1. Operates as an organized body of knowledge, constantly augmented and refined,
2. Involves a lengthy training/education period,

3. Operates so as to serve its clients best,
4. Operates autonomously and exercises control over members,
5. Develops a community of practitioners through professional standards,
6. Enforces a code of ethics and behavior,
7. Establishes uniform standards of practice, and,
8. Provides full professional mobility.

An alternative approach is that of Klegon (1978) who proposes two aspects to define a profession, an internal dynamic and an external dynamic. The internal dynamic relates to the strategies used by the profession such as establishing a code of practice whilst the external dynamic relates to the economic, political, social and intellectual influences which cannot be the exclusive domain of the "profession."

Allen (1991) has grouped Klegon's strategies as follows

1. *Formulation of a code of ethics:* once formulated, this code must be promoted as a symbol of the desire of the profession to serve the public.
2. *Delineation of the area of expertise:* exclusive domain of practice must be identified and protected from encroachment, the knowledge base of the profession validating the professional claim.
3. *Control of education and entry:* education should be university based and closely monitored by the professional association(s). Further education might be required before entrance to the association(s).
4. *Definition of competence levels:* promotion of differing classification of membership with reward in prestige and status for those who attain higher levels of expertise.
5. *Determination of standards:* utilizing their autonomy, the profession will determine their own standards of practice.
6. *Image building:* public promotion of positive image of the profession and by convincing the public of its professionalism, the occupation will be rewarded with professional recognition and status.
7. *Professional unification:* the profession must be united as factionalism undermines public confidence.
8. *Achieving a relationship with the State:* a balanced relationship with the State is required and achieved through legislative recognition and registration.

The final point above is an important contemporary issue for professions. In order to achieve a monopoly, or at least licensure and control, a profession must have a special relationship with the State, sometimes called the **regulative bargain**. Macdonald (1999) makes the point that even when a profession has an apparent monopoly it may still have to compete in the market against others who can provide similar, substitute or complimentary services. It must therefore at least defend and probably enlarge the scope of its activities or its **jurisdiction**.

This will be discussed further in relation to both policing and forensic science.

Medicine and the Law: Classical Professions: Can Policing and Forensic Science Learn from these Professions?

Medicine and the law are often quoted as examples of professions against which any occupation aspiring to achieve professional recognition should be compared. In this context it is important to more fully understand how medicine and the law achieved professional status as "classic" disciplines in a more modern era. The reality is that this is far from a simple story and often the simplified version is that of the development of the Anglo-American model. Macdonald (1999) analyses in depth the emergence of medicine and law as professions in Britain, the United States of America, Germany and France against a matrix of their history and different state systems. The striking, fact is that the evolution of both "professions" is very different indeed across even these four countries. Hence, it is a gross oversimplification to consider that there is a global shared professional model for either medicine or the law.

For example, Macdonald argues that the underlying canvass against which medicine and the law emerged in Britain goes back to an ancient and historically low level of state involvement and bureaucracy which meant the extension of state power over the institutions of civil society emerged relatively late in Britain. Although both professions are linked to the state, their high level of autonomy originates in practices and forms that go back to the Middle Ages and which had not been subordinated to the "civil service." Importantly medicine and the law in Britain were able to regulate their own education and training and, hence, control entry to their professions. The role of academic institutions by contrast has not been controlling but merely delivery of what the professions deem necessary as an "entry" to their professions.

The evolution of medicine and the law in the United States is more complex and heavily influenced by a populist climate and a desire to open knowledge based occupations post-independence to all. For example, Macdonald (1999) states that *"in response to these state pressures legislatures deprived the medical societies of their licensing powers and American medicine was reduced to a condition of factional disorganisation*." (at p. 83)

Because medicine and the law were deprived of their organizational base and traditional values seen in Britain they had to rely on their expert knowledge as a basis for claim to special recognition. The lack of an organization also meant the universities played a much more important role in passing on knowledge than was the case in Britain.

In the late 1880s as professional bodies reappeared *"the chief bases of their 'professional project' were their modern knowledge and the institution in which it was lodged, the university."* (Maconald 1999 at p. 84)

If the Anglo-American model had important differences then the evolution of the medical and law professions in France and Germany had even greater differences.

In France the state had a much higher degree of control and responsibility which reduced professional power and increased the influence of universities. Similarly in Germany universities were long established and status was focused on the "educated middle class" or Bildungsburgertum. This was in turn strongly associated with the civil service and academia rather than with the professions.

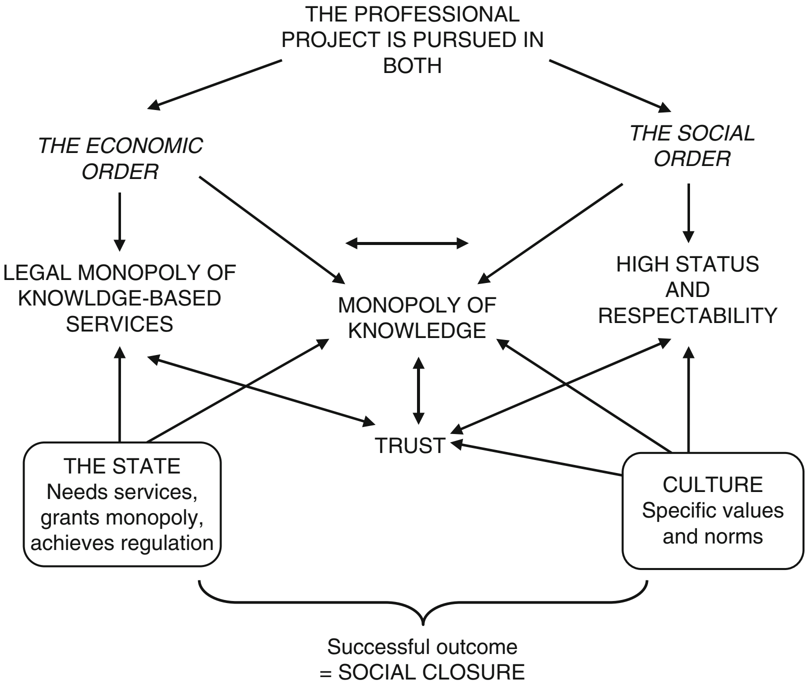
In summary, Macdonald concludes that "*the political ideology in America is a compound of nationalism, liberalism and populism while in Britain traditionalism replaces populism and colours the other two components. In France and Germany these elements are also to be found, but in different proportions and with the important addition of a centralised state, less penetrated by civil society*." (at p. 97)

Hence, it is probably unhelpful to refer back to the "classic" form of knowledge and development of professions for a "modern" society. Those occupations seeking to *now* achieve professional recognition need to understand that specialist knowledge is now more complex and more organized into disciplines (arguably more divided). There is now a general reluctance for the state to grant a special position. However, the state may see value in using professional bodies as an instrument of regulation.

Knowledge and the Professions

Adam Smith, quoted at the opening to this entry, was one of the leaders in the "enlightenment." A consequence of this movement was the exponential growth in knowledge and so called **cognitive growth** (Gellner 1988, p. 116). In premodern society knowledge was tightly controlled, owned and difficult (even dangerous) to question. Professional knowledge in the modern world is more complex. In one sense knowledge is now open to all, irrespective of status. Knowledge is no longer under the "guardianship" of a few. In this changed paradigm professionals increasingly will rely on certification and credentialing of higher level qualifications to underpin their claims to being a profession. Macdonald (1999, p. 163), proposes that to understand professions the starting point must be to define **professional work**. The context of professional work, the control of that work differentiating in types of work and the notion of jurisdiction, previously mentioned, are all important in the profession laying claim for its work. However, he argues that the quality that characterizes professional work at a knowledge level is the concept of **abstraction**. Abbott (1988) captures this in the following quote "*. . .abstraction is*

Forensic Science Professions, Fig. 1 A working theory of the professions: a conceptual outline (From Macdonald 1999)



THE PROFESSIONAL PROJECT IS PURSUED IN BOTH
THE ECONOMIC ORDER
THE SOCIAL ORDER
LEGAL MONOPOLY OF KNOWLDGE-BASED SERVICES
MONOPOLY OF KNOWLEDGE
HIGH STATUS AND RESPECTABILITY
TRUST
THE STATE Needs services, grants monopoly, achieves regulation
CULTURE Specific values and norms
Successful outcome = SOCIAL CLOSURE

the quality that sets interprofessional competition apart from competition among occupations in general. Any occupation can obtain licensure (e.g. beauticians) or develop a code of ethics (e.g. real estate). But only a knowledge system governed by abstractions can redefine its problems and tasks, defend them from interlopers, and seize new problems – as medicine has recently seized alcoholism, mental illness, and hyperactivity in children, obesity, and numerous other things. Abstraction enables survival in the competitive system of professions." (1988, p. 9)

However, the concept of professional work needs to be more than about technique. In the modern world the possessor of knowledge and technique adds value through the exercise of **professional judgment**. The ever increasing move to standardization and codification has benefits and value and arguably, makes knowledge more accessible to a more educated public. However, taken to extremes (perhaps the Crime Scene Investigation or CSI effect?), this can undermine the role of professionals to apply appropriate cognitive processes encapsulated as professional judgment.

The Concept of a Professional Project

The professional project is the term Macdonald uses (1999) to present a conceptual model for the professions (Fig. 1).

This model brings together the matrix of factors which any occupation seeking to achieve recognition as a profession must consider. Policing and forensic science are assessed against this model and important differences identified which have implications for how these two occupations interact in a broader criminal justice system.

Toward a Policing Professional Project

The professionalization of police has been the subject of an enormous international literature and it is simply out of scope to review this literature in this entry. As was seen for medicine and law even the Anglo-American "story" of the development of these professions shows two quite distinct pathways. Similarly with two continental European countries they showed significant differences.

Hence, international interest in professionalization of policing will not necessarily translate into a universal model. In this regard the professional project is a more useful concept as it recognizes in particular the role of the state and culture as key drivers. These influences will be significant variables at a national level. For example, the role of police is influenced by the legal system and how it operates.

The starting point for any profession is defining a body of knowledge. It can be argued that there is sufficient specialist knowledge relevant to policing to constitute a body of knowledge although there is no broad agreement as to the academic level of that knowledge. It is certainly not the case that even a vocational qualification is a pre requisite for entry to policing in many countries. In Australia the then Australasian Police Ministers Council (APMC) in 1990 agreed to five major outcomes necessary to attaining full professional status. One of these was that national education standards and formal higher education qualifications were necessary for full professional status.

In 2001 the Australasian Police Professional Standards Council (APPSC) was tasked with advancing police professionalization. Suffice to say that although some jurisdictions in Australia have committed to graduate level entry, and others support an associate degree or vocational equivalent, there is still no general acceptance that police studies (*and* hence knowledge) are sufficiently distinct to form a necessary body of specialist knowledge. Stone and Travis (2011) in a paper titled "Toward a New Professionalism in Policing" state that "*for any profession to be worthy of that name, its members must not only develop transportable skills but also commit themselves both to a set of ethical precepts and to a discipline of continuous learning.*" Further, they observed that if the values of policing are really professional and not local, what is needed is a genuine national coherence in the skills, training and accreditation of police. (Stone and Travis 2011, p. 19).

The title of the above paper does send out a warning and that is not to confuse "professionalism" with developing a profession. As has been discussed previously it is entirely possible to deliver a professional service without meeting the tenets of a profession.

It is yet to be seen if the prediction of Stone and Travis (2011, p. 19) that "*the attraction of the new professionalism is likely to feed a flowering of specialist professional associations, bachelors and masters degree programs*" will be achieved.

Regrettably in 2012 the aspiration of the APMC stated in 1990, of formal higher education qualifications, have not been achieved in Australia. Certainly progress has been made in developing national educational standards but these have been set at a technician, vocational level.

By 2006 yet another report prepared for the Police Commissioners of Australasia identified six key objectives for the attainment of full professional status, these being:

1. Develop a definition of the profession of policing.
2. Implement university-based education for policing.
3. Develop a body of knowledge.
4. Propose ongoing professional development.
5. Develop registration and standards for policing.
6. Establish a professional body for policing.

(Lanyon 2007)

It is disturbing that even in an advanced country such as Australia there is still a need to develop a definition of the profession of policing. A further 6 years has seen little hard progress towards the realization of any of these goals.

It has also been observed that much of the discussion about professionalization of policing takes place at a senior manager and executive level and broad commitment by "rank and file" members is questionable.

Perceptively it has been said that "*occupations that fail to lead the agenda in advancing their own professionalization may well forfeit that role to other more influential agencies*" (Lanyon 2007, p. 122). Following a major review of police leadership and training in England and Wales (2011). Neyroud recommended the creation of a new professional body for policing. This recommendation has been accepted by the UK government who announced in December 2011 their intent to establish a new police professional body in 2012. Although the governance structure for this new body has not yet been made public it seems clear that there will be a greater degree of central government regulation and control of the professional aspects of policing. The Police Minister is quoted as saying that *"it's striking that while doctors, lawyers, teachers and nurses have their own professional bodies, police officers do not."* (Anon 2011a)

Indications are that this new body will have an independent chair from outside the police establishment and that it will eventually receive a royal charter similar to other professional bodies.

As discussed earlier in this entry state interest in professions is likely to increase with greater formal regulation. The lack of genuine professional member organizations in policing does not place the practitioners in a strong position to influence their journey towards full professional status.

Furthermore, policing as an occupation no longer has a monopoly of services with private security and other government enterprises sharing the "market."

It would probably be an exaggeration to say that there is a crisis in policing or with the public view from a status and respectability viewpoint. However, clearly this would vary widely at a global level. However, ongoing issues with police corruption and integrity do nothing to support the move to policing being accepted as a profession and police more often than not are increasingly subject to additional external oversight through independent integrity commissions. In this regard policing also falls short of the "trust" awarded through self regulation to professions.

A final aspect of a profession which is worthy of comment is that of full professional mobility. Implicit in this criterion is that this would be facilitated by mutual recognition of qualifications, training and rank or level. With some exceptions, and at senior police ranks, policing falls well short of full professional mobility.

Towards a Forensic Science Profession

Robertson (2011a) has discussed the issues relevant to assessing whether or not forensic science can meet the criteria of a true profession. In this discussion the professional project model will be used as the template against which this assessment will be made. This follows the same approach as for policing and enables a comparison of the status and progress of these two occupations towards achieving professional status.

The first criterion is that of a body of knowledge. In addressing this criterion it is important to consider what is the relevant body of knowledge. If forensic science is considered to be merely the application of core sciences such as biology, chemistry and physics to addressing science issues which may end up in a legal setting, then that body of knowledge is science knowledge. While this body of knowledge is always to an extent tentative and evolving, nobody would argue that science knowledge is not a sound basis underpinning all science based professions. It can be argued that the forensic dimension is merely context and in this respect forensic science is no different from any other occupation which relies on the application of science. The issue then becomes not one of underlying knowledge but rather one of how well that knowledge is applied and used. In the modern world, with a heavier focus on disciplines, forensic science can be considered to be simply a discipline or group of disciplines.

The US National Academies of Science (NAS) report on "strengthening Forensic Science in the United States: A Path Forward" (Anon 2009) commented that the: "*forensic science enterprise is hindered by its extreme disaggregation – marked by multiple types of practitioners with different levels of education and training and difference professional cultures and standards for performance.*" (at pp. 5–11)

The report also observed that "*of the various facets of under-resourcing, the committee is most concerned about the knowledge base,*" further commenting on the lamentable state of funding for forensic science research.

Crispino (2011) has argued that there is a unique scientific basis for recognizing forensic science as a distinct discipline. Although it can be argued that it is a "chicken and egg" situation the existence of numerous academic programs on forensic science could be put forward as further evidence in support of the proposition that there is a specific body of knowledge. At least some of these education programs pre date the "CSI" driven expansion in forensic programs within universities and some have been around for several decades. A pragmatic view of the world would recognize that forensic science is an academic specialization, is here to stay, and that there are sufficient unifying concepts for it to be considered a distinctive discipline. This is not to deny the need to improve the underpinning knowledge base and the need for a much enhanced research effort. As present there is no statutory requirement for entrants to the forensic profession to have a specific forensic qualification. Whilst there is an emerging trend toward accreditation of forensic education programs and toward individual certification, including commitment to ongoing education and training or continual professional development, these fall short of being mandatory requirements for professional practice. In this sense forensic science can be considered to be at best an immature profession with respect to its knowledge base (and any sense of a monopoly of knowledge) and the related education and academic/research structures.

Although a degree is a requirement of some forensic membership organizations for levels of professional recognition, many forensic occupations either have no educational pre-requisites for entry or these are set at a lower than degree level. In itself this does not preclude forensic science being considered a profession as it is possible to have a technician level within a professional structure.

Perhaps more worrying is that the culture of forensic science falls short of what would be expected of a profession, and specifically, the lack of acceptance, or commitment to research and development. (Robertson 2011b). It has also been observed that at least for some aspects of forensic science the cultural setting is closer to policing than science.

The question arises as to whether or not forensic science as an occupation should be part of a policing organization. The NAS report (Anon 2009) was clear on this point in recommending *"removing all public forensic laboratories and facilities from the administrative control of law enforcement agencies or prosecutor's offices."* (at pp. 5–17)

The factual situation is that there are numerous models and organizational structures at a global level through which forensic science is delivered (Robertson 2012). There is no ideal model and the "state" largely determines its needs, service delivery model and grants either monopoly or creates a market. An example of this is the current situation in England and Wales where the "state" has created a market for the provision of some aspects of forensic science, going as far as withdrawing from any public ownership of forensic laboratory services. However, even here it needs to be recognized that the "state" retains ownership of the majority of forensic science through its police services provision of crime scene, fingerprint and other forensic disciplines. One mechanism introduced in England and Wales to ensure scientific standards are met, has been the establishment of the Office of the Forensic Regulator (Anon 2011). At a level below the "state" level the third party accreditation of forensic services, assessed against relevant standards (most often ISO – 17025), goes someway to regulating levels of professional delivery if not the profession.

As a profession is the "body of persons" in that occupation the role of representative organizations is important. Forensic science societies and organizations play a useful and increasingly important role in "professionalising" the profession. However, these fall well short of the status and authority of similar groups in professions such as medicine, the law or pharmacy. As has been discussed earlier in this entry it is somewhat misleading to compare an evolving profession today, with the structures seen in the "Anglo" experience of pre-modern professions such as medicine and the law. In today's world the "state" is likely to relinquish less autonomy and more likely to demand greater regulation of emerging professions.

Notwithstanding, as with policing, forensic science would benefit from more mature member organizations focused on representing the professional interests of their members. It is perhaps surprising that forensic science has "escaped" the degree of formal regulation applied to more mature professions (see Robertson 2011a, discussing the regulation of Health professions in Australia).

Finally, there are limited barriers to the mobility of forensic science professionals and these relate more to employer barriers than to any science based barriers, provided the "employee" can meet the organizational educational entry requirements. The one exception to this is perhaps in some police services where there is still a requirement for the forensic employee to be a police member.

Conclusions

Forensic science and policing cannot escape the close interaction essential to the investigation of crime, whether or not, they belong to the same or different organizations. This "marriage" may be seen by some as a "marriage made in hell" and by others in a more positive light *but*, like any marriage, it will only work where both parties work together and where the relationship matures and evolves over time. Forensic science is still a relatively new occupation, far less a new profession. Policing is an older occupation but still largely a product of modern times. In this entry it is argued that the relationship between forensic science and policing would benefit from both occupations maturing into genuine professions. The professional project is a useful way to describe the journey ahead should forensic science and policing wish to evolve to full professional status. The practical working interactions between police and forensic science would surely be improved if both occupations more closely met the ideal requirements of a profession with shared core values.

Fraud Victimization

Kristy Holtfreter
School of Criminology and Criminal Justice,
Arizona State University, Phoenix, AZ, USA

Overview

Generally defined, fraud victimization refers to a form of economic crime. A variety of crimes might be included in this category, but fraud victimization generally takes one of two forms: victimization of organizations, or victimization of individuals. There is considerable evidence indicating that fraud victimization continues to increase, and that losses experienced by victims of fraud greatly exceed those of street crime. Given that many fraud victims are reluctant to report their victimization to criminal justice officials, the problem is likely even more severe than official statistics suggest.

This entry examines key issues in the study of fraud victimization. Definitions and examples of occupational fraud and personal fraud are provided, with special attention to the nature and context of these offenses (e.g., the importance of fraud targeting and the methods of targeting victims). Theory and research on both forms of fraud victimization are presented. In addition to financial losses, other outcomes of fraud victimization (e.g., negative publicity, consumer confidence, reporting behavior, and risk perceptions) are considered. Directions for future research and implications for the prevention of both types of fraud victimization are discussed.

As noted at the outset, fraud victimization can take a variety of forms. Victimization of organizations, which includes occupational fraud, is primarily perpetrated by employees. Victimization of individuals, which includes consumer fraud, may be perpetrated by businesses or other individuals. Each is discussed in more detail in the sections that follow.

Victimization of Organizations

Occupational Fraud Defined

Occupational fraud, defined as “the use of one’s occupation for personal enrichment through the deliberate misuse or misapplication of the employing organization’s resources or assets,” takes place in organizational settings (Association of Certified Fraud Examiners, 2006, p. 6). This definition can be further divided into three categories of occupational fraud: asset misappropriation, corruption, and fraudulent statements. Examples of asset misappropriation include theft of cash or other inventory. Reports indicate that asset misappropriation is by far the most common form of occupational fraud. Examples of corruption include bribery and other forms of wrongful use of influence in business transactions. Finally, examples of fraudulent statements include falsification of an organization’s financial documents or other (i.e., nonfinancial) documents, such as an employee’s resume or credentials. Although the nature of these forms of occupational fraud varies, all are considered violations of trust because they go against an employee's fiduciary duties to the organization. Along these lines, occupational fraud is generally considered to be a form of white-collar crime (Holtfreter 2005).

Theory and Research

Offender Characteristics

The demographic characteristics of offenders who commit occupational fraud are similar to those who have been convicted of other forms of white-collar crime. For example, one study found that men committed slightly more than half of detected occupational frauds (Holtfreter 2005). The same research revealed that most offenders held employee-level positions, as opposed to managers or higher-level executives, were approximately 41 years old on average, and had greater than high school education. The results from this study are comparable to those reported by previous researchers studying white-collar crime in that the sample is best described as "middle class" (see e.g., Weisburd et al. 1991).

Motivation and Opportunity for Fraud

Early studies of white-collar crime identified non-shareable financial problems (e.g., involvement in gambling or other vices) as primary motivations for embezzlement and related offenses in the workplace (Cressey 1953). Many of the most well-known, early studies of fraud and other forms of white-collar crime were conducted when men made up the majority of the American work force. As a result, understanding of these offenses was based almost exclusively on the behavior of males. In perhaps the most comprehensive study on white-collar crime criminal careers, offender motivations mirrored those identified by Cressey, including alcohol addiction and a desire to finance higher education (Weisburd et al. 2001). Subsequent research found that women's rationalizations differed from those of their male counterparts in that women were often motivated by caring for family members (e.g., to pay medical bills for a sick child) (Zietz 1981). More recent research confirms that opportunities to commit fraud are linked to the offender's position within the organizational hierarchy (Holtfreter 2008a). In many large corporations, it is still the case that higher-level positions are held by men.

Victim Characteristics

The available data show that there is no set profile of a "typical" organization victimized by occupational fraud. The breakdown of victims in Holtfreter's (2005) study of 1,142 organizations included privately held businesses (32.1 %), publicly traded companies (30.8 %), government agencies (24.8 %), and nonprofit organizations (11.2 %). Organizational victims ranged in size, including subcategories ranging from 1–99 employees (36.7 %), 100–999 employees (20.3 %), 1,000–9,999 employees (25.8 %) to 10,000 or more employees (17 %). Apart from the employing organization itself, there may also be other, external victims of occupational fraud. For example, some types of fraud (e.g., corruption) may extend to consumers who purchase products from publicly traded companies or private businesses. External victims of occupational fraud are difficult to identify, as they may not even be aware that they have been victimized. On average, it is estimated that organizational victims lose approximately 5 % of their annual revenues to occupational fraud. Factors that predict the amount of losses experienced may vary, depending on the organization (Holtfreter 2008b). To be sure, the type of organization itself may influence the amount lost to occupational fraud victimization, as does the available security measures (e.g., internal audits).

Victim Reporting

Despite the losses experienced by organizational victims of fraud, many organizations remain reluctant to take formal legal action against their perpetrators, and instead choose to handle the offending employees internally. In Holtfreter's (2008a) study, initiating criminal proceedings against the offending employee was more likely among government agency victims. Both the age and education of the offender decreased the likelihood of reporting behavior. Although legal characteristics (e.g., criminal history and crime serious) are associated with legal decision making at later stages of criminal processing (e.g., sentencing), these factors did not appear to play a role in early-stage victim decisions. Among those victims who did not take legal action, fear of negative publicity was the primary reason cited, followed by reaching a private settlement, the perception that legal action was too costly, lack of evidence, and fear of a countersuit.

Future Research and Implications for Crime Prevention

Procedural Justice and Legitimacy

The research on fraud victimization of organizations suggests several directions for future research, as well as some important implications for crime prevention. In particular, more research on employee motivation for occupational fraud is needed. Although a variety of personal motivations outside the organization have been documented, additional research focusing on within-organizational factors would provide more direct insights for employers. For example, perceptions of unfair treatment and/or inequities in pay might contribute to employees' beliefs that fraud victimization is justified (Greenberg 1990; 1993). Recent research confirmed that perceptions of fair treatment and organizational justice are associated with lower levels of misconduct in the workplace (Wolfe and Piquero 2011). Given that this study focused on just one government organization – a police department – it will be important for future research to replicate the findings in other organizational settings.

To help prevent fraud, organizations should examine the effectiveness of their existing control mechanisms, such as audits and other forms of security. Such steps are consistent with routine activity theory's emphasis on target hardening and increasing the presence of capable guardians. To be more proactive in preventing fraud, organizations should also consider more aggressive hiring practices. Along those lines, careful background checks of employment histories, personal references, and criminal records should be implemented for all prospective employees (Holtfreter 2004).

Personal Fraud Victimization

Consumer Fraud Defined

Consumer fraud is a form of personal fraud victimization. Specifically, it consists of "intentional deception or attempted deception with the promise of goods, services, or other benefits that are non-existent, unnecessary, were never intended to be provided, or were grossly misrepresented" (Titus 2001:57). Although the nature of consumer fraud continues to evolve, there is evidence to suggest that this type of victimization has existed since biblical times (Holtfreter et al. 2005). According to the Federal Trade Commission (FTC), nearly one-third of adults in the United States report being targeted by fraud perpetrators on an annual basis, resulting in 11.2 % of the population being victimized (Anderson 2004). The FTC estimates yearly financial losses to be $680 million. The median financial loss experienced by personal fraud victims is approximately $220 per victim (Anderson 2004). These losses far exceed those experienced by victims of common or serious "street" crime. Taken together, these alarming statistics necessitate a closer look at this growing problem.

Before identifying directions for crime prevention, key issues in the study of consumer fraud victimization are discussed. As noted previously, this entry includes the nature of victimization, with special attention to context. Types of fraud and common methods of targeting are examined, followed by theory and research. In addition to financial losses, other outcomes of fraud victimization (e.g., consumer confidence, reporting behavior, and risk perceptions) are considered. This section concludes with a discussion of the implications for the prevention of consumer fraud victimization and the identification of avenues for future research.

Fraud Targeting

As noted above, contact between the victim and offender represents a necessary, but not sufficient, condition for personal fraud victimization to take place. In their attempts to target potential fraud victims, perpetrators use a variety of methods. Consumers are targeted via the same forms of media used by legitimate businesses.

For example, while many transactions still occur face-to-face, technological advances have increased the nature and availability of ways to reach consumers. These include old standbys of telemarketing "cold calls," and television infomercials, as well as via print media sources, such as mail, newspapers, periodical ads, and catalogs. As discussed below, the Internet has become a widely used mechanism for the perpetration of consumer fraud.

Internet Use and Fraud Targeting

More recently, the creation and expansion of the Internet has provided fraudsters with virtually unlimited opportunities to contact potential victims. Over 221 million Americans use the Internet on a daily basis. They do so for many reasons, such as sending e-mails, reading news, entertainment, and for financial purposes (e.g., to manage bank accounts or pay bills). Online shopping represents one of the most common forms of Internet activities. Although consumer fraud scams vary considerably, evidence indicates that perpetrators are increasingly using the Internet to approach their victims. According to the Federal Bureau of Investigation (2001), Internet fraud is: "any fraudulent scheme in which one or more components of the Internet, such as web sites, chat rooms, and e-mail, play a significant role in offering non-existent goods or services to consumers, communicating false or fraudulent representations about the schemes to consumers, or transmitting victims' funds, access devices, or other items of value to the control of the scheme's perpetrators." Governmental and media sources indicate that reports of Internet fraud are on the rise. Fraud targeting and victimization online have only recently begun to be explored within the context of criminological theory.

Theory and Research

Routine Activity Theory

Cohen and Felson's (1979) routine activity theory is one of the most prominent theoretical explanations for victimization. According to this perspective, aggregate changes in opportunity structures, combined with a lack of capable guardianship, will increase the convergence in time and space of motivated offenders and suitable targets. Early research in this tradition focused on the ways in which demographic variables increase risk of victimization. For example, in the context of street crime, males, minorities, and single people have higher risks of victimization. Subsequent studies have suggested that it is the behaviors of individuals, not demographics themselves, that put potential victims into contact with motivated offenders. Along these lines, deviant lifestyles that include activities such as drug use, prostitution, and other illegal behaviors increase exposure to victimization.

More recently, scholars have applied routine theory activity to the study of consumer fraud targeting and victimization (Holtfreter et al. 2008; Reisig et al. 2009; Pratt et al. 2010). Consistent with the theory, researchers have focused on identifying consumer behaviors that reflect "unguarded exposure." The first test of this theory in a fraud context revealed that remote-purchasing activities (e.g., responding to telemarketers, purchasing items from the Internet, ordering products after seeing an infomercial, and ordering products through the mail) increase consumers' risk of being targeted for fraud (Holtfreter et al. 2008). In this study, these activities did not, however, increase victimization. Rather, as discussed in more detail below, the relationship between routine activities and fraud victimization depends on targeted individuals' levels of self-control.

Building on Holtfreter et al.'s (2008) research, Pratt et al. (2010) examined fraud targeting in an Internet-specific context. This study drew on routine activity theory and consumer behavior research to understand how personal characteristics and online routines increased consumers' exposure to motivated offenders. The results indicated that the correlates of online fraud targeting differ from those regularly linked to street crime targeting. For example, young, minority males tend to be both targets and victims of violent crime. In comparison, individuals targeted by Internet fraud are younger and more educated.

Low Self-control

Self-control remains one of the strongest known correlates of crime. In Gottfredson and Hirschi's (1990) original formulation of self-control theory, they argued that individuals who lack self-control are more prone to engage in crime and a variety of crime-analogous acts. Those with low self-control are also shortsighted, impulsive, and tend to pursue their own self-interests without considering the potential consequences of their behavior. Schreck (1999) was the first to extend these ideas to the crime-analogous context of victimization. Along these lines, low self-control increases individuals' risks of victimization. Following Schreck (1999), subsequent research demonstrated considerable support for self-control as a theory of vulnerability for a variety of crimes. Initial applications of self-control theory focused on street crime, where indicators of low self-control are more readily visible to would-be offenders (e.g., someone who appears to be drunk in public) (Schreck et al. 2002).

In the context of fraud victimization, signs of low self-control (e.g., financial risk-taking behavior) are not so easily observed. With this in mind, Holtfreter et al. (2008) examined the relationship between low self-control, routine activities, and consumer fraud victimization. As discussed previously, consumers' routine activities increased their chances of being targeted by fraud perpetrators. Low self-control, on the other hand, did not influence targeting, which was expected in this particular victimization context.

Consumer Confidence

In addition to financial losses, fraud victimization may be associated with a variety of other, and potentially negative, life outcomes. Along these lines, researchers have also begun to examine the influence of fraud victimization on several unique outcomes. As is the case with any type of crime, it follows that the experience of fraud victimization may influence consumers' attitudes toward the police and other legal authorities. Throughout the United States, criminal justice system authorities frequently rely on measures of confidence, support, and trust as indicators of organizational performance and legitimacy (Tyler 2001). Citizen levels of legitimacy are important because they are highly correlated with cooperation with the police and related outcomes (e.g., reporting crime). Reisig and Holtfreter's (2007) study of 918 adult consumers in the state of Florida revealed that less than half of respondents had either "a great deal" or "quite a bit" of confidence in the ability of legal authorities to respond to consumer fraud victimization. This research also showed that younger consumers, the less educated, recent fraud victims, and financial risk-takers all had lower levels of confidence. These results suggest that public awareness campaigns and fraud prevention efforts should target these particular consumer groups.

Risk Perceptions

Reisig et al.'s (2009) study of 573 adult Internet users showed that socially vulnerable individuals and those who were financially impulsive perceived higher levels of risk associated with making online credit card purchases. Those with higher perceived risk levels altered their behavior in two important ways: (1) by spending less time online and (2) making fewer online purchases. However, despite perceiving higher risks, financially impulsive Internet users did not engage in similar risk-reduction strategies. The results of this study suggest that efforts designed to educate Internet users about online fraud victimization may achieve limited success when it comes to reaching financially impulsive consumers. Accordingly, crime prevention measures that are designed to harden targets (e.g., increased Internet security, pop-up blocking software, web encryption, and the like) will arguably have a greater impact on the reduction of fraud victimization (Holtfreter and Holtfreter, 2006).

Reporting Behavior

Despite the dollar losses experienced by fraud victims, there is some evidence to suggest that this form of victimization remains underreported. This is a trend that mirrors that of organizational fraud victims. Copes et al. (2001) examined these issues in a telephone survey of 400 Nashville, Tennessee residents. This research indicated that victims with higher levels of education, and those who were victimized by strangers, were more likely to report their experiences to criminal justice authorities. Older individuals and those who were married were also more likely to report their victimizations. Finally, the amount of money lost was the strongest predictor of victim reporting behavior. Consistent with previous studies, the authors hypothesized that victim self-blame may contribute to underreporting. Unlike the victims of many other forms of crime, personal fraud victims may attribute the cause of their victimization to their own behaviors (e.g., trying to make money on an investment "opportunity"). In turn, the shame associated with self-blame may make victims reluctant to report.

Future Research and Implications for Crime Prevention

General and Specific Population Studies

General population studies continue to be important for a number of reasons (Holtfreter et al. 2006). For example, they are particularly well suited to criminological theory testing, and also permit researchers to calculate estimates of fraud targeting and fraud victimization rates. Perhaps even more importantly, they allow for the identification of consumer segments that may be most at risk for victimization, which is particularly beneficial when it comes to implementing strategies for public awareness and crime prevention. Moving beyond these steps, more in-depth studies of specific, at-risk populations are also useful. Research utilizing college student samples provides insight into crime prevention for this segment of the population. However, less is known about fraud targeting and fraud victimization at the other end of the age distribution: the elderly. While reports from popular media often suggest that fraud perpetrators aggressively target elderly consumers, the research to date has been mixed. To improve understanding of the nature and incidence of fraud targeting and victimization against the elderly, and to better guide crime prevention policy, more comprehensive studies of this population are needed.

Cross-cultural Comparisons

With a few exceptions, the bulk of research on fraud victimization has been conducted in the United States. However, the international research to date tends to confirm many of the findings reported by American researchers. For example, both low self-control and routine activities have received empirical support in non-American countries (van Wilsem 2011; Van Wilsem in press). A recent study using data from 6,201 Dutch consumers found that people with low self-control had significantly higher risks of victimization (van Wilsem in press). In the same study, consumers who actively shopped online as well as those participating in online forums were also at greater risk of fraud victimization. In sum, these findings suggested an indirect relationship between low self-control and fraud victimization in that consumers with low self-control tend to be more involved in risky online activities. Another recent study authored by van Wilsem (2011) examined the links between online activities, offline activities, and different types of victimization. This survey of 6,896 Dutch residents in the general population found support for a reciprocal relationship between distinct routine activities and distinct forms of victimization. Put differently, the results suggested that it is possible for online routines to lead to traditional victimization, and for offline routines to lead to online victimization.

Given the global reach of this problem, this body of research could be extended by including fraud victims from multiple countries within the same study. Such comparative research would contribute to the growing support for a general, integrated theory of fraud targeting and fraud victimization based on self-control and routine activity frameworks.

Victim-Offender Overlap

A recent and promising trend in the fraud victimization literature is the examination of victim-offender overlap. This research suggests that a common underlying trait, low self-control, partially explains the overlap between fraud offending and victimization exposure. These findings are consistent with the research examining the relationship between low self-control and offending as a unique outcome, as well as studies supporting low self-control as a risk factor for victimization. Holtfreter et al. (2010b) study of college students found support for low self-control as a predictor of fraud offending, fraud victimization exposure, and the overlap between these two outcomes. Research by Holtfreter et al. (2010a) also confirmed a link between low self-control and fraud offending. In sum, individuals with low self-control tend to make impulsive decisions, engage in risky behaviors, and are more likely to act on opportunities promising quick returns for little investment. Future research should expand on this work by studying the relationships between low self-control,offending, and victimization in general population samples.

Victim-Offender Relationships

The available literature suggests that crimes of violence (e.g., assault) are most often perpetrated by offenders known to the victims. In comparison, the research suggests that the nature of many forms of fraud targeting and victimization (e.g., online fraud) does not require a personal relationship between victim and offender. Nonetheless, additional insights into the relationships between perpetrators, targets, and victims are clearly needed. Other forms of fraud victimization (e.g., credit card theft) may be more easily perpetrated by offenders who already have an established relationship with the victim (e.g., family members). Given that prior victimization is a risk factor for subsequent victimization, it is also possible that victims of violent crime may be at greater risk for fraud victimization. To be sure, additional research could shed light on these relationships. Future studies should attempt to identify the relationships between targets, victims, and offenders, and also consider whether other forms of victimization are linked to fraud.

Conclusion

It is clear that occupational fraud and consumer fraud result in significant financial losses to organizations, individuals, and in many instances, those who are not directly victimized by these offenses (e.g., the general public). The theoretically informed research literature on both forms of fraud victimization has advanced considerably in recent years, adding to our understanding of these crimes. As technology continues to advance, scholars, criminal justice system officials, and victim service providers, among others, will continue to face challenges as they study and respond to fraud victimization.

French Colonial Police

Emmanuel Blanchard
Centre de Recherches Sociologiques sur le Droit et les Institutions Pénales (CESDIP), Université de Versailles, Guyancourt, France

Overview

The question of policing is consubstantial to that of colonization and was raised at a very early stage, not just in diplomatic or military terms, but also with respect to the various manners of civility, regulation, and discipline that were to be expected from a good policing service. The notion of colonial policing, however, can hardly account for the many policing practices encountered in the various territories, with their diverse judicial and political statuses. It tends to foster a uniform vision of policing organization and practices, even though none of this was ever centralized, or even standardized, in this vast empire. Most importantly, it tends to conceal the fact that policing tasks were handled by multiple organizations and agents, many of whom were not, technically, actual police. Still, the very existence and usage of this phrase – colonial policing – suggests that, regardless of place and time, colonial authorities had their own set of policing practices and violent behaviors, which were partly distinct from what was prevalent in metropolitan France.

From a chronological point of view, the legacy of slavery and plantation power as well as the continued domination over various territories (e.g., some West Indies or Indian Ocean islands) must be considered: the hiatus between the first French colonial empire (built under the *Ancien ré gime*, during the seventeenth century in particular) and the second (refounded on the rubble of Napoleon's defeats, starting with the conquest of Algeria in 1830) should not be overstressed. Only in the late nineteenth century, however, considering the developments and reforms happening in the home country did colonial policing issues gradually and partially gain autonomous status, distinct from wider concerns about the frailty of colonial domination. Indeed, colonial domination only exceptionally reached the "pacification" stage, even though this goal was continually reasserted by civilian authorities, closely associated to their military counterparts.

State of Knowledge

Colbert complained as early as 1667 that "very little concern has been shown so far in New France for the policing and civil life of Algonquians and Huron." He considered this "long-standing neglect" a mistake that ought to be remedied promptly (Havard 2009). The word "*police*" was at the time highly polysemic in French. Indeed, the indeterminate nature of the term speaks volumes, insofar as police forces, under the *Ancien Régime* already, were associated to a civilizing mission with a particular focus on extending the reach of law. On its own, however, the "law and order" diptych cannot fully account for the nineteenth to twentieth-century colonial policing in the French empire – the period studied here.

The issue of policing organization and practices in the colonial context had to wait until the nineteenth century to be raised in concrete fashion. In the early days, the task of pacifying newly conquered territories was largely entrusted to the military. Only in areas specifically designed to receive European settlements was the creation of policing bodies seriously considered. A police commissioner (*commissaire de police*), for instance, was appointed in the immediate aftermath of the capitulation of the Dey of Algiers, on 5 July 1830. As evidenced by available documents, his meager staff spent many years focusing exclusively on managing and disciplining the "populace" and the "unwanted" freshly disembarked from Europe. Until the late nineteenth century, archives make scant mention of the "natives" ("*indigènes*"), who seldom appeared as a problem to be tackled by policing agents. The "gendarmerie of Africa," which was also created in the wake of the landing in Alger regency (June 1830) and was primarily conceived as a provost body for the supervision of locally stationed troops, occasionally took part in combats for the extension of colonized territories. Only under the Third Republic was it endowed with law and order enforcement responsibilities with regard to indigenous populations not governed by military administration.

Whenever it was felt that the action of armed forces should be supplemented by the creation of police units, the dominant method consisted in importing or adapting models or institutions that were prevalent in metropolitan France, two of which – the gendarmerie and the Paris prefecture of police – were frequent sources of inspiration. These flows of policing practices and frameworks from the home country to the colonies should not, however, lead us to underestimate other legacies that also contributed to the shaping of colonial policing: the settlers themselves but also privately owned companies, the Army, indigenous troops, country policemen and rangers, and colonial officials whose prerogatives could be extended with respect to the remoteness of their post (such as the *gardes-cercle*) have all been endowed with policing and penal capacities right until the decolonization era. Most importantly, in remote countryside areas, colonial authorities have endeavored to build upon local hierarchies and authorities, thus sparing themselves the task of having to establish specific policing bodies. While state order reigned supreme in "islands of domination" (in cities and along railways mainly), it was replaced in many places (plantations, concessions) by private authorities or by traditional social control mechanisms, so that the policing and judicial systems of settlers were only called upon as a last resort option or instrumentalized to pressure the promoters of local order.

Given this proliferation of policing agents and organizations, trying to distinguish between the "civilian" and the "military" makes little sense (Blanchard et al. 2011). The ongoing concern was the cost-effective, non-staff-intensive law and order maintenance. This perspective, however, left little room for insights going beyond the hackneyed remarks about natives being receptive only to the language of force. Hence, troubles were systematically interpreted as potential rebellions that might upset the entire edifice of colonial domination: despite many natives having been enrolled and various segments of the population having voluntarily rallied, while others had pursued arrangements and interests that they would be keen to stand for, colonial power remained exogenous. It was never able to take root in true cultural hegemony or in any political legitimacy reaching beyond the small circle of direct beneficiaries of this mode of government. A major indicator of the frailty of colonial power at the time is the way policing agents, administrative elites, and even the community of ordinary settlers tended to construe dreaded but simple attacks on private property as suggesting a general dissent against the balance of power – if not threats on their own existence.

Characteristics such as a lack of specialization of policing functions (which were closely linked to tax levying and statute labor) and a limited interest for crime repression, although not peculiar to the colonial setting, nevertheless do point to the principles of cheap government and under-management. The pattern has been well described by George Orwelle with respect to Burma (Orwelle 1998), but it also applied to most territories comprising the French empire. In an even more fundamental way, this pertained to some of the inner contradictions of the political project regarding settlements: enticed by separatism and rejecting any increase of tax pressure – which they felt should exclusively burden indigenous populations – settlers tended to impede the development of a specialized, professional policing apparatus. Thus, it is that in the years 1898–1900, their representatives in the *départements* of Algeria kept complaining of growing insecurity while simultaneously pressuring the authorities to obtain the withdrawal of the gendarmerie, which they considered too costly and too formal in its enforcement style.

The only positive aspects in their eyes were the reinforcement of the action of armed forces and of emergency powers (in particular the 1881 "*Code de l'indigénat*," a set of specific criminal rules for natives, which in fact legalized longstanding practices). Such tensions with civil authorities and police organizations could be found in many other places until the decolonization era. A case in point is the Kingdom of Cambodia under French protectorate, where the colonial administration, far from deferring to financiers and settlers, actually tended to moderate their excesses, providing a legal and practical framework that prevented extreme prejudice toward the natives, which might otherwise have triggered an uprising (Guérin 2008). The buffering role played by police forces in such circumstances should, however, not be overstated. Colonial policing did embrace the whole array of founding violence (land expropriation, physical constraint, attacks against local cultural and religious practice) traditionally associated to "despotic" colonial administrations that, as was the case, placed themselves under the auspices of the "sword" (Orwelle 1998).

The judicial inflation that can be observed in a colonial situation – "the empire of law" described by Emmanuelle Saada (2002) – was accompanied by the deployment of "coercive networks" (Sherman 2009), of which police forces were a mere segment. This removes a lot of interest from any attempts at reporting on policing in a colonial setting from an institutionnal perspective, since the coercive practices experienced by the colonized could hardly be accounted for. In the case of the French empire, the task is even made almost impossible by the fact that no centralized agency was ever put in charge of designing and evaluating such policies – i.e., there was no equivalent of the British *Colonial Police Service* nor was any formal, shared employment scheme ever deployed throughout the colonies. While some officers did circulate across colonies, they made up a tiny minority of the numerous police deployed in the empire. Furthermore, ambitious and thorough historical research focusing on the local variations and characteristics of an empire encompassing a great many different institutional frameworks is made impossible by the sheer scarcity of available studies: no overview, no synthesis, and no comparative research have been published so far, which is why the French case cannot be considered on par with the UK (Sinclair 2006) or the Netherland models (Bloembergen 2011). Indeed, the most recent synthetic works published on French police forces have almost nothing to say on the imperial dimension of policing, focusing instead on metropolitan France (Anderson 2011), even though the latter can hardly say to have been estranged from the overseas at the time.

Current Research

Recent or current research by young scholars and the abundance of studies on the gendarmerie (Luc 2010) do however allow us to outline what the mechanisms of policing have been in certain territories. On a general level, Florence Bernault's insights on colonial prisons, which were often administered by policing bodies, are a good starting point: "the colonial prison did not apprehend delinquents according to a single judicial register (. . .) it sought to maintain the racial and juridical hierarchies upon which colonial rule was founded, thus reproducing a violent, personalized, and circumscribed power (. . .) As the vanguard of these confining tactics, colonial prisons thus illuminate how European regimes in Africa survived as enterprises of unending conquest" (Bernault 2003).

Florence Bernault rightly insists that the conquest endeavor was an ongoing one. "Pacification" was never taken for granted, but remained a violent, uninterrupted process, which however varied in intensity according to place and time. But it is no less true that initial periods of military domination were generally followed by deliberate attempts at establishing civilian authorities, epitomized, among other symbols, by their police forces. In many territories gendarmes remained for a long time (sometimes as late as Word War II) the only actual, however furtive, colonial presence identified by the locals.

Using a – necessarily reductive – process approach, the timeline highlighted by John McCracken regarding the British empire, and more precisely Malawi (McCracken 1992), can be adapted to the French empire: an "era of coercion" encompassing the first decades of domination, followed by an "era of control," then one of "collaboration" (the interwar period), and finally a "crisis of authority" after World War II. Clearly, this pattern is not set in stone, and periods may overlap. Most importantly, it must be inscribed in singular colonial trajectories, which depend heavily on when the conquest was made as well as on the frequency and punch of violent actions of resistance to colonial order.

The gendarmerie has been the main colonial police force: its military police dimension (both as a provost body and because of the military status of gendarmes) made it a privileged tool in the conquest phase and during the "era of coercion." For instance, on 16 May 1843, about 30 gendarmes were involved in the battle of Taguin or more precisely in a raid against the *smala* of Abd El-Kader (Jaulin 2009), which resulted in the taking of more than 3,000 prisoners and major spoils (a "feat" that still adorns the flag of the French national gendarmerie). In Madagascar the gendarmerie's contribution to *pax gallica*, as imposed by Gen. Gallieni, was rather short lived (1901–1904, although a gendarmerie detachment was reestablished in 1931). But in the whole empire, the colonial gendarmerie did take part in numerous battles, regardless of the precise dates of territorial annexations. In 1918, it supported the French Army after France was granted a mandate on the Levant from the League of Nations. Incidentally, the Lebanon gendarmerie was on the front line – and targeted – during the 1925 Druze insurgency (Faisant de Champchesnel 2010). From this moment on and until the accession to independence, however, locals gendarmes tended to side with insurgents, and the resulting struggles, pitting gendarmes vs. gendarmes, highlighted the limits of the French policy of fueling ethnic and religious divides. Even where the colonization process was initiated in the diplomatic framework of trans-imperial competition instead of bringing about a war of conquest, the phrase "era of coercion" refers to those moments when French authorities were trying to tighten their grip. The kingdom of Cambodia, where a protectorate treaty had been signed between King Norodom and France in 1863, is a case in point: certainly, the 1885 uprising was stifled by military interventions, but it was used as an opportunity to reinforce the militiamen of the indigenous guard, who also acted as a police force. In particular, they were in charge of supervising tax collection and organizing statute labor days, up to and including the Highlands, an area where dissent toward central authority, whether Khmer of French, was at its highest (Guérin 2008).

The "era of control" should be understood as both (a) the moment when military head count decreases and powers are transferred to civilians (for instance, in 1871 in the main districts of Algeria) and (b) the period when new policing methods are being developed to control people, following technological innovations from metropolitan France. In Madagascar at the turn of the century, General Gallieni extensively resorted to photography for the census and racial classification of the population. Generally speaking, although colonial police forces tended to be understaffed and underfunded, they were at the cutting edge of anthropometric and identification techniques. These intellectual, technological, and human investments were markedly associated to specific representations of crime as pertaining to entire populations, which in many areas of the empire translated into collective fines and punishments.

From a technical and organizational point of view, the protectorate of Tunisia was a precursor, equipped, as early as 1890, with a judicial identification service similar to that created only a few years before at the Prefecture of police. Indeed, in the early 1890s, Alphonse Bertillon himself played a key part in the establishment of the Algiers judicial identification service. Similar bureaus were subsequently opened in the AOF (French West Africa), the AEF (French Equatorial Africa), Madagascar, and Indochina. But the most accomplished version of this anthropometric form of control – the best researched at least, thanks to the works of Ilsen About (2011) – occurred in Saigon. The anthropometric identification bureau was institutionalized in 1897, as part of the immigration services. Carding (forcing people to have an ID), fingerprints, and anthropometry were made instrumental in a vast census and registration project encompassing all natives and foreign Asians. Even though opposition from multiple sources (congregations, consular representatives, part of indigenous elite) eventually caused the shelving of this ambitious project, by 1917 the bureau had managed to gather some 700,000 records, complete with fingerprints. Indochina in this domain acted as a laboratory.

The emphasis on identification as a trait of colonial policing is further enhanced if one integrates metropolitan France into the global picture of the colonial empire (Rosenberg 2006). In Paris, after an identity card for foreigners had been established in 1917, French nationals of colonial origin were the next target (Blanchard 2011). A North African brigade was thus created at the Paris Prefecture of police in 1925, with multiple prerogatives (administrative and social in particular) aiming to feed a database that would list all colonized people originating from North Africa (90 % of whom were Algerian Muslims enjoying French citizenship, meaning that they needed no specific documents whatsoever to settle in metropolitan France). Yet these panoptic aspirations were never entirely fulfilled: given the rules governing the political representation of certain segments of the colonial world, from the 1930s onwards (especially after World War II), the colonized were sometimes able to oppose such designs, which in any case appeared to be limited by the sheer scope of their technical and financial requirements. Still, from the interwar period onwards, in metropolitan France as in the empire, political surveillance of the colonized became a policing priority. In 1922 in Dakar, the creation of a Central Service for the Policing and Safety of French Western Africa (*Service central de police et de sûreté de l'AOF*), whose structure was replicated in each of the component colonies (*Service central de police et de sûreté du Sénégal*, *Service central de police et de sûreté du Dahomey*), epitomized this concern. The general objective of controlling mobility and preserving disciplined, segregated urban spaces for the benefit of European minorities came on top of a hidden agenda: thwarting the ability of the better-educated colonized (the "evolved") to travel and act (Brunet-La Ruche 2012). These people were suspected – sometimes quite rightly so – of anti-colonialist or nationalist activism. As a matter of fact, during the interwar period, and especially in the AOF, this channeling of policing means and services into political surveillance contributed to relocating the fears and representations of insecurity from rural areas to the cities, where criminality was on the rise but did not seem to be eliciting any tailored policing response (Fourchard 2006).

The weight of political defiance toward indigenous elites partly explains why the notion of an "era of collaboration" does not apply to the French empire quite as it does to the British empire. No movement of indigenization proper has ever taken place in the higher ranks of the policing hierarchy. To a certain extent, policing management in the French empire was more reminiscent of the Belgian approach than the British method. In Belgian Congo, for instance, the *Force Publique* created in 1885 never entrusted any natives with leadership positions (Lauro 2011). The same applied to most of the French empire: with the exception of a handful of commissioners, "Africanization," and more generally indigenous access to managing positions, was only engaged in the very last years of colonization. Moreover, such developments were seldom considered as preparing a transition toward independence. In some cases, the requirements (educational, legal, etc.) were raised to such a level and the will to confront political and violent protests was so strong that any increase of staffing levels was matched by a corresponding growth in the ratio of European-born recruits (such was the case, for instance, for the gendarmerie in Algeria). None of the French police bodies ever surmounted the quandary of importing mainland operational methods and gradually implementing a shared legal framework without making it increasingly difficult to gather intelligence from the locals (Thomas 2008). Indeed, the chasm from local circles was such that intelligence services often had to resort to broad, hackneyed ideological patterns (the Communist threat, pan Arabism, the influence of foreign nations) which actually stood in the way of taking the full measure of protests or local separatist movements. In defense of these services, it should be said that nationalist, religious, and communist movements and motivations were so enmeshed – during rural uprisings in Vietnam (1930–1931), for instance – that deciphering the redistribution of anti-colonialism was an extremely difficult task.

Anti-colonialism was in fact eventually recognized from an institutional perspective – the African Democratic Rally (RDA), founded in 1946, is a prime example – and was sometimes able to weigh in on policy and policing developments. Political surveillance, which had been considerably reinforced all along the 1940s, was thus gradually loosened as the recognition of African states made progress: in 1958, both the Intelligence and the Judicial Identity services of the AOF were even officially disbanded, but the gendarmerie managed to grab some of their files and prerogatives (Papa Dramé 2010). Most importantly, in the wake of World War II, recruitment processes became more bureaucratic. The written word as well as legal proceedings took greater importance, both in daily tasks and in terms of career development: French-speaking, higher-educated colonized people massively took over the intermediate echelons of the hierarchy. Joël Glasman has convincingly shown how, in the case of Togo, such developments were both (a) inscribed in how part of the population adjusted to the colonizers standards and (b) loaded with contradictions and oppositions, not only within policing bodies but also among the local elites (Glasman 2010).

This standardization process, however, should not be overestimated: even in the *départements* of Algeria, where metropolitan rules and frameworks had supposedly been best integrated, the creation of the first constabulary academy was only decided in 1949, 1 year prior to that of the AOF in Dakar. Indeed, colonial police forces were never known to put a strong emphasis on disciplining and educating their personnel. Thus, restraining the use of force was never considered a priority, or even a reality. In the mid-1950s, Albert Memmi could write of the colonizer, with good reason, that “a machine-gun burst into a crowd of colonized causes him merely to shrug his shoulders” (Memmi 1965). Even during allegedly quiet periods – in terms of violent unrest against colonial domination – marked by a relative professionalization of policing by civil bodies instead of military ones, this reliance on shootings and killings was noticeable: in Tunisia in 1937–1938, both in the mining area of Gafsa (March 1937) and in Tunis (9 April 1938), union (CGT) and political (Néo-Destour) rallies and demonstrations triggered bloody repression. Massive use of gunfire by policemen, gendarmes, and colonial troops killed dozens.

During the so-called “crisis of authority” period, these shootings grew in both magnitude and frequency. In May 1945, for instance, in Sétif and Guelma (Algeria), vigilante European settlers sided with the police forces, who in turn had received support from the Army (Peyroulou 2009). They coordinated not just to suppress Algerian unrests but also to arrest, intern, and quite often kill or dispose of anyone suspected of belonging to the separatist movement. Parts of the casualties, which numbered in the thousands, were actually caused by shelling, from both sea and air. Ever since the interwar period, in the Maghreb and Middle East in particular, air policing had been used not only for land surveying but also to subdue outbreaks by the colonized: firepower was supposed to make up for scant police and military staffing on the field (Omissi 1990). Inspired by the Italian conquest of Libya (the 1912 bombings) as well as the action of the Royal Air Force in Afghanistan and Iraq in particular (1919–1920), the French also resorted to this ploy. After a few experiments in Morocco (the Rif War), they made the most of air domination to suppress the Druze rebellion of 1925–1926. The city of Damascus was massively shelled, and the residents of Druze and Muslim neighborhoods subjected to what can only be dubbed a terrorization policy. This particularly lethal use of air policing was designed to match the movements of Army troops and police forces, the gendarmerie in particular. The idea was to make up for their notorious and accepted understaffing.

Still, the “crisis of authority” period saw a rapid increase of police staffing: notwithstanding the decolonization wars (Indochina, Cameroon, Algeria), the growing intensity and attendance of protest demonstrations as well as the ever-increasing burden of the standards and regulations in metropolitan France left no other option. To develop but one example, the head count of the AOF gendarmerie (including Togo) rose from less than 300 in 1946 to almost 1,200 in 1957 (all of them “white,” bar two). Auxiliary gendarmes (black Africans) numbered 700 in 1946 and more than 2,625 in 1957. In Togo alone, from the 1930s to the 1950s, police staffing levels doubled but – more importantly maybe – remained quite low at less than 1,000 men at the end of the colonial era (Glasman 2010). Hence, even though the relative weight of uniformed service personnel (vigilantes, guards, gendarmes, constables) was particularly significant in the colonial state (from one third to one half of the entire personnel in Togo, a lower proportion whenever more Europeans were present), the overseas police-to-population ratio remained lower than in the home country. While in the 1950s, France had on average one police per 250 citizens (a ratio that was only matched in the most watched cities in Africa, such as Abidjan), the figure could drop down to less than one per 1,500 in certain cities in AOF (such as Kayes in French Sudan).

This lack of personnel is sometimes put forward as an explanation to the disproportionate use of force by policing authorities: gunfire in this case is interpreted as a means of compensating the powerlessness of outnumbered police doing their best to keep the crowd at a distance. Much like its British counterpart (e.g., with the 1919 Amritsar massacre), the French empire was marked by the permanence of this logic consisting of slaughtering protesting crowds of colonized people, as evidenced by the now well-documented case of the December 1952 repression of the Casablanca riot (House 2012). These casualties, however, which numbered in the hundreds each time, can hardly be attributed to any panic on the part of supposedly outnumbered, and therefore overwhelmed, personnel: not only was the police receiving support from colonial troops and vigilante settlers, but the same logic of massive, lethal gunfire against demonstrating colonized was also at work in metropolitan France at the same period (Blanchard 2011). While the Paris police had stopped using firearms to disperse demonstrations (even unauthorized ones) as early as the 1930s, gatherings of colonized people were treated differently. On 14 July 1953, for instance, six Algerian demonstrators were killed by police fire on the *place de la Nation*. In 1961, dozens of Algerians succumbed to the blows and bullets of the Paris police, who on 17 October conducted what has got to be considered a pogrom (House and MacMaster 2006). More than the format of policing or the actual behavior of demonstrators (police response hardly varied, irrespective of the peacefulness of demonstrations), it is the racial-political condition of the colonized that determined both the nature and degree of the policing techniques employed.

The last years of the colonization era had very little to do with a transition period. What entire segments of the police forces offered instead was a violent toughening of their stance. In Algeria, the police units were largely involved in the massive use of torture during the war of independence. The collusion between a majority of policemen and the most extreme supporters of French Algeria (the *OAS*, Secret Army Organization, in particular) contributed both to destabilizing legal authorities (in May 1958 and April 1961) and to protracting the fights beyond the cease-fire signed in March 1962. Aside from this well-known example, parts of Africa were also plagued by counterrevolutionary warfare, especially Cameroon, where the struggle against the partisans and maquis of the Union of the Peoples of Cameroon (UPC), sparked amidst extreme violence in the late 1940s, lasted a further decade after the independence had been proclaimed in 1960 (Mbembe 1996).

Postcolonial Legacies

The “racial coloration” of the colonial situation pointed out by Georges Balandier is undoubtedly one of the major characteristics of colonial policing (Balandier 1970). “Racial segregation” might actually be more to the point, insofar as local police were never able to impose the legitimacy of their prerogatives on European settlers: Amandine Lauro’s remark about Belgian Congo – black police were not even allowed to pick up drunk white people in the gutter – also applied in the French part of that colony (Lauro 2011). Conversely, and more tragically, Europeans never gave up their individual right to punish the colonized: whenever police action was considered not to be harsh enough, it would be complemented by punitive raids and the creation of vigilante militias. Beyond such paroxystic circumstances, urban police forces were the main tool for managing populations, and their primary task was to safeguard the feeling of close-knit community, the hygiene, and the tranquility of the “European city.” They were, however, never granted the wish to restrict indigenous access to European residential spaces to the sole servants. It is true that – as opposed to what was the case in Ghana or British Nigeria – no official segregationist policy (creating separate neighborhoods for Europeans, migrants, or minorities) was ever enforced in the cities of the French empire. Still, policing authorities – through vice squads in particular – did restrict and keep under surveillance the least movement across racial and colonial borders.

The question of prestige was so pressing for Europeans that many of them were actually not welcome in the colonies. Those who were allowed to settle there had to conform to a set of rules that worked as just as many markers of the superiority of French civilization. Close attention was paid to gender relations and roles: civil servants in particular were briefed on the subject and deprecatory discourses on the sexuality or virility/feminity of the colonized abounded. Police forces, in their surveillance reports for instance, contributed to spreading these stereotypes. More importantly, they played a direct part in the regulation of the sex trade. Studies by Christelle Taraud on North Africa (Taraud 2003) and Isabelle Tracol-Huynh on Vietnam have shown that prostitution regulationism in the colonies cannot be measured by the yardstick of hygienism, the primacy of the patriarchal family model, and the extension of police prerogatives, as was the case in metropolitan France. There was of course no lack of such dimensions, but the primary issue was the drawing of clear gender and racial lines in the government of the people.

In Vietnam, where marriages between colonizers and the colonized were more frequent than in North Africa and mixed-blood children more numerous, indigenous concubines of "Europeans" were even considered prostitutes (Tracol-Huynh 2010). Prostitutes, in turn, were *de facto* organized into a regulatory and penal hierarchy based on racial criteria. Other trade categories, loosely defined but highly visible, such as dancers or singers, were also under tight surveillance, which varied, however, depending on the means available to the police, the proportion of settlers in the overall population, and how the majority population responded to such regulatory and policing intrusions. In the Shanghai French concession for instance, eradicating or even regulating the massive prostitution – which predated colonial domination – was never really considered (Henriot 2001). Still, the fact that healthcare protective measures, however scarce, only catered for European clients clearly indicates that, even in this highly specific colony, the seeds of a racialized population policy had been sown.

This policy also reached metropolitan France, especially through the police or military institution consisting of organizing prostitution spaces dedicated to immigrants or North African troops (the military brothels aka "*bordels militaires de campagne*"). This was one among many aspects of the distinctive brand of policing applied to the colonized, whose condition was deeply affected – especially during the Algerian war of independence – by recurrent identity checks, frequent roundups, and administrative detention. They were also targeted by positive policies such as welfare (access to healthcare, job search support) and collective housing (accommodation facilities for migrant workers that were built starting in the 1930s, with a second wave launched in the late 1950s). While sometimes improving their living conditions and facilitating their understanding of mainland rules and bureaucracy, which differed significantly from what they had known overseas, these programs nevertheless followed a logic of control that did not vanish after the independences. To assess the weight of colonial legacies, one only has to look at the careers of former colonial administrators or officers, who started out managing agencies in charge of supervising the colonized (especially during the Algerian revolution) before heading immigrant support services. Such careers also epitomize the hybridization of policing repertoires, which became a blend of population control, political surveillance, and welfare.

Controversies on the colonial matrix governing the police control of immigrant or racialized populations did not, however, cease with the retirement of the last personnel to have started out at the time of the colonies or in the ranks of these particular agencies. Today, the colonial "difference principle" no longer is a founding principle of specific measures and programs. Sociological studies, however, unanimously demonstrate the existence of racialized gradations in terms of the ability to stand up for one's rights against policing authorities, police influence, and the use of force – especially lethal force. In France today, the best-known aspects of the racialization of policing practices are police "blunders" (often a euphemism for "killings") and the repeated, often illegal identity checks performed on young, nonwhite males: depending on their clothing habits, black or Arab-looking young men are 2-15 times more likely to have their identity checked than other categories of the population (Jobard and Lévy 2009). While certainly not all targeted persons can be linked to the former French colonial empire (or even its current remains, notably in the West Indies and Indian Ocean – the Mayotte and Réunion islands), it cannot be denied that the control of the colonized was one of the historical operators in the process of policing racialization. The weight of colonial policing's legacy has thus become a controversial issue, fiercely debated both in academic circles and in the media of contemporary France.

Colonial continuities are no monopoly of the former home country: many a policing institution has been passed on, almost "as is," to newly independent states. The few local police have often contributed to the training of younger generations, with the support of the French cooperation services (after the independences, as before, many police commissioners from West African states attended Saint-Cyr au Mont d'Or police academy, in the Lyon area). The most striking and symbolic legacy has got to be the flock of national gendarmeries in former French colonies: 150 years after Napoleon's conquests, the decolonization era acted as a second age for the spreading of the gendarmic model. From Ivory Coast or Mali to Syria and Lebanon, through Tunisia or Algeria in particular, the forces that stemmed from the French legions of colonial gendarmerie have played their part in several of the episodes of repression and political transition that are currently at the heart of geopolitical news. Beyond the racialized management of populations and the religious minorities policy that so deeply affected the Levant, for instance, only time and an intensification of research will tell whether these policing and gendarmic legacies (in their linguistic, symbolic, material, and organizational dimensions) have produced other continuities.

Front Door and Backdoor Sentencing

Synonyms

Parole; Recall; Release; Sentencing

Overview

In the literature on criminology and criminal justice, much more appears to have been written on sentencing "law" than on sentencing "practice." And those who write on sentencing, law or practice, have tended to write about "front door" sentencing: the rules as well as the judicial decisions which impose the initial sentence. But most systems allow some form of "backdoor" resentencing: for example, judges may reduce the sentence on proof of cooperation and progress or administrators may recall to prison those who had been released "early." Most criminal justice systems allow some sort of "early" release from prison and also recall to prison offenders who somehow "fail" in the community. This entry argues that understanding "sentencing" involves understanding that it is not just a "one-off" event, but more of a continuous or ongoing process, which should be subject to regular judicial review or oversight.

Introduction

"Sentencing" is normally understood to be the process which happens in court, when an appropriate punishment is imposed on an offender, by a judicial authority. The way in which this happens varies across jurisdictions and within jurisdictions and across time. For example, common law jurisdictions tend to separate a criminal trial into two separate and distinct parts: one which focuses on the decision whether someone is to be found guilty or not of an offence and a separate sentencing stage or hearing which decides on the appropriate sentence. However, in many countries, particularly in continental Europe, the court may decide on conviction and sentence in one process (e.g., the sentence is part and parcel of the French concept of *condamnation*).

We are immediately faced with some definitional issues which make comparisons so difficult. When is a penalty a "sentence"? Are those who are diverted away from the criminal justice system by formal or informal cautions or warnings "sentenced" (see Padfield et al. 2012)? What about those who are compulsorily detained in mental hospitals, who may or may not have been convicted of their "crimes"? Is the outcome of mediation (increasingly common in a variety of jurisdictions) a "sentence"? What about fixed penalties and the increasingly popular but often misunderstood "restorative justice"? These are all arguably forms of "sentence," even when administered administratively and not by a court. But when is a court truly a court? Who is a "judge" or what is a "judicial authority"? None of these are easy questions to answer. It is not even clear when a sentence ends: public protection concerns have led many countries to continue to monitor offenders, either formally or informally, even after the completion of their sentence (see, e.g., the English MAPPA or multiagency public protection arrangements). Others allow civil "preventive detention" (e.g., Germany).

Then we reach the main difficulty, for current purposes. There is often a gulf between the sentencing law prescribed by law and what happens "on the ground." I have found it useful to borrow from the French and to identify three different "levels" of sentencing frameworks (see Delmas-Marty et al. 2003). I think the French language works more efficiently here than the English in creating neat labels:

- *La peine encourue* (to be found in the formal law, whether English statutes or continental *Codes Pénales*), which is the possible sentence, that which is permitted or prescribed by the law. Many of those (particularly many academic criminal lawyers from non-common law jurisdictions!) who look to study sentencing do not look beyond these formal legal rules.
- *La peine prononcée* is the sentence given by the judge(s) in court. There has been remarkably little work done around the world analyzing actual sentencing decisions. We may well know how many burglars, for example, are given a custodial sentence in a particular jurisdiction in a particular year, but often we know very little about how the judge(s) reached their decision. The recorded sentence alone gives no insight into the factors which affected the judge, into the way that aggravation and mitigating factors influence individual decisions. There is remarkably little good quality and systematic information about judicial practice (though there have been attempts to gather it: see Tata and Hutton (2002, especially Chap. 19) or the work of the Sentencing Council in England at http://sentencingcouncil.judiciary.gov.uk/docs/CCSS_Experimental_Release_web.pdf)
- *La peine appliquée or executée*. These are the sentences actually served by offenders. Particularly when we look at custodial sentences, it seems rare that offenders have to serve the precise sentence imposed in court. And even those serving sentences in the community may have their sentence modified during the course of its implementation, of course. It is even more difficult to gather reliable data on this area of sentencing. As we shall see, sentences may be extended or curtailed. They may be varied according to the offender's rehabilitative needs and/or his or her cooperation with the sentencing and administrative bodies. Short sentences of imprisonment are very often suspended if (but only if) the offender engages (adequately) with probation services. This entry seeks to argue that sentencing should be seen more as an ongoing process than a one-off event.

All three stages or levels of sentencing are authorized by law, but these labels are to my mind useful as they help us to distinguish law as applied in practice from the law found in statutes or in books. They allow us to contrast the formal rhetoric of statutory penalties with the law as it is implemented. I also adopt the distinction between “front door” and “backdoor” sentencing for similar reasons: it is important to remember that what the judges say when sentencing someone may not accord very closely to the sentence the offender will actually serve in practice. Unfortunately, too much political and academic attention has focused on what is often known as “front door sentencing,” but what happens at the “backdoor,” while often invisible, is just as important. Indeed, because it is often invisible, we must be even more vigilant to ensure due process (fair procedures and fair outcomes).

Front Door Sentencing

In Law

The formal rules of sentencing are laid down by law. Normally, the framework will be laid down by a Parliament or other elected body. This “framework” will vary enormously from jurisdiction to jurisdiction: many countries have a very detailed sentencing code, others a more confused (or confusing) collection of legal rules. The formal law normally lays down maximum sentences, but sometimes minimum or a range of possible sentences. Sometimes a sentencing regime is designed around a court regime: offences are categorized (felonies as opposed to misdemeanors or indictable as opposed to summary offences, crimes as opposed to delicts, etc.). Thus, offences may be subdivided according a court hierarchy or simply according to “seriousness.” The nature of the “judge” may vary: many jurisdictions involve lay judges, sometimes for less serious crimes (e.g., lay magistrates), sometimes for more serious cases (juries). In many jurisdictions the jury has absolutely no role in sentencing, but in others it may decide or in some sense affect the sentence, sometimes deciding with the judge, or sometimes alone, in isolation from the judge(s).

There is widespread agreement that the purposes of sentencing should be identified, but how this is done in law is less easily agreed. Thus, the English and Welsh judge must have regard to the following purposes (see s. 142 of the Criminal Justice Act 2003):

> the punishment of offenders
>
> the reduction of crime (including its reduction by deterrence)
>
> the reform and rehabilitation of offenders
>
> the protection of the public
>
> the making of reparation by offenders to persons affected by their offences

Would it be more “effective” to have one priority? Some constitutions grant a constitutional right to rehabilitation: for example, Article 27(3) of the Italian Constitution provides that punishments must aim at resocializing the convicted (Gualazzi et al. 2010). How this applies in practice of course needs to be monitored by empirical research.

Most people would agree that a key requirement is consistency. Consistent sentences are desirable, not least so that the system is fair, and perceived to be fair. But legislating consistency and indeed fairness is no easy business! Nor is it easy to monitor or assess how well a system is achieving consistency. Many jurisdictions have experimented with sentencing grids or frameworks or matrices and have created bodies (often “councils”) to advise either legislatures or the judiciary in the development of guidelines (see Tonry and Frase 2001; Tonry 2007). Appeal courts and academic treatises often offer detailed guidance. This topic is raised here simply to make the point that much time and effort has been extended on developing consistency in “front door” sentencing but much less, as we shall see, on consistent or principled “backdoor” sentencing decisions (though some of the first guidelines in the US system were parole guidelines, intended to correct for the wide differences and perceived arbitrariness of judicial sentencing).

Imprisonment remains the most common sentencing option for serious crime. Some countries, of course, continue to authorize the killing of offenders, implementing a lawful death penalty (see Hood and Hoyle 2008). From a European perspective, this contravenes human rights norms. For most legal systems, imprisonment is the main sentence for the more serious offences. It may be indeterminate or determinate. Some European countries (Croatia, Norway, Portugal, and Spain) have no provision for indeterminate or life sentences of any sort. Of those that do have life sentences, some have mandatory life sentences for some offences (UK, Turkey), while for many, life is only ever at the discretion of the sentencing judge or judges. Total life sentences, life without any possibility of parole, are rare. Some countries permit full or whole-life "tariffs" (there are, e.g., about 30 prisoners in England who know they are serving their whole life in prison) but most have a limit, fixing a minimum term which must be served before a prisoner can be considered for release. Many systems do not individualize this tariff, but simply specify a fixed minimum term to be served. What is important for our purposes is to recognize that without a clear understanding of the rules on getting into prison, we can have little understanding of the rules on getting out. Similarly, the rules on getting out, or on early release, make little sentence without a clear understanding of the rules on getting in. It may be easier to calculate release dates when sentences are of determinate or fixed term lengths. But as we shall see, this is by no means always the case.

Then there are sentences which are served in the community: often involving a financial penalty or the supervision of a probation service. The line between custodial and noncustodial sentences is not easy to understand. In many countries, a sentence of imprisonment may be suspended, with or without conditions, partially or fully. This does not mean that the sentence should not be categorized as a custodial sentence, but the imposition of such a sentence poses both theoretical and practical difficulties. In the Israeli context, Sebba (2001) explains that the sentence of community service work was introduced deliberately as a "prison" sentence, served in the community – in large measure to serve as an encouragement to the courts to confine the use of the sanction to cases sufficiently serious to have justified a sentence of imprisonment in its traditional sense, but doubtless it was also to make clear to a wider "audience" that a community sentence was not a soft alternative.

On what grounds should a court, having decided that an offence (or offender) crosses "the custody threshold," step back and suspend the sentence? I have argued that the concept of the "custody threshold," much used in England, is deeply unhelpful, maintaining the unnecessary fiction that even short custodial sentences are somehow "bigger" punishments than alternatives served in the community (Padfield 2011c). What should be the sanctions for minor breaches of conditions attached to noncustodial penalties? Not custody presumably, since the original offence was deemed not to deserve custody. Suspended and community sentences reflect the confusion of purposes: punitive, rehabilitative, and so on. Some systems combine fines and imprisonment. Others specify that they are only alternatives. And many allow "ancillary" penalties which are often the most burdensome components of the sentence: offenders may be deprived of certain rights (the right to drive, even the right to vote in some countries) or ordered to keep in contact with the authorities for many years. Compensation (to victims) and confiscation (of the profits of crime) may be ordered. Given the complexity of options available, it is perhaps not surprising that the practice of sentencing is difficult to understand.

In Practice

In most countries the penalty is "individualized." The judge or judges select an appropriate sentence or package of sentences for this particular offender. This sentence will normally be announced in open court and publically recorded. Judges are usually rightly required to explain their reasons – though the extent to which they do this varies from jurisdiction to jurisdiction and indeed within jurisdictions practice may vary over time ("moral homilies" come in and out of fashion). Understanding judicial reasoning is not always easy. Most systems require the sentencer to fix a sentence according to the culpability of the offender and the seriousness of the offence, and inevitably this requires some subjective assessment. The role played by aggravating and mitigating factors in reaching the "right" sentence is not well understood, in theory or practice (see Roberts 2011), and it is often difficult to obtain data which helps one understand the reasoning of judges in individual cases.

Here, it is important to explore the literature on discretion. Dworkin famously pointed out that "discretion, like the hole in a doughnut, does not exist except as an area left open by a surrounding belt of restriction. It is therefore a relative concept" (1977: 39). Many writers have sought to explore the use and abuse of discretion in sentencing (see Tata and Hutton 2002; Tonry 2007 for international examples). One interesting conclusion has been that, in jurisdictions which have sought to "control" the abuse of discretionary sentencing powers by grids or guidelines, there has often been (paradoxically) an expansion in discretionary powers elsewhere in the process: most obviously, prosecutors may initiate and control plea or sentence bargains, for example, to avoid rigid sentencing options. This entry seeks also to point out a different paradox: that while much attention has been paid in many jurisdictions to attempt to control or limit the discretionary power of the front door sentencer, "backdoor" sentencers still often have vast powers which may in effect undermine attempts to develop consistency. These powers often remain invisible to both the legal and academic communities.

Backdoor Sentencing

Noncustodial Sentences

What happens when a fine is not paid? This is more of a problem in some countries than others. The sanction for nonpayment may be a tougher penalty: a community punishment or even custody. This hardly seems to be a suitable response when the original offence only merited a fine. With community penalties, similar problems may arise in relation to noncompliance. Regular review may be better than allowing noncompliance to develop to such an extent that those involved in supervising the penalty feel that a custodial response becomes inevitable. Who supervises the payment of fines or the performance of community punishments? The answers to these questions vary enormously: fine enforcers may be administrative bodies or court-employed staff or private bodies acting under contract.

The front-line enforcers of community orders are in many countries called "probation officers," but this term is far from universal (they may be criminal justice social workers, justice assistants, or simply part of the prison administration: Padfield 2012a, b). What it is to be a "probation officer" also varies from jurisdiction to jurisdiction and over time within jurisdictions. One interesting issue is whether these "probation officers" should be part of the same service which runs prisons. In England, probation officers were clearly for many decades "officers of the court," but an increasing concern with the "silo mentality" which divided prison and probation services, thus failing to allow sentences to function "seamlessly" from custodial to community parts, led to the creation of an umbrella organization, the National Offender Management Service (NOMS). But rather than leading to a "seamless" sentence, we have seen the further fragmentation of services, exacerbated by shortage of resources in the community part of the system. The Americans use the term "corrections" to create an impression of coherence and continuity. The same arguments are taking place elsewhere: in France the *service pénitentiaire d'insertion et de probation* (SPIP), the equivalent of the English probation service, has long suffered as the poor relation of the prison estate. The SPIP or the probation officer may have delegated powers to enforce or "police" poor performance – more often, they will have to bring the nonconforming offenders back before a "court" (Herzog-Evans 2011a, b, 2012). Sanctions for poor performance can vary enormously. So do processes.

Custodial Sentences: Early Release

In reality, most custodial sentences are in effect partially suspended. Most prisoners leave prison before the full term of the sentence imposed in court has passed. In many countries there may be a system of remission, which is clearly fixed by law. Thus, in France, every prisoner gets an automatic *crédit de réduction de peine* (CRP), which can only be lost in the case of proven bad behavior in prison (the prison governor or prosecutor (*procureur)* can ask the supervising court to disallow the credit): 3 months remission is given for the first year of imprisonment and 2 months per year in subsequent years. The rules are more complex for the most serious offences when the credit can, curiously, be disallowed for medical reasons (see, Reuflet 2010). For short sentences the CRP is 7 days per month. As well as automatic remission, many systems allow a discretionary remission to those who make serious efforts at rehabilitation or to those who have helped the authorities.

Thus, the term "early release" is itself a deeply contested term (see van Zyl Smit and Snacken (2009, Chap. 8). Many authors prefer to speak simply of "release" or "conditional release." But not all releases are necessarily "conditional" (and the weight of conditions can vary enormously). "Early" release of course has both disadvantages and advantages. The fact that the public may see "early release" as a "cop out," a pragmatic and cynical way of letting prisoners escape paying the true price of the their crime, may fuel the political punitive rhetoric which (paradoxically) sees more and more people sentenced to longer and longer sentences. The advantages of "early" release to both the offender and the State are perhaps obvious: by limiting the length of sentences, the overall cost of sentences is reduced. These costs include not only the financial costs (which are enormous) but also the human and social costs. The negative effects of imprisonment are explored elsewhere in this encyclopedia. Where priority is given to the reintegration of prisoners into free society, it will often make sense to speed the process of release as much as possible. Early release rules can also help prison authorities maintain discipline in prison, by offering a "carrot" to encourage good behavior. But not all prisoners seek early release: in some jurisdictions prisoners may prefer to "max out"; in the USA and some European countries, prisoners can in effect refuse parole, serving all of their sentence in prison, or are released unconditionally, without any supervision post-release (see, e.g., Bauwens et al. (2012) on the situation in Belgium).

Who makes the decision to release a prisoner? In some countries, or for some prisoners, the rules may be fixed. The prisoner may have to serve a fixed proportion of their sentence. But many systems allow a certain flexibility: perhaps a decision on release is taken by the prison authorities or by a formal court. In some jurisdictions, the competent authority for conditional release is always a judge (a special chamber of the District Courts in Germany or the *tribunaux d' application des peines* in France). Elsewhere, the decision may be taken by a hybrid body composed of judges and experts or lay members. The Parole Board of England and Wales has been held not to be adequately "independent" to comply with the requirements of Art. 5(4) of the European Convention on Human Rights, which requires that "everyone who is deprived of his liberty by arrest or detention shall be entitled to take proceedings by which the lawfulness of his detention shall be decided speedily by a *court* and his release ordered if the detention is not lawful." But in fact, today, the Parole Board takes few release decisions, now focusing on the release of indeterminate sentence prisoners and those recalled to prison: first release will usually be fixed by law or taken by prison governors (operating a discretionary Home Detention Curfew scheme, which allows prisoners to be released up to 135 days before the midpoint in their sentence (the point at which release becomes automatic), subject to a curfew monitored electronically: see Padfield 2009). This decision should be taken by, or, at the very least, be closely overseen by, independent judicial authorities, especially, it might be argued, in prisons which are run by private sector companies.

The reality, of course, is that the "formal" decision is hugely constrained or may in reality have been taken by other decision-makers, earlier in the process. For example, many "parole boards" are unlikely to authorize release unless a "release plan" has been secured. If a plan has not been prepared, or unless the probation officer supports release, the court or board is unlikely to order or permit release. The extent to which a prisoner is involved in developing a release plan varies enormously: in many jurisdictions, prisoners feel that the "plan" is imposed on them with little discussion or debate. It is not only the presence or absence of a release plan which affects the decision-making. Danzigera et al. (2011) tested the common caricature that justice is "what the judge ate for breakfast." They looked at parole decisions made by experienced judges in Israel and, perhaps surprisingly, concluded that merely taking a food break may indeed lead a judge to rule differently in cases with similar legal characteristics. We should question not only who takes the decision but how the decision is taken.

Is a released prisoner still technically a prisoner? It may be useful to describe them this way in order not to give a false feeling of "freedom." Thus, in England and Wales, the moment of "release" can be confusing. Prisoners may be released at "half time" and yet then be required to live in "approved premises" where the rules may be more restrictive than they were in a prison (where the emphasis will have been more on perimeter security than on internal control). This raises, once again, the thorny question of the categorization of prison sentences and of prison regimes (well discussed in Cid and Tebar 2012).

Prisoners released "conditionally" may be subject to a very wide range of possible conditions. Probably a standard condition (which may or may not need to be articulated) is that the offender should not re-offend. German law distinguishes directives ("Weisungen") from obligations ("Auflagen"). Directives are imposed in order to influence the offender's behavior and to prevent reoffending, whereas obligations are meant to fulfill the victim's or society's desire for satisfaction, for example, by compensating the victim or by making a payment to a nonprofit organization or the state or of community service (Pruin 2012). In many jurisdictions, the conditions include:

– Meeting and keeping in touch with a probation officer
– A residence obligation, with possible curfew, which may or may not be electronically monitored
– Treatment by a psychiatrist/psychologist/medical practitioner
– A positive work obligation (or a requirement not to take work with certain groups, such as children)
– An obligation to make payments to victims
– A requirement not to reside in the same household as children
– A requirement not to approach or communicate with named people
– A requirement to avoid a particular area
– A requirement to attend courses for confronting addictions, improved driving, anger management, etc.
– A drug testing condition

In some US jurisdictions, the conditions may also be loss of civil rights or even a duty to pay supervision fees (Parole and Prisoner Reentry in the United States). Conditions are often complex, difficult to understand, and sometimes contradictory. The literature on life on license is small (but see Appleton (2010) for a detailed and complex picture of the lives of released discretionary life sentence prisoners in England). But when we come to consider the reasons why licenses are revoked, it is important to consider whether the practice of parole supervision might be more supportive (e.g., see Travis 2002). The reality of life for ex-offenders is often challenging, even precarious (see Standing 2011). They face many practical, health, and economic difficulties, including those associated with housing, unemployment, family, and substance misuse. Parole conditions can "get in the way" and make an already precarious lifestyle unworkable. While the conditions may make it easier to monitor the offenders, they can also make it more difficult for people to "go straight" (Maruna 2001). Further, academic research is needed which focuses less on reconviction outcomes and more on prisoners' perceptions of their lived experience (Padfield 2012a, b; Digard 2010, are an excellent small example).

Many systems of discretionary release rely on actuarial risk predictors. Others rely on more clinical assessments. Even those systems which allow "automatic" early release may continue to be used. The Risk Management Authority in Scotland maintains a detailed directory of approved assessment tools, including summaries of the published evaluations of each tool (see www.RMAscotland.gov.uk). Of course, actuarial assessments can only ever be predictors. It is very dangerous to move from these generalized risk assessments to the applications to the lives of real people. There will be false-positives (those who are predicted to re-offend and who don't) and false-negatives (those who are predicted not to re-offend, but who do so). As well, it can be immensely difficult for the individual to "live down" a risk assessment (see Padfield 2011b).

Custodial Sentences: Revocation of License/ Recall to Prison

While there is a small literature on the law and practice of release and parole (particularly in the USA and common law context and increasingly in Europe: see Padfield et al. (2010)), the international academic literature on parole or license revocations seems to be emerging very recently. It can sometimes appear as though academic interest ends with release: as though release is the end of the story. But the reality of release from prison is very different. Successful reintegration, or reentry, is notoriously difficult (see Maruna 2001). Desistance from a criminal lifestyle rarely happens overnight: prisoners serving sentences in the community may be returned to prison for "failures" on license. The costs of incarceration and failure are enormous, but how do we measure success and failure? It may be that insufficient attention is paid to what for some offenders are significant successes (e.g., turning up most of the time for appointments). It is all too easy to conclude that poor attendance is a failure!

Conditional release may end for a variety of reasons. Most common may be allegations of fresh offences. Of course these new offences do not necessarily have to be proved before revocation take place. So the "recall" may be initiated in effect by the police when they arrest a suspect. There are important questions about the status of offenders on license when rearrested: should they be unconvicted prisoners until the new offences are proved? Prisoners may remain in prison even after allegations are dropped or after they have been acquitted in court (see Padfield 2012a, b). Others will be brought back to prison because their behavior on license or on parole has caused significant concern to those who have the responsibly of supervising them in the community (see Collins 2007). These reasons may be very difficult for the prisoner to challenge. There are in many jurisdictions stark contrasts between the judicialized release process and the executive decision to recall to prison. The process for challenging recall may be administrative or judicial. Often it is very slow and impenetrable (see Padfield (2012a, b) and the special issue of the *European Journal of Probation* which carries articles from nine different European jurisdictions: Volume 4, Issue 1, 2012, freely available at www.ejprob.ro). In many jurisdictions the number and percentage of prisoners who are in prison as parole violators or for alleged breaching of their conditions is rising sharply. It may well be that this increasing number may have a significant impact on the stability of the prison population: angry and embittered prisoners are difficult to manage. Thus, there are practical as well as "human right" reasons for us to be concerned about this issue.

Why have scholars not followed developments in the law and practice of release and recall to prison more closely? Part of the explanation may well be the division between criminology and law in many countries. And within law, there is often a vast divide between criminal lawyers (whose role often seems to end when their client is sent to prison) and public or administrative lawyers (who are involved in challenging decisions taken by prison authorities). Yet there does seem to be a slowly growing recognition that backdoor sentencing is as "important" as front door sentencing. Might the time be coming when the same lawyer sees it as their responsibility to support their client throughout the whole of the criminal justice process? The provision (i.e., funding) of good quality legal advice and representation is of course also fundamental.

Another important consideration is the purpose of sentencing, which we started with in the introduction to this entry. Do the same purposes apply to backdoor sentencing as to front door sentencing? In the USA the concept of "reentry" seems to have won a certain symbolic or rhetorical importance (see Petersilia 2003; Travis and Visher 2005). In Europe, the concepts of rehabilitation or reintegration are more common: but all point towards an aspiration to include ex-offenders within the wider community. Yet governments are often more focused on excluding the “dangerous”: on public protection and more exclusionary means of reducing recidivism. The human rights discourse helps to remind us that offenders are individuals, not statistics. If we do not focus on this, we may regret that there is not just a front and a backdoor into the prison system, but simply a revolving door (see Weaver et al. 2012).

Conclusions

This entry has sought in particular to encourage a closer enquiry into the relationship between “front door” sentencing with the less studied “backdoor.” The danger of this brief entry is that it results in simple generalizations. Yet sentencing is a complex process. The decision-making process may be structured by the law, or unstructured, and some stages in the process may be less or more structured than others. A dilemma flows through all legal processes: the tension between the need for certainty and the need for flexibility. In order to be fair, some flexibility may well be necessary. For example, some prisoners will be released early on compassionate grounds: can the grounds for this be spelt out precisely in advance? Flexibility means discretionary powers, and discretion is the first cousin of discrimination. Dworkin’s doughnut (an American ring doughnut, not a British doughnut!), mentioned earlier, is interesting because of the surrounding belt of restriction: the socio-legal context of decision-making (for a fuller introduction to the literature on discretionary decision-making, see Gelsthorpe and Padfield 2003). In seeking to monitor the fairness of sentencing decisions, we need to be particularly vigilant about gender and racial discrimination (see Thompson 2009; Turnbull and Hannah-Moffat 2009; Barry and McIvor 2010; Hannah-Moffat and Yule 2011).

We need therefore to consider who is making these front door and backdoor decisions and in what conditions. We have noted that these “judges” are also severely constrained by decisions taken earlier in the process. Parole or probation officers often hold the key to release. Their role is vital yet confusing: often empowered simultaneously to monitor and to support, as well as to sanction (Lynch 1998). If sentencing is, as is argued here, a series of very different decisions, often made by very different “players” within the process, the importance of close oversight is obvious. Due process, the rule of law and the separation of powers suggest that judicial oversight is essential.

Lawyers, psychologists, psychiatrists, criminologists, sociologists, and anthropologists all have a vital role in developing the analytical tools which help us understand the whole sentencing process: from the moment of arrest perhaps or from charge and plea bargain, to release and recall, to successful reintegration. Vast differences exist between times and place, and political agenda and legal frameworks vary. Yet there are some common themes, which include an increasing literature on legitimacy and on fairness in sentencing. The right to individual liberty is fundamental; the power of the state should never be arbitrary. The rules on sentencing ought to be clear and to be enforced fairly and transparently.

Hybrid gangs

Overview

Traditional depictions of gang organization have been erroneous or static or were unable to be measured. Relying on these traditional depictions, modern rhetoric regarding organization is that gangs have evolved into hybrid groups that participate in nontraditional behavior such as merging and cooperating with rival gangs. Examining this phenomenon through emic perspectives suggests an alternate explanation. Previous literature has indicated that gangs are very loosely organized, and more recent works have demonstrated that gangs are social networks rather than structured groups. The following essay comparatively examines gang organization through the social network lens.

Key Issues/Controversies

Gang organization has long been a topic of dispute in gang research. Outside of the academic realm remains a pervasive conceptualization of gangs in the American media and law enforcement rhetoric as one of national, highly organized, violent, drug-dealing entities. If this viewpoint were true, then it would indeed be worthy of the fear that it inspires. The problem is that academic research consistently shows that there is little to no validity to this conceptualization (Klein 1995). From the early gang literature, continuing to present day research, there are no strong indications that gangs are highly organized, but instead are loose, fluid affiliations.

If gangs are not the national entities they are believed to be, then what organizational structure do they have? After the millennium, police reports began to note "new" organizational structures that law enforcement agencies were unfamiliar with. This lead to further definitional problems and the introduction of groups referred to as "hybrid gangs." Believed to be significantly different than "traditional gangs" in composition and behavior, hybrid gangs are described as having:

> . . .members of different racial/ethnic groups participating in a single gang, individuals participating in multiple gangs, unclear rules or codes of conduct, symbolic associations with more than one well-established gang (e.g., use of colors and graffiti from different gangs), cooperation of rival gangs in criminal activity, and frequent mergers of small gangs. (Starbuck et al. 2004, p. 200)

More and more law enforcement agencies began reporting this phenomenon,

G. Bruinsma, D. Weisburd (eds.), *Encyclopedia of Criminology and Criminal Justice*,
DOI 10.1007/978-1-4614-5690-2, © Springer Science+Business Media New York 2014

specifically as characteristic of late-onset gangs or gangs that appeared in cities post-1990 (Starbuck et al., 2004), and it began entering the collective knowledge of the mainstream. In 2008, the History Channel's series *Gangland* aired an episode called "Sin City." This episode, set in Las Vegas, Nevada, highlights hybrid gangs as an evolutionary advancement and emphatically states that multiple associations among gang members of different gangs are more deadly, but never explains why.

The sensationalism of claims that gangs have reached evolutionary advancement and presented increased danger called for further investigation, more so due to "hybrid gangs" not appearing in the literature beyond Thrasher's (1927) reference to gangs that included different racial/ethnic groups. However, under closer scrutiny, the fluid behaviors associated with hybrid gangs have been appearing in the literature since Yablonsky (1959) argued that gangs were near groups rather than solid organizations. More recently, some research has presented evidence that gangs are porous social networks intertwined with other gang networks and have been so for quite some time (Fleisher 2002). Differing viewpoints may be explained by the use of etic or emic methodology. Etic methodology is the imposition of an outsider's (i.e., law enforcement) interpretation of a phenomenon; in this case the behavior is believed to be a new gang structure. Alternatively, using emic methodology or understanding phenomenon from the respondent's point of view or, in this case, the gang member's point of view explains gang fluidity and nontraditional membership as elements of a social network system (Fleisher 2002; Weisel 2002).

Outside observers may be imputing meanings to gang behaviors that would be understood quite differently from the perspective of the gang member. Examining the literature more thoroughly may help clear up the disputed perspectives on the subject: Is the "hybrid gang" a new phenomenon? Are gangs more like social networks than organizations? Or are these social constructions that amount to "putting old wine into new bottles?"

Structural Typologies

Research has consistently presented gangs as marginally or very loosely organized and widely varied in the activities in which they engage. These findings have led to differing ways in how scholars have interpreted gang structures. For example, in a national survey of 385 police agencies, 45 % indicated that the typical gang was loose knit, and 47 % noted no formal structure in typical gangs (Weisel 2002). However, Weisel (2002) also reported regional differences in gang structure with police indicating more loosely structured delinquent gangs in the Southeast and Midwest, more violent gangs in the West, and more income-generating gangs in the Northeast. Smaller cities were more likely to have delinquent gangs, which engaged in criminal activity but had little involvement with drugs. Furthermore, violent gangs and drug selling gangs most often did not have consistent leadership or a highly structured organization.

Weisel (2002) takes an unusual step and includes in-depth interviews with members of the Black Gangster Disciples and Latin Kings in Chicago and Lincoln Park Piru and Logan in San Diego. Consistent with stereotypes, the Black Gangster Disciples and Latin Kings had extensive organizational structure. In accordance with most literature, the San Diego gangs had little structure, and members considered the groups to be friendship/kinship networks. While some gangs appear to be highly organized, an extensive amount of research indicates that most gangs are not as highly organized as generally believed (Klein 1995; Huff 1996; Decker et al. 1998; Fleisher 1998; Miller 2001).

Attempting to make systematic sense of gang organization has led to a plethora of gang typologies. Although these typologies may be useful in identifying characteristics of a gang at the time of the study, they present the assumption that the gang is static. Typologies focusing on particular criminal activity do not capture the social processes of the gang or a particular gang's relationships with others. Some of the typologies rely on precarious variables such as amount of drug use and type of crime engaged in or threat level, which have extreme within-group variation and are not stable over time. Klein's (2002) structural typology provides measurable variables and thus more utility, but does not take fluidity, permeability, or networking behavior into account.

Gang structures are anything but static, but the dynamic gang processes of changing, merging, or splintering have rarely been examined in considerable depth. Most authors have been cursory on the subject, and there has been little in-depth investigation. The information that has been gained concerning these processes was obtained, while scholars investigated gang structures and whether or not they had changed over time.

An intriguing contribution to the extant knowledge on the subject comes from Weisel, (2002) whose interviews portray mergers such as the Black Gangster Disciples forming from the combined gangs of the Black Disciples, Gangster Disciples, and High Supreme Gangsters. Interviews in San Diego also revealed that Logan splintered into "Logan Trece" and "Red Steps" as the gang grew larger and natural boundaries emerged. Unfortunately more detailed information about these mergers and splinter groups was not provided. Spergel (1990) argues that splintering develops from internal competition or if more criminal opportunity becomes available. Monti (1993) argues that it is the lack of control over larger gangs that causes them to split and that age-graded cliques are like gang building blocks that can merge, dissolve, and reassemble. Weisel (2002) views the process of merging and splintering through organizational theory, arguing that a path to organizational equilibrium explains why some groups dissipate and others break off from larger groups until a stable number of organizations are reached. This theoretical approach explicitly ignores the gang member worldview in favor of the assumption that gangs can be called organizations.

It is no surprise that relational behavior and emic perspectives are not often considered when discussing gang organization because doing so would recognize gangs as dynamic processes rather than static structures. Processes are much harder to define and subsequently eschewed by agencies that would like clearly labeled categories. Even though gang relationships are often sidestepped, they are nonetheless important. The gang as a criminological topic is predicated on the idea that individuals are committing crime in a group. The group as characterized by names, colors, symbols, and the like has become such a preoccupation that the relationship of "who" is committing crime together has been ignored. Not all organizational arguments have missed this dynamic. In Cloward and Ohlin's (1960) typology of delinquent subcultures, they recognized that criminal subcultures necessitated adult criminals to indoctrinate younger people into illicit activities or at the very least model illegitimate behavior.

Although limited by focusing only on Mexican-American gangs in San Antonio, Texas, Valdez (2003) provides a typology that further bridges gang structure and social network dynamics. One of the gang types is the "criminal-adult-dependent gang," which is a highly organized group that is focused on earning illegal income usually through drug sales. Adults outside of the gang provide the group with weapons, drugs, stolen merchandise, protection, and extensions to their criminal networks. Valdez (2003) notes two subtypes of this category. One of the subtypes is a family network in which the adult criminals are closely related to the gang members. The other subtype is dependent on a prison gang, which exerts control over the street gang. Either way, the importance of gang relationships is stressed. If members of different categorical groups work together, then at what point do organizational lines become blurred or nonexistent?

Hybrid Gangs or Social Networks?

Largely untouched by academic researchers, the "hybrid" gang phenomenon has been discussed primarily by law enforcement agencies such as Missouri's Kansas City Police Department (Starbuck et al. 2004). The "hybrid" gang is not a new term or idea. It was initially used by

Thrasher (1927) to describe gangs of mixed race/ethnicity, but in the modern era, the term encompasses many other characteristics as well. Different than most traditional depictions of gangs, which described gangs as being comprised mostly of lower class and minority males, police in many jurisdictions are starting to report hybrid gangs. These gangs in late-onset localities (i.e., post-1990) have a greater mix of race/ethnicity, with an increase of white youth, the presence of more females, and a larger proportion of middle-class teens (Howell et al. 2002). Additionally, it appears that members may switch gangs or participate in multiple gangs (Starbuck et al. 2004). For example, in San Antonio, 8 out of 15 former gang members interviewed had switched gangs or belonged to multiple gangs, and two gangs had switched their entire allegiance (Bolden 2012). Although San Antonio agencies have reported gangs since the 1950s, the gangs appeared to have the same "hybrid" characteristics that were being pointed out in emergent gangs.

Cooperation between gangs that are sometimes rivals is also noticed by law enforcement, as is the mixing of gang symbols from Chicago- and Los Angeles-based gangs. Just as these gangs are engaged in cafeteria-style offending, they are selecting characteristics of different established gangs. This gives further credence to the idea that gangs have now become popular brand names (Klein 1995). The use of the term "hybrid gangs" to describe groups that have more fluid membership and nontraditional membership (Starbuck et al. 2004) is an illustration of etic methodology,

In emic methodology, the idea of self-identifying oneself as a member of a particular gang becomes relevant. Fleisher (2002) argues that self-nomination as a gang member refers to both an attribute and a relational aspect of membership. Gang research tends to examine membership as an attribute and neglect the relational component. However, it is of great importance that self-nomination is a statement of having a particular relational status to other people. Fleisher (2002) used social network analysis to examine the nature of gang member relationships between females and how these affiliations affected gang participation. In explaining a gang member's ego network, which is the group of people that an individual directly interacts with on a regular basis, Fleisher (2002) found many members had relationships with people from other gangs than their own. Furthermore, while gang members certainly associated with other members of their gang, Fleisher found that none of the gang members knew all of the other members in their gang. The members who knew the most members in their gang only knew 10 % of the members in their gang. The gangs studied ranged from large Midwestern gangs such as the Gangster Disciples and Vice Lords to an independent gang called the Fremont Hustlers. It would seem that his conclusions may not be as relevant to smaller gangs, but Fleisher was revealing that individuals knew, interacted with, and spent time with several other gang members, in different gangs, rather than exclusively with people who identified themselves as being in the same gang.

The actual ego networks of each gang member, or the people they regularly interacted with, were fairly small and often included members of other gangs. Fleisher (2002) argued that the status of gang membership provided social capital and being included in the social networks of other gangs would further increase someone's social capital. While Bolden (2012) notes that gang members often referred to positive interactions with members of other gangs, Decker et al. (1998) provide one of the only studies that actually examined relationships among gangs. Studying 26 Gangster Disciples and 18 Latin Kings in Chicago, as well as 20 members of Logan Heights and 21 members of Lincoln Park Piru in San Diego, Decker et al. (1998) found that relationships with other gangs were very common. All of the San Diego gang members reported maintaining relationships with other street gangs, while 80 % of the Gangster Disciples and 75 % of the Latin Kings maintained these types of relationships. Furthermore, all of the Latin Kings and Logan Heights members maintained relationships with prison gangs. Eighty-seven percent of the Gangster Disciples and 75 % of the Lincoln Park Piru also maintained relationships with prison gangs. Although some would argue that gang alliances are brittle (Monti 1993), they do not deny that gangs assist each other in varying ways. Decker et al. (1998) provide us with evidence that in spite of often being overlooked, gang relationships are common and these networks may be an important part of the gang experience.

With data from a gang task force in New Jersey, McGloin (2007) also provides evidence that gangs are more aptly described as social networks and rather than being structured organizations, the gang boundaries are dynamic and opaque. Also using social network analysis, Papachristos (2006) did not find cohesion in gangs as a whole, but strong cohesion in subgroups of the gang. These ego networks were responsible for specific crimes and behaviors indicating that crimes are ego network related rather than gang related or motivated (Fleisher 2002). This is an alternate interpretation to the idea of organizational cooperation between rivals in hybrid gangs (Starbuck et al. 2004). Understanding gangs from a social network standpoint can help clear up the ambiguities in determining whether individuals or whole groups work together. It can also examine whether the "hybrid" label is a valid concept or if it is a misinterpretation of kinship/friendship networks.

The gang members in Weisel's (2002) study saw the gang as a friendship network, which is consistent with the findings of Fleisher (2002). Furthermore, though Yablonsky (1973) has been attacked for his depiction of the gang as sociopathic and violent, few have paid attention to his concept of the gang as near group. Yablonsky (1959) reported that gang members had no measurable number of members, no definition of membership, no specific roles, no understood consensus of norms, and no clear flow of leadership to action. Weisel (2002) placed the particular gangs studied in an organizational context because they portrayed orientation towards goals and organizational continuity. However if gangs lack the vast majority of organizational aspects as pointed out by Yablonsky (1959), can they really be considered organizations?

Viewing gangs in an organizational context forces categorical boundaries that may only exist in the mind of the outside observer. As gang characteristics noted by Yablonsky (1959) indicate, there is much more fluidity to gangs and gang members, and gang boundaries may be much more porous. The organizational viewpoint may also lead to an ecological fallacy of assuming that members of different gangs engaging in activity together means gangs are working together. Finally, this idea ignores the viewpoint of gang members that gangs are kinship/friendship networks. Confusing or misinterpreting the relationships of gang members may have led to the present label of "hybrid gangs." Viewing gang processes from a social network viewpoint clears up this confusion by distinguishing relationships among gang members as well as among gangs.

State of the Art

Examination of what law enforcement call hybrid gangs is in its infancy and as of yet has not received serious empirical investigation. Whether gangs have actually changed or these processes have previously existed and been overlooked, the "hybrid" gang label implies fluid membership between gangs, a lessening of violent events in joining and leaving gangs, more interaction among gangs, and a selective mix of identifying elements of well-known gangs. These gangs are also claimed to be late-onset (i.e., post-1990) gangs that are characterized as having an increase in females, an increase of whites, and an increase of middle-class youth. These apparent differences challenge many previously used assumptions of gangs as social islands with impermeable boundaries.

A considerable amount of literature informs us that gangs tend to not be highly organized structures but rather loose conglomerations of clique structures (Decker and Curry 2000; Fleisher 2002; Klein and Crawford 1967; Papachristos 2006). These conglomerations are not highly cohesive as a whole, albeit stronger cohesion occurs among particular cliques. These smaller cohesive cliques dilute the influence of the overall gang in favor of the immediate people that an individual interacts with. Lerman (1967, p. 71) describes the gang subcultural unit as "a network of pairs, triads, groups with names, and groups without names." What has not been discussed in the literature, with the notable exception of Fleisher (2002, 2006), is who is actually in these particular cliques.

If these smaller cohesive units are in networks, then the most viable framework for examining gang member relationships emerging from previous literature is social network analysis (SNA). Social network analysis is both a theoretical framework and a methodological approach. From a theoretical standpoint, people belong to intricate webs of social relationships that influence their lives in a myriad of ways and affect occupational chances, general opportunities, and perceptions of the world (Simmel 1955; Papachristos 2006). Social networks can be analyzed on the group level through degree centrality and density or by using individual ego networks as the unit of analysis. The ego network refers to the social ties/bond the individual has to other individuals. Until recently social network analysis has rarely been used to study gangs. Klein and Crawford (1967) and, more recently, McGloin (2005, 2007) and Papachristos (2006) have used this framework to examine cohesion of members within a gang, finding that there were cohesive subgroups or cliques but not strong cohesion in the gang as a whole. Fleisher (2006) used nomination of friends to identify ties between members of different gangs such as the Gangster Disciples, Vice Lords, and Stones, which are sometimes rivals. Fleisher argued that affiliation in the same categorical gang was not sufficient to foster sentiment between members. Even if members hung out with each other, they often indicated preference for other friends that were not a part of their own particular affiliation. Preference was also related to the social capital created by network relationships. Social capital in networks makes more actions and opportunities available (Papachristos 2006). Fleisher (2006) argues that even though belonging to a gang provides a level of social capital, gang member relationships are based more on the expanded social capital that a connection provides rather than affiliation with a particular group.

Fleisher (2006) explains that the use of other methods to study gangs has resulted in the concept of the bounded group. Although it makes obvious sense that gang members, like most other people in society, interact in many different social circles and utilize agency in choosing who to associate with, resulting in their not being bound by the gang per se, the conventional depiction of the gang member as the folk devil allows for easy disregard of viewing any behavior of the gang member as normal. Ironically, Cotterell (1996) comes to conclusion that interactional behavior between gang members is actually more fluid and less stable than other adolescent cliques. Cliques are groups of people who spend time together. Usually adolescents belong to many cliques with different sets of friends in varying contexts, such as sports teams, neighborhood friends, and school friends. In gangs, however, membership provides the individual with the social capital to more freely move between cliques. Cotterell (1996, pp. 33–34) describes gangs as "a series of changing microsystems. The individual joins one group for a time, then leaves, and rejoins or moves on to another."

Ayling (2009), who views gangs as organized criminal networks, theoretically argues that the weak links between gang network hubs or "loose couplings" make the gang functionally resilient against both law enforcement suppression and attacks from other groups. Damage done to one hub or clique will not destroy the entire network. Furthermore, the clique type network removes the sluggish and burdensome chain of command, allowing members enough freedom to instantly act and have improvisational responses to immediate concerns. Using police data, McGloin (2005) identified particular gang members as “cut-points” or the only connection or intermediaries between the different cliques within a gang.

Controversies and Questions

Methodology

Papachristos (2006, 2009) challenges Fleisher’s (2006) characterization of gang membership as relational attributes and argues instead that they are social groups based on the patterned actions that are caused by relational ties. Arguing that gangs are groups and not “pedagogical constructs,” Papachristos (2009) examines gang network relationships and demonstrates predictable patterns of homicide activity. Fleisher (2006) explains however that methodological choice will cause this discrepancy, and indeed Papachristos uses (2006, 2009) police data to examine gang networks.

Using emic methodology and qualitative interviews in San Antonio, Texas, and Orlando, Florida, Bolden (2010) expands on Fleisher’s work, which was conducted with female gang members, by not only identifying ties among male and female members of different gangs but also the nature and consequences of those network ties in regard to “hybrid” gang processes, such as belonging to multiple gangs, switching gangs, and fluidity of joining or leaving gangs. The social network of the gang member allows for expansion of social capital and expanded opportunities in the urban arena.

The following example is an ego-network depiction of a gang member in Orlando, Florida (see Fig. 1). **Caribe** self-identifies as belonging to Hoover Folk, yet his most common interactions were with members of different gangs. His social group that he spent time partying and getting high with consisted of two Bloods and a Latin Queen, all of which are the traditional primary enemies to his gang. The other members of Caribe’s ego network, a Crip and a member of a Jamaican Posse, are his business associates that he engages in illicit profit-oriented activity with.

Caribe-Hoover Folk	Progeny-ATF Compton Crip
Curly/Smokey-Nine-Trey Gangster Bloods	
Machete-Young Shottaz (independent)	Silk-Latin Queen

This example of one gang member’s ego network has profound implications for the study of gang organization, which include:

(a) This is not a categorical group (no shared name, signs, symbols, etc.).

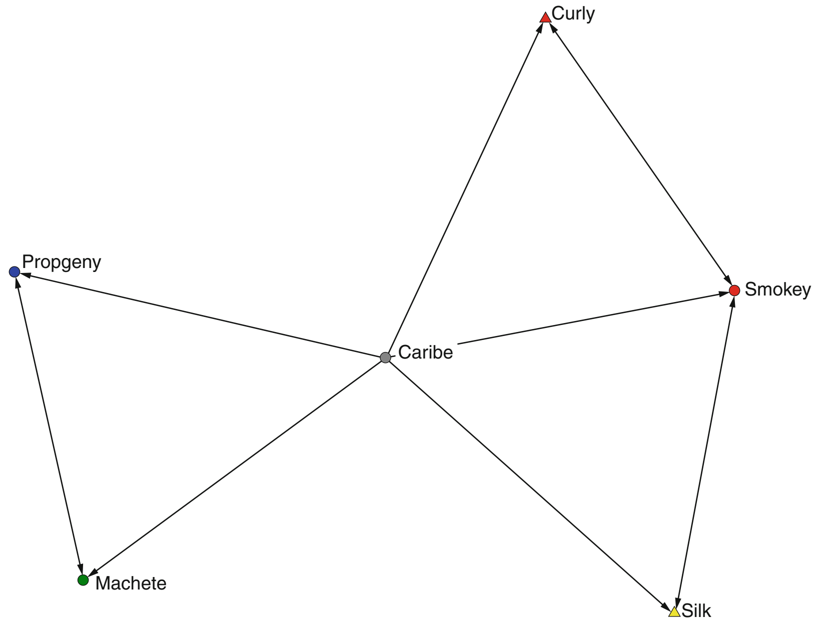
(b) From an etic standpoint, this would be seen as one group and labeled as a hybrid gang. From an emic standpoint, this is not one group, but two separate segments of an ego network.

(c) Criminal activity is being committed by gang members together, but they are not in the same categorical gang. This becomes especially relevant to jurisdictions that define gang activity along the lines of categorical variables.

(d) Rather than gangs cooperating, this illustrates individual gang members cooperating.

(e) If the crime occurring in this network is considered gang crime, which bounded categorical group is attributed with the crime? If these actors commit a homicide together, which gang is credited for it?

Bolden (2010) found that all but 2 of the 48 current and former gang members he interviewed indicated that strong relationships along the lines of kinship, business, friendship, conflict-partners, sports, school, and romance existed between themselves and members of rival gangs. Many of these relationships were primary, in the sense that more time and activity, both criminal and benign, was spent with members of other gangs than members of their own gangs. Also of interest was that 22 of the interviewees were gang migrants from Chicago, Los Angeles, and New York, where they described the same dynamics occurring.



Gangs and Social Networks, Fig. 1 Caribe ego network

Evolution

Though there is more academic support for understanding gangs as social networks than there is for the "hybrid gang" label, the question of emergence still remains. Both Fleisher's (2002) and Bolden's (2010) studies were post-1990, clearly placing the networks studied in the late-gang onset era. This is not evidence that the networking phenomenon is new. It could be that the behavior was not previously noticed. Indeed, four of Bolden's (2010) interviewees participated in gang activity prior to the 1990s (one in the 1960s, three in the 1970s), and all indicated the same relational activities. Furthermore, Reymundo Sanchez (2000) chronicles his criminal activity as a Latin King in the early 1970s, which includes more criminal cooperation with members of other gangs including rivals than activity with the Latin Kings.

The evidence of preexistence, though not strong, indicates that to some extent the cooperation between rival gang members is not a new occurrence. This question remains open, but as it concerns history, it may be that we cannot ascertain the answer. What is more pertinent are the modern conceptions of gang organization. Will evidence that gangs are fluid, dynamic, network structures continue to be overlooked by all but a few in favor of static structural interpretations, or will we deign to entertain other arguments about gang organization?

Social network analyses of gangs are not new but have been relatively unused. Investigative hurdles in this regard are the lack of dissemination of SNA as a viable research option and training in this methodology. These analyses may require specific software programs such as UCINET that researchers have not had any training with. Furthermore, the data used in these analyses have to be very specific, and any quantitative data gleaned from police reporting would need some detailed component of gang member relational ties. Due to this major hurdle, researchers need to find agencies that already keep rich data or direct the data collection process from the onset of a study.

Key studies using social network analysis have been few and far between largely due to the difficulty of gaining access to the required information and the lack of dissemination regarding SNA as a viable option. Expansions of studies of this nature are extremely important because the question of organization has characterized the field of gang research for quite some time. The vast majority of literature indicates that most gangs are loose-knit pseudo-organizations, yet the idea of an organized group persists in the collective mind of the public and law enforcement. Examining the literature more carefully and more specifically from the gang member's perspective rather than an outsider's viewpoint indicates that the gang is a fluid network of connections between members of different "groups" that give said members the social capital needed for expansion and access in the street. Perceived gang boundaries seem to be more of an imposition of an outsider's insistence on categorical distinctions but may have nothing to do with the actual social activity of the gang member. Indeed, outsider insistence on categorical relationships ignores relational ties and their importance when it comes to who is actually committing crime together. Using alternate tools for study will help our field avoid the trap of adhering to outdated concepts and bring us closer to understanding the phenomenon at hand.

Gendarmerie Policing

Clive Emsley
Department of History, The Open University,
Milton Keynes, UK

Overview

Gendarmerie is a form of policing that is primarily military in its structure, organization, and chain of command. The form and the name originated in France, but during the nineteenth century, the institution spread across Europe, the European world, and its empires. Generally speaking these institutions functioned alongside other police bodies that were more civilian in appearance and which answered to local government or to ministers whose portfolio was internal domestic or judicial affairs; in contrast the Gendarmeries usually were answerable to a minister of war/defense.

Origins

The contemporary French *Gendarmerie nationale* likes to trace its origins back to the Middle Ages, and the knights commissioned to protect the king's territories while he was absent on crusade. A more plausible beginning is the Edict of Paris (1539) by which François I extended the competence of the provosts of the marshals of the French Army (*les prévôts des maréchaux*) and of their companies (*maré chaussées*) to include anyone guilty of highway robbery within France. By the end of the reign of Louis XIV in 1714, the companies' jurisdiction had been extended to most serious offenses from burglary to murder, from rape to arson, and from popular disorder to coining. But, in keeping with the general complexities of the old regime, there was little uniformity in structure and the ranks. Moreover, many men had purchased their ranks for the various opportunities that such a position offered rather than through any desire to enforce the king's law (see, in general, Luc 2005).

The death of Louis XIV and the end of his incessant wars left a weak treasury and fears that a flood of mendicants and vagabonds would engulf France; the lack of money limited what could be done about these fears. However, in 1720 Claude Le Blanc, the minister of war, initiated a series of reforms designed to improve the *maréchaussées* and thus the internal security of provincial France. Henceforth, the companies were to have a uniform hierarchy and structure, and they were to be financed by the state. The jurisdiction of each individual company was to be tied to a *généralité*, the most meaningful unit of provincial administration; the men, recruited from former soldiers with good records, were to be stationed in bodies of generally four to six men in small barracks that were positioned on the main roads. This was essentially the structure that remained in operation until the French Revolution though there were minor amendments, such as the introduction of a system of patrolling in pairs carrying a *Journal de Service* that was to be signed by a notable such as the mayor or the *curé* in each community that the patrol visited; the *Journal* was inspected monthly by senior officers. In addition there was a gradual increase in the size of the force from around 3,000 men following Le Blanc's reforms to some 4,000 on the eve of the Revolution.

As with most police institutions, the *maréchaussée* had its critics and its supporters. There were those who protested that patrols were never to be found when they were required and that the men could be high handed, brutal, and corrupt or else too old, too infirm, or drunkards incapable of carrying out their duties. Local administrators disliked the fact that the men were not responsible locally but to the minister of war. The fact that the small brigades were required to supervise ballots for the militia, to check the passports of travelers, and to enforce order at local fairs and village festivals could provoke hostility among local communities. But there is also evidence that the men were accepted, well integrated, and often married into the community that they served. General inspections revealed a few men who were too old or infirm to carry out their tasks and that there was a sprinkling of total incompetents and drunks in the ranks. The guarantee of a pension in 1778 went some way towards removing the aged and physically unfit, and it seems fair to conclude that the institution improved as the eighteenth century wore on. Moreover, the justice provided by the *maréchaussée* through the *prévôtal* courts was generally quicker, and at least where beggars and the severity of punishments were concerned, it was arguably more balanced and moderate. Comments, both critical and favorable, were to be found in the *cahiers de doléances* that were drawn up at the beginning of the Revolution. There was some disquiet about *prévôtal* justice, but many of the *cahiers* argued for an expansion of the force to improve security (Emsley 1999, pp. 33–5).

The Revolution and Reorganization

A proposal for reform of the *maréchaussée* was on the table at the beginning of 1789, but it was rapidly overtaken by events. Over the next 2 years, there were debates about whether a police institution should be military; one of the principal opponents of a military police was Maximilien Robespierre. There were criticisms of the *prévôtal* courts, notably by the Comte de Mirabeau, and these were abolished in September 1790. The following February a law was passed reorganizing the force under the new name of the *Gendarmerie nationale*. This suggested a link with the past: the Gendarmerie had been an elite cavalry regiment in the royal household under the old regime and dated back to the fifteenth century. But the adjective "national" stressed its link to the nation and the new legal structure with its promise of equality before the law and the rights of men and citizens. The newly named force remained a military organization; its deployment in small barracks along the main roads was maintained together with its system of patrolling. But while the force was both military and national, appointments were devolved to the new provincial administrations – the *départements*. Moreover, the continuing power struggles of the Revolution and the demands of both civil and international war provided a decade of institutional disruption for the *Gendarmerie* in addition to major problems of law and order maintenance.

In the early years of the Revolution, and following the requests from the *cahiers* for a bigger and better police institution, the *Gendarmerie* was increased to 7,250 men; in April 1792 it was increased again to 8,700. But these were paper figures. Many *départements* failed to recruit to their quotas, and as the war required more and more soldiers to defend the frontiers, the state itself began to deplete the brigades by taking over half of the men back into the army. The reduction in numbers took no account of the country's internal difficulties. In addition to the policing tasks that had been undertaken by the old *maréchaussée*, the skeleton brigades of the *Gendarmerie* had to deal with counterrevolutionary activities, especially the west, with White terror gangs in the south, and also with bandit gangs swollen by deserters and, as successive governments made moves towards a comprehensive policy of conscription, by draft-dodgers. In addition, as with every institution in Revolutionary France, periodically men were purged as politically suspect. And, while gendarmes were supposed to be functionaries of the state and the nation, a gendarme serving in his region of origin or in his wife's native region faced problems of where his loyalty should lie. The gendarmes' military backgrounds probably ensured that they were less susceptible to such pressures than other police officers, but they were certainly not immune. Moreover, given the variety of languages and patois spoken in France at least until the end of the nineteenth century, it was always useful for a small *Gendarmerie* brigade (as had happened with the old *maré chaussée*) to have one or two local men, well versed in the local dialect.

But if there were problems for the *Gendarmerie* during the 1790s, the institution also ultimately showed itself to be invaluable in helping to reestablish order and imposing the state's concept of both law and the nation. The directory launched a fierce policy of military repression to suppress brigandage and disorder. The consulate continued this policy and took all the credit for its broad success. Once a greater degree of order had been established, it has been argued, the consulate and then the empire developed a security state in which the Revolution's democratic aspirations gave way to a tutelary administration and judicial apparatus that employed surveillance and regulatory control to maintain order (Brown 1997). The *Gendarmerie* played a key role in both the initial military repression and then in the new surveillance system, for which it also provided a small-scale coercive capability should the need arise.

As first consul, Citizen-General Bonaparte had his own ideas about the structure and deployment of the *Gendarmerie*. He favored fewer mounted gendarmes and more men on foot, particularly where the geography was unsuitable for horses. But he also knew how to choose capable subordinates, and in the case of the *Gendarmerie*, he chose tough, no-nonsense, plain-speaking army veterans. General Louis Wirion had experience of organizing the *Gendarmerie* in the 13 new *départements* of the northeast that had previously formed the Austrian Netherlands. Wirion was charged with reorganizing the force in the counterrevolutionary west. General Etienne Radet had commanded the 24th *Gendarmerie* Division that covered four of the most turbulent *départements* of the south. He was beginning to get a grip on the region when Bonaparte first met him on his return from the disastrous Egyptian campaign. As first consul Bonaparte summoned Radet to Paris to draw up plans for reorganizing the *Gendarmerie* as a whole.

Wirion stressed the image of the ideal gendarme as a courageous army veteran who was honest, moral, sober, and literate. He was to be a man that the local community looked up to and trusted; he was to know every part of his district intimately. Radet's ideas were formulated in an organizational order issued at the end of January 1801. This enlarged the total corps to 16,500 men. There were to be 2,500 brigades of six men deployed in the provincial *départements*; two-thirds of these were to be mounted. There were also to be four elite companies, two mounted two on foot, that were to be deployed to protect the first consul (and later the emperor) and his palaces. The officers were all to receive their commissions from the head of state; the other ranks were to be vetted by a *départemental* committee composed of the prefect and two officers from the force. Finally there was to be a headquarter staff under a general appointed as the *Premier Inspecteur Gé néral de la Gendarmerie*. Radet, by his own account, turned down the latter appointment and it went to General (later Marshal) Moncey. Wirion went off to establish the *Gendarmerie* in newly conquered Piedmont; Radet undertook similar tasks across the new French Empire. His toughness and aggression offended many civilian officials; unsurprisingly, when Napoleon needed a man to arrest the Pope in 1809, it was Radet who volunteered.

Moncey was a rather more refined individual than Wirion and Radet, but he could be prickly. Throughout his tenure as inspector general, he remained determined to maintain the *Gendarmerie*'*s* separation from other police institutions within Napoleon's France. But this, according to Joseph Fouché who served as minister of police for much of the period of the empire, suited Napoleon's intention to pursue a policy of divide and rule when it came to the police. There was a separate military police under General Duroc in his capacity as grand master of the palace. The Prefect of Police had responsibility for policing in Paris and reported to the minister of police, while civilian police, principally the *commissaires*, in the provinces also linked with the minister as well as with his fellows in the interior and justice. Moncey kept his command at a distance from the Ministry of Police; at the same time, he and Fouché confronted each other over a range of issues setting the tone for the "war of the polices" that continued in France for the next two centuries (Lignereux 2003).

The force that developed during the Revolutionary and Napoleonic period set the tone for the future in other ways. It remained proud of its standing as a military body. While it was sometimes useful to send individuals or small groups in civilian clothes to reconnoiter a town or village before a move to search out and apprehend deserters, it was formally stated in the various decrees regulating the institution that gendarmes always acted in uniform. Indeed, this became a matter of pride with many, and in 1857, Captain Frédéric de Bouyn requested an audience with Napoleon III concerned that the corps was being required to act in secretive ways and to investigate people's politics. Nothing in the force's behavior, he explained, "should excite suspicion, nothing should imply that its duties are mysterious and shadowy" (quoted in Emsley 1999, p. 127). The captain's open expression of his concerns stalled his career; others, however, who were less reticent in making political efforts on behalf of the government, tended to prosper.

The legacy of the Revolution and the Napoleonic adventure made it difficult for a state agency like the *Gendarmerie* to stand aloof from the politics of nineteenth-century France. Yet many gendarmes seem to have tried to be as honest, moral, and sober as Wirion, and the regulations insisted. Many individual brigades worked hard on behalf of the communities to which they were posted; they tracked down offenders, provided assistance in time of natural disaster, and so forth. But, in addition to the occasional demands for overt political action, they also had one other duty that could easily bring them into conflict with those communities; it fell to the gendarmes to ensure that when the demand was made, conscripts were collected and brought to the appropriate muster points. It also fell to the gendarmes to go in pursuit of refractory conscripts and deserters. Increasingly the *Gendarmerie*, together with other parts of Napoleon's bureaucratic state, wore down the opposition, but the enormous demand for men in 1813 sparked a new, furious wave of violence and disorder invariably directed at the gendarmes.

Continuity, Change, and Recurrent Issues in the Nineteenth Century

The French Revolution had proclaimed the Rights of Man and, of course, equality along with liberty and fraternity. Gendarmes were supposed to ensure a citizen's rights and to enforce the law equally among citizens, but the political turbulence that accompanied the various stages of the Revolution and the memory of Napoleon's empire that followed its fall left a legacy in which the different varieties of police in France were often seen as tied to, or acting at, the behest of those in power. At different stages of the Revolution, a few gendarmes were accused of disaffection and purged. When the Bourbons were restored for the second time, both Moncey and Radet faced courts-martial. *Départemental* committees, similar to those of the Revolution, were revived by the Bourbons to vet new recruits, and with varying degrees of determination, they also purged those who had shown, or continued to show, zeal for "the usurper." Yet in the various political upheavals of the restoration and the July Monarchy, while the *départemental* companies sent regular reports to Paris about the economy and political attitudes, most of the brigades appear to have aimed to fulfill their basic duties of maintaining order and protecting their local communities.

The elite *Gendarmerie* companies in the capital, whose functions mainly involved public order and ceremonies, earned the hostility of the Parisians for aiding Charles X's attempted coup in the July days of 1830. A *Gendarmerie mobile* was established in the wake of the 1830 Revolution, revived in 1848 and revived again under Napoleon III. But most of the small provincial brigades, whose daily patrols focussed on supervising and maintaining local tranquility, enforcing regulations and dealing with crime, sat tight during the revolutions and watched events.

As president of the Second Republic, Louis Napoleon feted the institution, but most provincial brigades saw discretion as the better part of valor and avoided confrontations with the peasant columns and the democratic-socialists who resisted his coup in 1851. Nevertheless, when the president became the Emperor Napoleon III, he maintained a close relationship with the *Gendarmerie* until the mid-1850s when, after the Imperial Decree reorganizing the force and outlining the essence of its service as a "continual and repressive surveillance" particularly in the countryside and on main roads, his interests moved more to reforming the police. The close relationship and the concept of "repressive surveillance" led to the concerns expressed by de Bouyn that the brigades were expected to comment on people's politics and to take an active role in elections.

Economic, political, and social life changed significantly in the French provinces during the nineteenth century, and the *Gendarmerie* was required to keep up both with the changes and with traditional sensibilities. The building of railways and movements of workers from different regions and countries led to increases in the workloads of some brigades and, occasionally, a decrease for others. Gendarmes provided coercive support for bailiffs in the eviction of workers from company housing or for local officials wanting to deal with unruly bars. At other times, however, they aided members of the working class and the poor. And this did not just mean acting in time of natural disaster or pursuing those responsible for criminal acts against poor people; a few gendarmes were known to give to charity the occasional monetary reward they had received, while others organized subscriptions to assist beggars. But an officious, self-important brigade commander who sought rigorously to enforce unpopular legislation especially, for example, on poaching or cabarets could provoke serious local hostility. The brigade commander at Bédarieux (Hérault) was one such, and his small barracks suffered the most violent and sustained attack following Louis Napoleon's coup leaving the brigadier, two gendarmes, and a gendarme's wife dead. Another of the Bédarieux brigade, however, was saved when a café proprietor intervened on his behalf; the gendarme had earlier broken regulations so as to permit the proprietor to attend a fellow radical's funeral. An informative statistical analysis of the attacks on gendarmes between 1800 and 1859 suggests a significant decline across the period and a corresponding growth in the legitimacy of the institution among the people in rural communities (Lignereux 2008).

The propertied classes generally showed approval of the force. Official literature painted the gendarme as a man cast in a heroic mold, honest, modest, and courageous. Descriptions of the small barracks sometimes suggested almost a monastic community, although any visit to a small barracks probably would soon have dispelled such a notion. The men, their wives and children, as well as their horses were all jammed in close proximity to each other. Moreover, while in some respects, his legitimacy grew among the plebeian classes; in various forms of popular culture, the gendarme was commonly portrayed as officious, stupid, and a figure of fun. In popular puppet plays, he might appear as an honest upholder of the law, but when up against shrewd working-class heroes like the Lyon weaver Guignol, he always came off second best. Perhaps the best known of the comic manifestations, however, are Gendarme Pandore and Brigadier Dussutour. Pandore, who first appeared in Gustav Nadaud's popular song written (and promptly banned) at the beginning of the Second Empire, feared God, was virile, but not very bright, and never questioned his superiors: "Brigadier, vous-avez raison!" Dussutour was the eponymous "Good Gendarme" of Léon Bloy's short story who confronts a division of invading

Prussians in 1871 with "I demand to see your papers" (see various articles in Luc 2003).

The close links that the *Gendarmerie* had enjoyed with Napoleon III meant that at the beginning of the Third Republic, the institution was regarded with suspicion by Republicans and the Left. There was general agreement that it should not have a political role and that it should stick to pursuing criminal offenders, maintaining order and enforcing various regulations. The *Gendarmerie mobile* was disbanded in 1885, and some advocated replacing the entire force with a *départemental* police while others urged that it be demilitarized. Such major changes were largely prevented because of the inability of the force's detractors to secure a majority among legislators for any one of their proposals during the early years of the new republic. At the same time, the gendarmes themselves could scarcely be faulted for the ways in which they accepted the role of defenders of the republic and enforced measures, such as the anticlerical laws, that critics of the regime opposed.

The Spread of the Model

In May 1806 Napoleon told his brother Joseph, who he had recently installed as King of Naples, that the Gendarmerie provided "the most efficient way to maintain the tranquillity of a country . . . it provides a surveillance half civil, half military spread across the whole territory together with the most precise information" (quoted in Emsley 1999, p. 56). As a part of Napoleon's empire, as a satellite state or as an ally, many regions of Europe had experience of the Gendarmerie model in the first decade or so of the nineteenth century. Even after Napoleon's fall, many of the rulers of these territories tended to agree with the emperor. Radet and Wirion had set up Gendarmeries in various parts of Italy. Under the restored Savoyard Monarchy, the restructured Piedmontese Gendarmerie, called the *Carabinieri Reale*, was to play a significant military role in the unification of Italy absorbing some of the other Italian Gendarmeries as it did so. Various German states had created Gendarmeries during the Napoleonic ascendancy and continued to deploy them thereafter. In Wùrttemberg, however, the German name of *Landjäger* was preferred, and in the Netherlands the former French name of *Marechaussee* was employed.

Even Napoleon's most consistent enemies created Gendarmeries as and when they thought it prudent. The Irish Constabulary emerged out of a series of initiatives taken by British administrators in Ireland and formalized by an Act of Parliament in 1822. The word "constabulary" was employed at least in part because of concerns about the French word Gendarmerie, but unlike its counterparts, the force was never linked to the Ministry of War (the War Office in British parlance). The Irish (from 1867 Royal Irish) Constabulary was seen by many administrators in the British Empire as a model for the kind of police that they required outside of the major centers of population in the colonies, and they often requested Royal Irish Constabulary officers and men to help create a new force. In Quebec what was originally the North West Mounted Police, and subsequently the Royal Canadian Mounted Police, is still known as *La Gendarmerie Royale du Canada*.

The Gendarmerie of Imperial Russia followed the track of its French counterpart beginning as a military unit established to police the Russian army of occupation in France following Napoleon's overthrow. It then acquired authority over the civilian population of Russia, but throughout the nineteenth century, it maintained a close link with the third section of the Tsar's Private Imperial Chancellery, the department responsible for political policing. Political turbulence in Spain during the 1830s led to the creation of the *Guardia Civil* in 1843, but in spite of the name, the force was militarized, under the direction of the minister of war and housed in small barracks virtually from its creation. In the Habsburg Empire, it was the Galician revolt of 1846 and the subsequent revolution of 1848 that convinced the government of the need for a Gendarmerie. States, like Greece and Romania, that emerged from the Ottoman withdrawal from Europe also created Gendarmeries as the best means of cementing the authority of the new rulers across their territories.

In addition to dealing with various forms of criminal activity, most gendarmes across continental Europe maintained a surveillance of the communities in which they served and collected information for the central government about the local economy, political attitudes, and any other apparently significant developments or events. They provided a first line of defense against popular disorder, and perhaps most significantly, they played a role in the evolving relationship between the nineteenth-century bureaucratic state and its people. Gendarmes in their barracks flying the national or imperial flag, celebrating national or imperial anniversaries and festivities, were the living manifestation of the state or empire for rural communities who rarely looked far beyond their immediate district. Across the continent they commonly assumed the same kind of attributes as those in France; they were portrayed in the official literature and their own corps literature as heroic, honest defenders of the law. The *Carabinieri* recruit, for example, was told how he was entering a family of men who depended on each other and who dedicated their lives to the good of others (Grossadi 1879). Gendarmes protected rural communities from bandits, brigands, and wild beasts; they pursued offenders and brought them to justice; they were the first to help communities in times of natural disaster. But there was an obverse side to these roles. If the state's gendarmes assisted the population, the population had to recognize its obligations to the state, and the gendarmes were also there to ensure that taxes were paid and that young men turned up as and when required for military service. Moreover, in the event of any form of labor or political unrest, the gendarmes were usually the first force available for the authorities to deploy against any demonstrators.

The First Half of the Twentieth Century

Although the French *Gendarmerie* carried out the orders of the Third Republic (1870–1940) loyally, in the 20 years or so before the First World War, it was often criticized as being inadequate for its tasks. The brigade structure meant that small disorders could be handled, but there was no *Gendarmerie mobile* available for dealing with significant industrial unrest and political demonstrations. There were a succession of discussions and proposals for reform put before the legislature, but they all foundered. The brigades, many of whom exchanged their horses for bicycles, were too isolated to deal with itinerant offenders or mechanized criminals such as the anarchist *bande à Bonnot*. The institution also suffered a major blow to its reputation during the First World War: for the first time since its creation it provided no front-line combat unit. Gendarmes were, however, deployed immediately behind the front line to enforce discipline and apprehend deserters. The *poilus* (soldiers) joked cynically about gendarmes, who were often noted for their heavy drinking, suppressing drunkenness among the front-line soldiers. They also scoffed that the front line ended where you met the first gendarme.

During the interwar period, the *Gendarmerie* like the rest of the French police, sought to modernize its fight against crime by developing its use of motor vehicles and telecommunications. Young officers appear also to have been keen to develop the corps role in criminal investigation (Haberbusch 2012). In addition to their traditional role in policing the countryside, and again like the civilian police, the *Gendarmerie* became increasingly preoccupied with the threat of communist subversion. A *Gendarmerie mobile* was reestablished in 1921 to deal with unrest, particularly in labor disputes. The right-leaning ministry that took the step had no desire to see the victorious army risking its reputation in such situations. But just over a decade later, the parliamentary committee appointed to investigate the Paris riots of 1934 concluded that at least on that occasion the *Gendarmerie mobile* was poorly led, inappropriately equipped, and lacking in useful intelligence. Yet in spite of the criticisms and the humiliation of its wartime involvement, the *Gendarmerie* remained loyal to the republic.

At the end of the First World War, the fear of communism and Revolution led to the creation of militarized police in both Germany and the Netherlands. During the summer of 1919 first in Prussia and then in other *Länder*, the nervous authorities set up “Security Police,” *Sicherheitspolizei* (or *Sipo*). These heavily armed police were viewed with suspicion by many in the SPD and by trade unionists. They were also suspected by the victorious allies as a means to circumvent the restrictions on the size of the German army. The *Sipo* did not outlive 1920; the Weimar Republic reverted to the more traditional policing structures, and the policing of rural areas by men designated as gendarmes continued through the Nazi period even as different police institutions were unified into the German Order Police (*Ordnungspolizei*). In the Netherlands rioting in Amsterdam in June 1919 led to the formation of the *Korps Politietroepen* which was incorporated into the army in 1922 and functioned alongside the *Marechaussee* and the *Rijksveldwacht* (state police) until the Second World War.

Elsewhere during the interwar years, other Gendarmeries found their loyalties tested by the turbulent politics of the period. In Italy the *Carabinieri*’*s* boasted first loyalty to the king and to Italy enabled it to ride out some of the problems following the Fascist takeover. However, it is at least arguable that a majority in the *Carabinieri* were more in sympathy with the radical Right than with the political Left and the corruption and clientelism of the Liberals. In Spain the *Guardia Civil* was torn over the formation of the Second Republic. Many in the guard saw their duty as maintaining order in Spain and judged a government on its ability to ensure that they were able to carry out this duty. When the Civil War broke out, a significant percentage of the guards went over to Franco, seeing him as a better hope for order in their beloved homeland – and they went over to Franco even if this meant shooting those among their officers who remained loyal to the republic.

The old rivalries between the Gendarmeries, primarily responsible to ministries of war, and the civilian police, responsible to the ministries of justice and the interior, also continued. Events in the Netherlands’ municipality of Oss during the 1930s provide a vivid example. The *Koninklijke Marechaussee* fought a successful campaign against serious crime in the district which prompted decorations from the queen for the commander and one of his staff but jealousy among the *Rijksveldwacht* and the municipal police. Subsequently, following a largely fruitless investigation of local municipal and religious authorities and the arrest of a factory owner and an insurance broker, the minister of justice prohibited further investigations and arranged to have the full brigade of the *Marechaussee* transferred elsewhere. Eventually a parliamentary enquiry was called to settle the matter which had turned into bickering between the ministers of justice and the interior as well as the minister of war and the *Marechaussee*. The civilian ministries’ dreams of creating a single, unified policing structure had to be shelved, and when reform came, it was imposed by the German occupiers who set out to amalgamate the *Rijksveldwacht* with the *Koninklijke Marechaussee* in March 1941. The aim was to create an institution modeled on the SS and loyal to the new German authorities.

The Second World War brought additional pressures. In France, determined to avoid the criticisms of its role in the previous war, the *Gendarmerie* deployed a combat unit. The combat unit drew on the younger, more energetic, and fitter gendarmes, and while experienced heads are important to policing, the drain on the provincial brigades appears to have had a negative effect. The recruits who came forward to fill the gaps during the German occupation were often well qualified, but many were using the institution as a way of avoiding *Service de travail obligatoire* in Germany and had no serious commitment to the job. In Vichy the *Gendarmerie* was purged of those elements that the government considered undesirable and a threat to France such as Jews and Freemasons. In both Vichy and the occupied zone, gendarmes were involved in enforcing the racial and political policies of the conqueror. In the early years of the occupation and Vichy, very few joined the resistance, but the Germans appear to have had suspicions about the *Gendarmerie* and occasionally picked on both officers and men, and by early

1944, many gendarmes appear to have been paying lip service to orders emanating from the occupying power. In France, Belgium, and the Netherlands, the different Gendarmeries, like other police institutions, faced issues of where their duty lay. The problem was especially acute in Belgium and the Netherlands where the vestiges of prewar governments had gone into exile in Britain. At the close of the war in all three countries, these became questions of the legitimacy for the different forces as members of the resistance and others sought revenge, and scapegoats and gendarmes were challenged and investigated as to whether they had put the emphasis on professional and patriotic duty (Campion 2011). The same problem arose in Greece where, in the wake of the German defeat, the country descended into civil war.

In Italy, loyalty to the king and to the concept of *Italia* enabled the *Carabinieri* to shift with wartime politics. When the war began, they loyally served the Fascist state; when Mussolini was overthrown, they were able to collaborate with the allies fighting their way up the peninsula. *Carabinieri* worked alongside allied military police in attempts to suppress the rampant black market and brigandage that appeared, especially in the south. In those areas that were occupied by the Germans, they collaborated but often in unique ways. The most notable and, as far as the *Carabinieri* itself is concerned, the most heroic example is the self-sacrifice of *vicebrigadiere* Salvo d'Acquisto who, in September 1943, voluntarily went before a German firing squad in order to save 22 innocent hostages. His last words, allegedly, were *Viva Italia*. But the allies were conscious of the *Carabinieri's* involvement with the Fascist state, and a mission, led by a senior English police officer and staffed by men from other British forces, set out to take the Fascist element out of all Italian police institutions. Similar British police missions were deployed in Austria and Germany; in the former the relaxed, some might say idle, attitude of the English commander ensured that Austrian Gendarmerie maintained the traditional characteristics of such a body. Paradoxically in the west of Germany, while the victorious allies were determined to denazify and demilitarize the police, the specifically military police of the Third Reich, the *Feldgendarmerie*, was the last military unit to be disbanded as its experience and discipline was considered too important in the struggle against the postwar crime wave. In postwar Greece, torn by civil war, another British police mission led by a former head of the Royal Ulster Constabulary (which had replaced, but closely resembled, the Gendarmerie-style RIC on the partition of Ireland) was keen to see the Greek Gendarmerie trained first and foremost as ordinary police and subject to civilian authority. Even so, the mission commander also recognized the virtue in a paramilitary Gendarmerie for the warring countryside.

To the Twenty-First Century

The rivalry and occasional friction between civilian police and Gendarmeries continued in the aftermath of the Second World War. Sometimes it sprang from the Gendarmeries' proud military tradition. In France, for example, during the last two decades of the century, morale in both the police and the *Gendarmerie* was periodically undermined by a variety of issues some of which resulted from shifting pressures in the job, such as the emergence of international terrorism and who should take precedence in handling it. There was also cultural change; more working wives and changes in the civilian working world challenged some of the traditional understanding of the gendarme's military commitment and subservience to old-style military discipline. The government could aggravate such concerns by suggesting a redefinition of ranks which brought a degree of unanimity between *Gendarmerie* and police but which also highlighted some better emoluments within the *Gendarmerie* as well as discrepancies between the responsibilities of different ranks in the different institutions. President Mitterand's creation of the *Groupe* *d'intervention de la Gendarmerie nationale* (*GIGN*) for his personal protection in the Elysée Palace with its additional responsibilities for anti-terrorism aggravated police-*Gendarmerie* relations, while the use of *GIGN* officers for investigating the president's opponents caused outrage beyond the ranks of the police and tarnished the *Gendarmerie's* image.

Elsewhere political involvement by senior gendarmes did their institutions little credit. Senior figures in the *Carabinieri* were suspected of taking their anti-communism further than was proper in a democracy. It was the refusal of members of the corps to leave their barracks that stifled an attempted coup led by a *Carabinieri* general in 1964. The Greek Gendarmerie was closely tied with the Colonels' junta that seized power in 1967. In the aftermath of the Colonels' fall, the Gendarmerie was united with the town police, yet the new police, while more closely tied to the civilian state, remains a military organization. Following the death of Franco, the *Guardia Civil* remained suspect in the eyes of many on the Left and the attempted coup of February 1981 in which a lieutenant colonel of the *Guardia* and his men seized the lower chamber of the Cortes confirmed such suspicions. The *Guardia Civil* survived the failed coup but came increasingly to resemble a civilian police, though it was not until 2009 that the traditional bicorn hat was replaced (except for ceremonial duties) with a more conventional baseball cap.

As the European Gendarmeries became more like civilian police institutions with, for example, the Belgian Gendarmerie's amalgamation with the country's civil police in 2000 and the bringing together of the *Gendarmerie nationale* and the *Police nationale* under the French Ministry of the Interior in 2009, so a new opportunity opened up for these corps in the wider world. It was argued that soldiers and marines lacked the necessary skills for establishing and maintaining basic law and order in failed states or states emerging from civil war or international conflict (Perito 2004). Police missions to such states as Bosnia, Kosovo, Iraq, and Afghanistan were commonly spearheaded by gendarmes. Even British Police missions under the auspices of the UK's International Police Assistance Board contained a disproportionate number of men from the old Royal Ulster Constabulary or its more civilian successor force (the Police Service Northern Ireland, PSNI) – but this successor force was itself well versed in crowd control and soothing the passions of rival communities (Sinclair 2012).

Globalization, concerns about organized crime on an international level, and the increase in demands for police missions like those to the new states emerging from former Yugoslavia combined to foster the creation of the European Gendarmerie (EGF) in 2006. The EGF, formalized by the Treaty of Velsen in October 2007, brought together gendarmes from corps of five of the EU's member states: France, Italy, the Netherlands, Portugal, and Spain. When Romania joined the EU, its Gendarmerie also became a member, while those of Poland and Lithuania were designated as partners. The intention was to have a force of up to 800 gendarmes available for deployment within 30 days of a request for assistance. The EGF was involved in NATO police missions, notably in Afghanistan, and it provided a small force to advise on security in Haiti following the earthquake of 2010. But the new institution raised fears, particularly about accountability, and there were even suspicions that EGF officers had been deployed to Greece during the disorders engendered by the crisis over Greek debt (see, e.g., www.golenxiv.co.uk/2011/10/foreign-riot-police-now-operating-in-greece/).

Gendered Theory and Gendered Practice

Marjorie S. Zatz and Heather R. Gough
School of Social Transformation, Arizona State University, Tempe, AZ, USA

Overview

Theoretical and empirical research on the relationships among gender, crime, and delinquency has grown in scope and sophistication in recent decades. Less apparent, though, is whether and to what extent these advances are reflected in current criminal and juvenile justice practices and policies. This entry briefly reviews major feminist and gendered theories of crime and delinquency and then turns to key laws, policies, and practices to assess whether these theoretical advances translate into improved policy and practice. We conclude with suggestions for how feminist scholarship can help shape gender-specific and culturally appropriate criminal and juvenile justice programming and training.

Introduction

Tough-on-crime and zero-tolerance laws and policies enacted in the United States in recent decades dramatically increased the number of women and girls processed through the criminal and juvenile justice systems. During this same era, another set of laws and policies sought to reduce violence against women and girls and to change the ways in which police, prosecutors, and judges respond to rape and intimate partner violence, in particular. To what extent do these legal reforms, as well as the practices of criminal and juvenile justice institutions, reflect theoretical advances and new knowledge about gender and crime? To address this question we, first, briefly summarize major feminist and gendered theories and perspectives. Second, we assess the extent to which recent criminal and juvenile justice policies and practices, as well as major legislative initiatives, reflect feminist perspectives. Third, we examine whether these reforms have successfully met feminist objectives or have been eroded and undermined and, if so, in what ways and to what effect. The entry concludes with suggestions for ways in which relevant theory and research might better inform criminal and juvenile justice policies and practices.

Feminist and Gendered Theories of Crime and Delinquency

This section briefly summarizes the principal theoretical perspectives on gender, crime and delinquency before turning to an assessment of their utility and visibility in criminal and juvenile justice policies and programs, as well as relevant legislation. Readers are referred to Chesney-Lind and Morash (2011), Miller and Mullins (2009), and Daly (1998) for more detailed reviews of cutting-edge theoretical work on gender, crime and delinquency, and compilations edited by Chesney-Lind and Pasko (2004), Heimer and Kruttschnitt (2006), and Zahn (2009) for examples of empirical research that has tested and refined these theories. It is also important to note that while much of this literature focuses on women and girls, a number of studies examine masculinities and crime to better understand how and in what contexts men engage in violence, both against women and against other men (e.g., Dobash and Dobash 1992; Messerschmidt 1993).

Most recent criminological research that explicitly examines gender can be categorized as studies of the "gendered ratio of crime," "gendered pathways," "gendered crime," and "gendered lives" (see Daly 1998:94–95). Studies of the *gendered ratio* of crime seek to explain the gender gap in self-reported and official rates of crime and delinquency. Research from this perspective often begins with what is known about male crime and delinquency and asks why women and girls engage in less crime. While some scholars examine individual level influences, feminist criminologists examining the gender gap tend to focus more on gendered social organizations and structural conditions, as these shape the types of offenses and contexts in which girls/women and boys/men commit crimes (e.g., Steffensmeier and Schwartz 2004).

Gendered pathways research examines the trajectories by which women and girls, and men and boys, move in and out of lawbreaking behaviors. Women's and girls' pathways often include histories of victimization and of strategies for coping with that victimization that may themselves be criminalized (e.g., substance abuse, running away, fighting back), further entangling them with the criminal and juvenile justice systems (Chesney-Lind and Pasko 2004; Daly 1992). Some research refers to the "blurred boundaries" between victimization and offending, but even when the boundaries are sharp, the focus here is on the most common paths to criminal and juvenile court and how those paths are structured by gender, race, class, and other sources of inequality.

Studies of *gendered crime* focus on the social context and situational qualities of offending by girls and women and by boys and men. Victimization may be a situational factor resulting in crime, as seen, for instance, when women kill their abusers. In other situations, though, crime and delinquency may be resources for gaining status, desired commodities, revenge, or simply a means of having fun. Much of this research emerges from sociological studies of "doing gender," reminding us that gender is performed in multiple ways, depending in large part upon the resources available, and those resources are themselves structured by gender, race, class, gender orientation, and age, among other dimensions (see, e.g., Miller 1998; Messerschmidt 1993).

Finally, research on *gendered lives* asks how gender structures the kinds of actions and identities women and girls, and men and boys, employ to survive. Examples are Maher's (1997) detailed analysis of sex work by women drug users and research on the differing types and effects of peer relationships among adolescent boys and girls (e.g., Giordano et al. 2003).

Regardless of which of these approaches is paramount, the most comprehensive theoretical and empirical studies of crime and delinquency attend to the multiple and intersecting ways in which gender, racial, economic, and other inequalities structure individuals' lives and choices in patterned ways. Borrowing from Miller and Mullins, we must study gender and gender inequality "at the macro level (overarching structural patterns of gender inequality and their effects on crime and delinquency), at the meso level (gender inequality within the context of social institutions such as family, school, and neighborhood) and at the micro level (interpersonal relationships within and across gender)" (2009:34).

Feminist Influences on Law, Policy, and Practice

The civil rights and feminist movements have led to major social and legal changes in the United States and, to varying extents, globally. They have provided social recognition for a variety of problems that had previously been defined as simply private harms. Yet empirical research and theorizing about gender, race, class, and other intersecting sources of inequality are not necessarily reflected in contemporary criminal and juvenile statutes, policies, and practices. Policies and programs that ignore how structural and institutional contexts shape and constrain individual lives are likely to be ineffective. As Miller and Mullins (2009) remind us, "taken-for-granted ideologies about gender" result in scholarship "that fundamentally misrepresents and misunderstands the nature of girls' delinquency and produces policies that are misguided at best, and quite harmful at their worst" (2009:31–32).

Legal Reforms

Since the 1970s, a number of significant legislative and policy initiatives have emerged in the areas of rape reform, intimate partner violence, and deinstitutionalization, among other issues. Many of these legal changes resulted from social protests and lobbying by feminist and civil rights organizations and reflect feminist thinking about crime and delinquency. Yet in most cases, the new laws were not as far-reaching as their advocates had hoped, and many were eroded further during the antifeminist backlash of the late 1980s and 1990s.

For example, the rape reforms that swept the United States in the 1970s were seen as a major victory at the time. They provided for rape shield laws, repealed requirements for corroboration, redefined resistance, and in some cases created the criminal statutes necessary for rape prosecutions, including the then novel concept of a crime of spousal rape. Yet as Caringella (2009) demonstrates, they have been largely educational and symbolic in value, with comprehensive rape reform still an unmet goal.

Similarly, public attention to intimate partner violence as a major social problem led in the 1980s to pro-arrest domestic violence legislation and policies in states across the USA and to passage of the Violence Against Women Act in 1994 (and its reauthorizations in 2000 and 2005), the Victims of Trafficking and Violence Protection Act of 2000 (and its reauthorizations in 2003, 2005 and 2008), and the Tribal Law and Order Act of 2010. These laws and policies succeeded in changing public understandings of rape and domestic violence, in particular, and brought these crimes out of the shadows. Yet they stopped short of the larger structural changes envisioned by their advocates and, in some cases, contributed to new problems. Most notably, as of 2000, nearly 60 % of states had passed either mandatory or arrest-preferred legislation, with the unanticipated and ironic consequence of increasing domestic violence arrests and prosecutions of women who were defending themselves against violent partners (Hirschel et al. 2007:265). Public attention to violence against women has also affected perceptions of women who ultimately kill their abusers. The "battered woman syndrome" legal defense helped judges and juries understand that in certain circumstances, killing one's abuser may be an understandable and even reasonable response to long-term abuse, yet women who did not fit stereotypic images of how battered women should behave did not receive the same level of concern and legal support. This was particularly problematic for women of color. More generally, the new laws and policies were a step forward in many ways, yet did not adequately address the experiences of racially and economically marginalized women, immigrants, lesbians, and transgendered persons who could not assume the same support from police and prosecutors as middle-class white women experienced.

Girls, as well as women, were impacted by these early reforms and by their often unanticipated consequences. The Juvenile Justice and Delinquency Prevention Act of 1974 called for deinstitutionalization of status offenders, the vast majority of whom were girls. Prior to that time, girls were incarcerated for lengthy terms, often longer than boys convicted of felonies, for minor acts such as truancy, running away, and other age-specific or "status" offenses that would not be crimes if the girls were over the age of majority. The intent of this legislation was negated, though, by zero-tolerance school policies, arrests of teenage girls for assault rather than incorrigibility when fighting with their parents, and other new laws and policies that expanded the pool of delinquent girls. These mechanisms, then, have come to be known as net-widening, relabeling, and upcriming (Chesney-Lind and Irwin 2008).

Policies and Practices

The greater willingness by police, schools, and other authorities to punish girls' misbehaviors as crimes, in combination with mandatory incarceration for a variety of drug and other offenses, has resulted in soaring arrest and incarceration rates for girls and women in recent years. However, while the percentage increases in these rates have been quite large, the total numbers of incarcerated females remain small compared to males. As a consequence of the vastly greater number of males in the system and the lack of knowledge about how best to meet the needs of female offenders, studies from the 1970s through the mid-1990s reported limited funds were available for at-risk and delinquent girls (figures range from 3 % to 8 %). In response, the 1992 reauthorization of the Juvenile Justice and Delinquency Prevention Act required that girls have adequate access to services, and federal agencies and research institutes began soliciting proposals for gender-responsive programs and staff training.

A review of the literature on programming for girls and women suggests three primary issues confounding efforts to better serve female offenders. First, as noted above, is the lack of adequate resources dedicated to the specific needs of women and girls. Even where programs have been developed, the funding is too often short term, preventing program sustainability and growth. Second, a number of studies have found that correctional and probation staff prefer working with males, characterizing women and girls as petty, whiney, and manipulative (see, e.g., Martin and Jurik 2007; Gaarder et al. 2004). It appears that the complexities of how and why women and girls become involved in the justice system, and the need to address a broad range of psychological, interpersonal, economic, and physical safety issues for rehabilitation and reentry, can overwhelm staff, especially in a context of inadequate resources. As a result, some probation and correctional officers come to see women and girls as simply overly emotional or needy and distance themselves from the individuals in their care. The third critical factor inhibiting better service provision is the shortage of gender-specific, culturally appropriate, and theoretically informed programming (Foley 2008). Effective programming must recognize and respond to the multiple and intersecting forms of inequality experienced by many of the girls and women in the system. These inequalities operate at structural, institutional, and interpersonal levels, functioning both as pathways into the justice system and as barriers to successfully stabilizing outside of the system.

In an effort to further our understanding of girls' offending and identify effective, evidence-based strategies for preventing and reducing girls' involvement in crime and delinquency, the Office of Juvenile Justice and Delinquency Prevention (OJJDP) convened and funded the Girls Study Group in 2004. Major outcomes of the Girls Study Group include publication of The Delinquent Girl (Zahn 2009), which is a comprehensive review of the state of the field; development of a curriculum to assist staff in addressing girls' unique experiences and recognizing how gender, race, culture, economic disadvantage, and other factors shape those experiences; and a review of assessment tools to ascertain their suitability for girls (see http://www.ojjdp.gov/programs/girlsdelinquency.html). OJJDP also compiled a Model Programs Guide, which lists programs from prevention through sanctioning to reentry, and they fund a number of gender-specific programs including substance abuse prevention inside and outside of correctional settings, as well as Girl Scouting in Detention Centers, which targets adjudicated or court-referred delinquent girls or girls who are wards of the state.

A second major resource for staff training and program development for delinquent girls was developed by the National Center for Crime and Delinquency (NCCD). Launched in 2008, the NCCD's Center for Girls and Young Women specifically addresses "advocacy, research, assessment services, staff training and evaluation to address juvenile justice and child welfare systems that are designed for boys and ill-equipped to meet the gender-specific needs of girls and young women" (http://justiceforallgirls.org).

The evolution of these programs demonstrates that policy, programming, and training are increasingly influenced by theoretical and empirical research elaborating the ways in which gender matters. Simultaneously, evaluations of these programs and interviews with incarcerated girls and women have advanced theorizing, especially with regard to theories centered on gendered pathways into delinquency and crime. Yet while feminist scholars seek to go beyond essentialized or simplistic models of how gender intersects with race, class, sexuality, gender identity, and other factors to shape the lived experiences of individual girls, the programs in place tend to be far less nuanced.

At the adult level, the National Institute of Corrections (NIC) funded and published a guide to gender-responsive strategies for female offenders (Bloom et al. 2003), maintains an online directory of programs for women involved with the criminal justice system (http://nicic.gov/wodp/), and offers a curriculum to support management and operations within women's prisons that draws at least in part on feminist theoretical and empirical research. Modules include women's pathways to prison, gender-responsive management principles, and methods of addressing staff sexual misconduct, among other topics.

Controversy continues to center, though, on the appropriateness of risk and needs assessment tools developed for use with male inmates – and especially the Level of Service Inventory-Revised (LSI-R) – when working with female offenders (see Morash 2009, for a summary of this debate). The NIC funded a multisite, multilevel (prison, probation, parole) Women's Classification Study to determine, first, whether assessment and treatment of gender-responsive needs pertaining to trauma, abuse, mental health, self-efficacy, self-esteem, parenting, and relationships are relevant to women's future offending and other adverse outcomes, and second, whether adding items tapping these gender-responsive needs improves the predictive validity of assessment tools such as the LSI-R. The research team affirmed that programming to address women's unique needs is relevant for criminal justice outcomes and that including gender-responsive items significantly improves the predictive validity of so-called "gender-neutral" tools (Van Voorhis et al. 2008). They caution, however, that the new instruments are intended for use in gender-responsive, evidence-based treatment centers where practitioners are skilled in addressing women's needs. Moreover, adequate resources must exist to support programming designed to "empower women, address and accommodate trauma, stabilize symptoms of mental health, accommodate family reunification, teach healthy relationships, facilitate communication with children, provide parenting classes, strengthen vocational, educational, and life skills, and provide gender-responsive substance abuse treatment" (Van Voorhis et al. 2008:19).

On the ground, though, the lack of resources and training significantly impedes efforts to offer gender-responsive programming. Perhaps the best-known program for women in state and county prisons and jails is Girl Scouts Behind Bars. This partnership between the Girl Scouts and the National Institute of Justice, begun in 1992, is designed to renew bonds between girls and their incarcerated mothers.

At the federal level, the Federal Bureau of Prisons' female offender educational, recreational, and job training programs are designed to be comparable to those available to men. While comparable programming is arguably better than no programming, as was the case for women for decades, the lack of gender-responsive programming in these core areas is problematic. Currently, the Bureau of Prisons' gender-specific programs are largely limited to medical and social services related to pregnancy and child birth, and to a 3-month community residential program (Mothers and Infants Nurturing Together) for female inmates who are pregnant at the time of commitment, low risk, and who meet other eligibility criteria. Aside from this program, women inmates in federal prisons may visit with their infants or older children only if the children are accompanied by an adult (http://www.bop.gov/inmate_programs/female.jsp).

Do These Policies and Programs Reflect Feminist and Gendered Theorizing?

While the legislative initiatives, policies, and programs discussed above broke new ground and, in some ways, reflect feminist concerns, they have also reinforced two dominant social constructions of women – first, as victims who must be protected and, second, as needing assistance in order to be "good mothers." Women are seen as rather passive in both of these constructions. There is little recognition that women have agency and are making choices that appear reasonable to them, given the structural conditions of their lives.

Taking steps to stop sexual and other forms of violence against women and recognition of the blurred boundaries between victimization and offending are of critical importance, but feminist and gendered theories remind us that this focus on women's victimization is insufficient for at least three reasons. First, it reinforces stereotypic images of women as weak and in need of protection. Second, it risks treating women as a monolithic, homogenous group rather than recognizing the patterned differences (based on race, ethnicity, class, gender identity, sexual orientation, age, physical ability, etc.) in their experiences and responses to victimization. For example, very few gender-specific programs incorporate culturally appropriate practices or address issues faced by lesbian and transgendered youth. And third, legislation and programming that focus on victimization tend to ignore the central problems of patriarchy, racial discrimination, and economic inequality that coalesce to make women vulnerable to men's violence in the first place. Thus, theoretical and empirical scholarship on gendered lives and gendered crimes reminds us of the complexity of women's and girls' (and men's and boy's) experiences, the multiple sources of inequality and disadvantage that may shape those experiences, and the diverse ways in which they respond to their circumstances (see similarly Hannah-Moffat 2010).

In addition to this focus on victimization, the second theme underscoring much of the programming for female offenders, and especially for those who are incarcerated, is based on their status as mothers or future mothers. These include traditional parenting classes and newer interventions such as prison nurseries, extended visitation for children, and programs such as Girl Scouts Behind Bars. This approach is beneficial, as studies confirm repeatedly that being able to spend time with their children is very important to the women and their children (e.g., Bloom et al. 2003; Chesney-Lind and Pasko 2004).

Nevertheless, this limited focus on women as mothers risks reinforcing gender, racial, and cultural stereotypes of women as defined by motherhood, hegemonic norms regarding what makes a woman a "good mother," and appropriate societal responses to "good" and "bad" mothers. Previous research has demonstrated that women who are perceived by court officials to be "good mothers" are granted some leniency and are less likely to be incarcerated, whether because their families are seen as capable of providing sufficient informal social control or because of the practical costs of caring for children of incarcerated mothers. Not surprisingly, perceptions of family roles and of appropriate sanctions when "good" and "bad" mothers transgress societal norms and laws have been found to intersect with race, class, and gender orientation. Contemporary legislation that mandates incarceration for a wide range of offenses and circumstances (e.g., probation violations) has resulted in incarcerating more women and, particularly, more poor women of color, than ever before. Yet a primary emphasis of much of the programming for incarcerated women focuses on one aspect of women's lives – trying to help them become better mothers – without adequately addressing other critical problems that they face (e.g., employment, housing, transportation, drug and alcohol addiction) or the systemic issues that shape women's choices.

Future Directions

There is a growing recognition among federal agencies such as the Office of Juvenile Justice and Delinquency Prevention and the National Institute of Corrections, as well as research centers such as the National Center for Crime and Delinquency, of the need for theoretically informed, evidence-based programs that are gender specific and culturally appropriate. Such programs will require sustained funding and ongoing evaluations to ensure that the most effective models are widely available. Lack of adequate resources to develop and maintain programming is especially problematic for incarcerated girls and women. Improved and enhanced staff training and support for probation officers, correctional and detention officers, and other court personnel is also of critical importance. This training should be designed to debunk cultural and gender stereotypes held by staff and provide them with a broader understanding of the multifaceted contexts and complexities of girl's and women's lives.

Increasingly, programming for girls and women incorporates recognition of gendered pathways and the blurred boundaries between victimization and offending. This must remain a central component of gender-responsive programming, but it is not adequate or sufficient to explain the varied and complex situations and structural conditions that result in women and girls – and men and boys – engaging in crime and delinquency. Attention to victimization histories must be augmented in a number of ways, including educational, employment, and interpersonal skill building. Peer and family relationships also must be explicitly addressed. Girls' delinquency often occurs within the context of their friendship and romantic relationships, and past and present family dynamics are often a factor in girls' and women's offending. Finally, programming for adolescents must recognize and address the ways in which concentrated disadvantage in neighborhoods and schools shapes girls' and boys' available options and choices.

In sum, curriculum development and staff training must continue to reflect differences in offending patterns (gendered ratios of crime and delinquency) but must also incorporate new understandings of gendered lives, gendered pathways, and gendered crimes if they are to be effective. Moreover, programming must take into account the structural, institutional, and interpersonal (i.e., macro, meso, and micro) forces and dynamics through which race, gender, and class collectively pattern, shape, and constrain individuals' choices and actions. Simultaneously, scholars are encouraged to partner with practitioners to develop, assess, and refine theoretically and empirically strong prevention and intervention models grounded in an understanding of the multifaceted ways in which gender matters.

Overview

The major theoretical paradigms in criminology developed with little to no consideration of sex or gender differences in offending. Insights from gender and feminist studies demonstrate, however, that ignoring sex and gender in explanations of crime is to the detriment of the field. In this essay, we discuss contributions of gender and feminist studies to criminology with an emphasis on gender research that developed within the major criminological paradigms as well as research that steps outside traditional paradigms to draw more explicitly from gender and feminist theory. These bodies of research have underscored the need to consider how gender influences male offending, female offending, and the gender gap in offending through shaping power arrangements, opportunities, definitions of the sexes, and identities. We propose that one of the most promising directions for future work in criminology lies in further integration of traditional criminological perspectives with emerging work on offending rooted in feminist paradigms and not yet integrated with some of the core insights from theories of offending.

Introduction

Research consistently demonstrates that males commit more crime than females. Perhaps because of the persistent gender gap in crime, the major criminological paradigms developed with little concern for understanding female offending. Indeed, early work often ignored females altogether or focused on explaining sex differences in behavior, but did not incorporate gender as a social process that might explain sex differences and similarities in criminal involvement. Insights from gender and feminist studies, however, have shown that ignoring gender prohibits full understanding of the sources not only of female offending but also of male offending and of the gender gap in offending.

In this entry, we discuss the contributions of gender and feminist studies to the major criminological paradigms – control, strain, and learning. In doing so, we discuss research that demonstrates that the variables and processes specified in traditional criminological theories are shaped by gender in ways that contribute to the gender gap in crime. Simply emphasizing that gender shapes these variables and processes, however, proves insufficient for understanding the social forces contributing to the gender gap in crime. As such, we highlight work that has drawn more heavily on feminist theorizing and gender studies to introduce new variables and processes – for example, power arrangements, gendered opportunities and constraints, and cultural meanings of gender – to traditional criminological theories. We maintain that these lines of work underscore limitations in traditional theories and suggest avenues for the expansion of criminological theory that are important not only for understanding the gender gap in offending but for understanding crime generally. We also discuss research on gender and crime that departs from traditional criminological theory to focus on relationships between masculinities, femininities, and intersectionalities and crime. This work has made important contributions to criminology beyond what has been achieved by work focused on traditional theories of crime. It is our view that more theorizing and research must integrate new gendered insights into traditional perspectives to provide more thorough understanding of the structural and social-psychological processes leading to male offending, female offending, the gender gap in offending, and gender/race/class differences in offending.

Theorizing Gender Vis-Vis Traditional Theories of Crime and Delinquency

Early theorizing in criminology provided only cursory explanations for the gender gap in illegality, positing that females have either less exposure to the processes and variables in traditional theories that promote illegal behavior or more exposure to those that control such behavior (Sutherland 1947; Gottfredson and Hirschi 1990). Some scholars have demonstrated that the concepts from traditional theories have gender-differentiated effects on crime and delinquency, proposing that these differences are linked to gendered processes that have remained largely unmeasured and under-theorized (e.g., LaGrange and Silverman 1999; Broidy 2001; Lonardo et al. 2009). There, of course, have been some important advances within each of the criminological traditions – control, strain, and learning – that have drawn heavily from feminist theory and gender studies (Hagan et al. 1987; Chesney-Lind 1989; Heimer 1996; Heimer and De Coster 1999). We discuss the development of each of these traditions and the contributions of feminist and gender studies to these traditions below.

Control Theories

According to control theories of crime, everyone would be tempted to break the law in the absence of social constraints. The prime focus in this category of theory, therefore, is not why people commit crime but why they refrain from illegal behavior. The most prominent perspectives in this tradition – Hirschi's (1969) social control theory and Gottfredson and Hirschi's (1990) self-control theory – were not formulated to address the role of gender differences in offending, although some research has moved in this direction. The power-control theory of Hagan and colleagues (1987), for example, was specifically formulated to address gender and sex differences in offending and, in so doing, contributed importantly to criminological thinking.

Briefly, Hirschi's (1969) social control theory suggests that bonds to society – attachment to conventional others, commitment to conventional pursuits, involvement in conventional activities, and belief in the single moral order – effectively explain offending regardless of the sex of the offender. Scholars subsequently have suggested that the process of social bonding may be gendered. For example, drawing on feminist theory about relationships to others, some scholars posit that females develop stronger attachments to others and that this is associated with lower rates of female than male offending (e.g., Heimer 1996). Although some scholarship concludes that family bonds influence female and male delinquency similarly (e.g., Kruttschnitt and Giordano 2009), other research supports the proposition that the process of bonding through attachments to others is gendered (e.g., Heimer and De Coster 1999). Additional research supports a gendered bonding perspective, reporting that conventional beliefs control delinquency more strongly for females than for males (Liu and Kaplan 1999). This research generally suggests that understanding sex differences in crime and delinquency may require thinking conceptually about gender and moving beyond the original statements of social control theory.

The same is true in the case of research based on Gottfredson and Hirschi's (1990) self-control theory. Proposed to be gender neutral, the theory posits that sex differences in low self-control – typified by impulsiveness, thrill-seeking, and an inability to delay gratification – are the primary cause of gender differences in law violation. More specifically, sex differences in offending result from the fact that females acquire higher levels of self-control because parents are more likely to monitor and punish misbehavior in daughters than sons (e.g., LaGrange and Silverman 1999). These differences established early in life are presumed to persist into adulthood. Beyond this, researchers have not often explored the possibility that the effect of self-control on illegality can vary across sex or that the processes of self-control may in fact be gendered. Pratt and Cullen's (2000) meta-analysis indicates, however, that the effect size of self-control is larger for females than for males. Theoretical discussion of the gendered reasons for such a difference has been minimal to date. This may reflect the fact that the theory is intended to be general and hence, in effect, gender neutral.

By contrast, power-control theory, developed by Hagan and his colleagues (Hagan et al. 1987), maintains that understanding sex differences in law violation requires a perspective that focuses explicitly on gendered power structures and control processes that relay gendered messages within families. Specifically, power-control theory maintains that gender differences in the control of sons and daughters, via emotional attachments and supervision, can be traced to power relations between mothers and fathers (Hagan et al. 1987). When fathers experience greater power than mothers in the workplace, this is said to translate into greater paternal than maternal power in the home (patriarchal households). When fathers and mothers have equal power in the workplace, they share more or less equally in power in the home (egalitarian households). These power dynamics shape the relative control of daughters and sons, through supervision and emotional attachments, which influences risk preferences and perceptions among boys and girls. These processes ultimately create a sex gap in delinquency that is larger in patriarchal households than in egalitarian households. In more recent formulations of the theory, risk orientations have been replaced with discussions of gender schemas related to appropriate behaviors and characteristics of the sexes

(Hagan et al. 2004). Empirically, research has supported the prediction that the sex gap in delinquency is larger in patriarchal families than in more egalitarian families because of gender-differentiated social control, gendered orientations toward risk, and gender schemas (e.g., Hagan et al. 1987, 2004). While some research fails to replicate some of these findings (e.g., Jensen and Thompson 1990), power-control theory has received a good deal of empirical support. This support demonstrates that traditional control perspectives that fail to consider the way in which gendered power structures shape controls and gendered messages within families offer an incomplete portrayal of the structural and social-psychological roots of law violation among both males and females.

Strain Theories

Strain theories maintain that crime is not an innate characteristic of individuals and instead focus on the social factors that promote offending. A central tenet of these perspectives is that illegality results from failure to achieve positively valued goals. Classic strain explanations focused on failure to achieve economic- or class-based status goals (e.g., Merton 1938; Cloward and Ohlin 1960), which some argue renders them entirely ineffective for explicating the sex gap in offending since females face more structural barriers to success in the economic realm than males (Chesney-Lind 1989). However, macro- and microlevel reformulations of strain theory coupled with insights from feminist and gender studies address this gendered challenge.

At the macrolevel, gender researchers have drawn on Cloward and Ohlin's (1960) extension of anomie/strain theory to emphasize that blocked legitimate opportunities do not always result in illegality because people also face barriers to economic success in the illegitimate world of crime. For instance, Steffensmeier (1983) proposes that the petty, nonserious, and non-lucrative nature of female crime can be explained largely by the fact that male-dominated illegal networks exclude or restrict women from organized criminal enterprises. This theme is one that finds prominence also in ethnographic work on economic street crimes, including robbery, burglary, and drug-trafficking (Miller 1986, 2001; Maher 1997 ; Mullins and Wright 2003). These studies demonstrate that the illegal activities associated with the highest pay, power, and status are largely the domain of males who have access to male-dominated street networks that operate to limit female participation in the most lucrative criminal enterprises in the streets. Daly's (1989) research shows that this pattern of exclusion applies also to white-collar crimes where women's opportunities are restricted by their occupational positions and limited access to both organizational resources and male-dominated criminal networks. Although these studies are not situated specifically in the strain tradition, they speak to strain theories by highlighting the importance of gender in shaping opportunities and constraints in the illegitimate world of crime. More generally, they demonstrate that understanding differences in crime across broad categories of not only gender but also of age, class, and race may require consideration of illegitimate opportunities that often are made accessible through social networks that tend toward homosocial reproduction.

At the microlevel, Agnew (2006) broadens the scope of crime producing strains beyond the economic realm by considering goals related to the pursuit of meaning, interpersonal relationships, and a desire for justice. His general strain theory posits that failure to achieve these goals produces negative emotions that promote crime when individuals lack social supports and legitimate coping resources.

In a gendered extension of this theory, Broidy and Agnew (1997) propose that gender socialization shapes the variables in general strain theory in ways that are relevant for understanding the gender gap in illegality. Specifically, they posit that the types of strains to which males and females are exposed, their emotional responses to these strains, and their coping mechanisms (including social support) are shaped by gender. For instance, they draw on feminist work to suggest that males and females experience different types of strains because they have gender-differentiated goals; females focus on maintaining relationships, nurturance, and the treatment of others in interaction, whereas males focus on goals related to economic success, personal achievement, and the outcomes of interaction. They propose that the gender-differentiated strains experienced by males and females are relevant for understanding the gender gap in offending because male-typical strains may be more conducive to illegality than female-typical strains. For instance, the male-typical strains of failure to achieve economic goals and criminal victimization are conducive to property and violent offending, respectively. Female-typical strains are less conducive to illegal behavior because such behavior often harms others or damages social relationships. Although research supports the notion that strains align with gender-differentiated goals, there is little evidence that male-typical strains are more likely than female-typical strains to produce crime and delinquency (see Agnew 2006).

Emotional responses to strain have been shown to be gendered in ways consistent with Broidy and Agnew's (1997) proposition that males and females both experience anger, but they do so in ways that are qualitatively distinct. That is, both males and females respond to strain with anger (Broidy 2001). However, female anger is more likely than male anger to be accompanied by depression, which Broidy and Agnew (1997) suggest tempers the impact of anger on their offending. This claim is not supported by empirical research, however (De Coster and Zito 2010). The proposition that coping and social support resources more effectively buffer the impact of strain on illegal behaviors among females than males also has not been supported empirically (see Agnew 2006).

Overall, strains and emotions are gendered in ways consistent with Broidy and Agnew's (1997) propositions. Empirical evidence indicates, however, that the gendering of strains and emotions is fairly unimportant for understanding the gender gap in offending. Instead, gender differences appear to emerge because males are more likely than females to respond to strain and negative emotions through illegal behaviors, suggesting that more emphasis should be placed on understanding the gendered messages males and females learn about appropriate methods for dealing with strain and expressing negative emotions.

The significance of Broidy and Agnew's (1997) research for understanding female offending may lay in the attention it draws to strains outside of the economic sphere. This insight has been at the center of some feminist research that focuses on physical and sexual abuse at the hands of family members as particularly relevant for understanding female crime because females are more likely than males to be the victims of such abuse in patriarchal society (see Chesney-Lind 1989). A common coping strategy for dealing with abuse at home – running away – has been criminalized, leading young girls to the criminal justice system or to the streets, where their opportunities for survival are limited, as discussed above. Given that females are valued as sexual objects in patriarchal society, prostitution becomes a viable survival strategy for these girls even though this strategy would be largely unavailable to similarly situated boys (Miller 1986; Chesney-Lind 1989). Although research shows that males and females are equally likely to respond to family abuse with delinquency (see Kruttschnitt and Giordano 2009), the theme underlying this work is that exposure to abuse, the types of abuse to which youths are exposed, and the reasons for abuse may be intimately informed by power relations in patriarchal society. That is, these studies highlight the importance of focusing on the unique problems and circumstances that lead females into crime and delinquency because they lead lives markedly different from males in patriarchal society. We believe this insight also highlights the importance of considering the ways in which patriarchy uniquely shapes males' lives in ways that may make them particularly crime-prone (e.g., Messerschmidt 1993).

Learning Theories

Learning theories contend that crime is motivated by social factors but move away from an emphasis on blocked goals and stressful circumstances to focus on the socialization and interactional processes by which individuals develop and internalize attitudes, behavior patterns, and definitions of situations that promote offending. The original statement of learning theory was Sutherland's differential association theory (Sutherland 1947), which was later reformulated as social learning theory (see Akers 1998). As with other traditional theories of crime, learning theories were not formulated to address sex differences in offending; however, because they focus on differences across groups in orientations toward crime and deviance, even the earliest versions included discussion of differences in the socialization experiences of females and males that are linked to differences in law violation (Sutherland 1947: 100–101). Following this observation, research on the gender gap has explored the ways that sex and gender shape the form and content of learning and interactions that lead to offending. The addition of concepts from feminist theory to this tradition emphasizes an important dimension of gender in society that has not been addressed in traditional learning theories – cultural definitions of gender, which like definitions of law are learned in interactions (e.g., Heimer and De Coster 1999).

A major tenet of learning theories of crime is that people learn definitions and behavior patterns that are both favorable and unfavorable to law violation in interactions with others; when a person's definitions and behavior patterns favorable to offending are in excess, law violation is likely to occur (Sutherland 1947; Akers 1998). Factors that affect interactional patterns – like sex and gender – can be expected to shape learning about crime and delinquency. Research shows that, regardless of sex, people learn law violation from interacting with criminal peers (e.g., Smith and Paternoster 1987) and deviant families (Lonardo et al. 2009). In terms of sex differences, research on juvenile delinquency shows that boys break the law more often than girls in part because boys have more deviant friends and, in some cases, because the impact (i.e., size of the effect) of peer influence is larger for boys (e.g., Heimer and De Coster 1999; Bottcher 2001).

Heimer's (1996; Heimer and De Coster 1999) reformulation of traditional differential association theory draws on the feminist argument that, traditionally, females have been more encouraged than males to focus on care, concern, and the maintenance of interpersonal relationships. Their research shows that close relationships with parents are more important for learning delinquent definitions among females and that a more direct parental control – supervision – is more relevant for boys' learning. These findings suggest that gender differences in learning crime cannot be understood in terms of only male-female differences in levels of supervisions and control, as emphasized by Sutherland (1947); rather, theory and research must also recognize that there are significant differences across sex in the mechanisms through which social groups (e.g., parents) communicate and affect the learning of definitions of crime and delinquency.

In addition, Heimer and De Coster (1999) maintain that it is not enough to consider the learning of definitions of the law; theory and research must also recognize that in gender-stratified societies, people are surrounded by strong cultural definitions of gender that become internalized and operate alongside definitions of the law to influence crime and delinquency. Because the dominant or hegemonic cultural definitions of femininity are more inconsistent with harming others (e.g., through theft or aggression) than are dominant definitions of masculinity, gender definitions would seem to be important for understanding criminal behavior. Indeed, research has shown that traditional conceptions of masculinity and femininity are important for understanding aggression and law violation (e.g., Simpson and Elis 1995; Heimer and De Coster 1999; Bottcher 2001). As such, learning theories cannot be limited to a focus on the cultural product of definitions of the law but also must acknowledge the role of definitions of gender.

Gender Studies, Feminist Theory, and Explanations of Offending

Other research on gender and crime – that is not clearly associated with the three dominant traditions in criminology – also emphasizes the importance of cultural definitions of gender for understanding crime. However, this work stresses the need to consider how race, class, gender, and sexuality shape persons experiences and definitions of gender in ways that deepen our understanding of law violation. We maintain that these developing lines of study are becoming important not for simply understanding gender differences but also for understanding variability in crime and violence among males and among females (De Coster and Heimer 2006).

There is a growing body of research that highlights the importance of hegemonic gender definitions – or culturally dominant ideals about gender. This work draws inspiration from gender studies, especially the theorizing of Connell (1995), which argues that societal definitions of masculinities represent a power hierarchy, with hegemonic masculinities being the idealized masculinity that is accessible to members of powerful groups, such as heterosexual white men from the middle and upper classes. By contrast, marginalized masculinity is constructed by members of oppressed groups as they try to navigate their disadvantages in terms of resources and power. The reaction of marginalized groups to hegemonic masculinity – unattainable to men who cannot demonstrate masculinity via legitimate avenues – can involve the use of violence and crime (e.g., Mullins et al. 2004). Messerschmidt (1993) argues that, over time, violence can become an accepted way to claim masculinity in communities that experience persistent blockage of legitimate avenues for "doing gender". In these settings, men can become culturally accountable to marginalized definitions of masculinity that are characterized by competition through the show of physical power, heterosexuality, and the use of violence (e.g., Mullins et al. 2004; Miller 2008).

Consistent with this, sociological studies suggest that claiming masculinity in extremely disadvantaged urban communities can require demonstrating "nerve" in various ways, including "throwing the first punch, getting in someone's face, or pulling the trigger" (Anderson 1999: 92). Research shows that these conceptualizations of masculinity have important implications for understanding law violation, including street crime and violence against women (e.g., Messerschmidt 1993; Mullins et al. 2004; Miller 2008). Although not born of traditional criminological theory, this line of work has very important implications for understanding variability in offending among males and across groups at different junctures of societal power. While it is clearly important for illuminating the "gender gap," research and theorizing on masculinities and offending has a good deal to offer to criminology *generally* – even to research that does not address sex differences. In short, it shows that "gender matters," in that constructing masculinities is a part of daily life that has implications for crime among men.

What has been less well developed is the relationship between femininities and offending. Some research proposes that normative conceptions of femininity are relatively incompatible with crime and violence (e.g., Simpson and Elis 1995; Heimer and De Coster 1999). This logic, however, has not accounted for variations in femininities but has focused on what gender studies scholars like Connell (1995) call "emphasized" or dominant femininities, which are most accessible to white, middle-class women (see Hill Collins 2004). These dominant femininities – which are inconsistent with the use of crime and violence to solve problems – support hegemonic masculinities and are sometimes not a cultural option for displaying gender among minority and poor women (Simpson 1991; Hill Collins 2004). Consequently, some researchers stress the need to focus on alternative forms of femininities that are more conducive to violence than the hegemonic form, resulting in discussions of "pariah" (Schippers 2007), "bad girl" (Messerschmidt 1997), and "racialized" (Hill Collins 2004) femininities.

Others suggest that females who break the law are not enacting alternative femininities but may be enacting masculinities or using law violation to protect feminine identities (Miller 2001). Indeed, ethnographic studies indicate that females in economically marginalized communities, like males, use violence instrumentally to garner respect and protect identities and reputations. Unlike males, who often are protecting identities as tough and masculine, females more often use violence to defend themselves against threats to their respectability or reputations as “respectable girls” (Miller 2001, 2008; Miller and Mullins 2006; Mullins et al. 2004). Additionally, it has been suggested that crime and violence by females can be a reaction to men displaying masculinity. For example, girls in gangs may act tough to avoid victimization (Miller 2001, 2008), and women may retaliate with violence and other crimes in response to prior and present abuse at the hands of men (Maher 1997). These examples may well be reactions to dangerous environments shaped by patriarchal power structures and not the enactment of hegemonic or alternative femininities.

Generally, there appear to be a variety of mechanisms through which gendered structures and identities influence crime and violence among females. Further articulation of these mechanisms is an important endeavor for the criminological community because theory and research on multiple masculinities and femininities may be particularly well suited for explicating the ways in which race, class, and gender intersect in the production of race-class-gender patterns of offending (De Coster and Heimer 2006).

Conclusions

This research shows that the variables and processes identified as important in the etiology of offending are gendered in ways that contribute to the sex gap in offending. This, of course, marks an important contribution to the understanding of crime and the sex gap in crime; however, a more comprehensive understanding of criminality by males and females requires consideration of variables and processes rooted specifically in gendered arrangements which have been highlighted in feminist and gender studies.

Researchers have incorporated feminist and gender studies into each of the theoretical traditions discussed, demonstrating the utility of wedding traditional criminology with gender and feminist insights by uncovering structural and social-psychological sources of offending by males and females that are shaped by gender – for example, power arrangements, illegitimate opportunities, and cultural definitions of gender – and that heretofore had been de-emphasized or ignored altogether (Hagan et al. 1987, 2004; Chesney-Lind 1989; Heimer and De Coster 1999). These feminist-informed studies are important not only for having reoriented traditional theories of crime but also for having laid the groundwork for the evolution of research on crime rooted more squarely in feminist and gender studies paradigms. This research, though not rooted in traditional criminology, proves promising for pushing traditional criminology forward as it becomes more fully incorporated into general theories of offending.

An important corrective to traditional criminology derived from emerging feminist scholarship on crime is that biological sex and gender socialization should be decoupled to allow for an emphasis on variations in gendered power, identities, and definitions within sex that give rise to offending differences within sex groups. Gender and feminist studies do not simply contribute to our understanding of the gender gap in crime; they significantly expand our understanding of the causes of crime. What we have learned is that even studies of male crime, for instance, are incomplete without consideration of how gender shapes everyday life. The incorporation of this insight into understanding crime is likely to be at the heart also of understanding variations in offending across groups and individuals situated at various junctures in race, class, and gender hierarchies (see De Coster and Heimer 2006).

An essential direction for future work in criminology lies in the integration of traditional criminological perspectives with emerging work on offending rooted in feminist paradigms. Miller and Mullins (2006) recently advised that the most promising direction for the future of feminist criminology resides in work that enriches its analyses of the gendered lives of males and females with work from the broader field of criminology. We add to this that the most promising direction for the future of criminological endeavors generally resides in drawing further insights from feminist studies that underscore the importance of considering how gender structures everyday life.

General Strain Theory

Robert Agnew
Department of Sociology, Emory University,
Atlanta, GA, USA

Overview

General strain theory (GST) states that strains increase the likelihood of crime, particularly strains that are high in magnitude, are seen as unjust, are associated with low social control, and create some pressure or incentive for criminal coping. Examples include parental rejection, criminal victimization, a desperate need for money, and discrimination. These strains increase crime for several reasons; most notably, they lead to a range of negative emotions, which create pressure for corrective action. Crime is one possible response. Crime may be used to reduce or escape from strains (e.g., theft to obtain money, running away to escape abusive parents), seek revenge against the source of strain or related targets, or alleviate negative emotions (e.g., through illicit drug use). A range of factors, however, influence the response to strains. A criminal response is more likely when people lack the ability to cope in a legal manner, are disposed to crime, and the costs of crime are low and the benefits are high. This entry describes the current status of GST, and is organized around a set of propositions dealing with (a) the nature of those strains conducive to crime; (b) the reasons why these strains increase crime; (c) the factors influencing or conditioning the effect of these strains on crime; and (d) efforts to apply GST to new areas, such as group differences in crime.

General Strain Theory: Key Propositions

General strain theory was first proposed in 1992 and has since inspired hundreds of research reports (see Agnew 1992, 2006; Agnew and Scheuerman 2011; Hoffmann 2010). This research has tested the theory, proposed revisions in it, and applied it to new areas. It is therefore important to describe the current state of GST. Further, it is an opportune time to do so, given that 2012 was the twentieth anniversary of the theory. This entry draws on the research to present an updated version of GST, stated in the form of several core and secondary propositions. Each proposition is followed by a definition of key terms, the rationale for the proposition, summaries of the relevant research, and suggestions for further research. Given the large body of research on GST, it is only possible to cite previous reviews of GST and certain of the more recent research. And what follows is of course the author's view of the current state of GST; others may argue for additional revisions in and extensions of the theory. In fact, the chapters on GST in this volume by Baron, Slocum, and De Coster propose several major extensions in GST.

As the propositions below make clear, the basic form of GST remains intact. Certain strains increase the likelihood of crime, in part through their impact on negative emotions, with a range of factors influencing the likelihood of a criminal response. But the original statement of theory has been revised and extended in numerous ways. As noted below, the theory now better specifies the types of strain most likely to result in crime, more fully describes why these strains increase crime, and lists additional factors that may condition the effect of strains on crime. Also, the theory has been extended to explain group differences in crime, offending over the life course, and a broader range of crimes and deviant acts. At the same time, the theory is in need of further development in several areas. Most notably, the theory needs to better explain why some individuals are more likely than others to cope with strains in a criminal manner. Related to this, there should be an effort to better link GST to biological factors and larger social forces – both of which influence the exposure and reaction to strains. And efforts should be made to apply GST to the control of crime and the analysis of the criminal justice system.

The Nature of Those Strains Conducive to Crime

1. *Certain strains increase the likelihood of crime*. Strains refer to events and conditions that are disliked by individuals (Agnew 1992, 2006). Strains are similar to "stressors," but the term "strain" is used to emphasize the fact that GST is derived from prior strain theories in criminology and that it does not focus on all stressors, but rather on a subset of stressors conducive to crime. Strains may fall into one *or more* of three broad categories: (a) the inability to achieve valued goals (e.g., monetary, status goals), (b) the loss or threatened loss of valued stimuli (e.g., material possessions, the death of family members), and (c) the presentation or threatened presentation of negative stimuli (e.g., verbal and physical abuse). For example, an insult may involve the failure to achieve a valued goal (respect), the loss of valued stimuli (respectful treatment), and the presentation of a negative stimulus (the insult itself). The three categories of strain are presented not because they are necessarily distinct from one another, but rather to ensure that researchers consider a broad range of strains.

1a. *Those strains most conducive to crime (a) are high in magnitude; (b) are seen as unjust; (c) are associated with low social control; and (d) create some pressure or incentive for criminal coping*. These characteristics increase the likelihood that strains will impact those intervening mechanisms that lead to crime (see below). For example, strains that are high in magnitude and seen as unjust, such as an unprovoked physical attack, are more likely to make individuals angry than strains without these characteristics, such as an accidental bump. Agnew (2001, 2006) provides further information on these characteristics, including strategies for their measurement. Strains that are high in magnitude are high in degree (e.g., a large versus small financial loss), are frequent, recent, of long duration, and expected to continue into the future. Also, such strains are high in centrality; that is, they threaten the *core* goals, needs, values, activities, and/or identities of the individual. Strains that are seen as unjust typically involve the voluntary and intentional violation of a relevant justice norm or rule. Strains associated with low social control involve little direct control by others, weak attachment to conventional others, and/or little investment in conventional institutions. An example is parental rejection. Juveniles experiencing this strain are usually poorly supervised by and weakly bonded to their parents. Finally, strains that create some pressure or incentive for criminal coping are easily resolved through crime and/or involve exposure to others who encourage or model crime. For example, that strain involving a desperate need for money is readily resolved through crimes such as theft, drug selling, and prostitution. That strain involving the inability to achieve educational success, however, is not so easily resolved through crime. To give another example, strains involving criminal victimization expose individuals to others who model crime.

Several specific strains tend to possess the above characteristics, including parental rejection; erratic, excessive and/or harsh discipline; child abuse and neglect; negative secondary school experiences (e.g., low grades, poor relations with teachers); abusive peer relations; work in the secondary labor market (jobs with low pay, few benefits, poor working conditions); unemployment, especially when chronic and blamed on others; certain marital problems (frequent conflicts, verbal and physical abuse);

the failure to achieve selected goals (thrills/excitement, autonomy, masculine status, the desire for much money in a short period of time); criminal victimization; residence in economically deprived communities; homelessness; and discrimination based on race/ethnicity, gender, and religion. Research suggests that these strains increase the likelihood of crime, with some being among the most important causes of crime (see Agnew 2006; Agnew and Scheuerman 2011; Baron 2009).

Researchers, however, need to devote more attention to certain of these strains, such as discrimination (e.g., Eitle 2002; Simons et al. 2003). Also, researchers should explicitly measure characteristics such as the magnitude and perceived injustice of strains, determining if variation in them affects crime (see Agnew 2006; Rebellon et al. 2009). Unfortunately, the research on GST sometimes employs measures of strain that are rather general; so it is not clear whether the strains examined possess the above characteristics. For example, researchers often measure the experience of strains by employing checklists that ask such things as whether a family member has died. But when explaining crime, it makes a great deal of difference whether the death involved a great-grandmother who died of natural causes (moderate magnitude, little injustice) or a brother who was shot by rival gang members (high magnitude, high injustice). Related to this, there is a need for *qualitative* research on the nature of and response to strains; such research will allow for the detailed measurement of the nature of strains and perhaps suggest other characteristics that should be considered when explaining crime.

1b. *Strains may be objective or subjective in nature, with subjective strains having a greater effect on crime*. Objective strains refer to events and conditions disliked by most people in a given group. Subjective strains refer to events and conditions disliked by the people experiencing them (Agnew 2006). Research indicates that individuals often differ a good deal in their subjective evaluation of a given objective strain, such as divorce. Some individuals view their divorce as the worst thing that ever happened to them, while others view it as a cause for celebration. Subjective strains should have a greater impact on crime since they are more likely to trigger negative emotional reactions and other of the intervening processes conducive to crime (see below). At the same time, objective strains may increase crime even when not subjectively disliked, since these strains may still have criminogenic effects (e.g., they may lower social and self-control). Most studies employ objective measures of strain, focusing on events and conditions assumed to be disliked by most people. The few studies that have examined both objective and subjective strains have produced mixed results; only some find that subjective strains have a stronger effect on crime (e.g., Froggio and Agnew 2007). More research is needed in this area, including research that measures the subjective interpretation of strains in more detail. For example, are strains perceived to be high in magnitude and are they blamed on others (a key component of perceived injustice). Baron (2008) provides an excellent illustration of the potential value of such research, finding that the manner in which unemployment is interpreted has a major impact on whether it affects crime.

1c. *Strains may be experienced, vicarious, and anticipated, with experienced strains having a greater effect on crime*. GST focuses on the individual's personal experiences with strains, but certain vicarious and anticipated strains may affect crime (Agnew 2006; Baron 2009). Vicarious strains refer to the individual's awareness of strains experienced by others. Such strains are more likely to affect crime if they involve close others, such as family and friends; the individual feels some responsibility for the welfare of these others; the strains have the characteristics listed in 1a; and the strains signal a threat to the individual. An example involves the shooting death of a fellow gang member by those in a rival gang. Anticipated strains refer to the individual's expectation that current strains will continue into the future or that new strains will be experienced. Anticipated strains are more likely to result in crime when individuals believe that they have a high probability of occurring in the near future and they have the characteristics listed in 1a. Experienced strains should be more likely to affect crime than vicarious and anticipated strains, since they pose a more direct and immediate problem for individuals. At the same time, research on criminal victimization indicates that the victimization of close others and the anticipated victimization of oneself may increase crime (Agnew 2002; Baron 2009). Research on other types of vicarious and anticipated strain is needed (e.g., financial hardship experienced by close others, the anticipation of financial difficulties by corporate executives).

1d. *Strains are more likely to affect crime when they are clustered together in time*. The temporal clustering of strains is more likely to result in the criminogenic effects described below, such as the taxing of legal coping resources (see Agnew 2006). And certain research suggests that crime is more likely when several strains are experienced at the same time (Slocum et al. 2005). This clustering effect implies an interaction: The effect of a given strain on crime will be stronger when other strains are present. It is often difficult, however, to examine the many interactions between multiple strains. But researchers can examine both the separate and the cumulative effects of strains, with the cumulative effect being measured in terms of the number of criminogenic strains experienced at the same time or close together in time. Crime should become more likely as this number increases. More research is needed in this area, however. Among other things, the nature of this cumulative effect needs to be better specified. For example, it may be the case that the cumulative strain measure has a nonlinear effect on crime, such that further increases in the number of strains beyond a certain threshold point have little effect on crime.

Why the Above Strains Increase Crime (Intervening Processes)

2. *The strains listed above increase the likelihood of crime for several reasons; most notably, they lead to negative emotional states, which create pressure for corrective action – with crime being one possible response*. Recall that strains refer to disliked events and conditions, with the most criminogenic strains being high in magnitude and perceived as unjust. Not surprisingly, these strains lead to negative emotions such as anger, frustration, and/or depression. These emotions create pressure for corrective action: Individuals feel bad and want to do something about it. Crime is one response. Research suggests that state anger partly explains the effect of strains on crime, especially violence. And research has begun to focus on the mediating role played by other emotions, such as depression (Agnew 2006; Agnew and Scheuerman 2011). It is beginning to appear that some types of strain may be more conducive to certain negative emotions than others, and that some negative emotions may be more conducive to certain crimes than others. For example, anger may be more conducive to externalizing behaviors such as aggression, while depression may be more conducive to internalizing behaviors such as drug use. More research is needed in this area. Research is also needed on the reasons why negative emotions increase crime; for example, anger may increase aggression because it energizes individuals for action, creates a desire for revenge, reduces concern for the consequences of one's behavior, and/or limits the ability to engage in many legal coping behaviors – such as negotiation (Agnew 2006).

2a. *Strains reduce the ability to legally cope, making crime seem like a rational option*. A large financial loss or chronic unemployment, for example, may exhaust one's financial resources, leaving few legal options for obtaining money. Consequently, crime may appear to be the most effective way to respond to strain. As such, strains may sometimes lead to crime in the absence of negative emotions (see Hoffmann 2010).

2b. *Strains may also increase crime because they foster traits conducive to crime, particularly negative emotionality/trait anger and low constraint/low self-control*. This is especially true of chronic strains (Agnew 2006; Colvin 2000). Chronic strains tax legal coping resources, such that individuals are more easily upset when they experience new strains (a key characteristic of trait anger and negative emotionality). Also, certain strains – such as harsh and erratic discipline – may foster low constrain or low self-control.

Individuals must be taught to exercise self-restraint, and this occurs when they are consistently sanctioned for misbehavior in a reasonable manner. There is limited support for these arguments, with several studies finding that strains reduce self-control and, especially, increase trait anger/negative emotionality (Agnew 2006; Colvin 2000). Further, these traits partly mediate the effect of strains on crime. More research is needed here, however, particularly longitudinal research.

2c. *Strains may increase crime because they reduce social control*. Strains frequently involve negative and unjust treatment by others, including parents, spouses, teachers, employers, and those in the criminal justice system. Such strains may reduce attachment to these others, as well as commitment to school, work, and the criminal justice system. Individuals experiencing negative treatment may also limit their contact with these others: in some cases, running away from parents, dropping out of school, divorcing spouses, and quitting jobs. This reduces direct control, since these others are less able to monitor and sanction criminal behavior. Further, these effects may weaken beliefs condemning crime, since ties to those others who teach conventional beliefs are undermined. Beyond that, certain strains – such as chronic unemployment and homelessness – overlap with low social control. Researchers usually do not examine the effect of strains on social control, but several studies – some of which are longitudinal – have found that strains reduce the major types of control (Agnew 2006).

2d. *Strains may increase crime because they foster the social learning of crime*. Strains may increase the likelihood of association with criminal peers, a point emphasized by classic strain theorists (see Agnew 2006). Strains increase association with criminal peers by weakening social control, which frees individuals to associate with criminal peers, and by increasing the appeal of criminal groups. In particular, criminal groups are often seen as a solution to the strains one is experiencing. For example, criminal groups often provide status, protection from others, and opportunities to make money. In additions, strains foster beliefs conducive to crime. Individuals being treated in a negative and unjust manner by others are more likely to develop justifications and excuses for crime (e.g., peer abuse justifies violence, chronic unemployment excuses theft). Several studies provide support for these arguments (e.g., Agnew 2006).

2e. *Strains may have both contemporaneous and lagged effects on intervening variables and crime*. The experience of particular strains most often has a contemporaneous effect on intervening variables and crime. For example, imagine that a parent ridicules a child. This ridicule likely has a fairly immediate effect on the child's anger and attachment to the parent, and may lead to delinquent acts in the near term – such as striking the parent or running away from home. But with time, the child's anger and dislike of the parent fades, along with the likelihood of delinquency. In certain cases, however, strains may have lagged as well as contemporaneous effects on delinquency. This is the case with strains that are very high in magnitude, such as sexual abuse, and with chronic or persistent strains. Such strains may lead to negative emotional *traits*, to long-term reductions in the ability to legally cope, to long-term reductions in social control, and to long-term associations with criminal others and beliefs favorable to crime. For example, parents who regularly discipline their children in a harsh manner may lead the children to develop the trait of negative emotionality, may permanently reduce levels of parental attachment, and may foster the belief that violence is an appropriate response to certain problems. As a result, this chronic strain is likely to have both a contemporaneous and lagged effect on delinquency. When longitudinal data are available, researchers should attempt to estimate the contemporaneous effects of strains on crime and, where appropriate, the lagged effects as well.

Factors that Influence the Effect of Strains on Crime (Conditioning Variables)

3. *There are numerous ways to cope with strains, with a range of factors influencing the likelihood of criminal coping*. Criminal coping is more likely among those who (a) have poor conventional coping skills and resources (e.g., poor

problem-solving and social skills, low self-efficacy, limited financial resources), (b) have criminal skills and resources (e.g., criminal self-efficacy), (c) have low levels of conventional social support, (d) are low in social control, (e) associate with other criminals, (f) hold beliefs favorable to crime, (g) have traits conducive to crime (e.g., negative emotionality, low constraint), and (h) are more often exposed to situations where the costs of crime are low and the benefits high (Agnew 2006). Researchers have added to the list of conditioning variables since GST was introduced in 1992, pointing to the importance of environmental variables such as religious involvement and traits such as low self-control (Agnew 2006; Jang and Johnson 2005). The research on conditioning effects, however, has produced mixed results – and this constitutes perhaps the greatest puzzle regarding GST. Agnew (2006) lists several possible reasons for these mixed results, including methodological problems that make it difficult to detect conditioning effects in survey research, problems in the measurement of certain conditioning variables, and the fact that researchers usually consider the conditioning variables in isolation from one another. Criminal coping should be most likely among those who possess all or most of the factors conducive to such coping, an argument that has received some support (Mazerolle and Maahs 2000).

Research is needed to better investigate these possibilities (see Agnew 2006). Also, researchers should attempt to better draw on the bio-psychological research, which suggests that there are substantial differences between individuals in their sensitivity and reaction to stressors. Biological markers for these differences have been identified, and researchers should examine whether they condition the effect of strains on crime (Moffitt et al. 2011). Further, researchers should draw on the coping literature, which describes a range of strategies that individuals employ to cope with stressors (Agnew 2006). Some strategies appear to be more effective than others, although the effectiveness of particular strategies may vary by the type of stress. For example, religious involvement may be an effective way to cope with the death of a family member, but not with peer abuse. Researches should determine if certain strategies are more often linked to crime and, if so, they should examine the factors affecting the use of these strategies. Related to this, researchers should also examine whether past experiences with strains *reduce* the effect of current strains on crime, particularly in cases where the past strains were successfully resolved. Past experiences with strains may improve one's coping skills and increase one's tolerance of current strains.

Extending General Strain Theory

4. *GST can help explain group differences in crime, including socio-demographic, community, and societal differences.* Certain groups have higher crime rates than others because they are (a) more exposed to the criminogenic strains described above; (b) more likely to react to these strains with negative emotions; and/or (c) more likely to cope with these strains and negative emotions through crime, because they differ in their standing on one or more of the conditioning factors listed above. GST has been used to explain gender, race/ethnic, age, social class, community, and societal differences in crime (e.g., Agnew 2006; Bao and Haas 2009; Brezina et al. 2001; De Coster and Zito 2010; Froggio and Agnew 2007; Jang and Lyons 2006; Kaufman et al. 2008; Perez et al. 2008; Simons et al. 2003; Warner and Fowler 2003). Research suggests that GST applies to a range of groups and that it often helps explain group differences in offending. However, it is somewhat difficult to generalize from these studies. They frequently examine different strains, emotions, and conditioning variables; employ different measures; and examine different types of samples. So at present, there is still some uncertainty about how groups differ in the extent and nature of the strains they experience, as well as in their reaction to these strains. More research is needed here. Related to this, criminologists should attempt to link GST with macro-level theories – which can shed light on why and how groups differ in strains and the reaction to them. GST is a social-psychological theory, but it is compatible with a range of

macro-level theories, including most critical theories, feminist theories, and Institutional Anomie Theory (see Agnew 2006). Such theories discuss group differences in the experience of certain strains (e.g., types of gender oppression) and often provide some insight into group differences in the reaction to strain (e.g., gender differences in values and levels of control).

5. *GST can help explain patterns of offending over the life course, including "adolescence-limited" and "life-course-persistent" offending* (see Agnew 2006; Slocum 2010). Offending increases during adolescence because the social environment and biology of adolescents are such that they experience more criminogenic strains and associated negative emotions, and are more likely to cope with these strains/emotions through crime. Some individuals offend at high rates over much of their lives because (a) they possess relatively stable traits that increase their exposure to criminogenic strains and their likelihood of criminal coping; (b) they are part of the urban underclass, which increases their exposure to criminogenic strains and their likelihood of criminal coping, with an amplifying loop being set into motion – their criminal and other negative responses to strains increase the likelihood of further strains; and/or (c) they experience "stress proliferation," wherein the experience of certain strains leads to further strains (e.g., chronic unemployment leads to family conflict). Several studies have found that the level of strain over time is associated with the level of crime, and recent research has begun to test the explanations for the patterns of offending just described (e.g., Agnew 2006; Eitle 2010; Slocum 2010).

6. *GST can help explain situational variations in crime, with such variations partly due to situational variations in strain – particularly provocations*. Most crime research focuses on the factors that create a general predisposition for crime, but even highly predisposed individuals only engage in crime in certain situations. The routine activities perspective has dominated the explanation of situational variations in crime, arguing that crime is most likely in situations where motivated offenders encounter attractive targets in the absence of capable guardians. But qualitative data suggest that crime is also likely in situations where individuals encounter much strain; most notably, violent crime often results when individuals are provoked by others, with such provocations usually involving verbal and physical abuse. And property crime appears more likely in situations where individuals have a desperate need for money (Agnew 2006; Hoffmann 2010). More research is needed here, particularly survey research that builds on the qualitative studies (see Slocum et al. 2005).

7. *GST can explain a range of crimes and deviant acts beyond street crimes, although the theory should be customized to maximize explanatory power*. GST has been applied to the explanation of white-collar and corporate crime, terrorism, states crimes such as genocide, self-harming behaviors such as suicide attempts and eating disorders, cyber-bullying, police deviance, and other criminal/deviant acts (e.g., Agnew et al. 2009; Agnew 2010a; Hay et al. 2010; Maier-Katkin et al. 2009; Piquero et al. 2010). It is often the case that "customized" versions of GST are developed for each type of crime and deviance, with each version pointing to those strains and conditioning variables that are especially relevant. For example, the strains that prompt corporate crime or terrorism differ somewhat from those that prompt street crimes, although many strains are relevant across a range of crimes.

8. *GST can guide efforts to control crime, with such efforts reducing the exposure to criminogenic strains and the likelihood of criminal coping*. A variety of approaches may be employed here, including (a) reducing those strains conducive to crime (e.g., reducing child abuse, raising the minimum wage); (b) altering strains to make them less conducive to crime (increasing the perceived justice of criminal sanctions through the restorative justice approach); (c) removing people from criminogenic strains (e.g., from abusive homes or schools); (d) equipping people with the traits and skills to avoid criminogenic strains (e.g., teaching people to behave in a less provocative manner); (e) altering the perceptions or goals of people to reduce subjective strain (e.g., reducing

the emphasis on consumerism); (f) improving coping skills and resources (e.g., teaching problem-solving skills); (g) increasing social support (e.g., mentoring programs); and (h) reducing the disposition for criminal coping (e.g., altering beliefs conducive to crime). There have not yet been any attempts to use GST to reduce crime, although GST is compatible with a range of successful crime control programs (see Agnew 2006, 2010b).

GST can also be used to shed light on the nature and operation of the criminal justice system. In particular, strains may influence the focus of the criminal justice system (e.g., high levels of strain in the general population, such as unemployment, may contribute to more punitive criminal justice policies). Related to this, strains may influence public attitudes toward criminal justice (e.g., individuals experiencing certain strains may place more emphasis on punitive approaches). Strains may also influence the attitudes, behavior, and effectiveness of law enforcement, court, and corrections workers (e.g., strains may contribute to police deviance and turnover among prison staff). And strains may influence the attitudes and behavior of those processed by the criminal justice system (e.g., prison strains may affect inmate behavior and recidivism). A few recent studies have applied GST to the analysis of the criminal justice system (e.g., Blevins et al. 2010), and hopefully more work will be done in this area.

Conclusion

General strain theory has much support and has established itself as one of the leading theories of crime. In particular, there is much evidence that the strains identified by the theory impact crime and that they do so partly through negative emotions. GST is also increasingly being applied to new issues, such as the explanation of group differences in crime and offending over the life course. At the same time, certain parts of the research on GST have produced mixed results, particularly research on those factors said to condition the effect of strains on crime; several areas of the theory are in need of further exploration; and numerous opportunities for applying the theory to new areas remain.

Low self-control; Self-control theory

Overview

The self-control-crime/deviance link has been well established empirically, with over two decades of studies indicating that self-control is a robust predictor of a host of criminal and analogous behaviors under an equally wide array of methodological conditions. This pattern appears to be such a "given" that the field has largely moved on to other areas of self-control research, such as assessing the other harmful consequences of self-control, like criminal victimization, to testing the degree to which self-control is or is not stable within individuals over time, and to examining the "causes" of low self-control. This entry takes stock of these more recent developments within the self-control tradition.

Introduction

Gottfredson and Hirschi's (1990) self-control theory has stimulated a considerable amount of research and discussion regarding the influence of low self-control on criminal and analogous behaviors. As originally formulated, Gottfredson and Hirschi's (1990) self-control theory predicts that individuals with low self-control are more predisposed to engage in a host of criminal and analogous acts. This is because those lacking self-control tend to pursue their own self-interest without consideration of the potential long-term consequences of their behavior. Criminal behavior therefore becomes attractive to those with low self-control because it can be exciting and immediately gratifying.

The self-control-crime/deviance link has been well established empirically, with over two decades of studies indicating that self-control is a robust predictor of a host of criminal and analogous behaviors under an equally wide array of methodological conditions (Pratt 2009; Pratt and Cullen 2000). To be sure, research has revealed that those with low self-control are significantly more likely to be a general offender, a versatile offender, a cheater on exams, a software pirate, and even a drunk-dialing user of profanity in public spaces (see Pratt and Cullen 2000; Reisig and Pratt 2011). These findings are sufficiently robust that criminologists have turned their attention to other areas of self-control research, such as the link between self-control and criminal victimization, the stability of self-control over time, and to the biological, familial, and contextual sources of low self-control. Each of these more recent developments is discussed here.

Self-Control and Victimization

It has been well established that, above all, individuals with low self-control are thrill seekers. In the pursuit of self-pleasure, such individuals feel the need to frequently engage in dangerous, reckless, and risky behaviors that provide them with a sense of excitement. Such individuals are unlikely to consider how their behavior may impact others nor would they be likely to spend time contemplating how engaging in such activities might put them at risk for numerous negative outcomes – one of the most serious of which may be victimization. Indeed, a large body of work has demonstrated that those who engage in deviance are more likely to be victims of crime, even when the degree of deviance is minor (e.g., Lauritsen et al. 1991; Turanovic and Pratt 2013a). Researchers have recently expanded upon these conclusions and have started to explore the relationship between self-control and victimization.

Traditionally, the study of victimization has been limited to situational approaches that emphasize the role of opportunity, such as routine activity (Cohen and Felson 1979) and lifestyle theories (Hindelang et al. 1978). Routine activity explanations suggest that individual patterns of behavior increase victimization through the space-time convergence of likely offenders, suitable targets, and the absence of capable guardians, while lifestyle theory similarly puts forth that individuals may engage in daily behaviors that expose them to crime and risky circumstances. In the past decade or so, scholars have broadened the scope of this inquiry by exploring other avenues that may explain victimization risk and looked further into why certain individuals are more likely to find themselves in high-risk situations. In particular, Schreck (1999) extended and reformulated Gottfredson and Hirschi's (1990) conceptualization of self-control into a theory of vulnerability. Schreck argued that the processes that determine individuals' lifestyle choices and exposure to risk could be explained by their levels of self-control. Put simply, because individuals with low self-control are shortsighted and take part in impulsive, unsafe behaviors, they may differentially place themselves in dangerous situations and might be less likely to take the precautions necessary to avoid being a victim of crime.

Specifically, Schreck suggested that each dimension of low self-control – lack of future orientation, risk taking, lack of empathy, low tolerance for frustration, lack of diligence, and preference for physical over mental activity – has the potential to increase individuals' risks of being victimized. In short, each element of low self-control is associated with an aspect of vulnerability, increasing the attractiveness of these individuals (and their belongings) to motivated and opportunistic offenders. For example, since individuals with low self-control tend to have a low tolerance for frustration and are quick to anger, Schreck argued that these individuals may be more likely to behave in a belligerent manner that can provoke a criminal attack. And since those with low self-control prefer physical over mental tasks, these individuals may be less likely to use their cognitive skills to assess and diffuse hostility. Instead, they may be more likely to react to threat in a defensive or aggressive manner, which may make the situation worse. Having low self-control may also seriously impede a person's ability to carefully and consistently protect his or her belongings. Due to shortsightedness and lack of diligence, such individuals may chronically fail to set alarms, lock doors, and become impatient with procedures associated with arming complex security devices.

Schreck's (1999) extension of self-control theory has received considerable empirical support, both in predicting violent and nonviolent victimization, especially among individuals who also engage in offending. While this area of research is still relatively new, existing studies have consistently found low self-control to be among the most important predictors of criminal victimization – a finding which has held up across a variety of contexts, even when controlling for other robust criminogenic risk factors. Specifically, empirical examinations have demonstrated that self-control increases vulnerability to personal, property, violent, and sexual victimization, as well as the likelihood of fraud and internet theft (Franklin 2011; Holtfreter et al. 2008; Schreck et al. 2006). It is important to note, however, that while self-control can strongly predict victimization in many forms, it has not been found to fully moderate the effects of routine activity/lifestyle variables on victimization. Indeed, self-control has been found to exert both direct *and* indirect effects on victimization. For instance, associating with deviant peers and engaging in "risky lifestyles" (such as offending, substance use, risky sexual behaviors) have also been found to increase the probability of victimization, independent of one's level of self-control (Franklin 2011; Schreck et al. 2006; Turanovic and Pratt 2013b). What these findings have brought to light is that neither self-control nor routine activity/lifestyle perspectives *alone* can fully account for victimization. As a result, scholars have been urged to integrate self-control and opportunity theories together in order to develop a more accurate and comprehensive understanding of victimization and vulnerability (see Holtfreter et al. 2008).

While empirical findings demonstrate the importance of combining self-control and routine activity/risky lifestyle perspectives to predict victimization, there has been substantial variation in how these routine behaviors are captured – most likely because a vast array of actions can potentially be deemed as "risky." For example, in their assessment of low self-control on disaggregated personal and property victimization, Schreck et al. (2006) conceptualized risky lifestyles as violent, property, and drug delinquency in addition to having delinquent friends, while Franklin (2011) incorporated such acts as risky sexual behaviors, illegal drug use, alcohol consumption, and pornography consumption in her assessment of self-control on violent sexual victimization. It is important for scholars to begin to systematically identify which types of risky lifestyles put those with low self-control most at risk for particular forms of victimization.

Because this area of research is still developing, relatively little is known about the effects of low self-control on types of victimization that are largely directed towards women, such as sexual assault and domestic violence. To be sure of the aforementioned studies conducted since Schreck (1999) proposed his vulnerability hypothesis, only a few controlled for gender (e.g., Holtfreter et al. 2008; Schreck et al. 2006), and less have looked at the impact of self-control on the victimization of women independent of men (e.g., Franklin 2011). While the research is in short supply, the findings of these studies are promising enough to invite further explorations into how self-control influences the unique victimization experiences of women.

Additionally, as research in this area progresses, scholars will likely devote more attention to the longitudinal consequences of self-control on victimization. Schreck et al. (2006) demonstrated that those with low self-control are more likely to experience repeated victimization, but the roles of routine activity/lifestyle factors in this process need to be explored further. Those with low self-control may be less willing, and less able, to restructure their "risky" behavioral routines following an initial victimization incident. For some, victimization may be a mere price to pay for the pleasure of engaging in deviant activities. All told, self-control is not only paramount to the study of criminality – it is also gaining support as a vital component to the study of victimization. While findings have been largely consistent in demonstrating that self-control is a robust predictor of victimization, additional research is still needed to help strengthen and clarify the preliminary work in this area.

The Stability (or Not) of Self-Control

One of the more controversial propositions regarding the general theory of crime concerns the "stability thesis" specified by Gottfredson and Hirschi (1990). They argued that self-control is developed early in childhood, usually by around the age of 10 or so, primarily through parental socialization efforts, and is relatively stable throughout the life course. This proposition is potentially problematic, of course, because of the well-known "age-crime curve," where individual rates of criminal behavior generally rise and peak in the late teen years and decline steeply from the early 20s and beyond. How, then, can the key "cause" of crime remain stable within individuals even though their participation in criminal behavior can vary considerably over time?

Scholars have examined this issue longitudinally with mixed results – where some studies indicate high levels of stability in self-control over time, at least in the short term (e.g., Beaver and Wright 2007), others have found evidence of more moderate correlations between measures of self-control taken at repeated points in time (e.g., Burt et al. 2006). Perhaps most telling is Hay and Forrest's (2006) analysis of data from the National Longitudinal Survey of Youth (NLSY) – a nationally representative longitudinal dataset. While their analyses revealed fairly strong stability in self-control overall, there was a nontrivial portion of the sample (16 %) whose levels of self-control changed substantially between ages 7 and 15.

Of course, an argument could be made that Gottfredson and Hirschi (1990) were really only referring to "relative" stability in this context; that is, the relative ranking between individuals should remain fixed over time even if absolute levels of self-control can change with age. Hirschi and Gottfredson (2001: 90) later clarified this point when they stated that "the *differences* [in self-control] observed at ages 8 to 10 tend to persist. . .Good children remain good. Not so good children remain a source of concern to their parents, teachers, and eventually to the criminal justice system" (emphasis added). Even so, Gottfredson and Hirschi (1990) were never explicit about *why* absolute levels of self-control would increase with age or what would explain the variation between individuals concerning how much or how little self-control would be gained over time.

A more fundamental problem, however, might have to do with the conceptualization of self-control itself (see, e.g., the discussion by Pratt 2009). In particular, criminologists' focus on individuals' *levels* of self-control has caused them to miss another key component within this theoretical tradition: within-individual *variability* in self-control. Indeed, recent research regarding changes in self-control over time (Hay et al. 2006), the disaggregation of the desire to exercise self-control versus the ability to exercise self-control (Tittle et al. 2004), Hirschi's (2004) own recent revision of self-control theory, and especially the recent research on the "depletion" of self-control under stressful conditions (Muravin et al. 2006) all hint at – to a greater or lesser degree – the importance of within-individual variation in self-control from one situation to the next. Since research into this question has only begun to emerge, it appears that the "stability thesis" of self-control is far from settled.

Part of the problem is that getting to this question empirically is no easy task. It requires either one of two things, the first of which would be longitudinal data with uniform indicators of self-control measured repeatedly over time, so one could assess directly changes that do or do not occur. In this scenario, it would be necessary to have a wide age range; that is, knowing how self-control changes (either absolutely or relatively) between, say, age 13 and 50, would be more empirically and theoretically important than knowing how it changes from age 13 to 15. A second approach would entail the use of experimental data where situational characteristics could be manipulated to induce self-control depletion under a variety of contextual conditions *that might actually occur in "the real world"* (e.g., conditions of economic deprivation and the reality of human interactions that follow from it, including the presence of, e.g., cultural values associated with the "code of the street" as identified). Neither of these approaches come cheap or easy. Nevertheless, pursuing them may be the next necessary step in self-control-crime research. And if additional research uncovers that self-control is, in fact, much more fluid and malleable over the life course than Gottfredson and Hirschi (1990) originally contended, the theory itself may need to be revised.

The Causes of Self-Control

While the link between self-control and crime/deviance has been consistently demonstrated empirically, what is less clear at this point is how self-control is established within individuals. The primary explanation regarding the genesis of self-control in the criminological literature is Gottfredson and Hirschi's (1990) parenting thesis. In short, Gottfredson and Hirschi contend that self-control will develop in children through effective parenting, where parents who monitor their kids' behavior recognize deviant behavior when it happens and punish such behavior consistently will produce in their children the internal control mechanisms necessary for resisting the temptations that criminal and deviant behavior provide.

Support for this proposition is certainly present. Polakowski's (1994) analysis of data from the Cambridge Youth Study; Feldman and Weinberger's (1994) assessment of 81 sixth-grade boys; the student samples analyzed by Cochran et al. (1998) and by Gibbs et al. (1998); and Hay's (2001) survey of 197 urban high school youth have all explored the dynamics of parenting and self-control. Others have followed suit as well (see, e.g., Pratt et al. 2004; Turner et al. 2005; Unnever et al. 2003), with Perrone et al. (2004) analysis of the data from the first wave of the National Longitudinal Study of Adolescent Health (a nationally representative sample of over 13,000 youth) providing some of the most convincing evidence. Indeed, with the exception of Cochran et al. (1998) study of self-control and academic dishonesty, the research conducted thus far generally lends credence to the notion that, net of statistical controls, parental efficacy is important to the process of developing self-control in children.

Nevertheless, empirical evidence has emerged indicating that the processes that establish individuals' levels of self-control are more complex than those specified by Gottfredson and Hirschi. Specifically, research has begun to emerge that examines alternative sources of low self-control. For example, research has found that indicators of biological predisposition (e.g., ADHD, indicators of neuropsychological deficits such as low birth weight and low cognitive ability; please see Kevin Beaver's contribution to this volume concerning the biological and genetic sources of low self-control) are significantly related to levels of self-control independent of measures of effective parenting (McGloin et al. 2006; Unnever et al. 2003). In addition, controls for such biological/neuropsychological factors tend to partially mediate – and in some cases fully mediate – the effect of parenting on the development of self-control (see, e.g., Wright and Beaver 2005). Taken together, this research indicates that certain biological and neuropsychological risk factors need to be considered in the formation of self-control.

Furthermore, criminologists have begun to focus on how different types of neighborhoods influence parenting behavior and, in turn, the development of self-control in children. The first study in this tradition was Pratt et al. (2004) analysis using data drawn from the National Longitudinal Survey of Youth (NLSY), which found that conditions of neighborhood deprivation significantly influenced measures of parental monitoring and socialization. Furthermore, such neighborhood conditions directly affected the development of self-control in children independent of measures of parental efficacy. A subsequent study by Hay et al. (2006) went a step further and found a significant interaction term between neighborhood conditions and parental efficacy on the development of self-control. As such, this work clearly indicates that community context is yet another factor that must be seriously considered by scholars with regard to the development of self-control in children.

Finally, Gottfredson and Hirschi (1990: 105) suggested that "like the family, the school in theory has the authority and the means to punish lapses in self-control." And as Denise Gottfredson (2001: 48) also observed, "schools have the potential to teach self-control and to engage informal social controls to hold youthful behavior in check." Empirical work has recently emerged that has tested these various propositions. Turner et al. (2005) analysis of the NLSY data revealed two conclusions along these lines. First, indicators of "school socialization" (which closely resembled typical parenting measures associated with the monitoring and supervision of children) were significantly related to the development of self-control independent of parental efficacy. Second, the effects of school socialization on youths' levels of self-control varied according to (i.e., interacted with) levels of parental efficacy, as well as conditions of neighborhood deprivation. In particular, the effect of school socialization on children's development of self-control was strongest when parental efficacy was low and when neighborhood conditions were criminogenic. These results therefore highlight the ability of social institutions – in this case the school – to "pick up the slack" for instilling self-control in children when other mechanisms, such as parents and the community, break down. Put simply, based on the body of empirical research presented above, it is clear that the causes of how and why self-control develops within individuals are far more complex than the simple parenting thesis offered by Gottfredson and Hirschi (1990).

Conclusions

When it comes to Gottfredson and Hirschi's (1990) general theory of crime, there is a lot that we know. For example, we know that the core theoretical proposition specified by Gottfredson and Hirschi – that a wide array of criminal and deviant behaviors are the result of low self-control – is extremely well supported in the criminological literature. Yet in the process of laying out why low self-control should lead to criminal behavior, they also made a number of corollary assumptions to support the self-control-crime thesis, such as those assumptions surrounding the link between self-control and victimization, the stability thesis, and the cause of low self-control.

Accordingly, we seem to know less about these corollary assumptions. On the one hand, it is true that there is convincing evidence of a link between self-control and victimization, that self-control is somewhat stable over the life course, and that parenting "matters" when it comes to instilling self-control in children. On the other hand, there seems to be equally convincing evidence that self-control is quite fluid and flexible within individuals and that the sources of self-control are far more varied and complex than Gottfredson and Hirschi said they should be. On balance, however, they were certainly on the right track.

And there are, of course, a number of other corollary assumptions regarding the general theory of crime that still remain relatively unaddressed. For example, Gottfredson and Hirschi also noted that self-control should predict crime and deviance equally well across various populations and subpopulations of people and that the relationship between self-control and problematic behavior should be roughly similar across racial and gender categories (known as the "invariance thesis") and that one's level of self-control should influence heavily the nature of one's peer group. Aside from a small handful of recent studies, none of these propositions have been adequately addressed in the literature, so how they end up shaking out for Gottfredson and Hirschi remains to be seen. Even so, from what we do know about the nature and consequences of self-control, it appears that the empirical attention and respect that have been afforded Gottfredson and Hirschi's theory is certainly deserved.

Overview

When it comes to explaining the causes of crime, criminals, and antisocial behavior, there is virtually an endless supply of ideas. Some of these explanations are based on mounds of data, such as theories that focus on the assumption that antisocial behavior is produced by peer pressure or exposure to maltreatment early in life. Other explanations, however, teeter on the absurd, such as the belief that all crime is due to the pursuit of economic gain. The point is that virtually any factor that could be linked to crime has, in some way, been spun into a criminological theory. A perusal of any introduction to criminology textbook is quite revealing by showing the tremendous breadth of factors and explanations that have been advanced to explain crime and that have yet to be falsified by the academic community. Interestingly, the factors that do not seem to get very much coverage by criminologists – at least not in a balanced format – are genetic factors. In fact, most criminologists argue that genetic factors have absolutely nothing to do with the development of criminal involvement and that only environmental factors matter (Wright et al. 2008a). Recent empirical-based research has called into question the assumption that genes have no effect on criminal involvement and instead have revealed that genetic factors are the dominant etiological influence for crime and antisocial behaviors (Ferguson 2010; Moffitt 2005; Rhee and Waldman 2002).

Genetic Effects and Antisocial Behaviors

One of the major obstacles to studying genetic effects is trying to provide accurate and reliable estimates of both genetic and environmental effects on crime and antisocial behaviors. One of the more common ways of accomplishing this goal is by making use of a naturally occurring experiment: twinning. There are two types of twins: monozygotic (MZ) twins and dizygotic (DZ) twins. MZ twins share 100 % of their DNA (i.e., they are essentially genetic clones of each other), and they also share the same environmental upbringings. DZ twins, in contrast, share only 50 % of their distinguishing DNA, but they too share the same environmental upbringings. By comparing the similarity on measures of crime/antisocial behavior of MZ twins to the similarity of DZ twins, it is possible to quantify the proportion of variance that is the result of genetic factors and the proportion of variance that is the result of environmental factors. The more similar MZ twins are to each other in comparison with DZ twins, the greater the genetic effect. Why? – since MZ twins and DZ twins are exposed to similar environments, the only reason that MZ twins should be more similar to each other than DZ twins is because they share twice as much genetic material.

Twin-based research thus provides an estimate of both genetic and environmental effects on variance in antisocial behaviors (Beaver 2008). Technically speaking, the proportion of variance accounted for by genetic factors is known as heritability. Unlike social science research that treats all environments as the same, twin-based research has helped to make the distinction between two types of environments: shared environments and nonshared environments. Shared environments are environments that are the same between twins (or siblings) and that systematically increase their similarity. Nonshared environments consist of any environmental factors that are different between twins and that make them dissimilar (Beaver 2008). For example, as it applies to crime, shared environments might include such factors as being reared in poverty or living in a disadvantaged neighborhood. Examples of nonshared environments might consist of factors such as having different peer groups or being treated differently by parents. When summed together, the effects of heritability, shared environmental factors, and nonshared environmental factors explain 100 % of the variance (Beaver 2009).

There has been a great deal of research using twin-based studies to estimate genetic, shared environmental, and nonshared environmental effects on an assortment of antisocial behaviors, such as crime, violence, aggression, and other types of antisocial behaviors (Beaver 2008; 2011; Miles and Carey 1997). The results of these individual-level studies tend to provide slightly different point estimates of heritability, shared environmental effects, and nonshared environmental effects depending on the sample analyzed and the precise measure of antisocial behavior investigated. When aggregated and averaged together, these studies tend to suggest that genetic factors explain about 50 % of the variance in antisocial behaviors, shared environmental factors explain between 0 % and 10 % of the variance, and nonshared environmental factors explain about 40 % of the variance (Beaver 2009; Ferguson 2010; Moffitt 2005). Instead of genetic factors having no effect like most criminologists assume, genetic factors appear to have the dominant effect on antisocial behaviors.

While twin-based research has been quite valuable in the quest for estimating genetic and environmental effects on antisocial behaviors, there are some limitations to this research design. Opponents of genetic research argue that these limitations are fatal flaws that bias the results and thus any findings generated from twin-based studies are not believable. Fortunately, there are a number of other research designs that can also be used to estimate genetic and environmental effects (Beaver 2009). These alternative research designs, moreover, are not host to the same limitations as twin-based studies and thus they can act as “checks” on the twin-based research designs. As long as the genetic and environmental estimates are relatively consistent across all research designs, then the likelihood that the results are being affected by limitations is low. However, if the genetic and environmental effects vary significantly across different research designs, then this pattern of findings would tend to indicate that the results are being systematically affected by the choice of research designs.

One of the alternative research designs that has been used in place of the traditional twin-based research design capitalizes on a relatively rare occurrence wherein MZ twins were separated at birth, adopted by different families, and raised without even knowing they had a co-twin (known as MZAs [monozygotic twins who were reared apart]). Later in life, they are often told by family and friends or discover through serendipitous events that they were born as part of a twin pair. Upon reuniting, researchers are presented with one of the most effective ways to estimate genetic effects. Since MZAs were reared in different environments and by different families, the only reason that MZAs can be similar to each other is because they share 100 % of their DNA. MZAs obviously are quite rare, but scientists at the University of Minnesota have established the Minnesota Study of Identical Twins Reared Apart (MISTRA) and have located more than 100 pairs of MZAs to interview and study (Bouchard et al. 1990). Upon learning of an MZA, investigators on the MISTRA project invite the twins to participate in their study where the twins undergo a weeklong series of tests designed to measure virtually every human characteristic. Overall, the results of the MZA studies have converged with those of traditional twin-based studies, indicating that genes are highly influential when it comes to crime, aggression, violence, and other antisocial characteristics (Beaver 2009).

Even though twin-based studies and MZA studies reveal results that are relatively consistent, there are still those opponents to genetic research that argue that MZA studies also are host to a number of different flaws. According to such critics, the genetic effects reported in MZA studies are also not believable. Luckily, there is yet another way to estimate genetic effects on antisocial behaviors: adoption studies (Beaver 2009). Adoption studies represent another accurate way to estimate genetic and environmental effects on behaviors and traits. To do so, adoptees are compared to their biological parents (with whom they have had little to no contact) and their adoptive parents (with whom they share no genetic material). The only reason that adoptees should resemble their biological parents on measures of antisocial behaviors is because of the genetic material they share with them. And, the only reason that adoptees should resemble their adoptive parents on measures of antisocial behaviors is because of the environment that they share with them. As with twin-based studies and MZA studies, adoption-based studies have revealed that crime and other types of antisocial behaviors are affected by genetic factors (Beaver 2010; Rhee and Waldman 2002).

Molecular Genetics and Antisocial Behaviors

When the results culled from twin-based studies and adoption-based studies are viewed simultaneously, they paint a very detailed and accurate picture indicating that crime, delinquency, and antisocial behavior in general are influenced in large part by genetic factors. While these studies have provided very compelling evidence establishing the genetic foundations to criminal involvement, they do not provide any information as to the specific genes that are involved in creating crime. The next logical step, therefore, is to uncover the particular genes that are associated with crime and antisocial behaviors. In order to do so, it is first necessary to be exposed to some of the basics of molecular genetics.

Genes are inherited on 23 pairs of threadlike structures called chromosomes. One pair of chromosomes is inherited maternally and the other pair is inherited paternally. Of these 23 pairs of chromosomes, there are 22 pairs of autosomes and one pair of sex chromosomes. For all genes located on the autosomes, there are two copies (one on the maternal chromosome and one on the paternal chromosome). When it comes to the sex chromosomes, there is a slightly different pattern of inheritance. Females have two X chromosomes and thus they have two copies of all genes located on the X chromosomes. Males, however, have one X chromosome (always inherited maternally) and one Y chromosome (always inherited paternally). As a result, males have only one copy of each gene located on the X chromosome and one copy of each gene located on the Y chromosome.

Most of the genes in humans do not vary from person to person which is why, structurally and anatomically speaking, humans look very similar to each other (e.g., two arms, two eyes, two legs, a heart). A small percentage of genes, somewhere around 1–10 % depending on how genetic differences are measured, do vary from person to person (Beaver 2009). Genes that can vary from person to person are known as genetic polymorphisms. For example, genes that are involved in creating height are genetic polymorphisms, which is what produces variation in the height of humans. Alternative versions of genetic polymorphisms are known as alleles (e.g., alleles that make someone tall or alleles that make someone short). Criminologists interested in examining the molecular genetic basis to crime and other antisocial behaviors focus on genetic polymorphisms because only genes that vary can explain variation in antisocial behaviors and traits (otherwise it would be analogous to trying to explain a variable (i.e., crime) with a constant).

Historically there has been much confusion among criminologists and social scientists over how genes ultimately affect criminal behaviors (Wright et al. 2008b). The overarching belief is that there is a single gene that decides whether someone will become a criminal; persons who have this gene will always become a criminal and persons lacking this gene will never become a criminal. This type of deterministic thinking is preposterous. Complex behaviors like criminal involvement are multifactorial meaning that they are produced by a combination of genetic and environmental factors. Moreover, criminal and antisocial behaviors are considered polygenic phenotypes. Polygenic phenotypes refer to human behaviors and traits that are affected by many genes, with each gene having only a small effect on the propensity to engage in crime. Seen in this way, genes work in a probabilistic way, where the presence of certain alleles increase or decrease the probability of an antisocial outcome (Beaver 2009). Each genetic variant, however, would only increase the odds of a crime and antisocial behavior by a relatively small margin, typically less than 10 %. Clearly there is nothing deterministic with this contemporary view of the ways in which genetic factors ultimately affect crime, delinquency, and antisocial behaviors.

During the past decade, there has been a considerable amount of molecular genetic research examining whether the alleles of certain genes predispose someone to engage in crime and violence. Although the results of this line of research have not always been entirely consistent, the main theme running across these studies is that genes that are involved in neurotransmission are the genes most likely to affect criminal involvement. Neurotransmission refers to the process by which neurons communicate with each other. Neurons are brain cells and in order for information to be processed across neuronal networks, adjacent neurons must communicate with each other to pass information from neuron to neuron. Neurons, however, are not physically wired together as there is a small gap – known as a synapse – that exists between neurons. So transmitting information between neurons requires that the synapse be bridged in some capacity. This is accomplished with neurotransmitters, such as serotonin and dopamine, which are chemical messengers that are released from the presynaptic neuron where they cross the synapse and lock into receptors on the postsynaptic neuron.

After the neurotransmitter has locked into the postsynaptic neuron, the neurotransmitters need to be removed from the synapse. There are two main ways that neurotransmitters are purged from the synapse. The first is through a process called reuptake. With reuptake, transporter proteins are released into the synapse where they seek out neurotransmitters, remove them from the synapse, and return them to the vesicles of the presynaptic neuron. The second way that neurotransmitters are removed is through enzymes that degrade neurotransmitters into inactive particles that are then flushed from the synapse. Both reuptake and enzymatic degradation work simultaneously to regulate levels of neurotransmitters. If something interferes with either of these processes or if either of these two processes is not working efficiently, then levels of neurotransmitters may deviate from normality. Importantly, there is a good deal of research linking variation in neurotransmitter levels to a range of psychopathologies, including aggression, violence, suicide, and crime (Brunner et al. 1993; Beaver et al. 2007).

Genes are involved in coding for the production of transporter proteins that are central to the process of reuptake. This is especially important because some genetic polymorphisms related to transporter proteins are functional, meaning that different alleles correspond to differences in the activity level of the transporter protein. For example, different alleles of a genetic polymorphism that codes for the production of the serotonin transporter protein (5HTTLPR) are associated with different transcriptional efficiencies (functional differences that may ultimately produce different levels of serotonin). Similarly, a gene that codes for the production of the monoamine oxidase A (MAOA) enzyme, which is responsible for breaking down neurotransmitters, also has a functional polymorphism (in the promoter region of the gene). Some alleles of this MAOA polymorphism code for the production of low MAOA activity, meaning that the MAOA is not as efficient at mopping up neurotransmitters from the synapse, while other alleles code for the production of high MAOA activity, which is much more efficient at removing neurotransmitters from the synapse.

Overall, molecular genetic research has provided some evidence tying variants of certain genes, such as dopaminergic genes (e.g., DAT1, DRD2, and DRD4), serotonergic genes (e.g., 5HTTLPR), and genes coding for the production of enzymes (e.g., MAOA and COMT) to various antisocial behaviors (Beaver et al. 2007; Caspi et al. 2002; Brody et al. 2011). These genes tend to have small effects, a finding which is consistent with polygenic explanations of human behavior. Perhaps partially as a result of the small effects associated with genes, genetic association studies are often plagued by an inability to replicate the original results. What this means is that after a study first reports a statistically significant association between a genetic polymorphism and an outcome, replication studies often fail to detect that same association in independent samples. There are a number of potential explanations for a failure to replicate, including the possibility that the original report was a methodological or statistical artifact. Consequentially, replication studies are of utmost importance when attempting to figure out whether a putative candidate gene is indeed related, perhaps causally, to a human trait/behavior.

Gene-Environment Interplay and Antisocial Behaviors

Although molecular genetic research has revealed that some genes are related to a variety of antisocial outcomes, the most cutting-edge genetic research examines the interplay between genetic factors and environmental factors (Moffitt 2005). There are two main types of gene-environment interplay that have been tied to antisocial behaviors: gene-environment interactions and gene-environment correlations. Gene-environment interactions capture the processes by which genetic effects are moderated by environmental factors and/or by which environmental effects are moderated by genetic factors. In short, gene-environment interactions can explain why two people who encounter the same stimuli may turn out quite differently. An example will help to clarify what is meant by a gene-environment interaction. Suppose that a study was examining a group of adolescents who were raised in a disadvantaged neighborhood with high rates of crime, poverty, and homelessness. Exposure to this neighborhood is certainly a criminogenic risk factor that heightens the propensity for engaging in crime and disrepute. Even so, most of the adolescents exposed to such conditions will not turn out to be criminal, but a handful of adolescents will develop into criminals. The million-dollar question, of course, is what accounts for these differential outcomes? The logic of gene-environment interactions can easily answer this question by drawing attention to the fact that for a criminal to develop they must (1) be exposed to a criminogenic environment *and* (2) have a sufficient genetic predisposition for crime. If either of these two factors is absent, then their independent effects are either muted or attenuated significantly. To summarize, then, gene-environment interactions refer to the fact that genetic effects are strongest when paired with environmental liabilities (and vice versa).

Much of the contemporary genetic research examining genetic effects on antisocial behavior and psychopathologies has been guided by gene-environment interactions. What this line of research has revealed is that the effects of specific polymorphisms on antisocial behaviors are structured in part by exposure to environmental liabilities and stressors. For example, the MAOA gene has consistently been found to be related to violence and aggression in males (Caspi et al. 2002; Haberstick et al. 2007; Kim-Cohen et al. 2006). Consistent with the logic of gene-environment interactions, however, the effect of MAOA only surfaces among males who have been abused and maltreated as children. For males who have not been abused as children, there is no effect of MAOA on antisocial behaviors. Similar findings have been observed with other genetic polymorphisms linked to antisocial propensities. These findings underscore the mutual interdependence of genes and the environment when trying to understand the etiology of criminal and antisocial behaviors.

Gene-environment interactions may also be integral to understanding why there are some problems with replicating molecular genetic findings. Molecular genetic research is often based on clinical, non-nationally representative samples. This necessarily means that the samples that are used to test for genetic associations are differentially exposed to environmental conditions. The respondents from one sample, for instance, may be exposed to severe poverty, whereas respondents from another sample may have been drawn from a wealthy population. If poverty acts as a trigger for a genetic effect to surface (i.e., a gene-environment interaction), then the genetic effect would be detected in the first sample, but not in the second. So, failing to recognize differential exposure to environmental liabilities may be one additional reason for why there is a failure to replicate some genetic associations with criminal behavior.

The second type of gene-environment interplay that has direct bearing on criminology is known as gene-environment correlation. Gene-environment correlation captures the effects that genes have on predicting and explaining variance in environmental measures (Beaver and Wright 2005; Scarr and McCartney 1983). To most criminologists and social scientists, even suggesting that an environment could be affected by genetics seems a bit odd. There is, however, a great deal of empirical evidence indicating that almost all environments are influenced, at least in part, by genetic factors (Beaver and Wright 2005). To understand how it is possible to estimate genetic effects on environmental measures, it is essential to revisit the twin-based methodology. Recall that with the twin-based methodology, the similarity of MZ twins on some behavior trait is compared with the similarity of DZ twins on that same behavior/trait. If MZ twins are more similar than DZ twins, there is evidence of a genetic effect on the behavior/trait. This same twin-based methodology can be employed to estimate genetic effects on environmental measures; the only difference is that an environmental measure is used in place of the measure of the behavior/trait. A pool of empirical research has used the twin-based study to estimate genetic effects on environmental measures, and the results have provided strong support in favor of gene-environment correlations for environments related to crime and delinquency (Beaver and Wright 2005; DiLalla 2002). For example, variance in measures of parental socialization (Beaver and Wright 2007; DiLalla 2002), exposure to antisocial peer networks (Beaver et al. 2009), stressful life events (Dick et al. 2006), and various dimensions of family life have all been found to be affected, to varying degrees, by genetic factors. While the precise heritability estimates ebb and flow across the environmental measures, on average, genetic factors account for around 25 % of the variance in most environmental measures (Kendler and Baker 2006). Some environments, such as exposure to delinquent peer groups, have much higher heritability estimates with genetic factors explaining about around 60 % of the variance (Cleveland et al. 2005).

In addition to twin-based studies, a small number of studies have also explored the possibility that certain genetic polymorphisms might explain variance in measures of criminogenic environments. While this line of research is still in its infancy, there is some emerging evidence linking specific genetic polymorphisms, such as dopaminergic polymorphisms, to negative parental socialization, to contact with delinquent peers, and even to the probability of getting married (Dick et al. 2006). As more and more social science datasets begin to include genotypic information, the number of genes that are found to be associated with specific environmental conditions will likely increase.

Establishing a link between genetic variance and environmental variance is important in unpacking the ways in which genes and the environment work together to produce human phenotypic variation. Nonetheless, simply establishing a link reveals nothing about the underlying processes that account for gene-environment correlations. Existing research, however, has delineated three different types of gene-environment correlations, each of which explains a different mechanism by which genes account for environmental variance (Scarr and McCartney 1983). These three types of gene-environment correlations are known as passive gene-environment correlation, active gene-environment correlation, and evocative gene-environment correlation.

Passive gene-environment correlation is grounded in the fact that parents pass along two entities to their children: genes and an environment. Given that the child is unable to pick and choose their genes and/or their environment, they passively receive these. Moreover, because both genes and the environment are traced to the same source – that is, parents – the two are likely to be correlated (Beaver 2009; Scarr and McCartney 1983). For example, highly aggressive parents are likely to pass along a genetic predisposition for aggression and violence to their children. At the same time, parents who are highly aggressive are also statistically more likely to abuse their children, live in low SES areas, and not supervise their children closely. All of these environments have been shown to increase the probability of antisocial behaviors. With passive gene-environment correlation, then, children are hit with a "double whammy" of risk factors, wherein they have the genetic predispositions for antisocial behavior and they are also born into an environment that also contributes to antisocial behavior. This process thereby captures part of the reason that criminogenic environments are affected by genetic factors.

The second type of gene-environment correlation is active gene-environment correlation. Active gene-environment correlation avers that genotype pushes or nudges people into certain environments that are compatible with their genetic predispositions (Beaver 2009; Scarr and McCartney 1983). To illustrate, a person who is highly aggressive and violent is likely to seek out environments that are conducive to these predispositions. So, they might join a gang or befriend other people who are violent, too. In this example, choosing a gang is not a random occurrence, but rather is structured in part by the genetic predisposition for violence and aggression. It is important to underscore the fact that there are not genes that are "for" any type of environment; rather, genes operate indirectly, such as via their effects on personality traits. Continuing on with the gang example, a part of the reason a person might choose a gang is because they are genetically predisposed to be violent, not because there is a single gene that tells the person to join a gang.

The last type of gene-environment correlation is known as evocative gene-environment correlation. With evocative gene-environment correlation, genotype elicits certain responses from the environment, which are ultimately correlated with their genotype (Beaver 2009; Scarr and McCartney 1983). A person with a bad temper (a genetically influenced phenotype), for instance, is likely to evoke negative responses from their environment. Evocative gene-environment correlations are virtually synonymous with child-effects models except that the effect is thought to flow directly from genotype. Consider two siblings: one who is genetically predisposed to be unruly and one who is genetically predisposed to be passive and compliant. The unruly child will likely evoke negative and harsh parenting, such as being spanked, while the compliant child will likely escape such discipline. In this case, parental discipline is differentially invoked against the two siblings, but the reason for this difference is the result of the genetically influenced propensities and temperaments of the two siblings.

The saliency of these three types of gene-environment correlation waxes and wanes over different sections of the life course. Passive gene-environment correlation is thought to be most evident early in life, especially during infancy and childhood. During this time period, children are under the control of their parents and have their parents' environment imposed on them. As children develop into adolescence, they begin to gain more autonomy and thus are able to follow their genetic predispositions without as much guidance and control by their parents. By the time of early adulthood when most children have moved out of their parents' home, they are able to follow their genetic predispositions without interference. Evocative gene-environment correlation tends to have relatively equal effects throughout life. In childhood, for instance, genetically influenced antisocial traits may elicit negative responses from parents; in adolescence, genetically influenced antisocial traits may elicit negative responses from peers and teachers; and in adulthood, genetically influenced antisocial traits may elicit negative responses from employers and from potential mates.

Taken together, the two types of gene-environment interplay – gene-environment interaction and gene-environment correlation – draw attention to the very real possibility that genes and the environment do not represent simple dichotomies (Beaver et al. 2009). Instead, a wealth of scientifically rigorous scholarship has shown that there is a close interdependence between genes and the environment and the way to understand the causes of all human phenotypes – including antisocial ones – is to examine these two influences simultaneously and to model directly the various types of gene-environment interplay.

Conclusions and Future Directions

During the past century, the field of criminology has made some enormous gains in terms of identifying the causes and correlates of crime, delinquency, and other types of antisocial behaviors. For the most part, however, all of these advancements have been on discovering the environmental underpinnings to criminal involvement. With the recent mapping of the human genome and with empirical studies strongly implicating genes in all human phenotypes, the time is ripe for criminology to begin to examine the dual influences of genes and the environment in the genesis of antisocial behaviors. Such an approach does not mean that all existing theories need to be abandoned. Instead, such an approach allows for a fuller integration of findings from biological sciences into mainstream criminological theories. This type of theoretical integration would likely pave the way for an explosion of knowledge about the developmental pathways to crime and violence. The knowledge flowing from this research could then be used to open up newer and perhaps more effective avenues for the treatment and rehabilitation of offenders that would ultimately increase public safety and reduce criminal involvement.
